5. Temperature and Humidity

5.1 The temperature of the air in the vicinity of the mixing operation, the dry materials, mixing water, molds, base plates, mixing bowl, moist closet or moist room, and storage water shall not vary from 73.4 °F (23 °C) by more than ±3 °F (±1.7 °C).

5.2 The relative humidity of the laboratory shall be not less than 50 %. The moist closet or moist room shall provide a relative humidity of not less that 95 %.

6. Graded Standard Sand

6.1 Sand used shall comply with the graded sand requirement of Specification C 778.

Passing Sieve	Percentage Retained
No. 100 (150-µm)	98 ± 2
No. 50 (300-µm)	72 ± 5
No. 30 (600-µm)	2 ± 2
No. 16 (1.18-mm)	none

NOTE 2—*Segregation of Graded Sand*—The graded standard sand should be handled in such a manner as to prevent segregation, since variations in the grading of the sand cause variations in the consistency of the mortar. In emptying sacks of sand into bins or in scooping sand out of bins or sacks, care should be exercised to prevent the formation of mounds of sand or craters in the sand, down the slopes of which the coarser particles will roll. Bins should be of sufficient size to permit these precautions. Devices for drawing the sand from bins by gravity should not be used.

7. Test Specimen

7.1 The test specimen shall be a 2 by 2 by 10-in. prism having a 10-in. gage length, or a 50 by 50 by 250-mm prism

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

having a 250-mm gage length. At least two specimens shall be prepared for each test.

8. Preparation and Assembly of Specimen Molds and Restraining Cage

8.1 Install the cap nuts firmly in place on the ends of the restraining rods and measure the restraining rods for length while they are at a temperature of 73.4 ± 1 °F (23.0 ± 0.5 °C).

8.2 The edges of the end plates of the restraining cage that contact the sides and bottom of the mold shall be thinly covered with a heavy mineral oil or light cup grease such as petrolatum. After assembly of the molds, place a restraining cage in each compartment. Seal the contact lines between the outer sides and base plate of the molds with paraffin or micro-crystalline wax. Thinly cover the interior faces of the molds with mineral oil and remove any oil or grease from the restraining cage rod and end plates.

9. Proportioning and Mixing of Mortars

9.1 Proportion the standard mortar by using one part of cement to 2.75 parts of graded standard sand by mass. Mix 800 g of cement, 2200 g of graded standard sand, and 400 mL of water to produce a batch sufficient for two test specimens.

9.2 Mix in accordance with the procedure for mixing mortars given in Practice C 305. Upon completion of mixing, shake the mixing paddle into the mixing bowl to remove excess mortar.

10. Molding Specimens

10.1 Start molding specimens immediately after completion of mixing. Place the mortar in the mold in two layers with the first layer just covering the restraining rod and the second layer slightly overfilling the mold. Compact each layer by tamping. Work the mortar into the corners, around the restraining rod, without striking the rod, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, strike-off the mortar flush with the top of the mold, and smooth the surface with a few strokes of the trowel.

11. Curing of Specimens

11.1 Immediately after completion of molding, cover the specimens with a polyethylene sheet, or other suitable material for preventing loss or gain of moisture, at the surface of the specimens. The cover should make contact with the surface of the mortar. Place the specimens in the moist room or moist cabinet.

11.2 Remove the specimens from the molds at an age of 6 ± ¼ h after the addition of water to the cement during the mixing operation (Note 3). Particular care must be exercised in this operation in order not to damage the specimens because of their low strength at this age. It is preferable to use the demolding devices referred to in 4.5 for freeing specimens from the base and side plates.

NOTE 3—At this time comparator readings may be made. Although these readings may differ slightly from the initial reading made on the restraining rod prior to molding the specimen, it can serve as a check on the initial reading which should be used as the basis for calculating the length change.

11.3 Cure the specimens in lime-saturated water at 73.4± 3.0 °F (23.0 ± 1.7 °C) until they have reached an age of 7 days ± 1 h, including the period in the molds, except that the temperature of the curing water shall be 73.4 ± 1 °F (23.0 ± 0.5 °C) for at least the last 15 min. At the end of this period, remove the specimens from the water one at a time, wipe with a damp cloth, and immediately make comparator readings with the cap nuts in place.

11.4 Return the specimens to curing in lime-saturated water at 73.4 ± 3.0 °F (23.0 ± 1.7 °C) until they have reached an age of 28 days including the period in the molds. At the end of the curing period, make comparator readings immediately after the specimens have been subjected to about 15 min of storage in water at 73.4 ± 1.0 °F (23.0± 0.5 °C) and in the same manner as described in 11.3.

12. Calculation

12.1 Calculate the expansion or shrinkage at any age as follows:

$$E_x = \frac{L_x - L_i}{10\,(250)} \times 100 \qquad (1)$$

where:

E_x = expansion at x age, %,
L_x = comparator reading of specimen at x age – reference bar comparator reading, in. (mm), and
L_i = initial comparator reading of restraining rod – reference bar comparator reading, in. (mm).

13. Report

13.1 Report the following information:

13.1.1 Number of specimens for each condition and date molded,

13.1.2 Source and identification of cement.

13.1.3 Age of specimen for each observation for length change,

13.1.4 Length-change data, expressed as linear expansion or contraction based on the length of the specimen at time of molding shall be reported as percent change dimension to the nearest 0.001 %, and

13.1.5 Any other pertinent information.

14. Precision and Bias [4]

14.1 *Precision*:

14.1.1 *Within Batch Precision*—The standard deviation of two bars made from the same batch and tested together was found to be 0.00276 %. Therefore two bars made from the same batch should not differ from each other by more than 0.008 % length change.[5]

14.1.2 *Single Operator Precision*—The single operator standard deviation has been found to be 0.0038 at seven and twenty eight days age, based on the average of two bars. Therefore the results of two properly conducted tests by the

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C01-1001.

[5] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

same operator on the same material should not differ by more than 0.011 % length change.[5]

14.1.3 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 0.0093 at seven and twenty eight days age, based on the average of two bars. Therefore the results of two properly conducted tests on the same material in two different laboratories should not differ by more than 0.026 % length change.[5]

14.2 *Bias*—A bias statement cannot be prepared due to the fact that absolute standards are not available.

15. Keywords

15.1 cement mortar; expansive cement; restrained expansion

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 807 – 08

Standard Test Method for Time of Setting of Hydraulic Cement Mortar by Modified Vicat Needle[1]

This standard is issued under the fixed designation C 807; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the time of setting of hydraulic cement mortar by means of the modified Vicat needle.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 min. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.)

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

C 845 Specification for Expansive Hydraulic Cement

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

D 1193 Specification for Reagent Water

3. Terminology

3.1 Terms used in this standard are defined in Terminology C 219.

4. Summary of Test Method

4.1 A mortar is prepared with the cement to be tested, using stipulated quantities of cement and water, and sufficient standard sand to produce a required consistency as determined by a stipulated penetration using the plunger of the modified Vicat apparatus. Mortar of the proper consistency is then tested for time of setting, using the needle of the modified Vicat apparatus for the determination of a stipulated penetration. The time required to obtain the stipulated penetration of the modified Vicat needle is the time of setting.

5. Significance and Use

5.1 The purpose of this test method is to establish whether or not a cement complies with a specification limit on time of setting. It has been found to be particularly applicable for the determination of the setting time of expansive cements (see Specification C 845).

6. Apparatus

6.1 *Tamper and Trowel*, conforming to the requirements of Test Method C 109/C 109M. In addition, the edges of the trowel when placed on a plane surface shall not depart from straightness by more than 1 mm.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.30 on Time of Set.

Current edition approved June 1, 2008. Published July 2008. Originally approved in 1975. Last previous edition approved in 2005 as C 807 – 05.

www.technobetar.ir

6.2 *Vicat Apparatus*, conforming to the requirements of Test Method C 187, with the following modifications:

6.2.1 For consistency determination, the plunger end of the movable rod shall be 17.5 ± 0.5 mm in diameter instead of 10 mm, and the total mass of the movable rod (including the 17.5-mm plunger) shall be 400 ± 0.5 g.

6.2.2 For time of setting determination, a 2 ± 0.05-mm stainless steel needle shall be substituted for the 1-mm needle. The total mass of the movable rod with the 2-mm needle shall be 300 ± 0.5 g.

6.3 *Mold for Consistency and Setting Time*—A smooth cylindrical brass ring 76 ± 0.5 mm inside diameter (3-in. brass tubing) by 40 ± 1 mm deep, cemented to a plane, non-absorptive plate, or smooth cylindrical brass cups having the above dimensions.

6.4 *Mixer, Bowl, Paddle, and Scraper*, conforming to the requirements of Practice C 305.

6.5 *Glass Graduates*, conforming to the requirements of Specification C 1005.

6.6 *Masses and Mass Determining Devices*, conforming to the requirements of Specification C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

7. Reagents and Materials

7.1 *Graded Standard Sand*, conforming to the requirements of Specification C 778.

7.2 *Mixing Water*—Potable water is satisfactory for routine tests. For all referee and cooperative tests, reagent water conforming to the requirements of Specification D 1193 for Type III or Type IV grade of reagent water shall be used.

8. Sampling

8.1 When the test is part of acceptance testing, sample the cement in accordance with Practice C 183.

9. Conditioning

9.1 Maintain the temperature of the room, dry materials, paddle, bowl, and molds at 23.0 ± 3.0 °C.

9.2 Maintain the temperature of the mixing water at 23.0 ± 2.0 °C

9.3 The relative humidity of the mixing room shall not be less than 50 %.

9.4 The moist closet or moist room shall be in accordance with Specification C 511.

10. Procedure

10.1 *Preparation of Mortar*:

10.1.1 Mix 750 g of cement, 375 mL of water, and the quantity of graded standard sand required to give the consistency specified below under "Test for Consistency" in accordance with the mortar mixing procedure described in Practice C 305.

10.1.2 Upon completion of mixing, place a layer of mortar about 20 mm in thickness in the mold and puddle with the tamper. Hold the tamper with the 25-mm side parallel to the radius of the mold for 14 strokes spaced equally around the outside of the mold. Apply an additional four strokes to the center of the specimen with the longitudinal axis of the tamper at the center of the mold and rotate the tamper 45° between each stroke. Then fill the mold to overflowing with mortar and puddle as specified for the first layer. Cut off the mortar to a plane surface flush with the top of the mold in two operations. First, with the trowel held at about a 20° angle, start at one side of the mold, 10 mm above the mold, and finish the stroke by cutting the mortar off the top of the mold at the opposite side. Second, starting from the opposite direction, cut the mortar flush with the top of the mold by drawing the straight edge of the trowel (held nearly perpendicular to the mold) with a sawing motion across the top of the mold.

10.2 *Test for Consistency*—Center the mortar confined in the mold under the movable rod of the modified Vicat apparatus described above. Bring the plunger in contact with the surface of the mortar and tighten the setscrew. Then set the movable indicator to the upper zero mark on the scale, or take an initial reading, and release the rod 35 to 50 s after starting to fill the mold. The mortar shall have the desired consistency when the rod settles to a point 20 ± 4 mm below the original surface 30 s after being released. Cover the bowl containing the remainder of the mortar with the lid while the consistency test is being made. Make trial mortars with varying percentages of standard sand until the desired consistency is obtained.

10.3 *Test for Time of Setting*—Mix the mortar remaining in the bowl at medium speed (285 ± 10 rpm) for 30 s after it has been found that the mortar has the proper consistency. Following the completion of the mixing, mold the test specimen as specified above. Immediately after molding, place the test specimen in the moist closet or moist room where it shall remain except when penetration tests are being made. Allow the time of setting specimen to remain in the moist closet or moist room for 30 min without being disturbed. Then, using the modified Vicat apparatus described above, bring the needle in contact with the surface of the mortar and tighten the setscrew. Set the movable indicator to the upper zero mark on the scale, or take an initial reading. Release the rod quickly by releasing the setscrew, and allow the needle to settle for 30 s. Determine the penetration of the needle at this time and every 30 min thereafter until the needle fails to penetrate to the bottom of the mold. Then, take penetration tests every 10 min until a penetration of 10 mm or less is obtained. Perform no penetration test closer than 10 mm from any previous penetration test or from the inside edge of the mold. Record the results of all penetration tests, and, by interpolation, determine the time when a penetration of 10 mm is obtained. The difference, in minutes, between the time of contact of cement and water in the mortar mixing procedure and the time a penetration of 10 mm is obtained is the time of setting.

10.4 *Precautions*—Maintain testing apparatus on a rigid surface, free of vibration during the penetration test. Do not oil the plunger of the Vicat apparatus at any time, but keep the plunger and guide bearing clean at all times.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:18 EDT 2010

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11. Calculation

11.1 Calculate the time of setting to the nearest one minute as follows:

$$\left(\left(\frac{(H-E)}{(C-D)}\right) \times (C-10)\right) + E \quad (1)$$

where:

E = time in minutes of last penetration greater than 10 mm,
H = time in minutes of first penetration less than 10 mm,
C = penetration reading at Time E, and
D = penetration reading at Time H.

12. Report

12.1 Report the time of setting in minutes, to the nearest one minute.

13. Precision and Bias

13.1 The multilaboratory standard deviation has been found to be 15.2 min. Therefore, the results of two properly conducted tests from two different laboratories on samples of the same cement should not differ by more than 43 min. (See Note 1)

13.2 No information can be presented on the bias of the procedure in this test method for measuring time of setting because no material having an accepted reference value is available.

NOTE 1—These numbers represent, respectively, the 1s and d2s limits as defined in Practice C 670.

14. Keywords

14.1 hydraulic-cement mortar; time of setting; Vicat needle, expansive

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 807 – 05, that may impact the use of this test method. (Approved June 1, 2008)

(*1*) Editorially revised the units statement in 1.2 to conform to ASTM Form and Style.

(*2*) Revised 6.1, 6.6, and 9.3.

(*3*) Editorially revised 11.1 and 12.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 807 – 08

Standard Test Method for Time of Setting of Hydraulic Cement Mortar by Modified Vicat Needle[1]

This standard is issued under the fixed designation C 807; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the time of setting of hydraulic cement mortar by means of the modified Vicat needle.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 min. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.)

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

D 1193 Specification for Reagent Water

3. Terminology

3.1 Terms used in this standard are defined in Terminology C 219.

4. Summary of Test Method

4.1 A mortar is prepared with the cement to be tested, using stipulated quantities of cement and water, and sufficient standard sand to produce a required consistency as determined by a stipulated penetration using the plunger of the modified Vicat apparatus. Mortar of the proper consistency is then tested for time of setting, using the needle of the modified Vicat apparatus for the determination of a stipulated penetration. The time required to obtain the stipulated penetration of the modified Vicat needle is the time of setting.

5. Significance and Use

5.1 The purpose of this test method is to establish whether or not a cement complies with a specification limit on time of setting. It has been found to be particularly applicable for the determination of the setting time of expansive cements (see Specification C 845).

6. Apparatus

6.1 *Tamper and Trowel*, conforming to the requirements of Test Method C 109/C 109M. In addition, the edges of the trowel when placed on a plane surface shall not depart from straightness by more than 1 mm.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.30 on Time of Set.

Current edition approved June 1, 2008. Published July 2008. Originally approved in 1975. Last previous edition approved in 2005 as C 807 – 05.

www.technobetar.ir

6.2 *Vicat Apparatus*, conforming to the requirements of Test Method C 187, with the following modifications:

6.2.1 For consistency determination, the plunger end of the movable rod shall be 17.5 ± 0.5 mm in diameter instead of 10 mm, and the total mass of the movable rod (including the 17.5-mm plunger) shall be 400 ± 0.5 g.

6.2.2 For time of setting determination, a 2 ± 0.05-mm stainless steel needle shall be substituted for the 1-mm needle. The total mass of the movable rod with the 2-mm needle shall be 300 ± 0.5 g.

6.3 *Mold for Consistency and Setting Time*—A smooth cylindrical brass ring 76 ± 0.5 mm inside diameter (3-in. brass tubing) by 40 ± 1 mm deep, cemented to a plane, non-absorptive plate, or smooth cylindrical brass cups having the above dimensions.

6.4 *Mixer, Bowl, Paddle, and Scraper*, conforming to the requirements of Practice C 305.

6.5 *Glass Graduates*, conforming to the requirements of Specification C 1005.

6.6 *Masses and Mass Determining Devices*, conforming to the requirements of Specification C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

7. Reagents and Materials

7.1 *Graded Standard Sand*, conforming to the requirements of Specification C 778.

7.2 *Mixing Water*—Potable water is satisfactory for routine tests. For all referee and cooperative tests, reagent water conforming to the requirements of Specification D 1193 for Type III or Type IV grade of reagent water shall be used.

8. Sampling

8.1 When the test is part of acceptance testing, sample the cement in accordance with Practice C 183.

9. Conditioning

9.1 Maintain the temperature of the room, dry materials, paddle, bowl, and molds at 23.0 ± 3.0 °C.

9.2 Maintain the temperature of the mixing water at 23.0 ± 2.0 °C

9.3 The relative humidity of the mixing room shall not be less than 50 %.

9.4 The moist closet or moist room shall be in accordance with Specification C 511.

10. Procedure

10.1 *Preparation of Mortar*:

10.1.1 Mix 750 g of cement, 375 mL of water, and the quantity of graded standard sand required to give the consistency specified below under "Test for Consistency" in accordance with the mortar mixing procedure described in Practice C 305.

10.1.2 Upon completion of mixing, place a layer of mortar about 20 mm in thickness in the mold and puddle with the tamper. Hold the tamper with the 25-mm side parallel to the radius of the mold for 14 strokes spaced equally around the outside of the mold. Apply an additional four strokes to the center of the specimen with the longitudinal axis of the tamper at the center of the mold and rotate the tamper 45° between each stroke. Then fill the mold to overflowing with mortar and puddle as specified for the first layer. Cut off the mortar to a plane surface flush with the top of the mold in two operations. First, with the trowel held at about a 20° angle, start at one side of the mold, 10 mm above the mold, and finish the stroke by cutting the mortar off the top of the mold at the opposite side. Second, starting from the opposite direction, cut the mortar flush with the top of the mold by drawing the straight edge of the trowel (held nearly perpendicular to the mold) with a sawing motion across the top of the mold.

10.2 *Test for Consistency*—Center the mortar confined in the mold under the movable rod of the modified Vicat apparatus described above. Bring the plunger in contact with the surface of the mortar and tighten the setscrew. Then set the movable indicator to the upper zero mark on the scale, or take an initial reading, and release the rod 35 to 50 s after starting to fill the mold. The mortar shall have the desired consistency when the rod settles to a point 20 ± 4 mm below the original surface 30 s after being released. Cover the bowl containing the remainder of the mortar with the lid while the consistency test is being made. Make trial mortars with varying percentages of standard sand until the desired consistency is obtained.

10.3 *Test for Time of Setting*—Mix the mortar remaining in the bowl at medium speed (285 ± 10 rpm) for 30 s after it has been found that the mortar has the proper consistency. Following the completion of the mixing, mold the test specimen as specified above. Immediately after molding, place the test specimen in the moist closet or moist room where it shall remain except when penetration tests are being made. Allow the time of setting specimen to remain in the moist closet or moist room for 30 min without being disturbed. Then, using the modified Vicat apparatus described above, bring the needle in contact with the surface of the mortar and tighten the setscrew. Set the movable indicator to the upper zero mark on the scale, or take an initial reading. Release the rod quickly by releasing the setscrew, and allow the needle to settle for 30 s. Determine the penetration of the needle at this time and every 30 min thereafter until the needle fails to penetrate to the bottom of the mold. Then, take penetration tests every 10 min until a penetration of 10 mm or less is obtained. Perform no penetration test closer than 10 mm from any previous penetration test or from the inside edge of the mold. Record the results of all penetration tests, and, by interpolation, determine the time when a penetration of 10 mm is obtained. The difference, in minutes, between the time of contact of cement and water in the mortar mixing procedure and the time a penetration of 10 mm is obtained is the time of setting.

10.4 *Precautions*—Maintain testing apparatus on a rigid surface, free of vibration during the penetration test. Do not oil the plunger of the Vicat apparatus at any time, but keep the plunger and guide bearing clean at all times.

www.technobetar.ir

11. Calculation

11.1 Calculate the time of setting to the nearest one minute as follows:

$$\left(\left(\frac{(H-E)}{(C-D)}\right) \times (C-10)\right) + E \quad (1)$$

where:

E = time in minutes of last penetration greater than 10 mm,
H = time in minutes of first penetration less than 10 mm,
C = penetration reading at Time E, and
D = penetration reading at Time H.

12. Report

12.1 Report the time of setting in minutes, to the nearest one minute.

13. Precision and Bias

13.1 The multilaboratory standard deviation has been found to be 15.2 min. Therefore, the results of two properly conducted tests from two different laboratories on samples of the same cement should not differ by more than 43 min. (See Note 1)

13.2 No information can be presented on the bias of the procedure in this test method for measuring time of setting because no material having an accepted reference value is available.

NOTE 1—These numbers represent, respectively, the 1s and d2s limits as defined in Practice C 670.

14. Keywords

14.1 hydraulic-cement mortar; time of setting; Vicat needle, expansive

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 807 – 05, that may impact the use of this test method. (Approved June 1, 2008)

(*1*) Editorially revised the units statement in 1.2 to conform to ASTM Form and Style.

(*2*) Revised 6.1, 6.6, and 9.3.

(*3*) Editorially revised 11.1 and 12.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 821 – 09

Standard Specification for Lime for Use with Pozzolans[1]

This standard is issued under the fixed designation C 821; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers all types of commercial hydrated lime such as: high-calcium, magnesium, or dolomitic-hydrated lime. By-product limes and slaked quick limes in dry, wet, or slurried form are also included.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

C 204 Test Methods for Fineness of Hydraulic Cement by Air-Permeability Apparatus

C 593 Specification for Fly Ash and Other Pozzolans for Use With Lime for Soil Stabilization

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this specification, refer to Terminology C 51.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *chemical factor*, *n*—a numerical value of the active constituents in the hydrated lime that react chemically with a pozzolan. The value is based on the combined calcium oxide equivalents of free calcium oxide, calcium hydroxide, and magnesium oxide. Calcium carbonate and magnesium hydroxide are excluded, since these compounds have been found to be nonreactive.

3.2.2 *pozzolanic receptivity index*, *n*—a performance factor incorporating both chemical quality and fineness, determined by Eq 3.

4. Chemical and Physical Requirements

4.1 The lime shall conform to the requirements listed in Table 1, except as noted in Section 5.

5. Performance Requirements

5.1 If the chemical factor, Blaine fineness, or pozzolanic receptivity index is below the limits given in Table 1, the lime shall be required to meet the applicable performance requirements listed in Table 2. Where such lime complies with the limits listed in Table 2, it shall be considered acceptable for use with pozzolans. However, it may be necessary to increase the lime content in the lime-pozzolan mixtures in order to meet minimum design criteria.

6. Test Methods

6.1 *Chemical Factor*:

6.1.1 Determine calcium oxide (CaO), magnesium oxide (MgO), and carbon dioxide (CO_2) contents in accordance with Test Methods C 25. When the magnesium oxide content is greater than 5 %, determine the peak height of magnesium oxide and magnesium hydroxide using standard X-ray diffraction procedures and calculate the ratio (*r*) of magnesium oxide to hydroxide using Eq 1. When the magnesium oxide is less than 5 %, the value of *r* shall be 0.30.

$$r = \frac{\text{cps MgO}}{\text{cps MgO} + 2.0\ (\text{cps Mg}(\text{OH})_2)} \quad (1)$$

where:

cps = counts per second of principal peaks corresponding to an interplanar spacing for MgO of 2.106 Å and for $Mg(OH)_2$ of 2.365 Å.

6.1.2 *Calculation of Chemical Factor*—Using the test results provided by 6.1.1 the chemical factor (C.F.) is determined by Eq 2:

$$\text{C.F.} = (\text{CaO}) - 1.27\ (\text{CO}_2) + 1.4\ r\ (\text{MgO}) \quad (2)$$

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved June 1, 2009. Published July 2009. Originally approved in 1975. Last previous edition approved in 2000 as C 821 – 78(2000).

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

TABLE 1 Chemical and Physical Requirements

Chemical factor, min	50
Blaine fineness, min, cm^2/g	10 000
Pozzolanic receptivity index, min	100

TABLE 2 Performance Requirements

Plastic Compositions:		
Lime-pozzolan strength, min, psi (MPa)	600	(4.13)
Nonplastic Compositions:		
Lime-pozzolan-aggregate strength, min, psi (MPa)	400	(2.76)
Vacuum saturation strength, min, psi (MPa)	400	(2.8)

6.2 *Blaine Fineness*—Calculate in accordance with Method C 204, except use the specific gravity of the lime in calculating the trial weight of the sample, and the weight finally chosen must result in a firm bed as described in Test Method C 204. Use the specific gravity of the lime and finally chosen weight to determine the porosity of the bed in accordance with Eq 2 of Test Method C 204, and use this porosity (as well as specific gravity) in calculating the surface area.

6.3 *Pozzolanic Receptivity Index (PRI)*:

$$\text{PRI} = \frac{\text{chemical factor} \times \text{Blaine fineness}}{10\ 000} \quad (3)$$

6.4 *Lime-Pozzolan Strength*—See Specification C 593, Section 7. The pozzolan used shall pass the requirements of Specification C 593 when tested with a lime having a pozzolanic receptivity index of 80 or higher.

6.5 *Lime-Pozzolan-Aggregate Strength, Freeze-Thaw Resistance*—See Specification C 593, Section 8. The pozzolan used shall pass the requirements of Specification C 593 when tested with a lime having a pozzolanic receptivity index of 80 or higher.

7. Sampling, Inspection, Packing, and Marking

7.1 The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with Methods C 50.

8. Keywords

8.1 hydrated; lime; pozzolans

SUMMARY OF CHANGES

Committee C07 has identified the location of selected changes to this specification since the last issue, C 821 – 78(2000), that may impact the use of this specification. (Approved June 1, 2009)

(*1*) This specification was reinstated with revision. A units statement was added in new 1.2 and subsequent paragraphs were renumbered. Reference to Terminology C 51 was added to Section 3 and Referenced Documents.

Designation: C 823/C 823M – 07

Standard Practice for Examination and Sampling of Hardened Concrete in Constructions[1]

This standard is issued under the fixed designation C 823/C 823M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This practice outlines procedures for visual examination and sampling of hardened concrete in constructions. Reference is made to the examination and sampling of concrete in prefabricated building units, precast products, and laboratory specimens.

1.2 The values stated in either inch-pound units or SI units shall be regarded separately as standard. Inch-pound units are shown in parentheses. The values stated in each system may not be exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

E 141 Practice for Acceptance of Evidence Based on the Results of Probability Sampling

3. Terminology

3.1 *Definitions*—For definitions of terms used in this practice, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *concrete constructions*, *n*—any object, unit, or structure that has been built of hydraulic cement concrete.

3.2.2 *category of concrete*, *n*—a specified level of quality in concrete that is observed to be in a definable range of condition as a result of service or test exposure, as distinguished from concrete in the same or related constructions that is either of differing specified quality or of the same specified quality but in observably different condition at the time of examination. It is also used to refer to concrete having a certain attribute or attributes. (see the Sampling Plan Section).

4. Significance and Use

4.1 The examination may provide a basis for laying out in situ testing of the concrete.

4.2 The sampling can provide materials for petrographic examination, in accordance with Practice C 856, chemical or physical analytical procedures, or any of a wide variety of

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates , and is the direct responsibility of Subcommittee C09.65 on Petrography.

Current edition approved July 15, 2007. Published August 2007. Originally approved in 1975. Last previous edition approved in 2000 as C 823 – 00.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

destructive or nondestructive tests to determine physical, mechanical, or structural properties of the concrete.

4.3 The results of examination and sampling carried out in accordance with this practice may be used for a variety of purposes and to serve a variety of objectives, some of which are discussed in the Procedural Plan Section.

5. Qualifications and Instruction of Personnel

5.1 *Qualifications*—The examination, formulation of sampling plan, and the sampling procedures shall be performed by persons qualified by education and experience to carry out such work, to operate equipment employed, to record and interpret observations, and to report upon the sampling plan and its execution. Technicians and workmen may be required to assist in the operations but appropriate training and supervision are mandatory.

5.2 *Instruction of Personnel*—This practice may be used by personnel employed directly by those for whom the examination and sampling program are conducted. The employer should tell the personnel in as much detail as necessary, the purposes and objectives of the examination, the kind of information sought, and the extent of examination and sampling desired. Pertinent background information should be made available. If the person to perform the work is highly experienced, the employer should seek his or her advice in delineating the investigation. The nature, extent, and objectives of the examination and sampling plan should be recorded, and the record may appropriately include the items under Agreements with Consultants.

5.3 *Agreements with Consultants*—This practice may be the basis for establishing arrangements between a purchaser of a consulting service and the consultant. The purchaser and consultant should jointly determine the nature, extent, and objectives of the examination and sampling program to be made, and should record their agreement in writing. The agreement may stipulate specific determinations to be made, observations to be reported, numbers and kinds of samples to be taken, level of reliability required for results of tests, portions of the constructions to be sampled, funds to be obligated, a time schedule for the investigation, or a combination of these and other conditions.

EXAMINATION OF CONCRETE IN CONSTRUCTIONS

6. Procedural Plan

6.1 *Objective*—The objective of the examination of concrete is to provide information that can be used to evaluate the condition of the concrete and the constructions, and to corroborate observed satisfactory performance, or to document and explain distress or failure. The examination of concrete in service or under test should be undertaken in accordance with a scope, an objective, and systematic procedures, all agreed upon between the responsible parties. The extent of the investigation and the procedures that are most appropriate for the examination depend upon a decision as to the objectives of the investigation and the level of reliability required of resulting test data. This decision may stipulate an authorized budget and a time schedule for completion of various stages of the investigation. The budget and time schedule can be modified following preliminary investigations and adjusted periodically as information accumulates.

6.2 *Purpose*—Investigations of the condition of concrete in service are usually undertaken for the following reasons: (*a*) to determine the ability of the concrete to perform satisfactorily under anticipated conditions of future service; (*b*) to identify the processes or materials causing distress or failure; (*c*) to discover conditions in the concrete that caused or contributed to satisfactory performance or to failure; (*d*) to establish methods for repair or replacement without hazard of recurrence of the distress; *(e)* to determine conformance with construction specification requirements; (*f*) to develop data to aid in fixing financial and legal responsibility for cases involving failure or unsatisfactory service; and (*g*) to evaluate the performance of the components used in the concrete. It is assumed that the manager of the investigation will begin with one or more working hypotheses, derived from information received or gathered, that are intended to explain the reasons for the condition or conditions of the concrete, and that will be continuously revised and refined as more information is received. It is intended that at the end of the investigation, an explanation will have been produced which is the best obtainable from the investigation of the available evidence concerning the mechanisms that operated to produce the condition or conditions of the constructions.

6.3 *Scope of Investigation*—The scope of an investigation of concrete in service may be limited to only isolated areas displaying deterioration. Or the investigation may be concerned with general distress, such as excessive deflection or collapse of structural members. It may involve study of the dislocation of entire structures or large portions of structures. The investigation may be confined chiefly to the study of the concrete, or it may require substantial research into other circumstances, such as foundation conditions, conditions of service, construction practices, and comparisons with other structures.

7. Preliminary Investigations

7.1 *Purpose*—The purpose of preliminary investigations is to establish the general condition of the concrete and the existence of any unsatisfactory condition, to describe its nature, and to estimate its extent and possible effect upon the performance, service life, and safety of the structure. An investigation of failure or inadequate performance of concrete in constructions is predicated upon a conclusion, usually by the owner or his representatives, that an unsatisfactory condition exists or is imminent. Such a conclusion may be in error, either because the observed condition is insignificant, or because the full extent of the actual distress or inadequacy has not been detected.

7.2 *Test Methods*—The preliminary investigation may include, as appropriate, visual inspection of the structure, review of plans and specifications for the work, and examination of available reports of project engineers and inspectors, compilation of available data on service conditions, petrographic examination in accordance with Practice C 856, and testing of a few selected samples of concrete and secondary chemical deposits in or on the concrete or both. Deflection or expansion

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:19:48 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

(or shrinkage) of typical portions of the structure might appropriately be measured. The condition of the concrete in place can be estimated using nondestructive testing procedures, such as impact devices and ultrasonic methods (see Test Method C 597). Selected critical portions of structures may be probed and sampled by drilling (Method C 42/C 42M). The cores may be tested in accordance with Test Method C 215. Borehole cameras and viewing devices have been found to be helpful in specific instances **(1, 2, 3)**.[3]

7.3 *Conclusions*—The findings of the preliminary investigation may allay all concern with respect to the condition of the concrete. In certain cases, the findings are adequate for a final conclusion on the significance of observed distress. Otherwise, care should be taken to assure that the preliminary investigation provides the information necessary to delineate a plan for the further investigations covered in Sections 8-14.

8. Assembly of Records

8.1 *Reports and Legal Documents*—The investigation of concrete performance should be preceded or accompanied by the assembly and critical review of records pertaining to the project specifications, construction contract, construction operations, concrete-making materials, weather conditions during and after construction, and the actual conditions of service. Such records should establish the specified requirements for the materials and the completed work, and may reveal circumstances or conditions that caused or contributed to the distress of the concrete. Records of operation and maintenance may describe the beginning and progress of unsatisfactory performance.

8.2 *Interviews*—Interviews with contractors, engineers, inspectors, tradesmen, and suppliers should be conducted to obtain pertinent information that is not included in the written record. Owners, occupants, and users of the constructions should be queried concerning the onset and progress of evident distress, especially with respect to possible relationship to any change of the conditions of use and service.

9. Detailed Investigations of Concrete in Constructions

9.1 *Procedures*—A detailed investigation of concrete in constructions should include all procedures that are required to achieve the approved scope and objectives within the authorized budget and time schedule. After the preliminary investigation to establish the general condition of the concrete and the extent of any unsatisfactory performance, the detailed investigation may comprise: (*a*) thorough examination of the concrete constructions; (*b*) surveys and field tests to define and evaluate the condition of the concrete in place and the safety of the constructions; and (*c*) taking samples to be examined and tested by laboratory procedures.

9.2 *Scope of Field Examination*—A detailed visual examination should be made by personnel familiar with concrete and concrete constructions. This examination should locate and describe all of the categories of concrete. All affected constructions or portions thereof should be identified and the external aspects of failure should be described as quantitatively as possible. The examination may be extended to aggregate sources in accordance with the procedures described in Practice C 295. Photographs of pertinent features of the constructions, their environs, and the manifestations of failure are valuable and should be obtained.

9.3 *Observations*—Features of the concrete to be noted especially include: (*a*) the nature and extent of cracking and fractures; (*b*) evidences of volume change, deflection, or dislocation of the constructions or portions thereof, which may include the closing or opening of joints, tilting, shearing, or misalignment of structural elements and shifting or misalignment of machinery; (*c*) the condition of exposed surfaces, especially such features as spalling, popouts, unusual weakness, disintegration, excessive wear, and discoloration; (*d*) evidences of cement-aggregate reactions; (*e*) secondary deposits on surfaces, in cracks, and in voids; and (*f*) the presence and extent of repair work and the quality of its bond to the original concrete.

9.3.1 Some of the features listed in this section can be detected more readily in laboratory examination.

9.3.2 Some of the other properties of the concrete requiring observation include: the thoroughness of consolidation; whether the concrete is air-entrained; evidences of segregation and bleeding; indications of extremely high, low, or normal water content; in the case of reinforced concrete, the condition of the steel and its location in the section; and the nature and condition of other embedded items.

9.3.3 Any phenomena indicating distress of the concrete should be studied in relation to possible causative or contributory factors, such as varying conditions of exposure over the area of the constructions; the sequence of placing operations; conditions prevailing during construction; sources of supply of concrete and concrete-making materials; identifiable problems of handling, placing, and finishing; conditions of curing and early protection; and the adequacy of the structural design and conformance to the plans. Varying conditions of exposure over the area of the constructions during and after construction may include the following:

9.3.3.1 Differences in thermal exposure to solar heating. Shaded portions probably are subjected to the lowest range of diurnal thermal cycles,

9.3.3.2 Differences in exposure to moisture, which may arise by orientation of the construction with respect to prevailing winds during times of rainfall or snowfall, and which will be affected by the diurnal thermal cycles,

9.3.3.3 Differences in the mineral composition of the subgrade so that part of the construction is located on a foundation containing swelling clay or containing unstable sulfides or sulfates, or

9.3.3.4 Differences of the moisture content of the subgrade during or after construction.

9.3.4 The foundation and subgrade materials and conditions should also be carefully examined if there is a possibility of their involvement in serviceability of the concrete.

9.3.5 The observations made, together with relevant information developed as described under Assembly of Records, and the results of the preliminary investigations as described in

[3] The boldface numbers in parentheses refer to the list of references at the end of this practice.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Preliminary Investigations, shall be assembled as may be appropriate into a report which shall either be submitted to those for whom the study was conducted or prepared for incorporation in a more comprehensive document covering other phases of an investigation of broader scope.

SAMPLING CONCRETE IN CONSTRUCTIONS

10. Requirements

10.1 Sampling each category of concrete should be done objectively so that the suite of samples taken is not weighted with unusually poor or unusually sound concrete. Samples may be taken to exemplify unusual or extreme conditions or features to aid in the identification of causes of distress or failure of concrete, but these samples should be kept apart from samples that are taken to exemplify statistically the properties of the concrete in place. Thus, the samples may be of two types, namely, (*a*) those that, together, are intended to be representative of the variability of the concrete in place, and (*b*) those that display specific features of interest but are not intended, individually or collectively, to be representative of any substantial proportion of the concrete in place. In order to be suitable for sampling, the concrete must have developed sufficient strength to allow removal of forms or temporary supports or to sustain required loads.

10.2 The samples should include portions of both near-surface concrete and concrete at depth, because the concrete may vary substantially with depth in the development of cracking, deterioration of the cement paste, progress of cement-aggregate reactions, and other features.

10.3 The samples should be sufficient in size and number to permit application of all necessary laboratory procedures upon different samples or portions of samples than those used for other tests except as noted under the section on Sampling for Compliance with Construction Specifications. Therefore, the sampling program should be arranged with foreknowledge of the laboratory testing program to be covered by the plan of the investigation.

10.4 The samples secured for each test procedure should be sufficient in number to provide an estimate that is of acceptable reliability as described in the Sampling Plan Section.

11. Sampling Plan

11.1 Representative samples should be taken in accordance with a prearranged plan that will meet the stipulations given under Sampling Concrete in Constructions. The plan should also conform with the recommendations of the Sections on Characteristics of a Probability Sampling Plan and Minimum Standards for a Probability Sampling Plan in Practice E 105. For guides in application of statistical methods to small numbers of samples, see Ref (**4**). Two sampling situations may arise, namely:

11.1.1 *Situation 1*—The preliminary examination and other information indicate that all of the concrete is in a similar condition and is of similar quality, or that it is infeasible without taking and testing samples, to determine whether or not the concrete is essentially uniform; and

11.1.2 *Situation 2*—The preliminary examination and other information indicate that the concrete is in two or more categories or comprises two or more portions that are or are likely to be of differing composition or quality.

11.2 Under Situation 1, sampling locations should be spread randomly or systematically over the area of interest. For large structures and substantial areas of pavement, the sampling sequence should be repeated at some predetermined frequency, such as for each 50, 100, 500 m^2 (500, 1000, or 5000 ft^2) of exposed concrete, as may be appropriate. Any method for determining sampling locations may be employed provided the locations are established without bias.

11.3 In Situation 2, samples may be taken for comparison with respect to several categories of performance by using the Chi-Square test (**5**).

11.4 *Recommended Sampling Method*—Prepare to scale an outline sketch or sketches or obtain scaled large photographs of the surface or surfaces from which representative samples are to be extracted, and subdivide the entire area, comprising all of the separate surfaces, into equal or approximately equal sections, at least ten in number and not less than the number of separate areas that are included in the investigation. Designate each section by a number or letter. Choose sections to be sampled by drawing numbered or lettered slips of paper at random from a container, or by using a list of random numbers or letters. Take samples, as by drilling, in accordance with the provisions of the section on Sampling Procedures at locations that are marked at random on the sketch of each of the indicated sections (Note 1).

11.4.1 In an investigation of test specimens or concrete products, the units to be examined and tested should be selected randomly by similar means from the lot or lots.

11.4.2 Prefabricated products of large dimension, such as building units, pipe, and piling, can be sampled by the recommended method as it is applied to structures and pavements.

11.4.3 The procedure should be modified as appropriate to provide for sampling concrete members or elements that have been removed from constructions that are under investigation.

NOTE 1—If it is necessary to avoid critical reinforcement, embedded hardware, or other construction features, shift the sampling location a minimum necessary distance to the north (or up on vertical surfaces). If such a move is not feasible, shift to the east, south, or west (or right, down, or left), alternatively considered, in that order.

11.5 *Sample Size*—For samples to be subjected to tests yielding a numeric value, the number of samples should be determined in accordance with the recommendations of Practice E 122, based upon the degree of confidence desired to be placed in the result. The quantity of concrete and the dimensions of pieces secured in the sampling operation should conform with the stipulations of the applicable method of test.

11.6 *Evaluation of Test Results*—Test results from samples obtained in accordance with Situation 1 are evaluated on the basis of the following statistics, average or mean values, $\bar{X}$; standard deviation of individual values, s. These statistics are computed as follows:

$$\bar{X} = \frac{\Sigma X_i}{n} \quad (1)$$

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:19:48 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$$s = \sqrt{\frac{\Sigma(X_i - \bar{X})^2}{n - 1}} \quad (2)$$

where:
X_i = an individual test result, and
n = the number of test results averaged.

11.6.1 *Evaluation of Test Results on the Basis of Variability*—Variability of test results within a group is indicated by *s*. Whether or not these statistics are excessively large can only be determined by comparing them with some prior knowledge about what the variability ought to be. The best information on what the variability should be is contained in the precision statement in the test method by which the results were obtained. Directions for obtaining an acceptable range for *n* individual results and an acceptable difference between the averages of two groups of tests from the same category of concrete are given in Practice C 670.

11.6.2 *Evaluation of the Quality of Concrete*—Quality of the concrete in question can be assessed by comparing the average of test measurements from a group within the category of questionable quality with one obtained from a category of good quality. A Student's *t* test may be applied to the difference between the two averages to make a decision whether the difference is significant or not (**6**). Before conducting the *t* test, other considerations must be borne in mind. These include the nature and intent of the constructions, the kinds of properties relevant to successful concrete in the constructions, the nature of any distress, the economics of maintenance, the need for repair, if any, and the desired service life of the structure.

11.7 Under Situation 2, each separate category of exposed surface of the concrete constructions, or each category of test specimens or concrete products should be treated individually as under Situation 1 to establish sampling locations and number of samples and to select particular specimens or product units for examination. For example, completely scaled, partially scaled, and unscaled areas of pavement concrete of a specified level of quality should be sampled separately in accordance with the recommended method so that three suites of samples are secured, each suite comprising concrete of a specific category and each conforming with the recommendations of Practices E 105 and E 122. Any number of suites of samples may be required for proper investigation of concrete that is within the scope of an approved plan so as to adequately evaluate concrete of differing specified levels of quality and concrete in differing condition following the service exposure.

11.8 For purposes of engineering surveys and research programs, the number of samples and their characteristics may be established by responsible personnel in accordance with the scope and objectives of the investigation.

12. Sampling for Compliance with Construction Specifications

12.1 To determine compliance of hardened concrete with requirements of codes or contract specifications, each sample of concrete should be sufficient in quantity and dimensions to permit performance of the applicable test procedure in accordance with the stipulations of the method of test.

12.2 The number of samples to be taken from each category of concrete should be established in accordance with recommendations of Practices E 105 and E 122 so as to provide a reliable estimate of the standard deviation and average value of the test results. The level of reliability required and the criteria for acceptance of the results as set forth in Practice E 141 should be established as a part of construction specifications or, if not, as a part of the sampling plan. In the event that no such stipulation has been established beforehand, not less than five samples shall be taken from each category of concrete for each test procedure stipulated in the Procedural Plan, except as provided in 12.3.

12.3 In some instances, two or more tests may be performed on the sample or samples, provided the tests performed initially do not modify the properties of the concrete to be evaluated by subsequent tests. Any such reuse or successive use of samples shall be stipulated in detail beforehand in the sampling plan so as to specify the kinds of tests that may be performed successively, the sequence of testing, and precautions to be taken in performance of the tests and handling of the sample during the course of the testing. Examples of permissible successive testing are unit weight followed by a compression test, air void content in accordance with Test Method C 457 followed by petrographic examination, and compression test followed by chemical test for cement content (provided care is taken to avoid loss of fragments of the specimen).

13. Sampling Procedures

13.1 In general, samples of hardened concrete from constructions, concrete products of large size, or large test specimens should be secured in accordance with the applicable sections of Test Method C 42/C 42M. Specimens of hardened concrete may be obtained by coring, sawing, or otherwise removing portions of the concrete (Note 2). Sawing or coring by rotary drilling (Note 3) is preferred for samples to be subjected to tests of physical properties or to petrographic examination. Caution should be used to avoid or to minimize fracturing the concrete or contamination of the sample with foreign substances. Use of sledges, chisels, and similar tools should be avoided. Their possible effects on the integrity of the sample must be considered during examination and testing of the samples.

NOTE 2—Care should be taken to avoid cutting critical sections of reinforcement, conduit, and duct-work.

NOTE 3—Diamond-drilled cores are preferred to shot-drilled cores, because the outer surfaces are smoother and reveal the composition and fabric of the concrete more clearly than shot-drilled cores.

13.2 Samples for examination may be secured from small beam or slab specimens or from small prism-shaped or columnar concrete products by sawing across the entire width and depth, for example at the third-points and the middle of the length. Samples from vertically cast concrete cylinders should be secured from top and bottom halves or top, middle, and bottom portions or by sawing the specimen longitudinally. These samples will represent any variability arising as a consequence of placing and compaction procedures, segregation, or bleeding. Similar procedures and precautions should be employed in securing samples from other types of test specimens and concrete products. Methods for obtaining portions of samples for testing purposes are outlined in 13.1, 13.2, and in Table 1.

TABLE 1 Minimum Depth of Sampling of Concrete for Testing Purposes[A]

Types of Construction	Thickness of Section, m (ft)	Minimum Depth to Be Sampled, m (ft)
Slabs, pavements, walls, linings, foundations, structural elements accessible from one side only	0.3 (1.0) or less	entire depth
	0.3 (1.0) or greater	0.3 (1.0)
Suspended slabs,[B] walls, conduits, foundations, structural elements exposed to the atmosphere at two or more sides; concrete products	0.15 (0.5) or less	entire depth
	0.15–0.6 (0.5–2.0)	one half the thickness or 0.15 (0.5) whichever is greater
Massive sections	0.6 (2.0) or greater	0.6 (2.0)

[A] The requirements of Table 1 may not provide the quantities or dimensions of samples that are required by the stipulations of Sections 11 and 12. In that case, the necessary additional quantity of concrete in pieces of appropriate minimum size should be taken at each sampling location in accordance with the requirements of Section 13.

[B] When suspended slabs are cored, it is desirable to leave the lower 1 in. or 25 mm uncored, so as not to lose the core by its falling from the barrel and to make it easier to patch the core hole.

13.3 If feasible, samples should be taken perpendicular to the layers in which the concrete was deposited. The sample should include the exposed surface, near-surface concrete, any concrete in contact with aggressive waters or other aggressive substances, and concrete at depth. Samples of isolated spalls or popouts should include representative examples of the spalls and popouts and the underlying and adjacent concrete. For sampling, various common types of concrete constructions, recommended minimum depths or thicknesses across which samples should be taken, are shown in Table 1. Deeper drilling may be required to determine the extent of cracking, condition of construction joints, extent of any cement-aggregate reactions, condition of concrete in contact with subgrade material, and variability of the concrete.

13.4 Samples should be identified and oriented by painted or inked markings on the material itself, if feasible. The concrete should be wrapped and sealed as may be appropriate to preserve the moisture content representative of the structure at the time of sampling, and should be packed so as to be properly protected from freezing or damage in transit or storage, especially if the concrete is very weak.

14. Information to Accompany Samples

14.1 The personnel who will supervise the laboratory tests, analyses, or examinations of the samples should receive complete information on the identity and sources of the samples and on the problem that is being investigated. In particular, they should be advised of and, preferably, consulted about the specific questions that are to comprise the objectives of the investigation.

14.2 Specific items of information that should be available to the supervisor or consultant are:

14.2.1 Location of the source of each sample, orientation of the sample, depth from which the sample was taken, and sampling procedures. Photographs of samples and of the sampling locations should be provided, if possible.

14.2.2 Report of both the preliminary and detailed field investigations, including a description of the performance of concrete in service and the results of the examination of the concrete in the field. The surveys, field tests, and other pertinent information on the constructions and sources of the concrete and concrete-making materials should be included.

14.2.3 Results of any tests or analyses that were performed on the concrete or concrete-making materials.

15. Keywords

15.1 construction; coring; deterioration; exposure condition; field inspection; hardened concrete; performance; petrographic examination; photograph; representative sample

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 823 – 00, that may impact the use of this practice. (Approved July 15, 2007)

(*1*) Changed the standard into a dual designation, adding new 1.2 and renumbering subsequent paragraphs.

(*2*) Revised the order of units in 11.2 and Table 1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 827 – 01a (Reapproved 2005)

Standard Test Method for Change in Height at Early Ages of Cylindrical Specimens of Cementitious Mixtures[1]

This standard is issued under the fixed designation C 827; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the determination of change in height of cylindrical specimens from the time of molding until the mixture is hard.

1.2 This test method covers height change measurements at early ages for cementitious mixtures of paste, grout, mortar, and concrete.

1.3 This test method is intended for determination of changes in height that occur from the time of placement until the specimen is fully hard. These include shrinkage or expansion due to hydration, settlement, evaporation, and other physical and chemical effects.

1.4 The values stated in SI units are to be regarded as the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.6 The text of this test method references notes and footnotes that provide explanatory information. These notes and footnotes shall not be considered as requirements of the test method.

2. Referenced Documents

C 1437 Test Method for Flow of Hydraulic Cement Mortar

3. Terminology

3.1 *Definitions*—The terms used in this test method are defined in Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *early-age change in height*, *n*—the measured increase or decrease in height of a laterally confined cylindrical test specimen from the time of molding to when the mixture becomes hard. The user may want to define this age as the time when a companion specimen of the same batch has reached the time of final setting by Test Method C 191 (paste), C 953 (mortar or grout), C 403/C 403M (concrete), or establish a predetermined age in minutes from the time the specimen is cast as the defined age to record the final measurement.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.68 on Volume Change.

Current edition approved July 1, 2005. Published August 2005. Originally approved in 1975. Last previous edition approved in 2001 as C 827 – 01a.

www.technobetar.ir

Changes in height are measured and expressed as a positive or negative change in the height of a test specimen that is restrained from lateral movement.

4. Significance and Use

4.1 This test method provides a means for comparing the relative shrinkage or expansion of cementitious mixtures. It is particularly applicable to grouting, patching, and form-filling operations where the objective is to completely fill a cavity or other defined space with a freshly mixed cementitious mixture that will continue to fill the same space at time of hardening. It would be appropriate to use this test method as a basis for prescribing mixtures having restricted or specified volume change before the mixture becomes hard.

4.2 This test method can be used for research purposes to provide information on volume changes taking place in cementitious mixtures between the time just after mixing and the time of hardening. However, the specimen used in this test method is not completely unrestrained so that the measurements are primarily useful for comparative purposes rather than as absolute values. Further, the degree of restraint to which the specimen is subjected varies with the viscosity and degree of hardening of the mixture.

5. Apparatus (see Fig. 1)

5.1 *Projected Light Source*, a lamp and a condensing lens of sufficient intensity to adequately project a light beam on a wall about 5 m (15 ft) from the light source. Protect the test specimen from heat from the light source and limit air movement (Note 1).

NOTE 1—Placing a sheet of transparent glass or plastic between the light source and the test specimens may be beneficial.

5.2 *Indicator Ball*, a spherical ball of nonabsorptive material with a density that is 55 ± 5 % of the density of the cementitious mixture being tested, having a diameter not more than 16 mm (⅝ in.) nor less than 6 mm (¼ in.), and composed of materials that have no reaction with the cementitious mixture during the test period.[3]

NOTE 2—A density of approximately 1.2 Mg/m^3 has been found appropriate for most uses of this test method. The density of the cementitious mixture may be calculated from values for "unit weight" obtained using Test Method C 138/C 138M (concrete) or C 185 (mortar, grout, or paste).

5.3 *Magnifying Lens System*, a magnifying lens system such that the image of the indicator ball produced by the projected light source is cast on the indicating chart about 5 m (15 ft) away at a magnification of 90–110×, mounted so as not to touch the test specimen when a test is in progress (see Note 3), and having a separate magnifying lens system for each specimen tested simultaneously.

NOTE 3—One magnifying lens system that has been found acceptable consists of two lenses: a projection and a relay lens enclosed in a sealed tube. In this system, the relay lens is located nearer the test specimen and has a focal length of 50.8 mm (2 in.) and is located approximately 115 mm (4½ in.) from the indicator ball. The projection lens has a focal length of 41.4 mm (1⅝ in.), and relative aperture of *f*1.6 and is 133.1 mm (5¼ in.) from the relay lens.

5.4 *Indicating Charts*, composed of stiff material approximately 600 mm (24 in.) high by 250 mm (10 in.) wide, with a white surface and a vertical black line 2 mm (1/16 in.) wide, centered and running the complete length of the chart, and a horizontal black line 1 mm (1/32 in.) in width midway on the chart, identified as the zero (0) or starting line, and 2-mm (1/16-in.) horizontal graduations above and below the zero line on the entire length of the vertical line, and a means for attaching this chart vertically and firmly to a distant wall.

5.5 *Molds*, rigid, watertight molds with a smooth interior surface made of steel, cast iron, or other nonabsorbent material nonreactive with the cementitious mixture being tested, cylindrical in shape, with internal height twice the internal diameter. Three sizes of molds are used in this test method with heights of 100, 150, 300 mm (4, 6, 12 in.).

5.6 *Rods*, two straight, steel tamping rods: one 10 mm (⅜ in.) in diameter and approximately 300 mm (12 in.) in length and the other 16 mm (⅝ in.) in diameter and approximately 600 mm (24 in.) in length. The 10-mm rod shall be used with paste, grout, and mortar. The 16-mm rod shall be used with concrete.

6. Test Specimen

6.1 Unless otherwise specified, prepare two test specimens from each batch to be tested simultaneously using duplicate test apparatus. For cement pastes, grouts, and mortars where all the aggregate will pass through a 4.75-mm (No. 4) sieve, use the 100-mm (4-in.) mold. For cementitious mixtures containing

[3] An 11-mm (7/16-in.) nylon plastic indicator ball has been found acceptable for most tests and is available from U.S. Plastics Corp., 1390 Neubrecht Rd., Lima, OH 45801.

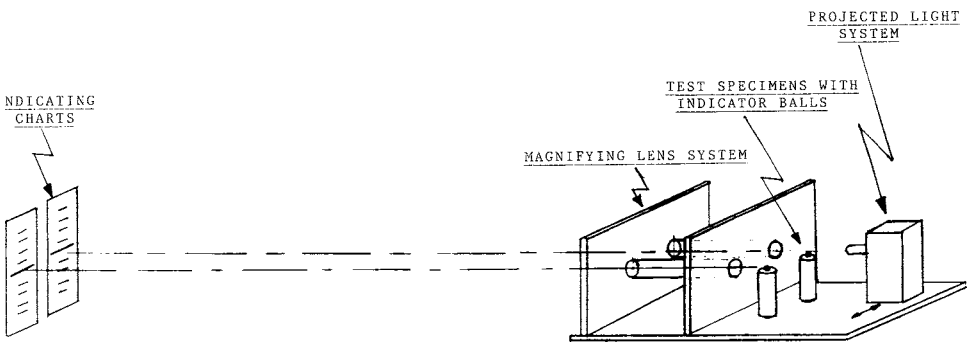

FIG. 1 Apparatus for Early Change in Height

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:19:45 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

aggregate that will not all pass through a 4.75-mm sieve, but which will all pass the 12.5-mm (½-in.) sieve, use the 150-mm (6-in.) mold. For concrete mixtures having particles retained on the 12.5-mm (½-in.) sieve or larger, use the 300-mm (12-in.) mold.

7. Calibration

7.1 *General*—Minimize any sources of light not required for the tests. Locate the test equipment and specimens on a surface substantially free of vibration during the test. If desired, use a single projected light source for both test specimens with duplicate magnifying lens systems and indicating charts.

7.2 *Apparatus Calibration*—Calibrate the entire apparatus prior to the start of each test. Darken the room, illuminate the projected light source, and place the dummy test specimens (preferably hardened test specimens) in the light beam before each of the magnifying lens systems. Adjust the location of each test specimen until a sharp, clear image of the indicator ball is produced on the indicating chart. Then reposition the indicating chart so that the indicating ball image falls on the zero line. Place a steel rod of known diameter (see Note 4) horizontally on top of each indicator ball and record the height of the image it produces on its respective indicating chart. The ratio of the image height to the actual rod diameter is the magnification of the lens system. Moving the projected light source, test specimen, and magnifying lens system toward or away from the indicating chart can change the magnification. Once proper magnification (90 to 110×) is obtained, remove the dummy test specimens and do not change the relative locations of the test apparatus during the test.

NOTE 4—The shank of a 2-mm (1/16-in.) twist drill bit has been found satisfactory for most tests.

8. Preparation of Mixtures

8.1 *General*—Bring all materials to a temperature of 23 ± 2.0 °C (73 ± 3 °F) before mixing. Other material temperatures shall be used for this test method when specified. Proportion all materials by mass in accordance with the specifications for the cementitious mixtures to be tested.

8.2 *Mortars, Pastes, and Grouts*:

8.2.1 Either hand mix or use a suitable mechanical mixer (see Note 5) for a mixing time of 4 min, unless otherwise recommended by the manufacturer. Place all the mixing water in the mixing bowl prior to introduction of the other materials for the batch. For mortar materials that are not premixed, the sequence of mixing shall be in accordance with Practice C 305.

NOTE 5—The mechanical mixer described in Practice C 305 is a suitable mixer. However, the clearances between paddle and bowl specified in this test method are suitable only for mortars made with fine aggregates that are finer than the 850-µm (No. 20) sieve. Mortars made with aggregates containing particles coarser than the 850-µm sieve may require special clearances or a different type of paddle to permit the mixer to operate freely and to avoid damage to the paddle and bowl.

8.2.2 Determine the consistency of he mixtures by the flow test in accordance with the applicable provisions of Test Method C 1437. If this procedure is used, the flow after 5 drops of the flow table in 3 s is 145 or less. A plastic mixture should have a flow of 100 to 125, and a flowable mixture should have a flow above 125 when tested by the preceding modification of Test Method C 109/C 109M but not less than 30 s when tested using the flow-cone procedure of Test Method C 939. A fluid mixture should have a time of efflux of 10 to 30 s when tested by the flow-cone procedure. The water required to produce the specified consistency shall be determined by the testing of trial batches. Fresh materials shall be used to make each trial. If not specified or recommended otherwise, use sufficient mixing water to produce a flow of 135 ± 5. For premixed mortars or grouts, use the amount of water suggested by the manufacturer for the intended application. The consistency should be determined and the values recorded for all tests.

8.3 *Concrete*—Mix concrete either manually or in a suitable laboratory mixer in accordance with the applicable provisions of Practice C 192/C 192M. Determine the consistency of the concrete by the slump test in accordance with the applicable portions of Test Method C 143/C 143M, and unless otherwise specified, use sufficient mixing water to produce a slump of 90 ± 15 mm (3½ ± ½ in.).

9. Molding Specimens

9.1 Fabricate 100-mm and 150-mm (4-in. and 6-in.) specimens by filling the mold in a continuous pouring operation for pourable mixtures or in three layers with consolidation of each layer by tapping the outside of the mold ten times with a 10-mm (⅜-in.) diameter rod in the case of mixtures that are not pourable. Fabricate 300-mm (12-in.) specimens in accordance with Practice C 192/C 192M.

9.2 Screed off the surface of the test specimen to the top of the mold. In cases where extreme shrinkage or expansion of material is anticipated, adjust the height of the test material to ±6 mm (¼ in.) with respect to the mold height.

10. Procedure

10.1 Place an indicator ball in the center of the surface of each specimen. Tap the indicator ball lightly so that approximately one half of the ball's diameter penetrates the test specimen mixture. Remove pieces of large aggregate directly under the indicator balls, and repeat the procedure. Then tap the outer side of the molds lightly three times so that the indicator balls can adjust to their own natural displacement level in the mixture. Position each specimen between the projected light source and the magnifying lens system. Adjust the position of the test specimens horizontally until the images of the indicator balls on the indicating charts are sharp and clear. Reposition the indicating charts so that the indicating ball images fall on the zero lines. Complete these activities in not more than 5 min after completion of mixing unless otherwise specified. Record this time as the start of the test. Unless otherwise specified, conduct tests with test specimens that are free to evaporate to the atmosphere. Record ambient air temperature and humidity. If a moist storage condition is specified, place a few drops of medium-weight motor oil on the test specimen surface to allow an oil film to cover the exposed surface of the test specimen. During the test, carefully place additional drops of oil on the test specimen surface by an eyedropper or other suitable means, taking care not to touch the indicator ball.

10.2 *Test Measurements*—Once the test specimens are placed in position, do not jar, touch, or move the test apparatus

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

until the completion of the test. Record movements of the indicator balls as projected on the indicating charts at 5-min intervals during the first 90 min, at 10-min intervals for the next 1 h, and at 20-min intervals thereafter until the mixture has hardened (Note 6). Clearly identify all readings from the charts as positive (+) for increase in height, and negative (–) for decrease in height, read to the nearest 0.1-in. (2-mm) graduation vertically, and record the time to the nearest 1 min (see Note 7).

NOTE 6—Time of hardening may be taken as the time of final setting as determined by Test Methods C 191 for cement pastes, C 807 for mortars and nonfluid grouts, C 953 for fluid grouts, and C 403/C 403M for concrete mixtures. Measurements may be continued after hardening, if desired.

NOTE 7—Automated recording of time and height is permitted as long as requirements for precision and accuracy are met

11. Calculation

11.1 *Change in Height of Specimen*—Calculate the changes in height of the test specimens as follows:

$$°H = (I/MH) \times 100 \quad (1)$$

where:

$°H$ = change in height, %: positive (+) for increase, negative (–) for decrease,
I = indicating chart reading, in. (mm): positive (+) for increase, negative (–) for decrease in height,
H = initial height of test specimen, in. (mm), and
M = magnification of lens system.

12. Report

12.1 Plot the changes in height as points on a graph, with increase (+) above the zero line and decrease (–) below the zero line. Report all change in height and time readings from the start of the test to conclusion, as percent versus time. Show the average of the data as a smooth curve. Calculate the maximum change in height using the largest indicating chart reading obtained during the test period and report as increase or decrease. In the event that both increase and decrease result, report the maximum change in height.

12.2 Report the following information:

12.2.1 Number and size of specimens tested and the date,

12.2.2 Source and identification of all materials used in the mixtures,

12.2.3 Flow, slump, or qualitative consistency of the mixture,

12.2.4 Magnification,

12.2.5 Temperature of the test mixture, ambient temperature at time of molding specimens, and ambient temperature and relative humidity throughout the test period if the test specimens are allowed to dry by exposure to the atmosphere,

12.2.6 Time interval from addition of the dry materials to the mixing water in the mixer to the time of start of test,

12.2.7 Magnitude and time of occurrence of maximum decrease, maximum increase in height, change in height at time of hardening of the mixture, and change in height at the conclusion of the test,

12.2.8 Appearance of bleed water on the test specimen surface during the test period, and

12.2.9 Any other information that may be pertinent.

13. Precision and Bias

13.1 *Precision*—The single-operator standard deviation for sand/cement mixtures has been found to be 0.12 % (Note 8) change in height. Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 0.34 % change in height.

13.2 The single-operator standard deviation for cement paste has been found to be 0.43 % (Note 8) change in height. Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 1.22 % change in height.

NOTE 8—These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670. Data were from tests of specimens 4 in. in height.

13.3 *Bias*—This test method has no bias because the value of the change in height can only be defined in terms of a test method.

14. Keywords

14.1 change in height; cementitious mixtures; concrete; expansion; grout height change; mortar; paste; shrinkage

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Designation: C 840 – 08

Standard Specification for Application and Finishing of Gypsum Board[1]

This standard is issued under the fixed designation C 840; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers the minimum requirements for the methods of application and finishing of gypsum board, including related items and accessories.

1.2 Details of construction for a specific assembly to achieve the required fire resistance shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing laboratories.

1.2.1 Where this specification is more stringent (size or thickness of framing: size and spacing of fasteners) than the fire-rated construction, this specification shall govern.

1.3 Where sound control is required for a gypsum board assembly, details of construction shall be in accordance with reports of acoustical tests of assemblies that have met the required acoustical values.

1.4 Unheated spaces above gypsum board ceilings shall be properly ventilated (see Appendix X2).

1.5 The various application systems are located in the following sections:

I	Application of Single-Ply Gypsum Board to Wood Framing Members	8
II	Application of Two-Ply Gypsum Board to Wood Framing Members	9
III	Application of Gypsum Board by Adhesive Nail-On to Wood Framing Members	10
IV	Semi-Solid Gypsum Board Partitions	11
V	Solid Gypsum Board Partitions	12
VI	Application of Gypsum Board with Adhesives to Interior Masonry or Concrete Walls	13
VII	Application of Gypsum Board to Rigid Foam Insulation	14
VIII	Application of Gypsum Board to Steel Framing and Furring	15
IX	Arches and Bending Radii	16
X	Application of Gypsum Board to Receive Tile by Adhesive Application	17
XI	Exterior Application of Gypsum Wallboard and Exterior Gypsum Soffit Board	18
XII	Floating Interior Angles	19
XIII	Control (Expansion) Joints	20
XIV	Foil-Backed Gypsum Board	21

The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.6 The text of this specification references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.7 The following precautionary caveat pertains only to Sections 6-24. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.7.1 For specific precautionary statements, see 4.1.1, 4.1.2, and 22.5.

2.3 *ANSI Standard:*
ANSI A 136.1 Organic Adhesives for Installation of Ceramic Tile, Type I and Type II[4]

3. Terminology

3.1 *Definitions*—Definitions shall be in accordance with Terminology C 11.

3.2 *Descriptions of Terms Specific to This Standard:*

3.2.1 *all-purpose compound*, *n*—a compound formulated and manufactured to serve as a taping or finishing compound, or both.

3.2.2 *critical lighting*, *n*—a condition where interior surfaces are flooded by natural or artificial lighting at an oblique angle.

3.2.3 *decoration*, *n*—paint (including primers), texture, coatings, and coverings such as wallpaper and sheet plastic materials designed to conceal or protect the surface of the gypsum board (see Appendix X3).

3.2.4 *dry type*, *n*—a compound in powder form to be mixed with water before use.

3.2.5 *drying type*, *n*—a compound that hardens by the evaporation of the vehicle used to make the paste.

3.2.6 *drywall primer*, *n*—a paint material specifically formulated to fill the pores and minimize the suction difference between gypsum board surface paper and the compound used on finished joints, angles, fastener heads and accessories, and over skim coatings.

3.2.7 *face panel*, *n*—outside ply of multiple layer gypsum board assemblies.

3.2.8 *finished wallboard*, *n*—wallboard that has had the joints taped, has had the joints, fastener heads, and flanges of accessories concealed with joint compound, and has been sanded to prepare the surface to receive job applied decoration.

3.2.9 *finishing*, *n*—the preparation of gypsum board surfaces to receive the field application of decoration.

3.2.10 *finishing compound (sometimes called topping compound)*, *n*—a compound used for successive coats over the taping or all-purpose compound that provides a smooth and level surface for the application of decoration.

3.2.11 *finishing of accessories*, *n*—the application of compound to flanges of accessories to create a monolithic surface.

3.2.12 *flange*, *n*—that part of an accessory extending over the face of the gypsum wallboard intended to become a part of the monolithic plane of the prepared surface.

3.2.13 *framing member*, *n*—that portion of the framing, furring, and blocking to which the gypsum board is attached.

3.2.14 *harden*, *v*—a condition reached when the compound has lost its plasticity to an arbitrary degree, measured in resistance to penetration or deformation.

3.2.15 *joint photographing*, *n*—a condition where the finished joint areas visible after final decoration.

3.2.16 *joint tape*, *n*—a strip of material designed to be embedded in compound to reinforce joints, cracks, or other small openings in or between gypsum boards.

3.2.17 *joint treatment*, *n*—application of joint tape and compound to the joint between gypsum boards.

3.2.18 *laminating compound*, *n*—a compound (abrasive) used to adhere gypsum board to gypsum board or other monolithic materials.

3.2.19 *moderate contact*, *n*—the edges and ends are butted at joints but not forced together.

3.2.19.1 *Discussion*—Small gaps not greater than ¼ in. (6 mm) are acceptable (see 7.4)

3.2.20 *parallel or vertical application*, *n*—gypsum board applied with the edges parallel to the framing member to which it is attached.

3.2.21 *perpendicular or horizontal application*, *n*—gypsum board application with the edges applied at right angles to the framing member to which it is attached.

3.2.22 *ready-mix type*, *n*—a factory-prepared compound ready to be used without the addition of water.

3.2.23 *required*, *adj*—pertaining to a mandatory obligation imposed by a force outside this standard, such as a building code, project specification, contract, or purchase order.

3.2.24 *setting type*, *n*—a compound that hardens by a chemical reaction and increases in straight through drying.

3.2.25 *skim coat*, *n*—a thin layer of skim coat compound applied over the entire surface of finished gypsum board.

3.2.25.1 *Discussion*—A skim coat is essentially a film of joint compound and is not applied at a readily measurable thickness. There is no specific mil thickness that constitutes a proper skim coat (See Appendix X8).

3.2.26 *skim coat compound*, *n*—joint compound, or a material specifically formulated and manufactured for use as a skim coat.

3.2.27 *specified*, *adj*—pertaining to a mandatory requirement of this standard or a referenced requirement (see 3.2.21).

3.2.28 *spotting fastener heads*, *n*—the application of compound to cover the fastener head to create a monolithic surface.

3.2.29 *taping compound (sometimes called embedding compound)*, *n*—a compound used for embedding and bonding joint tape and for the first coat over the heads of fasteners and flanges of accessories.

3.2.30 *taping of joints*, *n*—the application of compound and joint reinforcing tape to the joints between adjoining gypsum boards.

3.2.31 *treated joint*, *n*—a joint between gypsum boards that has been covered with joint tape and joint compound as specified in 22.3.3.1, 22.3.3.2, or 22.3.3.3.

3.2.31.1 *Discussion*—Strip moldings or similar devices shall be permitted.

4. Environmental Conditions

4.1 *Application of Gypsum Board, Joint Treatment Materials, and Adhesives*—Room temperature shall be maintained at not less than 40 °F (4 °C) during application of gypsum board except when adhesive is used for the attachment of gypsum board. For the bonding of adhesive, joint treatment, texturing, and decoration, the room temperature shall be maintained at not less than 50 °F (10 °C) for 48 h prior to application and continuously thereafter until completely dry.

4.1.1 When a temporary heat source is used, the temperature shall not exceed 95 °F (35 °C) in any given room or area.

4.1.2 Adequate ventilation shall be maintained in the working area during installation and curing period.

4.2 Gypsum board shall be protected from direct exposure to rain, snow, sunlight, or other excessive weather conditions.

NOTE 1—Where manufacturers' recommendations differ from the above, follow their recommendations.

4.3 Ready-mixed joint compounds shall be protected from freezing, exposure to extreme heat, and direct sunlight.

5. Materials and Manufacture

5.1 *Gypsum Boards*— A family of gypsum sheet products as defined in Terminology C 11.

5.1.1 *Type X (Special Fire-Resistant) Gypsum Wallboard, Gypsum Backing Board, Water-Resistant Gypsum Backing Board, or Exterior Gypsum Soffit Board*—Gypsum board that provides a greater degree of fire resistance than regular gypsum board as defined in Specification C 1396/C 1396M.

5.1.2 *Foil-Backed Gypsum Wallboard or Gypsum Backing Board*—Regular or Type X gypsum board with foil laminated to the back surface. The foil is a vapor retarder.

5.1.3 *Predecorated Gypsum Board*—Gypsum board with a decorative wall covering or coating applied in-plant by the gypsum board manufacturer.

5.2 *Gypsum Wallboard*— See Specification C 1396/C 1396M.

5.3 *Gypsum Backing Board and Coreboard*—See Specification C 1396/C 1396M.

5.4 *Water-Resistant Gypsum Backing Board*—See Specification C 1396/C 1396M.

5.5 *Exterior Gypsum Soffit Board*—See Specification C 1396/C 1396M.

5.6 *Gypsum Ceiling Board*—See Specification C 1396/C 1396M.

5.7 *Finishing Materials*:

5.7.1 *Compounds*—Taping compound, finishing compound, and all-purpose compound shall meet the requirements of Specification C 475/C 475M.

5.7.2 Mix compounds in accordance with the manufacturers' directions.

5.7.3 *Joint Tape*—See Specification C 475/C 475M.

5.8 *Fasteners*:

5.8.1 *Nails*—See Specification C 514.

5.8.2 *Screws*:

5.8.2.1 See Specification C 1002 for screws for fastening gypsum board to wood members, steel members less than 0.03 in thickness, and to gypsum board.

5.8.2.2 See Specification C 754 and Specification C 954 for screws for fastening gypsum board to steel members from 0.033 to 0.112 in. in thickness.

5.8.3 *Staples*—No. 16 USS gage flattened galvanized wire staples with 7⁄16-in. (11.1-mm) wide crown outside measurement. Legs shall have divergent points.

NOTE 2—Use only for the base ply of two-ply gypsum board application.

5.9 *Adhesives*:

5.9.1 *Fastening Gypsum Board to Wood Framing*—See Specification C 557.

5.9.2 *Fastening Gypsum Board to Steel Framing*—As specified by the manufacturer.

5.9.3 *Laminating Gypsum Board to Gypsum Board*—Laminating compounds, taping compound, or adhesive shall be as specified by the manufacturer.

NOTE 3—Adhesives for the installation of ceramic tile, see Appendix X4.

5.10 *Framing Members*:

5.10.1 Wood framing members shall conform to PS20, American Softwood Lumber Standards. The surface to which abutting edges or ends are attached shall be not less than 1 ½ in. (38.1 mm) wide. For internal corners or angles, the bearing surface shall not be less than ¾ in. (19.1 mm).

5.10.2 *Steel Studs, Furring Channels, and Runners,* Non-Load Bearing—See Specification C 645.

5.10.3 *Gypsum Studs*— Specification C 1396/C 1396M, not less than 1 in. (25.4 mm) thick by 6 in. (152 mm) wide. Studs shall be either solid or laminated.

5.11 *Accessories*—See Specification C 1047.

5.12 *Water*—Water shall be clean, fresh, and potable (suitable for domestic consumption).

5.13 *Face Panels*—Face panels shall be ½ in. (12.7 mm), 5⁄8 in. (15.9 mm), or multiple laminations of regular or Type X gypsum board.

5.14 *Core Board*—Core board shall be ¾ in. (19.1 mm) or 1 in. (25.4 mm) either single thickness or multiple layers to the required thickness.

6. Substrate, Surface Preparation

6.1 The attachment surface of any framing member shall not vary more than 1⁄8 in. (3.2 mm) from the plane of the faces of adjacent framing members.

6.2 Wood framing shall be as straight and true as possible. Wood framing shall be securely attached following acceptable engineering practices and as required for the intended design.

NOTE 4—For installation of wood framing, see Appendix X5.

6.3 Metal framing members shall be of the proper size and design for their intended use and shall be installed in accordance with Specifications C 754 or C 1007 as required.

6.4 Devices or items attached to framing members, including the fasteners used to attach such devices or items, shall not protrude more than 1⁄8 in. beyond the surface to which the gypsum board is to be applied.

6.5 Masonry or concrete walls shall be dry, free of dust, oil, or form release agents, protrusions or voids, or foreign matter that inhibit bond for adhesively applied gypsum board.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:05 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.6 All framing members and substrate shall be installed so that after the gypsum board has been applied, the finished surface will be in an even plane.

6.7 Gypsum board shall be kept free of any dirt, oil, or other foreign matter that cause a lack of bond. Foreign matter shall be removed.

6.8 All dents or gouges on the face of the gypsum board shall be brought up to a smooth level plane with the surface of the board.

6.9 Mechanical fasteners shall be set below the plane of the surface of the board.

6.10 All joints shall be true and even.

6.11 All gypsum board shall be tight against the framing member or substrate.

6.12 Deflection at design load of horizontal (ceiling) framing members supporting gypsum board shall be not more than L/240 of the span.

7. Application of Gypsum Board

7.1 *General*:

7.1.1 *Method of Cutting and Installation*—Gypsum board shall be cut by scoring and breaking or by sawing, working from the face side. When cutting by scoring, the face paper shall be cut with a sharp knife or other suitable tool. Gypsum board shall be broken by snapping the gypsum board in the reverse direction, or cut the back paper with a knife or suitable tool.

7.1.2 Cut edges and ends of the gypsum board shall be smoothed to obtain neat joints when installed. Holes for pipes, fixtures, or other small openings shall be scored on the back and the face in outline before removal or cut out with a saw or special tool designed for this purpose. Where gypsum board meets projecting surfaces, it shall be scribed and cut neatly.

7.1.3 When gypsum board is to be applied to both ceiling and walls, the gypsum board shall be applied first to the ceiling and then to the walls.

7.1.3.1 Gypsum board applied to walls shall be applied with the bottom edge spaced not less than ¼ in. (6 mm) above the floor.

7.1.4 Where used at edges or ends, fasteners shall be spaced not more than 1 in. (25 mm) from edges and not less than ⅜ in. (9.5 mm) from edges and ends of gypsum board (except where floating angles are used). Perimeter fastening into the partition plate or sole at the top and bottom shall not be required except where the fire ratings, structural performance, or other special conditions require such fastening. While driving the fasteners, the gypsum board shall be held in firm contact with the underlying support. Application of fasteners shall proceed from the center or field of the gypsum board to the ends and edges.

7.1.5 Nails shall be driven with the heads slightly below the surface of the gypsum board, avoiding damage to the face and core of the board, such as breaking the paper or fracturing the core.

7.1.5.1 Length of nails shall be as shown in Table 1.

7.1.6 Screws shall be driven to provide screwhead penetration just below the gypsum board surface without breaking the surface paper of the gypsum board or stripping the framing member around the screw shank.

7.1.6.1 Length of screws shall be as shown in Table 1.

7.1.7 Staples shall be driven with the crown parallel to the framing members, in such a manner that the crown bears tightly against the gypsum board without cutting into the face paper.

7.1.7.1 Staple attachment shall be restricted to the base plies only of gypsum board in a multi-ply system.

7.1.7.2 Length of staples shall be as shown in Table 1.

7.1.8 The gypsum board shall be kept tight against the framing.

7.1.9 The external corners shall be protected with a metal corner bead or other suitable type of corner protection that shall be attached to supporting construction with fasteners or a crimping tool nominally 6 in. (152 mm) on centers (see Section 3 and Fig. 1).

7.2 Gypsum board shall not be used where it will be exposed to temperatures more than 125 °F (52 °C) for extended periods of time.

7.3 Gypsum board joints shall be located so that no joint will align with the edge of an opening unless control joints are to be installed at these locations.

7.4 Joints between gypsum boards shall be constructed with the gypsum board edges in moderate contact.

TABLE 1 Fastener Length for Gypsum Board Application to Wood Framing[A]

Gypsum Board Thickness[B] in. (mm)	Minimum Nail Length[C] in. (mm)	Minimum Screw Length in. (mm)	Minimum Staple[D] Length in. (mm)
¼ (6.4)	*E*	*E*	*E*
⅜ (9.5)	1 ¼ (32)	1 (25)	1 (25)
½ (12.7)	1 ⅜ (35)	1 ⅛ (28)	1 ⅛ (28)
⅝ (15.9)	1 ½ (38)	1 ¼ (32)	1 ¼ (32)

[A] Where fire resistance is required for gypsum board systems, fasteners of the same or larger length, shank diameter, and head bearing area as those described in the fire-rated design shall be used.

[B] For other thicknesses, for multi-layer applications, or for application over rigid foam insulation, fasteners shall be of sufficient length to penetrate framing not less than ⅞ in. (22 mm) for nails, ⅝ in. (15 mm) for screws, and ⅝ in. (15 mm) for staples.

[C] The maximum penetration for nails shall not exceed 1 ¼ in. (32 mm).

[D] Staple attachment is restricted to base layers of multi-layer systems only. See 7.1.7.1.

[E] For application over existing solid surfaces or in multi-layer applications only—see [B] above for required fastener length.

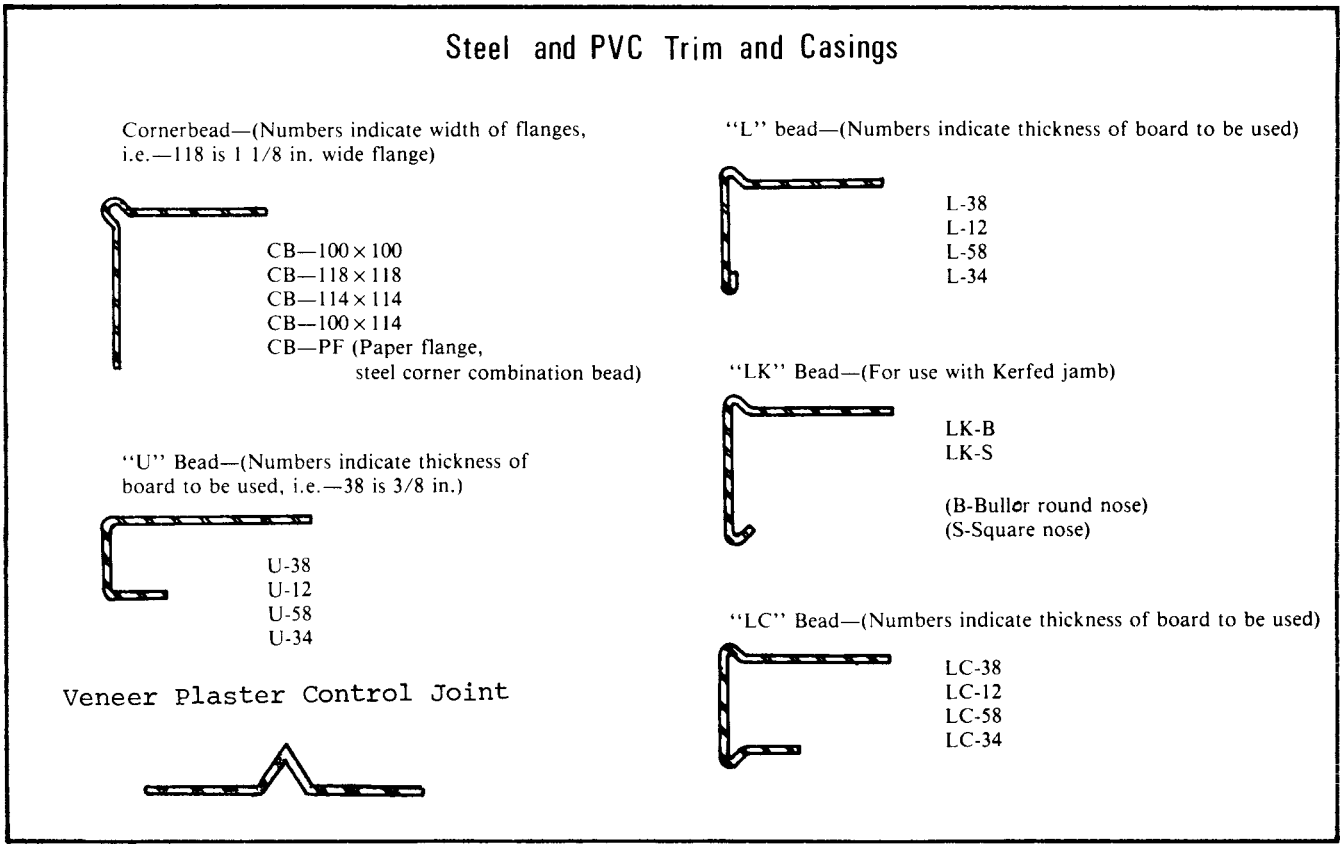
www.technobetar.ir



NOTE 1—All dimensions are in inch-pound units.

FIG. 1 Accessories

7.5 Joints shall be staggered, and joints on opposite sides of a partition shall not occur on the same stud.

7.6 Gypsum board used in building construction shall be not less than 8 in. (203 mm) from the finished grade in fully weather and water protected siding systems, and not less than 12 in. (305 mm) from the ground within properly drained and ventilated crawl spaces. Where ground moisture or humidity is extreme and/or continuous, the crawl space ground surface shall be covered with a vapor barrier.

8. System I: Application of Single-Ply Gypsum Board to Wood Framing Members

8.1 The maximum spacing for framing members for single-ply gypsum board assembly shall not exceed those shown in Table 2.

8.1.1 The ¼-in. (6.4-mm) thick gypsum board shall not be used in single-ply applications on either walls or ceilings.

8.2 In single-ply installation, all ends and edges of gypsum board shall occur over framing members or other solid backing except where treated joints occur at right angles to framing or furring members.

8.3 End joints shall be staggered and joints on opposite sides of a partition shall be arranged to occur on alternate framing members.

8.4 Application using nails.

8.4.1 Where a specific degree of fire resistance is required for gypsum board assemblies, nails of the same length, shank diameter, and head bearing area, as those described in the fire test report, shall be used.

8.4.2 *Single Nailing*—Nails shall be spaced a maximum of 7 in. (177.8 mm) on centers on ceilings, and a maximum of 8 in. (203.2 mm) on centers on walls (see Fig. 2).

TABLE 2 Maximum Framing Spacing for Single-Ply Construction[A]

Single-Ply Gypsum Board Thickness, in. (mm)	Application[B]	Maximum Framing Members On Centers Spacing, in. (mm)
Ceilings:		
⅜ (9.5)[C]	perpendicular	16 (406.4)
½ (12.7)	parallel	16 (406.4)
⅝ (15.9)	parallel	16 (406.4)
½ (12.7)	perpendicular	24 (609.6)
⅝ (15.9)	perpendicular	24 (609.6)
Sidewalls:		
⅜ (9.5)	perpendicular or parallel	16 (406.4)
½ (12.7) or ⅝ (15.9)	perpendicular or parallel	24 (609.6)

[A] Gypsum board ceilings to receive hand or spray-applied water-based texture material shall be applied perpendicular to framing and shall be either (i) ½ in. (12.7 mm) Gypsum Ceiling Board (see Specification C 1396/C 1396M) applied to framing not more than 24 in. (610 mm) on center, or (ii) other gypsum boards not less than ½ in. (12.7 mm) thick for 16 in. (406 mm) on center framing and not less than ⅝ in. (15.9 mm) thick for 24 in. (610 mm) on center framing.

[B] Nails for gypsum board applied over existing surfaces shall have a flat head and diamond point, and shall penetrate not less than ⅞ in. (22.2 mm), nor more than 1 ¼ in. (31.8 mm) into the framing member.

[C] ⅜-in. (9.5-mm) single-ply gypsum board shall not be applied to ceilings where the gypsum board supports insulation.

www.technobetar.ir

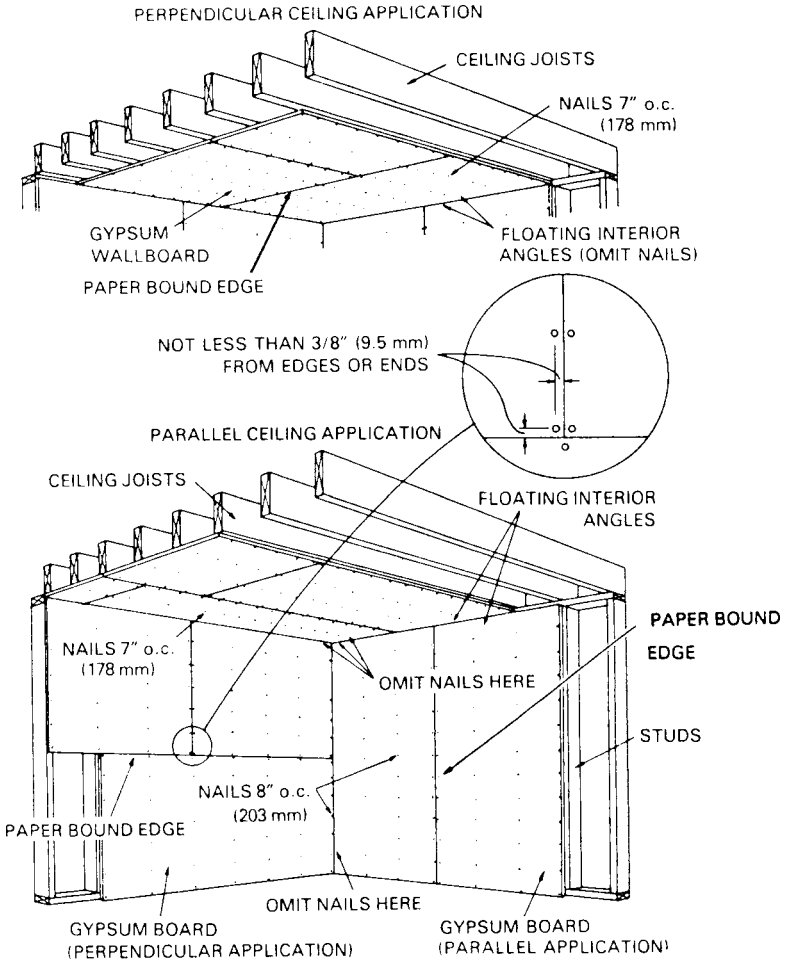

FIG. 2 Single Nailing

8.4.3 *Double Nailing*—Nails shall be spaced as shown in Fig. 3 and driven as follows:

8.4.3.1 Starting at the center of the gypsum board, nails shall be applied as shown in solid dots in row 1, then rows 2 and 2A, 3 and 3A, 4 and 4A, always nailing from center to edges of sheet. The gypsum board shall be kept tight against the framing.

8.4.3.2 Second nails, shown by circles, shall be applied in the same manner as the first nails, also starting at row 1.

8.4.3.3 As an alternative procedure, the second nail shall be applied immediately after all nails in each row are driven in accordance with 8.4.3.2.

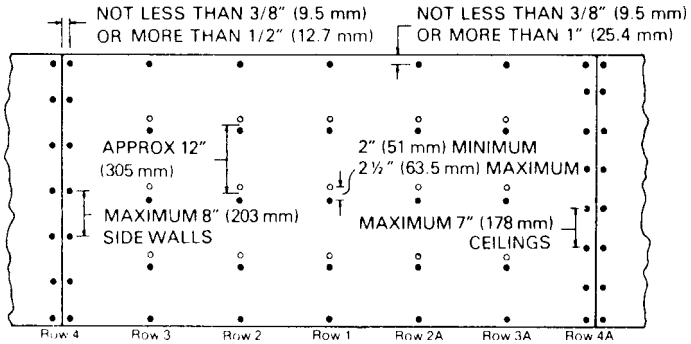

FIG. 3 Double Nailing

8.4.3.4 Single nailing shall be used on the perimeter of the gypsum board, unless otherwise specified.

8.4.3.5 Nails shall be inspected for compliance with 7.1.5 after the second nails have been set.

8.5 *Spacing of Screws*—Screws shall be spaced not more than 12 in. (304.8 mm) on centers along framing members for ceilings and 16 in. (406.4 mm) on centers for walls where the framing members are 16 in. on centers. Screws shall be spaced not more than 12 in. on centers along framing members for ceilings and walls where the framing members are 24 in. (609.6 mm) on centers.

8.5.1 When using a combination of fasteners consisting of nails along the perimeter and screws in the field of the gypsum board, the spacing between a nail and an adjacent screw shall be not more than the spacing specified for screws in 8.5.

9. System II: Application of Two-Ply Gypsum Board to Wood Framing Members

9.1 The maximum spacings for framing members for two-ply gypsum board assemblies shall not exceed those shown in Tables 3 and 4.

NOTE 5—See Section 2 for adhesive application method.

9.2 The fastener length for the base ply of gypsum board shall be as indicated in Table 1.

TABLE 3 Maximum Framing Spacing for Two-Ply Assemblies, Fasteners Only, No Adhesive Between Plies[A]

Gypsum Board Thickness, in. (mm)		Application Direction		Maximum On Centers Spacing of Framing, in. (mm)
Base Ply	Face Ply	Base Ply	Face Ply	
Ceilings:				
¼ (6.4)	⅜ (9.5) or ½ (12.7)	perpendicular	perpendicular	16 (406.6)
⅜ (9.5)	⅜ (9.5) or ½ (12.7)	perpendicular	perpendicular	16 (406.6)
½ (12.7)	⅜ (9.5) or ½ (12.7)	parallel	perpendicular	16 (406.6)
½ (12.7)	½ (12.7) or ⅝ (15.9)	perpendicular	perpendicular	24 (609.6)
⅝ (15.9)[B]	½ (12.7) or ⅝ (15.9)	perpendicular	perpendicular	24 (609.6)
Walls:				
¼ (6.4)	¼ (6.4) or ⅜ (9.5) or ½ (12.7)	perpendicular or parallel	perpendicular or parallel	16 (406.6)
⅜ (9.5)	¼ (6.4) or ⅜ (9.5)	perpendicular or parallel	perpendicular or parallel	16 (406.6)
½ (12.7)	¼ (6.4) or ⅜ (9.5) or ½ (12.7)	perpendicular or parallel	perpendicular or parallel	24 (609.6)
⅝ (15.9)	¼ (6.4) or ⅜ (9.5) or ½ (12.7) or ⅝ (15.9)	perpendicular or parallel	perpendicular or parallel	24 (609.6)

[A] Gypsum board ceilings to receive hand or spray-applied water-based texture material shall be applied perpendicular to framing and shall be either (i) ½ in. (12.7 mm) Gypsum Ceiling Board (see Specification C 1396/C 1396M) applied to framing not more than 24 in. (610 mm) on center, or (ii) other gypsum boards not less than ½ in. (12.7 mm) thick for 16 in. (406 mm) on center framing and not less than ⅝ in. (15.9 mm) thick for 24 in. (610 mm) on center framing.
[B] ⅝-in. (15.9-mm) board shall be permitted to be applied perpendicularly at 16 in. (406 mm) spacing.

TABLE 4 Maximum Framing Spacing for Two-Ply Assembly Fasteners with Adhesive Between Plies[A]

Gypsum Board Thickness, in. (mm)		Application Direction		Maximum On Centers Spacing of Framing, in. (mm)
Base Ply	Face Ply	Base Ply	Face Ply	
Ceilings:				
¼ (6.4)	¼ (6.4) or ⅜ (9.5) or ½ (12.7)	perpendicular	perpendicular	16 (406.6)
⅜ (9.5)	¼ (6.4) or ⅜ (9.5) or ½ (12.7)	perpendicular	perpendicular	16 (406.6)
½ (12.7)	¼ (6.4) or ⅜ (9.5) or ½ (12.7)	parallel	perpendicular	16 (406.6)
½ (12.7)	¼ (6.4) or ½ (12.7) or ⅝ (15.9)	perpendicular	perpendicular	24 (609.6)
⅝ (15.9)	¼ (6.4) or ½ (12.7) or ⅝ (15.9)	perpendicular	perpendicular	24 (609.6)
Walls:				
¼ (6.4)	¼ (6.4) or ⅜ (9.5) or ½ (12.7)	perpendicular or parallel	perpendicular or parallel	16 (406.6)
⅜ (9.5)	¼ (6.4) or ⅜ (9.5)	perpendicular or parallel	perpendicular or parallel	16 (406.6)
½ (12.7)	¼ (6.4) or ⅜ (9.5) or ½ (12.7)	perpendicular or parallel	perpendicular or parallel	24 (609.6)
⅝ (15.9)	¼ (6.4) or ½ (12.7) or ⅝ (15.9)	perpendicular or parallel	perpendicular or parallel	24 (609.6)

[A] Adhesive between plies shall be dried or cured prior to joint treatment application.

9.2.1 Base layer end joints parallel to and on the same side of framing members shall be staggered between alternate courses of gypsum board and from base layer joints on the opposite side of the framing members.

9.2.2 Base layer edge joints parallel to framing members shall be staggered on opposite sides of the framing members.

9.3 When adhesive is not used between the plies, the two plies of gypsum board shall be applied as indicated in Tables 3 and 5. The face ply shall be applied with the number of nails or screws required for normal single-ply application. Fastener length for face ply application shall be as indicated in [B] of Table 1. Face ply joints that are parallel to framing shall fall over framing members and be offset from the base ply joints when two plies of gypsum board are parallel.

9.4 When an adhesive is used between the plies (laminated face ply), the two plies shall be applied as indicated in Tables 4 and 5. If the two plies are applied in parallel direction, the joints in the face ply shall be offset from the joints in the base ply.

9.4.1 Joints in the face ply need not occur over the framing members. The adhesive used between the two plies of gypsum board shall be uniformly applied over the back surface of the face ply of the gypsum board before it is erected or to the face surface of the base ply. The face ply of gypsum board shall be placed in position and fastened with nails or screws to hold gypsum board in place until the adhesive develops a bond.

9.4.2 Permanent fasteners shall be used around the perimeter 12 in. (304.8 mm) on centers and 16 in. (406.4 mm) on

TABLE 5 Base Layer Fastener Spacing for Multi-Layer Gypsum Board Application

		Base Layer Nail Spacing in. (mm)		Base Layer Screw Spacing in. (mm)		Base Layer Staple Spacing in. (mm)	
Location	Framing Spacing in. (mm)	Where Face Layer is Laminated	Where Face Layer is Mechanically Attached	Where Face Layer is Laminated	Where Face Layer is Mechanically Attached	Where Face Layer is Laminated	Where Face Layer is Mechanically Attached
Walls	16 (406)	8 (203)	24 (610)	16 (406)	24 (610)	7 (178)	16 (406)
	24 (610)	8 (203)	24 (610)	12 (305)	24 (610)	7 (178)	16 (406)

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

centers along framing members for the face ply of gypsum board applied on ceilings.

9.4.3 In place of nails and screws, the face ply of gypsum board applied on walls shall be held in position by shoring with props and headers, or other temporary support to ensure a pressure for bonding. Permanent fasteners shall be used on top and bottom of wall not more than 16 in. (406 mm) on centers. Nails or screws used to hold the gypsum board face ply shall be left in place and finished in the same manner as for single-ply gypsum board application (see Section 10).

9.5 Base layer joints and fasteners shall not be required to be taped or finished. Face layer joints and fasteners in multi-layer systems shall not be required to be finished unless required for appearance or decoration or as required for fire resistance.

10. System III: Application of Gypsum Board by Adhesive Nail-on to Wood Framing Members

10.1 Except as herein modified, application shall be in conformance with Section 8.

10.2 Surfaces of gypsum board and framing to receive the adhesive shall be free of dust, dirt, grease, or any other foreign matter that cause bond loss. Foreign matter shall be removed.

10.3 A bead of adhesive ⅜ in. (9.5 mm) in diameter shall be applied to the face of all wood framing members, except plates, that support the gypsum board. The adhesive shall be spread to an average width of ¾ in. (19 mm) and an average thickness of 1⁄16 in. (1.6 mm). See Fig. 4 for application patterns.

10.3.1 Where a joining of two adjacent pieces of gypsum board occurs on a framing member, two parallel beads of adhesive shall be applied, one near each edge of the framing member.

10.4 Adhesive shall be applied to no greater area than can be covered with gypsum board within the "open time."

NOTE 6—"Open time" is the time period available for working with certain adhesives before they set in accordance with the adhesive manufacturer's specification.

10.5 *Fastener Spacing*:

10.5.1 If the properties of the adhesive ensure bridging between the gypsum board and the wood framing, nailing shall not be required in the field of the board for walls. In such cases, perimeter nailing, 16 in. (406.4 mm) on centers, shall be required.

10.5.2 When the properties of the adhesive are such that there is no positive bridging between the gypsum board and the wood framing, either temporary field nailing or temporary bracing shall be used to ensure contact between the gypsum board, the adhesive, and the wood framing, until the adhesive develops a bond.

10.5.3 Unless specified otherwise by the adhesive manufacturer, fastener spacing shall be in accordance with Table 6.

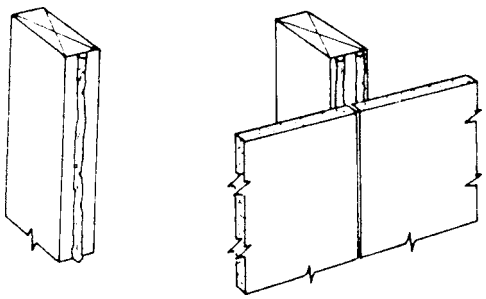

FIG. 4 Adhesive Application Patterns

11. System IV: Semi-Solid Gypsum Board Partitions

11.1 *Installation*:

11.1.1 Runners or studs shall be installed where required to provide support at exterior walls, partition junctions, terminals, external corners, door frames, and at other locations.

11.1.2 The gypsum board face panels and studs shall be positioned vertically.

11.1.3 The gypsum studs shall be laminated to face panels not more than 24 in. (609.6 mm) on centers and located at face panel vertical joints and at vertical centerline of panel.

11.1.4 Gypsum studs shall be laminated to face panels prior to erection or as erection of partition proceeds. A starter face panel shall be erected vertically at an intersecting wall. The starter panel shall be plumb and secured to the floor, the ceiling, and the vertical runners.

11.1.5 The next face panel adjacent to the starter panel shall be erected by butting its edge and end firmly to the starter panel and the ceiling. Erection of the face panels shall continue by laminating exposed faces of gypsum studs as work progresses.

11.1.6 Openings in partitions for doors and electrical outlets shall be carefully and accurately marked and cut.

11.1.7 Laminating compounds or adhesives shall be of a consistency and volume that will cover approximately three-fourths of the stud surface after lamination.

11.1.8 Type G screws shall be used to ensure a continuous bond between face panels and studs, and shall be spaced not more than 36 in. (914 mm) on centers.

11.1.9 Openings or changes in direction of partitions shall be reinforced with additional studs laminated in place at the following locations:

11.1.9.1 *External Corners*—Between the face panels in the corner opposite vertical runners.

11.1.9.2 *Abutting Walls*—Between the face panels of a partition to reinforce junction of an abutting wall.

11.1.9.3 *Door Openings*—Locate a vertical stud within 3 in. (76.2 mm) of door frame for reinforcement, and place a stud horizontally over the door header.

12. System V: Solid Gypsum Board Partitions

12.1 Non-load bearing solid partition consisting of gypsum coreboard faced on each side with gypsum board panels.

12.2 *Installation*:

12.2.1 Floor and ceiling runners shall be installed according to the layout and shall be secured not more than 24 in. (610 mm) on centers. Vertical runners shall be installed where specified in 11.1.1.

12.2.2 For partitions located parallel to and between ceiling members, steel or wood blocking not more than 24 in. (609.6 mm) on centers shall be provided to fasten ceiling runners prior to erection of ceiling.

12.2.3 Face panels shall be attached to runners at not more than 24 in. (609.6 mm) on centers.

TABLE 6 Fastener Spacing with Adhesive or Mastic Application and Supplemental Fastening

Framing Member Spacing, in. (mm) On Centers	Ceilings, in.		Partitions Load Bearing, in.		Partitions Nonload Bearing, in.	
	Nail	Screw	Nail	Screw	Nail	Screw
16 (406.4)	16	16	16	24	24	24
24 (609.6)	12	16	12	16	16	24

12.2.4 Coreboard shall be installed prior to the installation of the face panel. Coreboard shall be attached not more than 24 in. (610 mm) on centers to the steel angles when steel angles are used as runners. When steel channels are used as runners to secure coreboard, attachment shall not be required.

NOTE 7—Combinations of wood and steel channels or angles will vary the installation procedure.

12.2.5 The adhesive shall be applied to the back surface of the face panels or the face of the coreboard as described for two-ply gypsum board construction (see Section 9).

12.2.6 The face panels shall be laminated to the core with sufficient pressure to ensure bonding. The joints of the face panels and core shall be staggered. To ensure the bond between face panels and core, fasteners shall be permitted.

13. System VI: Application of Gypsum Board with Adhesive to Interior Masonry or Concrete Walls

13.1 When applying gypsum board to monolithic concrete, brick, or concrete block, the adhesive shall be applied directly to the back of the gypsum board or on the wall in continuous beads not more than 12 in. (304.8 mm) on centers or daubs spaced not more than 12 in. (304.8 mm) on centers each way.

13.1.1 Beads shall be not less than ⅜ in. (9.6 mm) in diameter to provide a continuous bond between the gypsum board and the wall surface.

13.1.2 Daubs shall be 2 to 3 in. (50.8 to 76.2 mm) in diameter.

13.2 The gypsum board shall be positioned ⅛ in. (3.2 mm) from the floor and provide a tight fit at abutting edges or ends. The gypsum board shall not be slid on the adhesive. Mechanical fasteners, or temporary bracing, shall be used to support gypsum board until adhesive sets.

13.3 Delay the joint treatment until the gypsum board is firmly bonded.

13.4 Foil-backed gypsum board shall not be used for direct adhesive application.

13.5 Direct adhesive application shall be used only on interior masonry or concrete walls above grade, or the inside of exterior masonry cavity walls with 1-in. (25.4 mm) minimum width cavity between the inside and outside masonry for the full height of the above grade surface to receive gypsum board. Surfaces to which gypsum board is to be adhesively attached shall be free of any foreign matter, projections, or depressions that will impair the bond.

14. System VII: Application of Gypsum Board to Rigid Plastic Foam Insulation

14.1 *Application of Furring and Plastic Foam Insulation to Masonry and Concrete Walls*:

14.1.1 Rigid foam insulation shall be applied to the masonry or concrete in accordance with the foam manufacturer's specifications.

14.1.2 Furring strips or special metal furring members shall be attached by mechanical means to the masonry or concrete wall surface either before or after application of the insulation, depending on the system used. The furring members shall be installed in accordance with Table 2 and at gypsum board terminations above suspended ceilings, around doors, windows, or other openings, and for cabinet and fixture attachment.

14.2 The gypsum board shall be applied to furring as described in 8.4.1 or 8.5. The mechanical fasteners shall not penetrate completely to the masonry or concrete.

15. System VIII: Application of Gypsum Board to Steel Framing and Furring

15.1 Screw application shall be applied in accordance with 7.1.6.

15.1.1 Screws shall be of sufficient length so that the threaded portion shall penetrate not less than ⅜ in. (9 mm) into the framing members.

15.1.2 Where resilient furring channels are used, the screws used to attach gypsum board to the furring channels shall not contact the framing.

15.2 *Framing Spacing*—Maximum spacing of steel framing and furring for screw application shall be as specified in Table 2 for single-ply gypsum board and as specified in Tables 3 and 4 for two-ply gypsum board.

15.2.1 Installation of steel framing shall be in accordance with Specifications C 754 or C 1007.

15.3 *Screw Spacing*:

15.3.1 Screw spacing for single-ply gypsum board and face ply of two-ply gypsum board with no adhesive shall be in accordance with 8.5.

15.3.2 Screw spacing for parallel applied base-ply of two-ply gypsum board over steel framing with no adhesive between the plies shall be not more than 12 in. (304.8 mm) on centers along the edges of the gypsum board and 24 in. (609.6 mm) on centers into the stud or furring channel in the field of the gypsum board.

15.3.3 Screw spacing for a perpendicularly applied base-ply of two-ply gypsum board over steel framing with no adhesive between the plies shall be not less than one screw at each edge of the gypsum board at each framing member and one screw midway between the edges at each framing member.

15.3.4 Screw spacing for perpendicular or parallel applied base-ply of two-ply gypsum board over steel framing with adhesive between plies shall be not more than as specified for single-ply gypsum board in 8.5.

15.3.5 Screw spacing on ceilings for the face-ply of two-ply gypsum board over steel framing with adhesive between plies shall be the same as specified for the base-ply gypsum board in 15.3.2 and 15.3.3.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

15.3.6 On wall surfaces with adhesive between the plies, the face-ply shall have only a sufficient number of screws to hold gypsum board in place.

16. System IX: Arches and Bending Radii

16.1 Where gypsum board is to be applied to the soffit of arches, it shall be carefully bent into place (see Table 7). If necessary, it first shall either be dampened or cut approximately 1 in. (25.4 mm) on centers on the back side. In the latter case, after the core has been broken at each cut, the gypsum board shall be applied to the curved framing member and fastened in place. At the arises of the arch (exterior or interior "corners" formed at the meeting of the adjoining angle surfaces), joint compound and joint tape or corner bead shall be applied. The tape or corner bead shall be snipped at intervals along one side so that the applied tape or corner bead conforms to the curved contour.

NOTE 8—To apply the board, place a stop at one end of the curve, then gently and gradually push on the other end of the board, forcing the center against the framing until the curve is complete.

NOTE 9—By thoroughly moistening the face and back paper and allowing the water to soak well into the core, the board will bend to still shorter radii. When the board thoroughly dries, it will regain its original hardness. Any subsequent joint treatment or decoration shall not be started until the gypsum board is thoroughly dry.

17. System X: Application of Gypsum Board to Receive Tile by Adhesive Application

17.1 Framing around tub enclosures and shower stalls shall maintain sufficient room to accommodate the inside lip of the tub, prefabricated receptor, shower pan, or membrane as shown in Figs. 5-7.

NOTE 10—This will necessitate furring out from the framing members the thickness of the gypsum board to be used (½ or ⅝ in. (12.7 or 15.9 mm)) less the thickness of the lip, on each wall abutting a tub receptor or subpan.

17.2 *Blocking or Backing*:

17.2.1 Where framing is spaced more than 16 in. (406 mm) o.c., blocking or backing shall be provided ¾ –1¼ in. (20–30 mm) above the top of the tub or receptor and at gypsum board horizontal joints in the area to receive tile.

17.2.2 Interior angles shall be framed or blocked to provide solid backing for interior corners.

17.2.3 Blocking, headers, or supports shall be provided to support the tub and other plumbing fixtures and to receive soap dishes, grab bars, towel racks, and similar items.

17.3 *General*:

17.3.1 Water-resistant gypsum backing board shall be used as a base for adhesive application of ceramic or plastic wall tile in wet areas such as tub and shower enclosures. Either regular gypsum board or water-resistant gypsum backing board shall be used as a base for tile in other areas. Water-resistant gypsum backing board and regular gypsum board shall not be used in extremely critical areas such as saunas, steam rooms, or gang shower rooms. Foil-backed gypsum board shall not be used as a base for tub or shower enclosures. Water-resistant gypsum board used as a base for tile or wall panels in tub and shower enclosures shall not be applied directly over a vapor retarder.

NOTE 11—The use of water-resistant gypsum backing board as a base for tile in wet areas is regulated by local codes. Consult local building codes for requirements.

17.3.1.1 Gypsum board shall not be used where there will be direct exposure to water or continuous high humidity

TABLE 7 Bending Radii

Gypsum Board Thickness, in. (mm)	Bent Lengthwise, ft (m)	Bent Widthwise, ft (m)
½ (12.7)	10 (3.05)[A]	—
⅜ (9.5)	7 ½ (2.29)	25 (7.62)
¼ (6.4)	5 (1.52)	15 (4.57)

[A] Bending two ¼-in. (6.4-mm) pieces successively permits radii shown for ¼ in. (6.4 mm).

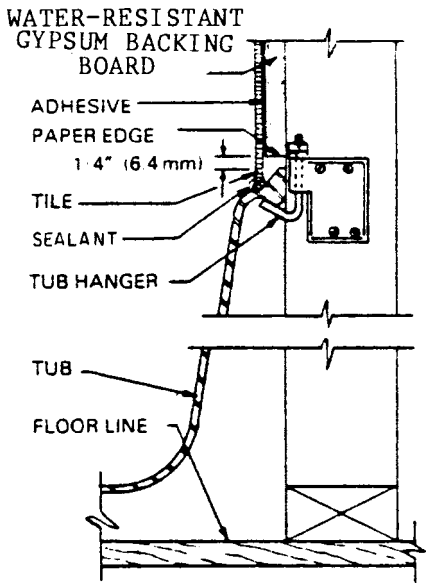

FIG. 5 Application of Gypsum Board at Bathtub Where WR Board Will Receive Ceramic Tile or Other Protective Covering

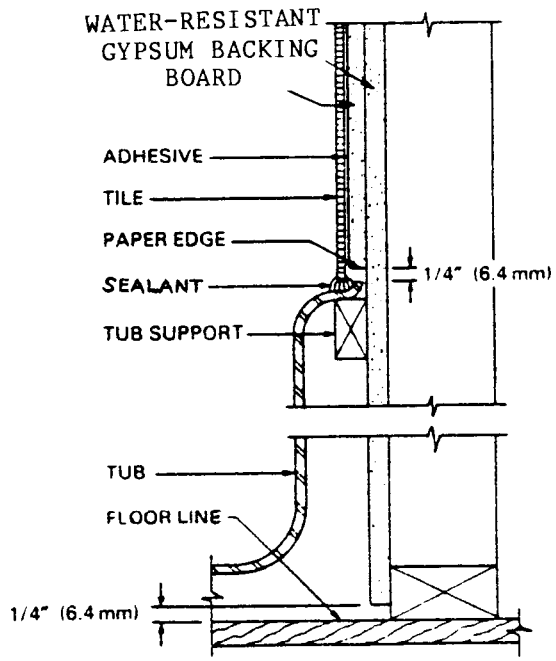

FIG. 7 Adhesive Application of Tile Over Gypsum Board

conditions such as are found in saunas, steam rooms, gang shower rooms, or indoor pools.

17.3.1.2 Foil-backed gypsum board shall not be used as a base for tub or shower enclosures.

17.3.1.3 Water-resistant gypsum backing board used as a base for tile or wall panels in tub and shower enclosures shall not be applied directly over a vapor retarder.

17.3.1.4 Ceiling framing spacing for water-resistant gypsum backing board ½ in. (12.7 mm) thick applied to ceilings shall be not more than 12 in. (305 mm) on centers.

17.3.1.5 Ceiling framing spacing for water-resistant gypsum backing board ⅝ in. (15.9 mm) thick applied to ceilings shall be not more than 16 in. (406 mm) on centers.

NOTE 12—Asphalt-impregnated felt is not considered a vapor retarder.

17.3.2 All multiple plies of gypsum board in wet areas shall be attached with mechanical fasteners.

17.3.3 Waterproof receptors, pans, or sub-pans shall have an upstanding lip or flange that shall be a minimum of 1 in. (25.4 mm) higher than the water dam or threshold contained in the entry way to the shower.

17.4 *Installation*:

17.4.1 Water-resistant gypsum backing board shall be applied with the factory edge spaced not less than ¼ in. (6.4 mm) above the lip of the receptor, tub, or sub-pan. Shower pans, receptors, or tubs shall be installed prior to the erection of the water-resistant gypsum backing board.

17.4.2 Water-resistant gypsum backing board shall be attached by nails or screws spaced not more than 8 in. (203.2 mm) on centers. When ceramic tile more than ⅜ in. (9.5 mm) thick is to be applied, the nail or screw spacing shall be not more than 4 in. (101.6 mm) on centers.

17.4.3 Where treatment of water-resistant gypsum backing board joints under tile in wet areas (tub and shower enclosures) is required, the compound and application thereof, shall be as required by the joint compound manufacturer for this specific use, or shall be protected from penetration of moisture or water (see X4.2).

17.4.4 All cut edges and openings around pipes and fixtures shall be sealed with a water-resistant flexible sealant to create a water-repellant barrier where water-resistant gypsum backing board has been cut and the gypsum core is exposed. Sealant shall be as specified in 17.4.4.1 and 17.4.4.2 or equivalent.

17.4.4.1 Ceramic tile adhesive complying with ANSI A 136.1, Type I or Type II.

17.4.4.2 Flexible sealant complying with Specification C 920, Type S, Grade NS, Class 25.

17.4.5 Certain fire or sound-rated gypsum board assemblies require the installation of an additional layer of water-resistant gypsum backing board (see Fig. 7). A ¼ in. (6.4 mm) clearance shall be maintained between the wallboard and tub rim, or shower base, as shown in Figs. 6 and 7.

NOTE 13—For installation of ceramic tile to gypsum boards, see X4.3.

18. System XI: Exterior Application of Gypsum Wallboard and Exterior Gypsum Soffit Board

18.1 Where gypsum wallboard or exterior gypsum soffit board is used for ceilings of carports, open walkways, porches, and soffits of eaves that are horizontal or inclined downward away from the building, the gypsum board shall be either ½ or ⅝ in. (12.7 or 15.9 mm) in thickness. Framing shall be not more than 16 in. (406 mm) on centers for ½-in. (12.7-mm) thick gypsum board and not more than 24 in. (610 mm) on centers for ⅝-in. (15.9-mm) thick gypsum board. The gypsum board shall be installed perpendicularly in accordance with the foregoing specifications except as herein modified.

18.2 Suitable facia and molding shall be provided around the perimeter to protect the gypsum wallboard and exterior gypsum soffit board from direct exposure to water. Unless protected by metal or other water stops, the edges of the gypsum wallboard and exterior gypsum soffit board shall be placed not less than ¼ in. (6.4 mm) away from abutting vertical surfaces. (See Figs. 8-10.) Joints and fastener heads shall be treated as specified in X3.6.

18.3 Exposed surface of gypsum board and exterior gypsum soffit board shall be treated as specified in X3.6.

www.technobetar.ir

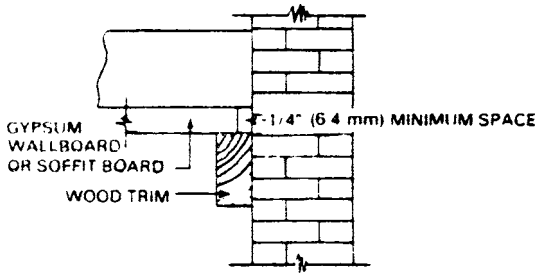

FIG. 9 Masonry Wall

18.4 Adequate ventilation shall be provided for the space immediately above installations (see Appendix X2).

19. System XII: Floating Interior Angles

19.1 Gypsum board shall be applied to ceiling first. (See Figs. 11-13.)

19.1.1 The floating angle method of application minimizes the possibility of fastener popping in areas adjacent to the wall and ceiling intersections for single-ply or two-ply applications of gypsum board to wood framing.

19.2 *Ceilings*—The first fastener into each ceiling framing member framed perpendicular to the intersection shall be located 7 in. (117.8 mm) out from the wall intersection for single nailing, and 11 to 12 in. (279.4 to 304.8 mm) for double nailing, or screw application.

19.3 *Walls*—Gypsum board shall be applied on walls so as to provide support for the floated edges of the ceiling gypsum board. The top fastener into each vertical framing member shall be located 8 in. (203.2 mm) down from the ceiling intersection for single nailing, and 11 to 12 in. (279.4 to 304.8 mm) for double nailing, or screw application. (See Figs. 11 and 12.) At wall vertical angles, the over-lapping board shall be applied so as to bring the back of the underlying board into firm contact with the face of the framing member behind it. Fasteners shall be omitted from the underlying board at the intersection. (See Fig. 13.)

20. System XIII: Control (Expansion) Joints

20.1 Control joints shall be either manufactured devices designed for this purpose or field fabricated from suitable materials.

20.2 Control joints shall be installed where indicated on the plans. Full height door frames shall be considered equivalent to a control joint.

20.3 Control joints in the gypsum board shall be specified by the architect or designer where any of the conditions described in 20.3.1-20.3.5 exist.

20.3.1 A control joint shall be installed where a partition, wall, or ceiling traverses a construction joint (expansion, seismic, or building control element) in the base building structure.

20.3.2 Control joints shall be installed where a wall or partition runs in an uninterrupted straight plane exceeding 30 linear feet (9100 mm).

20.3.3 Control joints in interior ceilings with perimeter relief shall be installed so that linear dimensions between control joints do not exceed 50 ft (15000 mm) and total area between control joints does not exceed 2500 sq ft (230 m^2).

20.3.4 Control joints in interior ceilings without perimeter relief shall be installed so that linear dimensions between control joints do not exceed 30 ft (9100 mm) and total area between control joints does not exceed 900 sq ft (84 m^2).

20.3.5 Control joints in exterior ceilings and soffits shall be installed so that linear dimensions between control joints do not exceed 30 ft (9100 mm) and total area between control joints does not exceed 900 sq ft (84 m^2).

20.3.6 A control joint or intermediate blocking shall be installed where ceiling framing members change direction.

20.3.7 Control joints shall be installed where specified by the architect or designer as a design accent or architectural feature.

20.4 Where a control joint occurs in an acoustical or fire-rated system, blocking shall be provided behind the control joint by using a backing material such as ⅝ in. (15.9 mm) type X gypsum board, mineral fiber, or other tested equivalent.

21. System XIV: Foil-Backed Gypsum Board

21.1 The application of foil-backed gypsum board shall conform to the specifications for the application of gypsum board. The reflective surface shall be placed against the face of the framing members. Foil-backed gypsum board shall not be used in the following areas:

21.1.1 As a backing material for tile in wet areas.

21.1.2 For the second ply on two-ply laminating systems.

21.1.3 For laminating directly to masonry or concrete.

21.1.4 In conjunction with electric heating cables.

22. Finishing of Gypsum Wallboard

22.1 *General*:

22.1.1 Compound for taping and finishing shall be either drying or setting types. Drying and setting type compounds shall not be mixed together unless specified otherwise by the joint compound manufacturer.

22.1.2 When applied, the compounds shall be of a chemical composition compatible with previous and successive coats.

22.1.3 No finishing operation shall be started until the interior temperature has been maintained at a minimum of 50 °F (10 °C) for a period of at least 48 h and thereafter until the compounds have completely dried.

22.1.4 When two-ply application is used with adhesives between plies, precautions shall be taken to ensure that the adhesive is thoroughly dried before any decorative finish is applied.

22.1.5 Adequate and continuous ventilation shall be provided to ensure proper drying and hardening of the compounds.

22.2 *Surface Preparation*:

22.2.1 Dirt, oil, and other materials that cause a lack of bond shall be removed from all surfaces to receive joint compound.

22.2.2 All dents, gouges, recesses, or other depressions shall be filled with compound and drawn to a level plane.

22.3 *Taping*:

22.3.1 Joint tape and joint compounds shall be applied using tools designed for this work and the compounds being used. Such tools include hand-held broad knives, trowels, or mechanical tools.

www.technobetar.ir

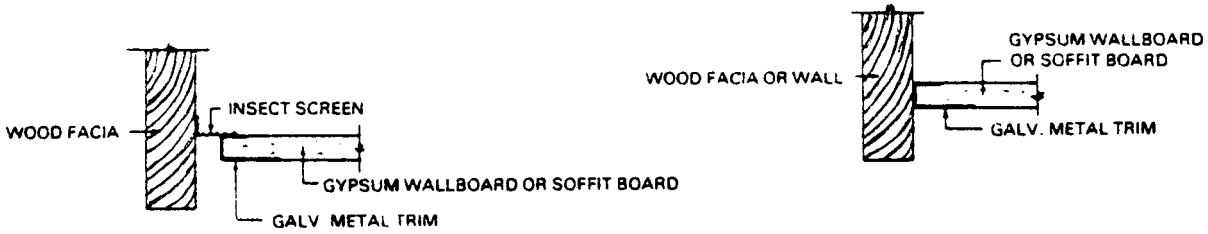

FIG. 10 Alternate Facia Details

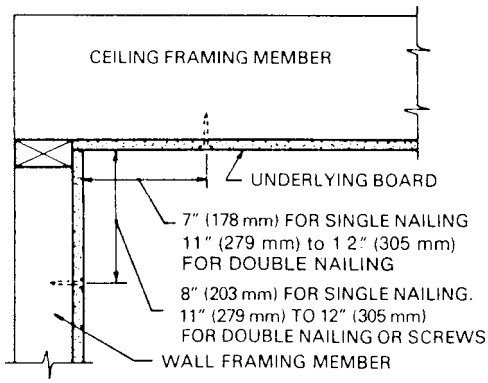

FIG. 11 Vertical Section, Ceiling Framing Member Perpendicular to Wall

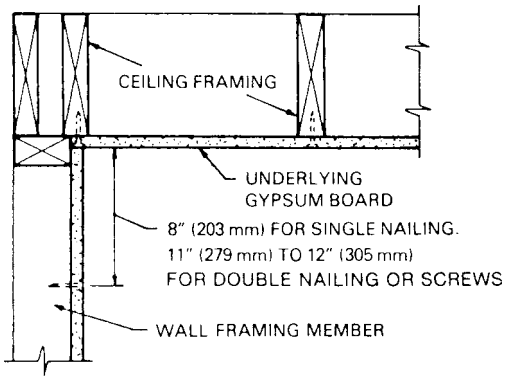

FIG. 12 Vertical Section, Ceiling Framing Parallel to Wall

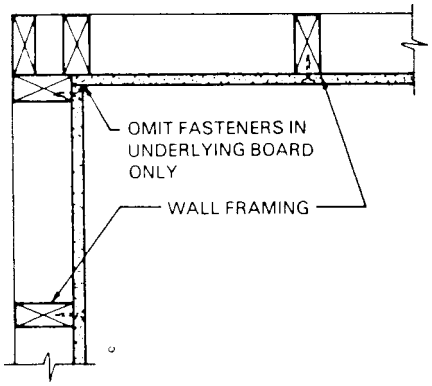

FIG. 13 Horizontal Section Through Interior Vertical Angle

22.3.2 Joint gaps not greater than ⅛ in. (3 mm) shall be prefilled with either ready-mix or setting type joint compound; joint gaps greater than ⅛ in. (3 mm) shall be prefilled with setting-type joint compound.

22.3.3 Joint tape shall be applied as described in 22.3.3.1, 22.3.3.2, or 22.3.3.3.

22.3.3.1 Paper tape shall be applied by applying joint compound to the joint (buttering), centering and pressing in the paper tape and wiping off the excess compound, or by mechanical tools designed for this purpose. Sufficient compound shall be left under the paper tape to bond the paper tape to the gypsum board.

22.3.3.2 Self-adhering glass mesh tape shall be applied to clean, dry gypsum board by centering the tape over the joint and pressing the tape firmly to ensure proper adhesion. A coat of setting type joint compound shall be applied over the tape and forced through the mesh so that it fills the joint in the underlying gypsum board and completely hides the weave of the glass mesh tape.

22.3.3.3 Glass mesh tape that is not self-adhering shall be applied and held in place with a rust resistant fastener (a staple or nail, etc.). A coat of setting type joint compound shall be applied over the tape and forced through the mesh so that it fills the joint in the underlying gypsum board and completely hides the weave of the glass mesh tape.

22.4 *Finishing*:

22.4.1 Finishing compound and all-purpose compound shall be applied with tools of sufficient width to extend a minimum of 3½ in. (89 mm) beyond both sides of the center of the joint tape. The compound shall be drawn down to a level plane. After the compound has dried, the surface shall be sanded (see 22.5) or wiped with a dampened sponge to eliminate high spots and excessive compound.

22.4.1.1 Coats of non-setting type compounds shall be thoroughly dry before sanding or the application of additional coats.

22.4.1.2 Additional coats of compounds shall be applied over setting-type compound either after it has set or, after it has set and dried.

22.4.2 Additional coats of finishing compound shall be applied with tools that will feather the material not less than 6 in. (152 mm) beyond both sides of the center of the joint tape. The compound shall be drawn down to a level plane.

NOTE 14—A smooth surface is achieved by lightly sanding or wiping the joint compound with a dampened sponge. Do not raise the nap of the paper of the gypsum board (see 22.5). See Appendix X3.

22.4.3 Fastener heads shall be covered (spotted) with successive coats of joint compound. The first coat shall be taping or all-purpose compound; the additional coats shall be finishing or all-purpose compound.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:05 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

22.4.4 All cut-outs shall be back filled with the compound used for taping and finishing so there is no opening larger than ¼ in. (6 mm) between the gypsum board and the penetrating element.

22.4.5 Accessories shall be finished with successive coats of joint compound. This surface, when completed, shall be flush with the surface of the gypsum board. The first coat over the flanges shall be taping or all-purpose compound; the additional coats shall be finishing or all-purpose compound.

22.4.6 The skim coat of joint compound or a material manufactured especially for this purpose shall be applied to the entire surface where Level 5 is required.

22.4.7 All tools and containers shall be kept clean and free from foreign materials.

22.4.8 Only potable water shall be used for mixing powder compounds or to thin premixed materials.

22.5 Approved protective respirators shall be worn when mixing dry compound or sanding.

22.6 *Levels of Finish*:

NOTE 15—The required level or extent of finishing of gypsum wallboard joints, fastener heads, and overall surface can vary with the location in a structure and the intended type of decoration. This section describes various levels of finishing, that is, number of applications of joint compound, sanding or other finishing techniques; the recommendations of manufacturers may vary from what is specified herein and as such are not part of these specifications. The relationship of levels of finishing with location and intended decoration is described in Appendix X8.

22.6.1 *Level 0*:

22.6.1.1 No taping, finishing or corner beads are required.

22.6.2 *Level 1*:

22.6.2.1 All joints and interior angles shall have tape embedded in joint compound. Surface shall be free of excess joint compound. Tool marks and ridges shall be acceptable.

22.6.2.2 Where glass mesh tape is used, the glass mesh tape shall be adhered or attached to the wall and have one coat of setting type joint compound over the surface of the joint.

22.6.3 *Level 2*:

22.6.3.1 All joints and interior angles shall have tape embedded in joint compound and shall be immediately wiped with a joint knife or trowel leaving a thin coating of joint compound over all joints and interior angles. Fastener heads and accessories shall be covered with a coat of joint compound. Surface shall be free of excess joint compound. Tool marks and ridges are acceptable.

22.6.3.2 Joint compound applied over the body of the tape at the time of tape embedment shall be considered a separate coat of joint compound and shall satisfy the conditions of this level.

22.6.4 *Level 3*:

22.6.4.1 All joints and interior angles shall have tape embedded in joint compound and shall be immediately wiped with a joint knife or trowel leaving a thin coating of joint compound over all joints and interior angles as described for Level 2. One additional coat of joint compound shall be applied over all joints and interior angles. Fastener heads and accessories shall be covered with two separate coats of joint compound. All joint compounds shall be smooth and free of tool marks and ridges (see 22.4.1.1).

22.6.5 *Level 4*:

22.6.5.1 All joints and interior angles shall have tape embedded in joint compound and shall be immediately wiped with a joint knife or trowel leaving a thin coating of joint compound over all joints and interior angles as described for Level 2. Two separate coats of joint compound shall be applied over all flat joints. One separate coat of joint compound shall be applied over interior angles. Fastener heads and accessories shall be covered with three separate coats of joint compound. All joint compounds shall be smooth and free of tool marks and ridges (see 22.4.1).

22.6.6 *Level 5*:

22.6.6.1 All joints and interior angles shall have tape embedded in joint compound and shall be immediately wiped with a joint knife or trowel leaving a thin coating of joint compound over all joints and interior angles as described for Level 2. Two separate coats of joint compound shall be applied over all flat joints. One separate coat of joint compound shall be applied over interior angles. Fastener heads and accessories shall be covered with three separate coats of joint compound. A thin skim coat of joint compound shall be trowel-applied to the entire surface. Excess compound is immediately sheared off, leaving a film of skim coating compound completely covering the paper. As an alternate to a skim coat, a material manufactured especially for this purpose shall be applied. The surface shall be smooth and free of tool marks and ridges (see 22.4.1.1).

23. Decoration

23.1 Surfaces finished to Levels 3, 4, or 5 shall be covered with a drywall primer compatible with the final decoration prior to the application of the final decoration.

NOTE 16—It is not the intent of this specification to assign responsibility for performance to specific trades.

24. Delivery, Identification, Handling, and Storage

24.1 All materials shall be delivered in the original factory sealed, unopened packages, containers, or bundles bearing the brand name, applicable standard designation, and the name of the manufacturer, or the supplier for whom the product is manufactured.

24.2 All materials shall be kept dry. Where gypsum board is stored outside, it shall be off the ground, properly supported on a level platform and fully protected from the weather or direct sunlight exposure. Adequate ventilation shall be provided to prevent condensation.

24.3 Gypsum board shall be neatly stacked flat, not on its end or edge, to prevent toppling, sagging or damage to the ends, edges, and surfaces.

NOTE 17—Gypsum board stacked on edge or end is unstable and presents a serious hazard in the workplace should it accidentally topple.

24.4 Ready mixed and dry compounds which have been mixed with water shall be stored at temperatures above freezing or temperatures specified by the manufacturer.

25. Keywords

25.1 ceiling; gypsum; wallboard; walls

APPENDIXES

(Nonmandatory Information)

X1. GENERAL INFORMATION

INTRODUCTION

These Appendixes give general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not a part of this specification.

X1.1 Scaffolding shall be constructed and maintained in strict conformity with applicable laws and ordinances.

X1.2 This work shall be properly coordinated with the work of other trades.

X1.3 Gypsum board shall be protected from the elements of weather before, during, and after application.

X2. VENTILATION ABOVE GYPSUM BOARD CEILINGS

X2.1 Adequate ventilation of attics or similar unheated spaces above gypsum board systems is essential to the performance of these systems and shall be designed and provided by others per ASHRAE Fundamentals Handbook or applicable building code.

X3. JOB APPLIED DECORATION

X3.1 Prolonged exposure of gypsum board to sunlight may cause problems in decoration.

X3.2 With the joints and fastener head depressions treated as specified in Section 10, interior walls of gypsum board may be decorated in any of the popular variety of finishes, such as texture or stipple, flat paint or flat enamel paint, wall paper, or vinyl wall coverings.

X3.3 Because the porosity and texture of the gypsum board differs from that of the joint treatment, the surface shall be primed and sealed as may be required for the subsequent finish coats.

X3.4 In rooms where high humidity may be encountered, such as the kitchen, bath, or utility room, a flat or semigloss enamel finish is recommended.

X3.5 Care should be exercised in the selection of primer and sealer paints to make sure they will perform satisfactorily, and fulfill the following functions:

X3.5.1 Equalize variations of suction over the entire surface.

X3.5.2 Provide a bonding surface or “tooth” for the paint to be applied.

X3.5.3 Avoid nap raising.

X3.6 Before applying the sealer, remove all loose dirt and dust by brushing with a soft brush or by rubbing with a dry cloth. Be sure the joint treatment is thoroughly dry before any application of sealer or paint.

X3.7 In applying primers or sealers, apply sufficient quantity to assure that the surface is completely covered. Follow the manufacturer’s printed directions and do not over thin. It is good practice to tint the sealer to approximately the shade of the finish coat. This will lead to better results in the finished job.

X3.8 In all cases where deep tones are to be used in the finish paint, best results will be achieved if the surface is first sealed. More than one coat of sealer may be necessary. Each coat must be thoroughly dry before applying another.

X3.9 Under normal atmospheric conditions, a waiting period of 12 to 18 h after application of primer-sealer should be observed before decoration is applied. In rainy, humid, and cold weather, a longer waiting period; sometimes as long as 36 to 48 h; may be necessary to make certain the sealer coat is absolutely dry.

X3.10 Exposed surfaces of gypsum board, as specified in Section 10 shall be painted with not less than two coats of exterior paint.

X3.11 Where semi-gloss or high-gloss paints are required or where severe lighting conditions occur, and prior to the application of a primer, a skim coat shall be applied to the

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

entire surface of the wallboard, including the taped joints, covered fasteners, and accessories, to reduce the absorption and texture difference between the joint compound and the face of the wallboard.

X4. APPLICATION OF SURFACING MATERIALS AND CAULKING

X4.1 Caulk all cut edges and openings around pipes and fixtures flush with waterproof, nonhardening caulking compound or Type I adhesive complying with ANSI A 136.1.

X4.2 Wall tile shall be used in combination with adhesive to protect the gypsum board and any water sensitive materials if present (such as joint compound) from penetration of moisture or water. Responsibility for performance of completed installation shall rest with the surface materials manufacturer or with the tile applicator.

X4.3 For application of ceramic, plastic, or metal wall tile, or plastic finished rigid wall panels, or other types of surfacing materials over gypsum board in wet or dry areas, the recommendations of the manufacturer of tile, wall panel, or other surfacing materials shall be followed.

X4.4 Apply the surfacing material down to the top surface or edge of the finished shower floor, return, or tub, or install so as to overlap the top lip of receptor, sub-pan, or tub. It shall completely cover the following areas:

X4.4.1 *Over Tubs without Showerheads*—Six in. (152.4 mm) above the rim of the tub.

X4.4.2 *Over Tubs with Showerheads*—A minimum of 5 ft (1.52 m) above the rim or 6 in. (152.4 mm) above the height of the showerhead, whichever is higher.

X4.4.3 *Shower Stalls*—A minimum of 6 ft (1.83 m) above the shower dam or 6 in. (152.4 mm) above the showerhead, whichever is higher.

X4.4.4 All gypsum board window sills and jambs in shower or tub enclosures shall be covered to a like height.

X4.4.5 The surfacing material shall be applied to the full specified height for a distance of at least 4 in. (101.6 mm) beyond the external face of the tub or receptor. Areas beyond an exterior corner are excluded.

X4.5 Where plastic finished rigid wall panels are used as a surfacing material, the following precautions shall be taken:

X4.5.1 The type and shape of moldings recommended by the manufacturer of the surfacing material shall be used. Recommended tub moldings shall be used at the base where the surfacing materials abut the tub, shower, floor, or curb. Such moldings shall be set in waterproof, nonhardening caulking compound.

X4.5.2 Joints shall be filled in such a manner as to leave no voids for water penetrations.

X4.5.3 A bead of adhesive shall be applied as a dam between the back surface of the finishing material and the tub or receptor to prevent any leakage of water at the joint.

X5. WOOD FRAMING REQUIREMENTS

X5.1 The following requirements should be included in the project specifications for framing and furring and are essential to provide a proper base to receive the gypsum board.

X5.2 All framing members to which gypsum board will be fastened shall be straight and true. Framing shall be in alignment and spaced not to exceed the maximum spacings shown in Table 2. Framing, bridging, and furring members shall be the proper grade for the intended use and members 2 by 4 in. nominal size or larger shall bear the grade mark of a recognized inspection agency. Framing, bridging, and furring shall be adequate to meet the design, or code loading, or both. Where there is an applicable local code, the framing shall be in accordance with the Manual for House Framing by the National Lumber Manufacturers. Supports shall be provided as necessary for the support of fixtures.

X5.3 When gypsum board is nailed to wood cross furring on ceilings, these furring members shall have a minimum cross section of 1½ by 1½ in. (38.1 by 38.1 mm) actual size and be spaced in accordance with 9.2 and 9.3. Where screw application is used, the furring member may be ¾ in. by 2½ in. (19.1 by 63.5 mm) actual size.

X5.4 Where wood furring is used over masonry or concrete, fasteners should be of a length that does not come into contact with the masonry surface.

X5.5 Insulating blankets or flanges of blankets shall not be applied over framing members that are to receive gypsum board.

X5.6 Foil-backed gypsum board may be used where a vapor retarder is required.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X6. PRECAUTIONS TO MINIMIZE POTENTIAL OF SAGGING

X6.1 Ensure framing spacing is adequate for thickness of board to be used. Ensure board is applied perpendicular to framing.

X6.2 Determine that excessive weight of insulation will not be added.

X6.3 Control the relative humidity within the structure by providing adequate ventilation before, during, and after board application. Watch for pouring of basement floors after board application.

X6.4 In cold weather, maintain inside temperature between 50 °F (10 °C) and 70 °F (20 ° C). Where portable heaters are used, make sure to remove the extra humidity they produce.

X6.5 Ensure the gypsum board is thoroughly dry and at ambient temperature before application.

X6.6 Ensure joint treatment is thoroughly dry before applying any decoration.

X6.7 Ensure that primer and paint coats are dry before the application of successive coats.

X6.8 Where hand or spray-applied water-based texture finishes are to be used on gypsum board ceilings under this specification either (1) ½ in. (12.7 mm) Gypsum Ceiling Board (see Specification C 1396/C 1396M) shall be used perpendicular to framing not more than 24 in. (610 mm) on center, or (2) other gypsum boards shall be used perpendicular to framing and board thickness shall be not less than ½ in. (12.7 mm) thick for 16 in. (406 mm) on center framing and not less than ⅝ in. (15.9 mm) thick for 24 in. (610 mm) on center framing.

X7. ELECTRIC RADIANT HEATING SYSTEMS FOR GYPSUM BOARD CEILINGS

X7.1 For guidance on the application of gypsum board in conjunction with a concealed radiant ceiling heating system constructed from thin sheet flexible radiant heating panels, or for the application of gypsum board after repair of existing concealed radiant ceiling heating systems constructed from heating cable or thin sheet flexible radiant heating panels see Guide C 1546.

X8. LEVELS OF FINISH

NOTE X8.1—Joint compounds used to conceal the joints and fastener heads can vary in density and surface character from the adjacent wallboard surface. Terms such as “industry standard” or “workman-like finish” are often used but not specific and can lead to subjective interpretation.

The architect, general contractor and owners frequently anticipate or expect a higher level of finish than the sub-contractor can determine from the specifications that are furnished for the bid process.

Reasons for specifying levels are: (*1*) many building are designed with walls and partitions abutting window mullions, long hallways, or atriums with large surface areas flooded with artificial and natural lighting; (*2*) paints and painting methods have changed over the years with wider use of spray equipment and reduce solids in paint; and (*3*) differences in absorption and drying, shrinkage of the compound, tool marks and ridges in the compound, or scuffing or raising of the nap of the face paper may all, or in part, combine to emphasize visual differences.

It is recommended that the painting specification provide for proper treatment to ensure uniform absorption over the entire surface. Any special finish such as gloss, which demands a more stringent requirement than the standard surface provides, should be specifically pointed out in the design process.

X8.1 *Level 0:*

X8.1.1 As stated, there is no finish required. To be used in temporary construction or whenever the final finish level has not been determined.

X8.1.2 Also could be used where non-predecorated panels will be used in demountable type partitions which are to be painted as a final finish.

X8.2 *Level 1:*

X8.2.1 Frequently used in plenum areas above ceilings, in attics, in areas where the assembly would generally be concealed, or in building service corridors and other areas not normally open to public view. Some degree of sound and smoke control is provided; in some geographic locations referred to as fire-taping. Where a fire resistance rating is required for gypsum board assembly, details of construction shall be in accordance with reports of fire tests of assemblies that have met the requirements of the fire rating imposed. Accessories optional at specifier discretion in corridors and other areas with pedestrian traffic. Tape and fastener heads need not be covered with a joint compound.

X8.3 *Level 2:*

X8.3.1 May be used when Water Resistant Gypsum Backing Board, Specification C 1396/C 1396M, is used as a substrate, or in garages, warehouse storage, or other similar areas where surface appearance is not of primary concern.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:05 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X8.4 *Level 3:*

X8.4.1 Used in appearance areas that are to receive heavy texture (spray or hand applied) finishes before final painting. Should not be used under smooth painted surfaces.

X8.5 *Level 4:*

X8.5.1 This method should be used where wallcoverings, flat paints, or light textures are specified.

X8.5.2 Release agents for wall coverings are specifically formulated to minimize damage if coverings are subsequently removed.

X8.5.3 The weight texture and sheen level of the wallcovering selected should be taken into consideration when specifying wallcoverings over this level of drywall treatment. Joints and fasteners must be sufficiently concealed if the material is lightweight, contains limited patterns, has a glossy finish or any combination of these areas. Unbacked vinyls are not recommended.

X8.5.4 In critical lighting areas, flat paints applied over light textures tend to reduce joint photographing. Gloss, semi-gloss and enamel paints are not recommended over this level of finish.

X8.6 *Level 5:*

X8.6.1 The highest quality finish is the most effective method to provide a uniform surface and minimize the possibility of joint photographing and of fasteners showing through the final decoration.

X8.6.2 This level of finish is required where gloss, semi-gloss, or enamel flat paints are specified or where critical lighting conditions occur.

X8.6.3 *Skim Coating with Joint Compound*

X8.6.3.1 A Level 5 gypsum board finish consists of joints finished with joint tape set in joint compound followed by a specified number of additional coats of compound over the tape, joint compound applied all over fastener heads and accesories, then the application of a "skim coat" of joint compound over the entire surface.

X8.6.3.2 A skim coat of joint compound is intended to conceal small imperfections in joints and on the surface of the gypsum board, smooth the texture of the paper, minimize differences in surface porosity, and create a more uniform surface to which the final decoration can be applied.

X8.6.3.3 A "skim coat" is essentially a "film" of joint compound and is not a readily measurable thickness. There is no specific mil thickness that constitutes a proper "skim coat."

X8.6.3.4 Section 22.6.6.1 describes a "skim coat" as being "trowel-applied" with intent being that the consistency (viscosity) of the joint compound be such that it can be applied by trowel if that is the tool chosen for the task. Other tools may be used for application so long as the trowel consistency is achieved.

X8.6.3.5 The objective of the application is to achieve total coverage of the entire surface with the "skim coat." This is typically accomplished by delivering the compound to the surface and using a drywall broad knife to force the compound into the surface pores and imperfections while shearing excess compound from the surface.

X8.6.3.6 A "skim coat" will not approximate a plastered surface.

X8.6.3.7 Once the skim coat dries, the gypsum board paper may show through and the treated joints, filled voids, and spotted fasteners will likely be visible.

X8.6.4 *Alternative Materials*

X8.6.4.1 When alternative skim coat materials as described in 3.2.26, 22.4.6, and 22.6.6.1 are used, the statements in X8.6.3 are applicable, except that the consistency (viscosity) of the material and the application procedure shall be as recommended by the manufacturer.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 840 – 07, that may impact the use of this specification. (Approved May 1, 2008)

(*1*) Revised Table 5.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 840 – 06, that may impact the use of this specification. (Approved January 1, 2007)

(*1*) Added new 7.1.3.1.
(*2*) Revised 17.4.4 and added new 17.4.4.1 and 17.4.4.2.
(*3*) Revised 22.3.3, added new 22.3.3.1, 22.3.3.2, and 22.3.3.3.
(*4*) Revised 22.6.2.2, 22.6.3.2, 22.6.4.1, 22.6.5.1, and 22.6.6.1.
(*5*) Revised Table 5
(*6*) Added new Note 11 and renumbered subsequent notes.

Designation: C 841 – 03(Reapproved 2008)ε1

Standard Specification for Installation of Interior Lathing and Furring[1]

This standard is issued under the fixed designation C 841; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

ε[1] NOTE—The units statement in subsection 1.2 was corrected editorially in July 2008.

1. Scope

1.1 This specification covers the minimum requirements for, and the methods of application of, interior lathing and furring to receive gypsum plaster applied in accordance with Specification C 842. Other materials are not prohibited from being used provided that their physical characteristics and durability under conditions of usage are at least equal in performance to those described.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 Details of construction for a specific assembly to achieve the required fire resistance shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing laboratories.

1.4 Where a specific degree of sound control is required for plastered assemblies and constructions, details of construction shall be obtained from reports of sound tests of assemblies that have met the requirements of Test Method E 492.

3. Terminology

3.1 *Definitions*—For definitions relating to ceilings and walls see Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *base coat*, *n*—the sum of the scratch and brown coats or the total coats in place prior to application of finish coats.

3.2.2 *contact ceiling*, *n*—a ceiling in which the lath is attached in direct contact with the construction above, without the use of main runners or cross furring.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for the Application of Gypsum and Other Products in Assemblies.

Current edition approved May 1, 2008. Published July 2008. Originally approved in 1976. Last previous edition approved in 2003 as C 841 – 03.

3.2.3 *furred ceiling*, *n*—a ceiling in which the furring used for the support of the lath is attached directly to the structural members of the building.

3.2.4 *suspended ceiling*, *n*—a ceiling in which the main runners and cross furring are suspended below the structural members of the building.

3.2.5 *main runners*, *n*—the members that are attached to or suspended from the construction above for the support of cross furring.

3.2.6 *cross furring*, *n*—furring members that are attached at right angles to the underside of the main runners or construction above for support of the lath.

3.2.7 *furring*, *n*—spacer strips fastened to a wall, ceiling, or planar element that create an even surface for the application of metal plaster bases or gypsum lath.

3.2.8 *primary members*, *n*—the members (main runners or structural supports) to which the cross furring is attached.

3.2.9 *metal plaster bases*, *n*—expanded metal lath, sheet metal lath, welded or woven wire lath.

3.2.10 *face side (gypsum lath)*, *n*—the side opposite the paper cover seam laps.

3.2.11 *surface transition*, *n*—the change in width of a surface, usually as a result of penetrations (doors, windows) or architectural demands.

4. Delivery of Materials

4.1 All materials shall be delivered in the original packages, containers, or bundles bearing the brand name and manufacturer's (or supplier's) identification.

5. Storage of Materials

5.1 All materials shall be kept dry, preferably by being stored inside. Where necessary to be stored outside, materials shall be stacked off the ground, supported on a level platform, and protected from the weather and surface contamination.

5.2 Materials shall be neatly stacked flat with care taken to avoid damage to edges, ends, or surfaces.

6. Materials

6.1 Wire Specification A 641/A 641M, Class 1 coating (galvanized) soft temper.

6.1.1 *Tie Wire and Hanger Wire*—Zinc-coated (galvanized) soft-annealed steel, or a material having equivalent size, corrosion resistance and strength. Wire diameters (uncoated) specified herein correspond with United States steel wire gage numbers as follows:

Diameter, in.[A]	(mm)	Wire Gage (U.S. Steel Wire Gage)
0.0348	(0.88)	No. 20
0.0410	(1.04)	No. 19
0.0475	(1.21)	No. 18
0.0540	(1.37)	No. 17
0.0625	(1.59)	No. 16
0.0800	(2.03)	No. 14
0.0915	(2.32)	No. 13
0.1055	(2.68)	No. 12
0.1205	(3.06)	No. 11
0.1350	(3.43)	No. 10
0.1483	(3.77)	No. 9
0.1620	(4.11)	No. 8

[A] Allowable variations in diameter shall be in accordance with tolerances as established in A 641/A 641M.

6.2 *Gypsum Lath*—Specification C 37.

6.3 *Expanded Metal Lath*—Specification C 847.

6.4 *Wire Lath*:

6.4.1 *Welded Wire Lath*, Specification C 933.

6.4.2 *Woven Wire Lath*, Specification C 1032.

6.5 *Fasteners*:

6.5.1 *Nails for Attaching Gypsum Lath*—Specification C 514. Nail size shall be in accordance with Table 1.

6.5.2 *Nails for Attaching Metal Plaster Base*—Galvanized roofing nails or common nails. length shall be as specified in 7.

6.5.3 *Screws*—Specifications C 954 or C 1002.

6.5.3.1 Screws for attaching gypsum lath shall be sized in accordance with Table 1.

TABLE 1 Screws, Nails and Staples[A,B] for Attaching Gypsum Lath to Horizontal and Vertical Wood Supports

Maximum Spacing, in. (mm)					Minimum Gage Requirements, in. (mm)			
Width of Lath	Thickness of Lath	Distance Between Supports	Number of Attachments per Bearing	Approximate Spacing *c* to *c* of Attachments	Length of Leg	Depth of Support Penetration	Diameter of Flat Head or Blued Nails or Crown Width of Staples[A]	Gage of Shank of Nails or Staples[A]
16 (406)	⅜ (9.5)	16 (406)	4	5 (127)	1⅛ (28.6) 1 (25.4)[A]	¾ (19) ⅝ (15.9)[A]	19/64 (7.5) 7/16 (11)[A]	13 16[A]
24 (610)	⅜ (9.5)	16 (406)	6	4½ (114)	1⅛ (28.6) 1 (25.4)[A]	¾ (19) ⅝ (15.9)[A]	19/64 (7.5) 7/16 (11)[A]	13 16[A]
16 (406)	½ (12.7)	24 (610)	4	5 (127)	1¼ (32) 1⅛ (28.6)[A]	¾ (19) ⅝ (15.9)[A]	19/64 (7.5) 7/16 (11)[A]	13 16[A]
24 (610)	½ (12.7)	24 (610)	6	4½ (114)	1¼ (32) 1⅛ (28.6)[A]	¾ (19) ⅝ (15.9)[A]	19/64 (7.5) 7/16 (11)[A]	13 (330) 16[A]
48 (1219)	⅜ (9.5) ½ (12.7)	16 (406) 24 (610)	8	4½ (114)	1⅛ (28.6) 1 (25.4)[A] 1¼ (32) 1⅛ (28.6)[A]	¾ (19) ⅝ (15.9)[A] ¾ (19) ⅝ (15.9) [A]		

[A] Galvanized staples.
[B] Screws for attaching gypsum lath to wood supports shall be Type W as described in Specification C 1002.

www.technobetar.ir

6.5.3.2 Screws for attaching metal plaster base shall have a 7⁄16 in. (11.1 mm) diameter pan washer head and a 0.120 in. (3.0 mm) diameter shank. The length shall be sufficient enough to allow for the threaded portion of the screw to project not less than 3⁄8 in. (9.5 mm) through steel framing when the lath is installed.

6.5.4 *Staples*—Staples for attaching gypsum lath shall conform to the requirements of Table 1.

6.5.4.1 Staples for attaching metal plaster base shall be 0.062 in. (1.6 mm) diameter, round or flattened steel wire with 3⁄4 in. (19.0 mm) crown. Lengths shall be as specified for individual systems.

6.6 *Paper or Other Backing*—When used on metal plaster bases, over solid backing, backing shall be securely held in place by, or attached to the metal plaster base. Metal plaster base shall allow for 1⁄4 in. (6.4 mm) self furring. The backing shall permit embedment of plaster.

6.7 *Accessories*—Shall be steel, coated, with a protective rust inhibitive coating after fabrication, or fabricated from zinc-coated (galvanized) steel, aluminum, zinc alloy, or high impact plastic. Plastic accessories shall be nmanufactured in accordance with Specifcation D 1784 or Specification D 3678. Aluminum accessories shall be clear plastic coated. All accessories shall have perforated or expanded flanges or clips shaped so as to permit complete imbedment in the plaster, to provide means for secure alignment, and to secure attachment of the accessory to the underlying surface. Accessories shall be designed for the intended use and to receive or to permit application of the specified plaster thickness.

6.7.1 Thickness of base material for accessories shall be not less than as shown in the following:

Base Material (mm)	Thickness of Base Material, in.
Uncoated steel/zinc	0.014 (0.36)
PVC	0.030 (0.76)
Aluminum	0.050 (1.27)

6.7.2 *Control Joints*—Shall be formed by using a single prefabricated member or fabricated by installing casing beads back to back with a flexible barrier membrane behind casing beads. The separation spacing shall be not less than 1⁄8 in. (3.2 mm) or as required by the anticipated thermal exposure range.

6.7.3 *Cornerite*—shall be not less than 1.75 lb/yd^2 (0.85 kg/m^2) expanded metal lath, galvanized, or given a protective coating of rust inhibitive paint after fabrication, or woven or welded fabric not less than 0.041 in. (1.04 mm) thick an weighing not less than 1.75 lb/yd^2 (0.85 kg/m^2), fabricated from galvanized wire. When shaped for angle reinforcing, cornerite shall have outstanding legs of not less than 2 in. (50.8 mm).

6.7.4 *Channels*—Shall be cold-rolled steel, free of rust with a coating of rust inhibitive paint or galvanized. Channels used in areas subject to corrosive action of salt air or other corrosive environments, shall be hot-dip galvanized. Weight of the channel shall be not less than as shown in the following:

Size		Weight	
in.	(mm)	lb/1000 lf	(kg/m)
3⁄4	(19)	277	(0.412)
1 1⁄2	(38)	414	(0.616)
2	(50)	506	(0.753)
2 1⁄2	(64)	597	(0.888)

6.7.5 Rod and flat (strap) hangers shall be mild steel, zinc coated or protected with a rust-inhibiting paint.

6.7.6 *Clips*—Devices for attaching framing members to supports or to each other; for attaching lath to framing members; or for securing lath to lath, shall be formed of zinc-coated (galvanized) steel wire or sheet, and of sufficient size and strength to support the intended load

6.7.7 *Striplath*—Shall be not less than 1.75 lb/yd^2 (0.85 kg/m^2) expanded metal lath, or woven or welded fabric of not less than 0.041 in. (1.04 mm) thick weighing not less than 1.75 lb/yd^2 (0.85 kg/m^2) fabricated from galvanized steel.

7. Installation

7.1 *General Requirements for Application of Lath and Accessories*:

7.1.1 Lath shall be installed with the long dimension at right angles to supports, unless otherwise specified.

7.1.2 Corner beads shall be installed to protect all external corners and to establish grounds. Corner beads shall be attached to the substrate in such a manner as to ensure proper alignment during application of plaster.

7.1.3 Metal accessories shall be installed so that flanges and clips provided for their attachment are covered by the base coat plaster.

7.1.4 *Control Joints*—Shall be installed in ceilings greater than 2500 ft^2 (232 m^2) in area and in partition, wall, and wall furring runs greater than 30 ft (9 m) in length. The distance between ceiling control joints shall not be more than 50 ft (15 m) in either direction. A control joint shall be installed where the ceiling framing or furring changes direction. The distance between control joints in walls or wall furring shall be not more than 30 ft (9 m). A control joint shall be installed where an expansion joint occurs in the base exterior wall or ceiling. A ceiling height door frame, installed in accordance with the spacing requirements set forth in this section, is not prohibited from being used as a control joint.

7.1.5 Where partition assemblies require the installation of control joints over the head of door frames to relieve stresses within the assemblies, such control joints shall be installed in the following manner:

7.1.5.1 Where control joints are located at the vertical center of the door opening two metal studs shall be installed not more than 1⁄2 in. (12.7 mm) apart over the center of the span at the head of the frame, with the lath installed so that a vertical joint occurs between the studs. A prefabricated control joint or casing beads shall be installed at the joint location.

7.1.5.2 Where control joints are located in line with the door jambs the procedure in 7.1.5.1 shall be followed with the exception that supporting members shall consist of two studs placed side-by-side.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:19:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.1.6 Casing beads or other suitable accessories, shall be used to isolate non-load bearing partitions from load bearing members.

7.1.7 *Workmanship*—Metal construction furring and lathing shall be erected so that finished plaster surfaces will be true to line, level, plumb, square, curved, or as required to receive specified plaster thickness.

7.1.8 Except where frames are required to be fully grouted with plaster, lath shall be inserted into jambs as far as possible and notched to pass anchors.

7.2 *Application of Gypsum Lath to Supports*:

7.2.1 *General*—Gypsum lath shall be installed so that vertical joints occur not less than one full stud space from edges of openings in walls or partitions.

7.2.2 Gypsum lath shall be installed with the face side out and the edges and ends butted together. End joints shall fall on different supports in alternate courses, or the lath shall be installed so that end joints are continuous on one support. In the latter case, the continuous end joints shall be covered with 3-in. (76-mm) wide strips of metal lath or welded or woven wire fabric, and the long edge joints of lath in alternate courses shall be offset or staggered.

7.2.3 Cornerite shall be installed on gypsum lath at all internal angles, and lightly nailed or stapled to the gypsum lath and not to the framing members. Cornerite shall not be used in unrestrained construction, or where other provisions are made for the treatment of internal angles.

7.2.4 Where gypsum lath sheets intersect or where joint surfaces are to be plastered without lathing (such as masonry), a casing bead shall be installed at the intersection or joining.

7.2.5 Gypsum lath shall be reinforced at the corners of doors, windows, or other openings with diagonally installed strips of striplath or wire lath, not less than 6 in. (152 mm) wide by 12 in. (305 mm) long.

7.2.6 Metal lath stripping shall be used to cover chases and similar breaks in continuity or horizontal or vertical surfaces that are to receive plaster. Stripping shall be extended not less than 3 in. (76 mm) on all sides of the openings.

7.3 *Application of Gypsum Lath to Wood Supports*:

7.3.1 Except where required otherwise, for certain fire-resistant construction, gypsum lath shall be securely attached to wood supports using nails, screws, or staples conforming to Table 1.

7.3.2 Nails and screws shall be driven so that the face of the head is flush with the face of the gypsum lath, and not less than ⅜ in. (9.5 mm) from the edges of the lath. Staples shall be driven with the crown parallel to the nailing members. The crown shall bear lightly against, but not cut into, the face of the lath.

7.4 *Application of Gypsum Lath to Metal Supports*:

7.4.1 Gypsum lath shall be attached to horizontal or vertical metal supports with staples, screws, or nails, or a combination thereof.

7.4.2 Screws shall be driven so that the face of the head is flush with the face of the gypsum lath and not less than ⅜ in. (9.5 mm) from the edges of the lath.

7.5 *Studless Solid Partitions (Gypsum Lath and Plaster)*:

7.5.1 Gypsum lath shall be plain, ½ in. (12.7 mm) thick, 24 in. (610 mm) wide, and, when applied vertically, shall be not more than 12 ft (3.7 m) in length.

7.5.2 Wood floor runners shall be secured to the floor using anchors spaced not more than 24 in. (610 mm) on center. Anchors shall penetrate floor surface to a depth of not less than ⅝ in. (15.9 mm). The width of such runners shall correspond to the overall partition thickness and their upper surface shall be grooved parallel to the length of the runner in the center to a depth of not less than ½ in. (12.7 mm) and to a width to accommodate snugly the thickness of the lath.

7.5.3 Metal floor runnersshall be anchored to bases and clips at not more than 24 in. (610 mm) on center. Runners shall be designed to hold the lower edge of the lath securely in position.

7.5.4 Metal ceiling runners shall be aligned with floor runners to ensure plumb installation of the lath. Metal ceiling runners shall be firmly secured to the ceiling construction.

7.5.5 Gypsum lath shall be of such length as to allow not less than ¼ in. (6.4 mm) nor more than 1-in. (25.4-mm) top clearance in the ceiling runner. Erect gypsum lath vertically so as to engage the ends in or to the floor and ceiling runners.

7.5.6 the vertical edges of the lath shall be aligned with the vertical joints interlocked or mechanically fastened with type G screws spaced not more than 12 in. (305 mm) on centers.

7.6 *Application of Metal Plaster Bases to Framing Members*:

7.6.1 *General*—The spacing of supports for the type and weight of metal lath used shall be in accordance with the requirements of Table 2.

7.6.2 *Attachments for Metal Plaster Bases to Wood Framing Members*:

7.6.2.1 Diamond mesh expanded metal lath, flat rib expanded metal lath, and welded wire lath shall be attached to horizontal wood supports with 1½ in. (38 mm), 0.1205 in. (3.06 mm) shank, 7⁄16 in. (11 mm) diameter head, barbed, galvanized, or blued roofing nails driven flush with the lath. The metal lath shall be attached to vertical wood supports with 6d common nails, or 1-in. (25-mm) long roofing nails driven driven in accordance with Table 1 or 1-in. No. 14 gage wire staples driven flush with the lath.

7.6.2.2 ⅜-in. (9.5-mm) rib expanded metal lath shall be attached to horizontal and vertical wood supports with nails or staples not less than ⅜ in. (9.5 mm) longer than required (7.6.2.1) to provide not less than ⅜-in. (9.5-mm) longer than required (see 7.6.2.1) to provide penetration in accordance with Table 1.

7.6.2.3 When used on vertical wood supports, common nails shall be bent over to engage not less than three strands of lath. When used for the application of rib lath, common nails shall be bent over to engage not less than one rib of the lath.

7.6.2.4 Other methods of attachment shalll be used when it can be shown they provide a carrying strength not less than that described in 7.6.2.1-7.6.2.3 may be used.

7.6.3 *Attachments for Metal Plaster Bases to Metal Framing Members*:

7.6.3.1 Metal plaster bases shall be attached to metal framing members with 0.048 in. (1.2 mm) diameter wire ties, clips, or modified truss (wafer-headed) screws installed so that the

TABLE 2 Types and Weights of Expanded Metal Lath, Sheet Lath, or Welded Wire Lath and Corresponding Maximum Permissible Spacing of Supports[A]

Type of Metal Plastering Base	Minimum Weight of Metal Base, lb/yd² (kg/m²)	Maximum Permissible Spacing of Supports Center for Center, in. (mm)				
		Walls (Partitions)			Ceilings	
		Wood Studs	Solid Partitions	Steel Studs, Wall Furring, etc.	Wood or Concrete	Metal
Expanded metal lath:						
Diamond mesh	2.5 (0.08)	16 (406)	16 (406)	16 (406)	12 (305)	12 (305)
	3.4 (0.12)	16 (406)	16 (406)	16 (406)	10 (254)	16 (406)
Flat rib	2.5 (0.08)	16 (406)	12 (305)	12 (305)	12 (305)	12 (305)
	2.75 (0.09)	16 (406)	16 (406)	16 (406)	16 (406)	16 (406)
	3.4 (0.12)	19 (483)	24 (610)	19 (483)	19 (483)	19 (483)
Flat rib (large opening)	1.8 (0.06)	24 (610)	24 (610)	24 (610)	16 (406)	16 (406)
⅜-in. (9.5-mm) rib						
	3.4 (0.12)	24 (610)	N/A	19 (482)	19 (482)	19 (482)
	4.0 (0.14)	24 (610)	N/A	24 (610)	24 (610)	24 (610)
Wire lath welded	1.4 (0.05)[B]	16 (406)	16 (406)	16 (406)	16 (406)	16 (406)
	1.95 (0.07)[C]	24 (610)	24 (610)	24 (610)	24 (610)	24 (610)

[A] Paper-backed lath shall be limited to lath having an absorbent and a perforated slotted paper separator only.
[B] Welded wire paper-backed lath, 16-gage, 0.0598 in., (1.52 mm).
[C] Welded wire, paper-backed lath, 16-gage face wire, 0.0598 in. (1.52 mm) face wire.

threaded portion of the screw will penetrate the metal supports not less than ⅜ in. (9.5 mm) and the head shall contact not less than three strands of lath.

7.6.3.2 Rib metal lath shall be attached to open web steel joists using single ties of galvanized, annealed steel wire, 0.048 in. (1.2 mm) in diameter, with the ends of each tie wire twisted together 1½ times.

7.6.3.3 Rib metal lath shall be installed to metal framing members with the point of the V rib in contact with the framing and attached to the framing by a screw driven through the rib so that the threaded portion of the screw penetrates the metal support not less than ⅜ in. (9.5 mm).

7.6.4 *Attachments for Metal Plaster Bases to Concrete Supports*—Rib metal lath shall be attached to concrete joists by loops of galvanized, annealed steel wire, not less than 0.076 in. (1.9 mm) in diameter, with the ends of each loop twisted together not less than 1½ times.

7.6.5 *Spacing of Attachments for Metal Plaster Bases*—Attachments for securing metal plaster bases to supports shall be spaced not more than 7 in. (178 mm) apart for diamond mesh and flat rib laths and at each rib for ⅜-in. (9.5-mm) rib lath.

7.6.6 *Lapping of Metal Plaster Bases*:

7.6.6.1 Side laps of metal plaster bases shall be secured to supports, and tied between supports at intervals not more than 9 in. (229 mm) on center.

7.6.6.2 Expanded metal lath shall be lapped ½ in. (12.7 mm) at edges, or the edge ribs shall be nested. Welded or woven wire lath shall be lapped one mesh at sides and ends. Expanded metal lath shall be lapped 1 in. (25 mm) at ends or ends shall be nested. When end laps occur between supports, the ends of sheets of all metal plaster bases shall be tied together with 0.048 in. (1.2 mm), galvanized, annealed steeel wire. Laps shall be located not more than 3 in. (76.2 mm) from the structural support. Lath shall be lapped not more than 3 in. (76.2 mm) in any direction.

7.6.6.3 Adjacent sheets of metal plaster base shall be installed so that metal laps onto metal and backing laps onto backing.

7.6.7 *Procedure for Application of Metal Plaster Bases to Ceiling Framing Members*:

7.6.7.1 Metal plaster bases shall be applied to ceilings first.

7.6.7.2 The ends of metal plaster bases shall be staggered.

7.6.7.3 Where furred or suspended ceilings greater than 50 ft (15 m) in either direction or 2500 ft² (232 m²) in area butt into or are penetrated by columns, walls, beams, or other elements, the following procedure shall be used: The sides and ends of the ceiling lath shall abut at the horizontal internal angles and terminate at a casing bead, control joint, or similar device designed to isolate the plaster membrane from the adjoining vertically oriented elements. Only casing beads shall be used at internal angles between ceilings, walls, or partitions. Lath shall not be continuous through control joints but shall be stopped and tied to the flanges of the control joint at each side.

7.6.8 Ends of sheets of diamond mesh metal lath and welded wire lath on partitions not abutting structural walls, columns, or floor-ceiling slabs shall be bent into or around vertical corners and continued on to not less than one support away from the corner. The ends of the sheets of lath shall be butted into corners when cornerite is applied over the abutting laths. Rib metal lath shall be butted into corners and cornerite shall be applied over the abutting laths.

7.6.9 The ends of metal plaster bases applied to load-bearing wall and partitions that abutt structural walls, columns, or floor-ceiling slabs shall be isolated from the adjacent surface at the interanl angle. Cornerite shall not be used at internal angles, only casing beads or control joint materials shall be used to isolate the lath and plaster from the abutting surface.

7.7 *Studless Solid Partitions (Metal Lath and Plaster)*:

7.7.1 Metal plaster bases used for studless solid partitions shall have the sides (long dimensions) of the sheet installed vertically. The plaster bases shall be wiretied to the ceiling

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

runners using ties spaced not mroe than 8 in. (203 mm) on center and mechanically anchored to the floor runners or base.

7.7.1.1 At vertical internal and external corners, metal plaster bases shall be bent and returned 6 in. (152 mm) on abutting surfaces. Rib metal lath shall be lapped ½ in. (12.7 mm) at sides, or the outside ribs shall be nested. Side laps shall be wire tied between supports at intervals not more than 9 in. (229 mm) on center.

7.8 *Suspended and Furred Ceilings (Metal Lath and Gypsum Lath Construction)*:

7.8.1 Hangers shall be of sufficient length to accommodate the ceiling construction.

7.8.1.1 Hangers (without inserts) shall be secured or otherwise embedded so as to develop full strength.

7.8.1.2 *Inserts*—Inserts for hangers shall be secured in concrete reinforced slabs so as to develop the full strength of the hangers that are attached to them.

7.8.2 *Hangers for Suspended Ceilings Under Wood Constructions*—Hangers shall conform with the requirements of Table 3 both as to size and maximum area to be supported, except as modified in this section. Hangers shall be attached to supports by one of the following methods:

7.8.2.1 Insert through holes drilled not less than 3 in. (76 mm) above the bottom of the joist with the upper end of the hanger twisted not less than three times around itself (see Fig. 1).

7.8.2.2 Twisted not less than three times around itself over not less than three 12d nails driven on a downward slant into

TABLE 3 Suspended and Furred Ceilings, Minimum Sizes for Wire, Rod, and Rigid Hangers; Minimum Sizes and Maximum Spans and Spacings for Main Runners; and Minimum Sizes and Maximum Spans and Spacings for Cross Furring

NOTE 1— 1 in. = 25.4 mm; 1 ft^2 = 0.093 m^2

HANGERS		
	Maximum Ceiling Area Supported, ft^2	Minimum Size of Hangers
Hangers for Suspended Ceilings	12.5	0.148 in. wire
	16	0.162 in. wire
	18	3/16-in. diameter, mild steel rod[A]
	20	7/32-in. diameter, mild steel rod[A]
	22.5	¼-in. diameter, mild steel rod[A]
	25.0	1 by 3/16-in. mild steel strap[B]
Attachments for Tying Runners and Furring Directly to Beams and Joists		
For Supporting Runners		
Single Hangers Between Beams[C]	8	0.106 in. wire
	12	0.135 wire
	16	0.162 wire
Double Wire Loops at Beams or Joists[C]	8	0.076 wire
	12	0.106 wire
	16	0.120 wire
For Supporting Furring Without Runners[C] (Wire Loops at Supports)		
Types of Support:		
Concrete	8	0.076 wire
Steel	8	0.062 (2 loops)[D]
Wood	8	0.062 (2 loops)[D]

SPANS AND SPACINGS OF MAIN RUNNERS[E,F]		
Minimum Size and Type	Maximum Span Between Hangers or Supports, in.	Maximum Center to Center Spacing of Runners, in.
¾ in., 0.3 lb/ft, cold	24	36
1½ in. 0.475 lb/ft, cold-rolled channel	36	48
1½ in., 0.475 lb/ft, cold-rolled channel	42	42
1½ in., 0.475 lb/ft, cold-rolled channel	48	36
2 in., 0.59 lb/ft, cold-rolled channel	60	48
1½ by 1½ by 3/16-in. angle	60	42

SPANS AND SPACINGS OF CROSS FURRING[E,F]		
Minimum Size and Type	Maximum Span Between Runners or Supports, in.	Maximum Center to Center Spacing of Cross Furring Members, in.
¼-in. diameter pencil rods	24	12
3/8-in. diameter pencil rods	24	19
3/8-in. diameter pencil rods	30	12
¾ in., 0.3 lb/ft, cold	36	24
	42	19
	48	16

[A] All rod hangers shall be protected with a zinc cadmium coating.
[B] All flat hangers shall be protected with a zinc or cadmium coating or with a rust-inhibitive paint.
[C] Inserts, special clips, or other devices of equal strength are substitutes for those specified.
[D] Two loops of 0.048 in. wire are substitutes for each loop of 0.062 in. wire when used for attaching steel furring to steel or wood joists.
[E] Spans are based on webs of channels being erected and maintained in a vertical position.
[F] Other sections of cold-rolled members of equivalent beam strength are substitutes for those specified.

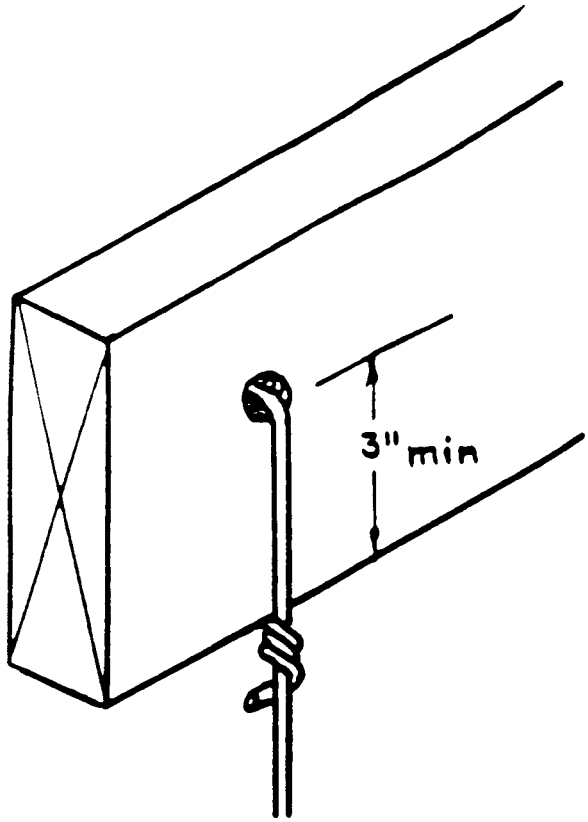

FIG. 1 Hanger Attached to Support Through a Drilled Hole

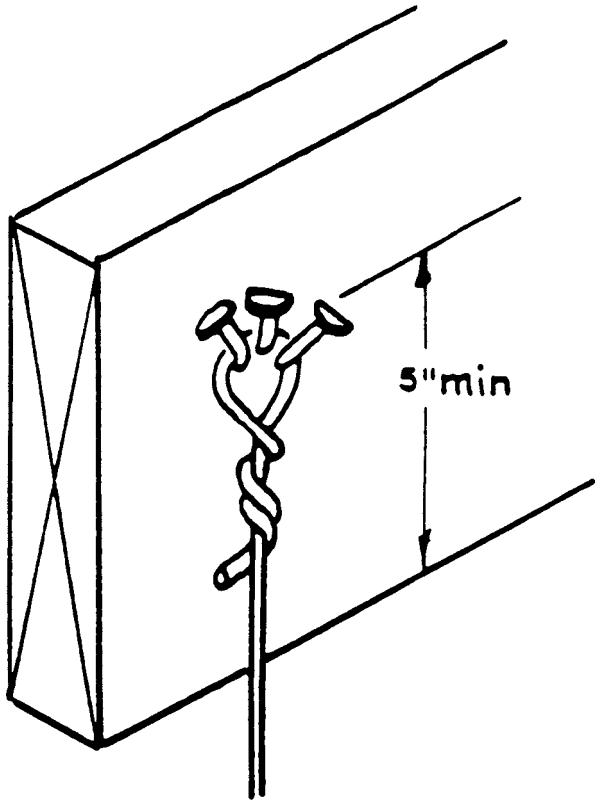

FIG. 2 Hanger Attached to Support Using Nails

the sides of joists not less than 5 in. (127 mm) from the bottom edge of the joist and not more than 36 in. (914 mm) on center (see Fig. 2).

7.8.2.3 Formed into a loop to accommodate four 1 ½-in. (38.1-mm), 0.148-in. (3.8-mm) diameter staples driven horizontally or on a downward slant into sides of joists, placing three near the upper end of the loop and the fourth to fasten the loose end (see Fig. 3).

7.8.2.4 Where spacing of supports is more than 4 ft (1.2 m) on center, 1½-in. (38.1-mm) No. 0 screw eyes, or equivalent, spaced not more than 3 ft (0.9 m) on centers shall be screwed into supporting wood construction so that the supported area shall be not more than 9 ft^2(0.8 m^2). The upper end of the wire hanger shall be inserted through the screw eye and in each case twisted not less than three times around itself.

7.8.2.5 Flat hangers shall be secured with two 12d nails driven through holes drilled in the hanger and clinched not less than 3 in. (76 mm) above the bottom of the joists (see Fig. 4).

7.8.3 *Minimum Size for Hangers*—Thickness of wire hangers, diameter of rod hangers, and sizes of flat hangers shall be in accordance with Table 3.

7.8.4 Where 1 by 3⁄16-in. (25.4 by 4.8-mm) flat inserts and hangers are used, 7⁄16-in. (11-mm) diameter holes shall be punched on the center line at the lower end of inserts and upper end of hanger to permit the attachment of the hangers to the insert.

7.8.5 Holes in both inserts and hangers shall be not less than ⅜ in. (9.5 mm) from the ends.

7.8.6 Flat steel hangers shall be bolted to 1 by 3⁄16-in. (25.4 by 4.8-mm) inserts with ⅜-in. (9.5-mm) diameter round-head stove bolts.

7.8.7 The nuts of bolts shall be drawn up tight.

7.8.8 Wire or rod hangers shall be saddle-tied or attached to main runners so as to prevent turning or twisting of the runners and to develop the full strength of the hangers and the runners. Smooth or threaded rod hangers shall be attached to inserts and runners with special attachments designed for this application.

7.8.9 The lower ends of flat hangers shall be bolted to the main runners, or bent tightly around runners and carried up and above the runners and bolted to the main part of the hanger. Bolts shall be ⅜-in. (9.5-mm) diameter, stove bolts.

7.9 *Main Runners*:

7.9.1 Minimum sizes and maximum spans and spacings of main runners for the various spans between hangers or other supports shall be in accordance with Table 3.

7.9.2 A clearance of not less than 1 in. (25.4 mm) shall be provided between the ends of main runners and abutting masonry or reinforced concrete walls, partitions and columns. Where special conditions require main runners to penetrate the plane of abutting masonry or concrete construction, a clearance shall be provided within such constructions of not less than 1 in.(25 mm) from the ends and not less than ½ in. (12.7 mm) from the tops and sides of the runners.

7.9.3 A main runner shall be located not more than 6 in. (152 mm) from the paralleling wall to support the ends of the cross furring. The ends of main runners shall be supported by hangers located not more than 6 in. (152 mm) from the ends.

www.technobetar.ir

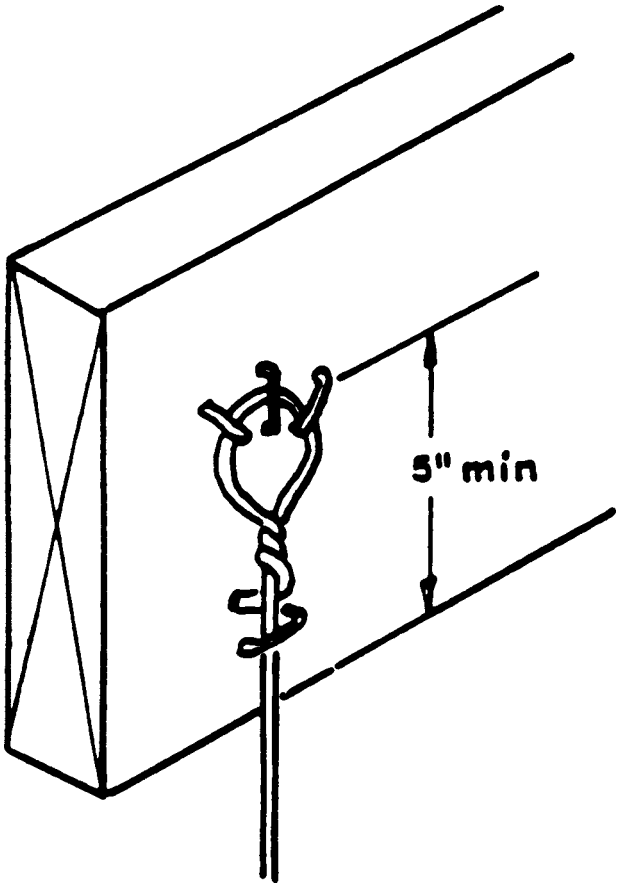

FIG. 3 Hanger Attached to Support Using Staples

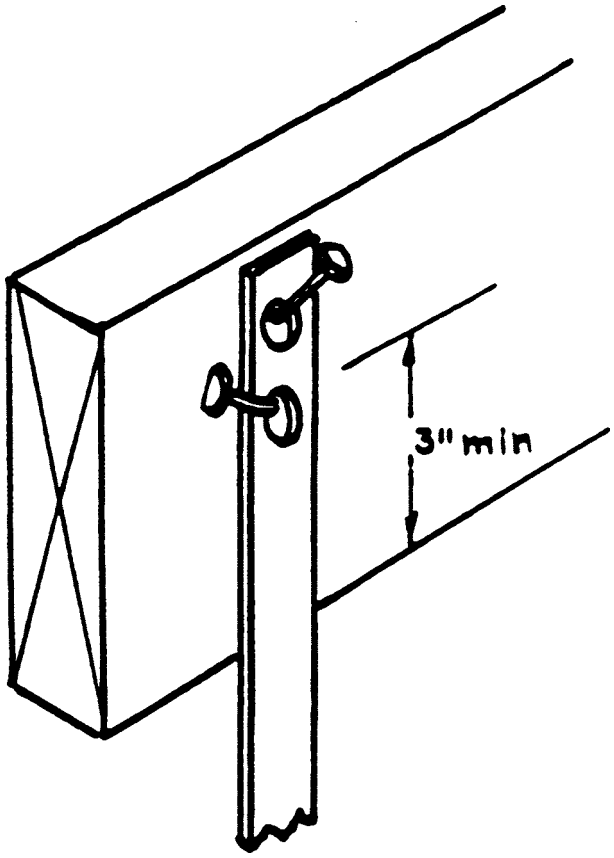

FIG. 4 Flat Hanger Attached to Support Using Nails

7.9.4 When main runners are spliced, the ends shall be overlapped not less than 12 in. (305 mm), with flanges of channels interlocked, and securely tied near each end of the splice with double loops of 0.062 in. (1.6 mm) galvanized wire or double loops of twin strands of 0.048 in. (1.2 mm) galvanized wire.

7.10 *Cross Furring*:

7.10.1 Minimum size and maximum spans and spacings of various types of cross furring for various spans between main runners and supports shall be in accordance with Table 3.

7.10.2 Cross furring shall be securely saddle-tied to main runners with 0.062 in. (1.6 mm) galvanized wire, or a double strand of 0.048 in. (1.2 mm) galvanized wire or with special galvanized clips, or equivalent attachments.

7.10.3 When cross furring members are spliced, the ends shall be overlapped not less than 8 in. (203 mm), with flanges of channels interlocked, and securely tied near each end of the splice with double loops of either 0.062 in. (1.6 mm) galvanized wire or twin strands of 0.048 in. (1.2 mm) galvanized wire.

7.10.4 Cross furring shall not contact abutting masonry or reinforced concrete walls or partitions.

7.10.4.1 Where special conditions require cross furring to penetrate the place of the abutting masonry orconcrete construction, the applicable provisions of 7.9.2 shall apply.

7.10.5 Main runners and cross furring shall be interrupted at control and expansion joints. The resulting intersections shall be constructed by splices, snugly tied, but loose enough to allow for lateral movement (telescoping) of the framing members and expansion and contraction of the plaster membrane.

7.11 *Metal Furring for Walls*:

7.11.1 Attachments for furring shall consist of nails driven securely into concrete or into masonry joints, short pieces of ¾ in. (19 mm) channels used as anchors driven into masonry joints, or other devices specifically designed as spacer elements. Furring shall be spaced horizontally not more than 2 ft (610 mm) on centers. Furring shall be spaced vertically in accordance with horizontal stiffener spacing so that it projects from the face of the wall enough to permit ties to be made.

7.11.2 Where dampproofing has been damaged in installation of attachments, the dampproofing shall be repaired with the same material before proceeding with the installation of the furring.

7.11.3 Horizontal stiffeners shall be not less than ¾-in. (19-mm) hot-rolled or cold-rolled channels, spaced not to exceed 60 in. (1524 mm) on center vertically, with the lower and upper channels not more than 6 in. (152 mm) from the floor and ceiling, and not less than ¼ in. (6.4 mm) from the face of the wall. Stiffeners shall be securely tied to attachments with three loops of 0.048 (1.2 mm) wire.

7.11.4 Vertical members shall be not less than ¾-in. (19-mm) cold-rolled channels, in accordance with requirements in Table 2. Members ahll be saddle-tied to horizontal members with three loops of 0.048 in. (1.2 mm) galvanized soft-annealed wire, or equivalent devices, at each crossing, and

www.technobetar.ir

securely anchored to the floor and ceiling constructions. If furring is not in contact with the wall, then channel braces shall be installed between horizontal stiffeners and the wall, spaced not more than 2 ft (600 mm) apart (horizontal spacing).

8. Keywords

8.1 furring; gypsum; lathing; plaster

ANNEXES

(Mandatory Information)

A1. GENERAL INFORMATION

The work shall include all labor, materials, services, equipment, and scaffolding required to complete the lathing and furring of the project in accordance with the drawings and specifications.

A1.1 *Floating Angle Construction*—Except where required otherwise for certain fire-resistive construction, nails or staples occurring less than 6 in. (152 mm) from internal angles shall not be prohibited from being omitted in the application of gypsum lath, provided each piece of lath is nailed to not less than two supports. Where lath abuts masonry, the angle shall not be“ floated” and a plaster stop or casing bead shall be used.

A1.1.1 Gypsum lath, for floating angle construction, shall be applied to ceiling areas first, so that the ceiling lath will be supported in the angles by the upper edge of the top course of lath applied to walls or partitions.

A1.2 *Wood Furring*—For the attachment of wall finishes, wood furring shall be not less than ¾ in. (19 mm) by 1½ in. (38.1 mm) (actual size) where applied to solid backing such as masonry. Wood furring attached to supports, spaced not more than 24 in. (610 mm) on centers, shall be not less than 1½ by 1½ in.

A2. TECHNICAL INFORMATION

A2.1 *Solid Plaster Partitions with Steel Studs:*

A2.1.1 Steel studs for solid plaster partitions shall be installed in accordance with Specifications C 754 and C 1007 and shall be of a size and number and located to provide backing at all corners. Steel studs shall be set to the required spacing, properly aligned, made plumb and true, securely anchored to the floor and ceiling construction, and temporarily braced, if necessary.

A2.1.2 Where studs do not fall at edges of openings, extra studs shall be added. Such studs shall be securely anchored to the door frames.

A2.1.3 Space above headers of openings extending to the ceiling shall be reinforced by installing studs 16 in. (406 mm) on center over the heads of the openings.

A2.2 *Hollow Metal Door Frames* for prefabricated steel stud, channel stud, lath and plaster hollow partitions.

A2.2.1 Door frames shall be installed in accordance with NAAMM Standard HMMA 840 .

A3. DESIGN AND ERECTION OF HOLLOW DOOR METAL FRAMES FOR PREFABRICATED STEEL STUD AND CHANNEL STUD, LATH AND PLASTER HOLLOW PARTITIONS

A3.1 *Hollow Metal Frames* (for Prefabricated Steel Stud, Channel Stud, Lath and Plaster Hollow Partitions):

A3.1.1 Metal studs shall be installed at each jamb of the steel frame by wiretying, bolting, or welding them to jamb anchors in the frame. The edges of the studs shall be inserted into the notches or other devices provided in the jamb anchor insert clips.

A3.1.2 The first stud on either side of the frame shall be fastened to suitable anchorage at the top and bottom of the partition in accordance with the instructions of the stud manufacturer. A second metal stud shall be placed not more than 2 in. (50 mm) away from the first stud, using adequate means of attachments between the two; or, two metal studs shall be attached to jamb anchors and securely fastened back to back.

A3.1.3 Where metal door frames have an adjustable strut equal in stiffness to a stud, running from each jamb to the ceiling, one metal stud shall be installed at each jamb in the manner previously noted.

A3.1.4 At the head of the metal frame, a section of metal floor track shall be placed horizontally within the head section, and fastened to the jamb studs with wire ties, screws, or welds.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:19:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Frames over 32 in. (813 mm) wide shall be provided with anchor insert clips spaced not over 24 in. (610 mm) on centers.

A3.1.5 Metal jack studs shall be installed over the head of the frame, spaced 16 in. (406 mm) on centers maximum, and shall be attached to the metal floor track. They shall be reinforced with a ¾-in. (19-mm) cold-rolled channel stiffener placed inside the partition and not more than 6 in. (152 mm) above the frame. Floor track is not required if one ¾-in. cold-rolled channel stiffener is placed horizontally on each interior face of the studs and not more than 6 in. above the frame. Channel stiffeners shall extend not less than two full stud spaces beyond the opening and shall be saddle-tied to each stud they cross.

APPENDIXES

X1. VENTILATION INFORMATION

X1.1 Adequate ventilation of attics or similar unheated spaces above gypsum plaster systems is essential to the performance of these systems and shall be designed and provided by others per ASHRE Fundamentals Handbook or applicable buildings code.

X2. GENERAL INFORMATION

X2.1 The work shall include all labor, materials, services, equipment, and scaffolding required to complete the lathing and furring of the project in accordance with the drawings and specifications.

X2.2 Scaffolding shall be constructed and maintained in strict conformity with applicable laws and ordinances.

X2.3 The work shall be coordinated with the work of other trades.

X2.4 Surfaces and openings shall be examined before furring or lathing is applied thereto, the proper authorities shall be notified, and unsatisfactory conditions shall be corrected prior to application of furring or lathing.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 842 – 05

Standard Specification for Application of Interior Gypsum Plaster[1]

This standard is issued under the fixed designation C 842; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the minimum requirements for full-thickness (in accordance with Table 1) interior gypsum plastering on gypsum, metal, masonry, or monolithic concrete bases designed or prepared to receive gypsum plaster.

1.1.1 Gypsum plaster applied to the interior side of exterior walls of masonry or concrete shall be isolated from the exterior wall.

1.2 Gypsum plasters shall not be used in exterior locations or interior "wet" areas.

NOTE 1—To secure desirable results, this specification should be coordinated with the provisions of Specification C 841. General information concerning full thickness gypsum plastering is contained in Annex A2, Annex A3, and Annex A4.

1.3 Details of construction for a specific assembly to achieve the required fire resistance shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing laboratories.

1.4 Details of construction to achieve required sound control shall be obtained from reports of tests conducted at recognized sound testing laboratories in accordance with the applicable sound tests of Test Methods E 90, C 423, or E 492.

1.5 The values stated in inch-pound units are to be regarded as the standard. The SI (metric) values given in parentheses are approximate and are provided for information purposes only.

1.6 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 5 Specification for Quicklime for Structural Purposes

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 28 Specification for Gypsum Plasters

C 35 Specification for Inorganic Aggregates for Use in Gypsum Plaster

C 59/C 59M Specification for Gypsum Casting and Molding Plaster

C 61/C 61M Specification for Gypsum Keene's Cement

C 206 Specification for Finishing Hydrated Lime

C 423 Test Method for Sound Absorption and Sound Absorption Coefficients by the Reverberation Room Method

C 631 Specification for Bonding Compounds for Interior Gypsum Plastering

C 841 Specification for Installation of Interior Lathing and Furring

C 1489 Specification for Lime Putty for Structural Purposes

E 90 Test Method for Laboratory Measurement of Airborne-Sound Transmission Loss of Building Partitions and Elements

E 492 Test Method for Laboratory Measurement of Impact Sound Transmission Through Floor-Ceiling Assemblies Using the Tapping Machine

3. Terminology

3.1 *Definitions:*

3.1.1 Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *catfaces*, *n*—blemishes or rough depressions in the finish coat.

3.2.2 *coat*, *n*—a thickness or layer of plaster applied over a surface in a single application.

3.2.2.1 *base coat, n*—the sum of the scratch and brown coats or the total coats in place prior to application of finish coats.

3.2.2.2 *brown coat, n*—the second coat of plaster applied in three-coat work.

3.2.2.3 *finish coat, n*—the last coat of plaster applied in either two-coat or three-coat work.

3.2.2.4 *scratch coat, n*—the first coat of plaster applied over a lath or other substrate.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for the Application of Gypsum and Other Products in Assemblies.

Current edition approved May 1, 2005. Published May 2005. Originally approved in 1976. Last previous edition approved in 1999 as C 842 – 99.

www.technobetar.ir

3.2.2.5 *three-coat work, n*—plaster applied in three successive coats, leaving time between coats for setting or drying, or both, of the plaster.

3.2.2.6 *two-coat work, n*—scratch and brown coats applied from the same mix with no time allowed for setting of the scratch coat before the brown coat is applied.

3.2.3 *gypsum ready mixed plaster, n*—calcined gypsum plaster, mixed at the mill with a mineral aggregate, designed to function as a base coat to receive various finish coats.

3.2.4 *metal bases, n*—expanded metal, welded or woven wire, or punched sheet metal plaster bases.

3.2.5 *smooth-trowel finish, n*—a finish resulting from steel troweling.

3.2.6 *texture finish, n*—a finish resulting from (*1*) trowel application followed by floating or texturing of the surface with any of a variety of tools using a minimum of water or (*2*) machine application which is or is not hand textured.

TABLE 1 Thickness of Plaster

Plaster Base	Thickness of Plaster Including Finish Coat, in. (mm)
Metal plaster base	5/8 (16) min
All other types of plaster base	1/2 (13) min
Unit masonry	5/8 (16) min
Monolithic concrete surfaces:[A]	
Vertical[BC]	5/8 (16) min
Horizontal[C]	1/8 (3) to 5/8 (10)

[A] Base coat plastering of the same proportions as specified for unit masonry is not prohibited from being used over plain or reinforced monolithic concrete, provided the surface is first covered with a metal plaster base or first coated with a bonding compound.

[B] Finish coat plaster applied direct to a bonding compound over vertical monolithic concrete shall be not more than 3/16 in. (4.8 mm) in thickness. Where more than 3/16 in. of finish coat is required to bring such vertical surface to a true plane, a base coat of plaster shall first be applied to the bonding compound.

[C] Where horizontal or vertical monolithic concrete surfaces require more than 3/8 in. (9.5 mm) or 5/8 in. (15.9 mm) of plaster, respectively, to produce required lines or surfaces, metal plaster base shall be attached to the concrete before application of plaster. Where concrete surface requires the application of more than 1 in. (25.4 mm) of plaster to produce required lines or surfaces, lath shall be applied over furring secured to the concrete.

4. Delivery of Materials

4.1 All manufactured materials shall be delivered in the original packages, containers, or bundles bearing the brand name and manufacturer (or supplier) identification.

5. Protection of Materials

5.1 Plasters and other cementitious materials shall be kept dry until used; they shall be stored off the ground, under cover, and away from walls with condensation and other damp surfaces. Metal products shall be protected, while stored, against rusting.

6. Environmental Conditions

6.1 *Temperatures*—Where the ambient outdoor temperature at the building site is less than 55 °F (13 °C), a temperature of not less than 55 °F (13 °C) and not more than 80 °F (27 °C) shall be maintained continuously inside the building for a period of not less than one week prior to the application of plaster (Note 2). Temporary heat shall be evenly distributed, using deflective or protective screens to prevent concentrated or uneven heat or cold on the plaster, and maintained until the permanent HVAC system is activated.

NOTE 2—The requirement should minimize the possibility of plaster cracking due to structural movements caused by thermal changes from outdoor temperature extremes during construction.

6.2 *Ventilation*—Sufficient ventilation shall be provided to remove excess water given off through the drying process. (See Appendix X2 for provisions for ventilating underside of roofs and glazed buildings with and without operable windows.)

7. Materials

7.1 *Gypsum Plasters*—The following plasters shall conform to Specification C 28:

7.1.1 Ready mixed.

7.1.2 Neat.

7.1.3 Wood-fibered.

7.1.4 Gauging for finish coat.

7.2 *Gypsum Casting and Molding Plasters*—Specification C 59/C 59M.

7.3 *Gypsum Keene's Cement*—Specification C 61/C 61M.

7.4 *Lime*:

7.4.1 *Finishing Hydrated Lime*—Specification C 206, Type S.

7.4.2 *Quicklime for Structural Purposes*—Specification C 5.

7.4.3 *Lime Putty for Structural Purposes*—Specification C 1489.

7.5 *Lime Putty*—Lime putty exceeding 8 weight % of unhydrated magnesium oxide shall not be used for finish coat plaster.

7.6 *Aggregates*:

7.6.1 *Aggregates for Base Coat Plaster*—Specification C 35.

7.6.2 *Aggregates for Finish Coat Plasters*—Specification C 35, except that gradation shall be within the limits specified in Table 2.

7.6.3 Sand for job mixed lime putty-gypsum gauged, sand float finish (see 9.6.6.1) shall be graded within the limits specified in Table 3.

7.7 *Water*—Water used in mixing and finishing plaster shall be potable, and free of such amounts of mineral or organic substances that affect the set, the plaster, or any metal in the system.

NOTE 3—Water containing salt or alum, or water in which tools have been washed, accelerates the "set" and may cause efflorescence. Water from stagnant pools and wells frequently contain organic or vegetable matter which may retard the "set," cause staining, or interfere with the bond.

Sieve Size	max	min
No. 16 (1.18 mm)	0	0
No. 30 (600 µm)	50	20
No. 50 (300 µm)	70	50
No. 100 (150 µm)	100	80

7.8 *Bonding Compounds*—Specification C 631.

8. Surface Preparation

8.1 *Substrates*—Surfaces of substrates for the application of gypsum plaster shall be free of materials that will inhibit bond or adhesion, shall be straight, plumb, level, square, and true to required plan angles and curves. See A2.5.

8.1.1 All accessories shall be securely attached to the substrate and be installed to accommodate embedment of flanges.

8.1.2 *Gypsum and Metal Lath*—Shall have been installed in compliance with Specification C 841.

8.2 *Conditioning of Surfaces*—All depressions in masonry and concrete surfaces deeper than ⅛ in. (3.2 mm) shall be brought flush to the surface with compatible materials prior to plaster application. Fins or protrusions extending more than 1/16 in. (1.6 mm) from the surface shall be removed. Protrusions less than 1/16 in. (1.6 mm) shall be feathered out with compatible materials prior to plaster application.

8.2.1 *Masonry*—All masonry surfaces shall be wetted immediately prior to the plaster application. No free water shall remain visible on the substrate surface.

8.2.1.1 Where the surface is too smooth to provide mechanical key, the surface shall be roughened or bonding compound shall be used. (See Annex A2.5 and A2.6.)

8.2.1.2 Where bond cannot be obtained over the entire surface by the methods specified in 8.2.1.1, self-furring metal lath shall be used in accordance with Specification C 841.

8.2.2 *Monolithic concrete*—bonding compounds shall be used prior to plastering all monolithic concrete surfaces. (See A2.6.)

8.2.3 Grounds, beads, and screeds shall be installed prior to the plastering as modified herein.

8.3 *Grouting*:

8.3.1 Metal bases for solid partitions shall be grouted with gypsum plaster leaving ¼ in. (6.4 mm) below the top edge of the base, and be formed with a center groove so that the lath extends ¾ in. (19 mm) below the top edge of the base, or plaster grout shall be placed after installation of lath.

8.3.2 *Metal Frames*—Hollow door and window frames shall be filled with gypsum plaster grout.

9. Mix Design

9.1 *Mixing, General*—All plaster mixing shall be done by mechanical means unless hand mixing is specified.

9.1.1 Retempered, partially set, frozen, caked or lumpy material shall not be used.

9.1.2 Each batch shall be mixed separately and mixers shall be free of all set and hardened materials prior to mixing each batch.

9.1.3 All tools shall be kept clean.

9.1.4 The setting time shall be not more than 4 h.

9.2 *Hand Mixing*—see Annex A3.1.

9.3 *Mechanical Mixing*—In accordance with manufacturer's printed directions. See Annex A3.2.

9.4 *Base Coat Proportions*:

9.4.1 *Gypsum Neat Plaster*—Proportions of sand, perlite, or vermiculite aggregate to 100 lb (45.4 kg) of gypsum neat plaster shall be not more than those specified in Table 4. (See A2.3 for equivalent measure for aggregates.)

9.4.2 *Gypsum Ready Mixed Plaster*—Shall be used with the addition of water only.

9.4.3 *Gypsum Wood-Fibered Plaster*—Proportion of damp, loose sand or perlite or vermiculite shall be not more than 1 ft^3 (0.028 m^3) to 100 lb (45.4 kg) of gypsum wood-fibered plaster.

9.5 *Preparation of Lime Putty*:

9.5.1 Lime putty shall be prepared from Type S hydrated lime or pulverized quicklime, in accordance with the manufacturer's printed directions.

9.5.2 *Hydrated Lime*—Type S lime shall only be used after soaking for the time period required in accordance with the manufacturer's printed directions.

9.6 *Finish Coat Proportions*:

9.6.1 Finish coats shall be either ready mixed or job mixed in accordance with Table 5 and Table 6.

9.6.1.1 Where thickness of the finish coat is more than ⅛ in. (3.2 mm), the proportion of the gypsum gauging plaster shall be increased to minimize shrinkage type cracks.

9.6.2 Troweled Finishes of lime putty gauged with gypsum gauging plaster or ready mixed gypsum plaster shall be proportioned in accordance with Table 5.

9.6.2.1 Where finish in 9.6.2 is to be applied over base coats containing perlite or vermiculite, the addition of not less than ½ ft^3(0.14 m^3) or not more than 1 ft^3 (0.028 m^3) of fine aggregate meeting the sieve analysis of Table 2 shall be added to the mix.

9.6.3 Troweled finishes of lime putty gauged with gypsum Keene's cement shall be specified as medium or hard and shall be proportioned in accordance with Table 5.

9.6.3.1 When finish in 9.6.3 is mechanically mixed, the water shall be placed in the mixer first, then the lime, the fine aggregate (if used), and finally the gypsum Keene's cement.

9.6.4 Troweled finishes of gypsum ready mixed plaster shall be mixed in accordance with Table 5.

9.6.5 Float finishes of lime putty gauged with gypsum gauging plaster shall be proportioned in accordance with Table 5.

9.6.5.1 When finish in 9.6.6 is to be mixed with sand, the sand shall be graded within the limits shown for basecoats in Specification C 35 except that all of the sand shall pass a No. 8 (2.36 mm) sieve.

9.6.6 Float finishes of lime putty gauged with gypsum Keene's cement shall be proportioned in accordance with Table 5.

9.6.6.1 When the finish in 9.6.6 is to be mechanically mixed wet, follow procedures in 9.6.3.1. For mixing dry, add lime

TABLE 4 Base Coat Proportions[A]

Plaster Base	Aggregates[B]		
	Sand		Perlite or Vermiculite[C]
	By Volume, ft³(m³), Damp and Loose	By Weight, lb (kg), Damp and Loose	By Volume, ft³(m³)
Over Gypsum Lath			
Two-coat work:			
Base coat	2½ (0.071)	250 (113)	2 (0.06)
Three-coat work:			
Scratch coat	2 (0.056)	200 (91)	2 (0.06)
Brown coat	3 (0.085)	300 (136)	2 (0.06)
or			
Scratch and brown coats	2½ (0.071)	250 (113)	...
Over Metal Lath			
Three-coat work:			
Scratch coat	2 (0.056)	200 (91)	2 (0.06)
Brown coat	3 (0.085)	300 (136)	2 (0.06)
or			
Scratch and brown coats	2½ (0.071)	250 (113)	...
Over Unit Masonry (Note 6)			
Two-coat work:			
Base coat	3 (0.085)	300 (136)	3 (0.085)
Three-coat work:			
Scratch coat	3 (0.085)	300 (136)	3 (0.085)
Brown coat	3 (0.085)	300 (136)	3 (0.085)
Over Monolithic Concrete[D]			
For base coat proportions applicable to monolithic concrete, see 10.2.1.			

[A] The proportions in Table 3 are applicable for both hand and machine application of plaster. See plaster manufacturer's instructions for application of machine-applied plaster.

[B] Use of an accurate device to measure quantities, such as a measuring box or container of known capacity, is highly encouraged. Where such a device is not available, six No. 2, square-edge (not scoop) shovels, with a blade approximately 8½ in. (216 mm) wide and 11 in. (279 mm) long, with the maximum depth of sides not more than 1½ in. (38 mm) higher than the face of the blade, and filled to an average depth of 4 in. (102 mm) of damp, loose sand, shall be considered as the approximate equivalent to 1 ft³ (0.028 m³).

[C] Where the plaster is 1 in. (25 mm) or more in total thickness, or where the finish coat is sand float, the proportions for the brown coat shall be not more than 3 ft³ (0.085 m³).

[D] For use of bonding compounds for plastering on monolithic concrete, see 8.2.2, and Footnotes in Table 1 and A2.6.

TABLE 5 Proportion of Gypsum To Not More Than Lime/Aggregate, with Dry and Wet Equivalents

	Dry						Lime Putty Wet Equivalent		
	Weight, lb (kg)			Volume, ft³(m³)			ft³(m³)	U.S. gal (litres)	lb (kg)
	Gypsum	Lime	Aggregate	Gypsum	Lime	Aggregate			
Troweled Finishes:[A]									
Lime putty with:[B]									
Gypsum gauging	100 (45.4)	225 (102)	0[A]	1 (.028)	3 (.085)	0	6.75 (.191)	52.5 (199)	450 (204)
Gypsum Keene's cement:									
Medium	100 (45.4)	50 (22.7)	0[A]	1 (.028)	1 (.028)	0	1⅛ (.032)	8¾ (33)	100 (45.4)
Hard	100 (45.4)	25 (11.3)	0[A]	1 (.028)	½ (.014)	0	⅝ (.018)	4½ (17)	50 (22.7)
Ready-mixed gypsum plaster	100 (45.4)	0	0	1 (.028)	0	0	0	0	0
Gypsum vermiculite	100 (45.4)	0	7 to 15 (3.2 to 6.8)	1 (.028)	0	1 (.028)	0	0	0
Floated Finishes:									
Lime putty with:									
Gypsum gauging	100 (45.4)	225 (102)	200 (90.7)	1 (.028)	3 (.085)	2 (.057)	6.75 (.191)	52.5 (199)	450 (204)
Gypsum Keene's cement:									
Medium	150 (68.0)	100 (45.4)	450 (204)	1½ (.042)	2 (.057)	4½ (.127)	2¼ (.064)	17½ (66)	200 (90.7)
Ready-mixed gypsum plaster[C]	100 (45.4)	0	0	1 (.028)	0	0	0	0	0
Gypsum-vermiculite	100 (45.4)	0	7 to 15 (3.2 to 6.8)	1 (.028)	0	1 (.028)	0	0	0
Gypsum-sand (job-mixed)[D]	100 (45.4)	0	200 (90.7)	1 (.028)	0	2 (.057)	0	0	0

[A] See 9.6.2, 9.6.3, 9.6.4 and 9.6.5.

[B] If additional hardness of finish coat is desired, increased amounts of gypsum shall be used; however, hard finishes shall not be used over lightweight aggregate base coats.

[C] Mixed with water only, in accordance with manufacturers' printed directions.

[D] Gypsum shall be neat, unfibered plaster.

TABLE 6 Trowel Finishes of Lime Putty Gaged With Gypsum Gaging Plaster Proportions

Proportions of Fine Aggregate[A,B,C]		
Not Less Than	Not More Than	Per
½ ft³(0.014 m³)	1 ft³(0.028 m³)	100 lb (45.4 kg) gypsum gauging
or ⅛ ft³(0.0035 m³)	¼ ft³(0.007 m³)	50 lb (22.7 kg) dry hydrated lime
or 1 U.S. gal (3.78 L)	2 U.S. gal (7.57 L)	1 ft³(0.028 m³) lime putty
or 1 pt (0.473 L)	1 qt (0.946 L)	1 U.S. gal (3.78 L) lime putty

[A] Where such finish coats are to be applied over base coats containing perlite or vermiculite, the addition of not less than ½ ft³ (0.014 m³) of fine aggregate, meeting the sieve analysis of Table 1 shall be added.

[B] For any of the above proportions, up to ½ ft³ (0.014 m³) of fine aggregate in accordance with Table 1 is not prohibited from being added to the mix.

[C] The largest particle size of aggregate and its proportion ratio will determine the degree of coarseness of the sand finish. The specifier shall indicate the maximum size desired.

first, then gypsum Keene's cement, and sand. This dry mix shall be mixed to a uniform color and then add water to achieve the desired consistency.

9.6.7 Float finishes of job mixed gypsum and sand shall be proportioned in accordance with Table 5 and Table 6.

9.6.8 Float finishes of ready mixed plaster and sand shall be mixed with water only in accordance with the manufacturer's printed directions.

9.6.9 Float finishes of job mixed plaster shall be proportioned in accordance with Table 6.

9.6.10 Float or textured ready mixed colored plaster shall be mixed in accordance with the manufacturer's printed directions.

9.6.11 Float or textured job mixed color plaster shall be proportioned in accordance with Table 5 or Table 6.

9.6.12 Special finishes shall be proportioned in accordance with the applicable provision of Table 5 or Table 6.

10. Application

10.1 *General*—Plaster shall be applied by hand or machine as specified herein.

10.2 *Plaster Thickness*:

10.2.1 Gypsum plaster shall be applied to the thickness specified in Table 1 . Plaster thickness shall be measured from the face plane of all plaster bases (Note 4).

NOTE 4—Installation of wood or metal grounds or plaster screeds will assist in achieving specified thicknesses.

10.3 *Application of Base Coats*:

10.3.1 *Two-Coat Work (see 3.2.2.6 and Note 5)*—The first coat shall be applied with sufficient material and applied with enough pressure to form a good bond to the substrate. The second coat shall be applied by doubling back before the first coat sets and with the plaster brought out to the grounds or screeds or specified thickness.

NOTE 5—Two coat work is not recommended over any type metal plaster base.

10.3.1.1 The plaster shall be straightened to a true plane without application of water leaving the surface porous and rough enough to provide a mechanical bond for the finish coat.

10.3.2 *Three-Coat Work (see 3.2.2.5 and Appendix X3)*—The first coat or scratch coat shall be applied with sufficient material and applied with enough pressure to form tight contact with and a good bond to solid plaster bases, or to form full keys through metal reinforcement. The first coat shall have sufficient depth of material leaving the surface sufficiently porous and rough (scratched or raked) to provide mechanical bond for the second or brown coat.

10.3.2.1 After the first or scratch coat has set, screeds shall be applied over the first coat prior to application of the second coat to ensure full plaster thickness. The second or brown coat shall be applied with sufficient material and pressure to ensure tight contact with the scratch coat and to bring the thickness of the second coat out to the grounds or specified thickness. The second coat shall straighten the surface to a true plane without application of water, and leave the surface sufficiently porous and rough enough to provide mechanical bond for the third or finish coat.

10.3.2.2 Metal base and metal frames for hollow partitions shall be plaster grouted prior to plastering, or shall be grouted solid between base or frame and plaster base at the time of plastering (see 8.3.1 and 8.3.2).

10.3.3 *Plastering on Monolithic Concrete*—All applicable requirements of 8.1, 8.1.1, 8.2, 8.2.1, 8.2.1.1, 8.2.2, A2.5, A2.6 and Table 1 footnotes shall be followed.

10.3.3.1 Walls and columns shall be prepared as in A2.5 and with one of the following: a) dash-bond coat; b) a bonding compound as in A2.6; c) metal plaster base; or d) two-coat plaster application as provided in 10.3.1 with a proportion of gypsum-neat-plaster-aggregate of 100-lb (45.4 kg) of plaster to not more than 3 ft³(0.085 m³) of aggregate.

10.3.3.2 Ceilings shall be prepared as in A2.5 and A2.6 and two coat work applied in accordance with 10.3.1.

10.3.4 *Solid Plaster Partitions with Steel Studs (Metal Lath and Plaster)*—Partitions shall be not less than 2 in. (51 mm) thick and shall have scratch, brown, and finish coats applied in accordance with 10.3.4.1-10.3.4.4. Where studs are temporarily braced, the bracing shall be maintained until the scratch coat on the lath side has set.

10.3.4.1 The scratch coat on the lath side shall be applied first, with sufficient material and pressure to form full keys and embed the lath and with sufficient depth of material to be scored to a rough surface immediately following its application.

10.3.4.2 The back-up coat on the channel side shall be applied in not less than two applications after the scratch coat on the lath side has set and partially dried. The first application shall completely cover the keys of the scratch coat. The second application shall bring the plaster out to the grounds in a true plane with the surface, left porous and sufficiently rough to provide mechanical bond for the finish coat. Extra water shall not be used in straightening the wall to a true plane.

10.3.4.3 The brown coat on the lath side shall be applied after the brown coat on the channel side has set, and left as specified for the finish coat.

10.3.4.4 Plaster shall extend to the floor, except that where plaster grouted combination metal bases and screeds are used, the plaster shall extend to the grout below the top of the base. Spaces between the grounds and all metal door frames shall be filled.

10.3.5 *Studless Solid Partitions (Metal Lath and Plaster)*—Partitions shall be not less than 2 in. (51 mm) thick, constructed

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:19:35 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

using either rib lath or diamond mesh (flat expanded) lath, and with plaster applied in the same number of coats as for solid partitions with steel studs (see 10.3.4).

10.3.5.1 Where rib metal lath is used, the scratch coat shall be applied first to the flat side with temporary bracing on the rib side.

10.3.5.2 Where diamond mesh lath is used, the temporary bracing shall be attached to either side and the scratch coat applied on the opposite side.

10.3.5.3 Sequence application of brown coats in accordance with one of the following methods:

(*1*) Brown coat shall be applied over the face of the scratch coat followed by the brown coat on the opposite side of the partition, or

(*2*) Brown coat shall be applied on the rib side of the metal lath, or on the back side of the scratch coat followed by the brown coat applied over the face of the scratch coat.

10.3.6 *Studless Solid Partitions (Gypsum Lath and Plaster)*—Partitions shall be not less than 2 in. (51 mm) thick and shall be three-coat work on both sides.

10.3.6.1 Scratch coat shall be applied approximately ⅜ in. (9.5 mm) thick with not less than 3⁄16 in. (4.8 mm) thickness at any point. The application shall be started at the side opposite the temporary bracing, then on the braced side without removing the bracing. The thickness shall be the same on both sides.

10.3.6.2 The brown coat shall be applied to the side opposite the bracing after the scratch coat has set and is partially dry. The bracing shall be removed when this brown coat has set and is partially dry. Both sides shall have been brought to 1⁄16 to ⅛ in. (1.6 to 3.2 mm) of the required thickness leaving a surface ready to receive a finish coat (see 10.3.4.2), which will bring the partition to an overall thickness of not less than 2 in. (51 mm).

10.3.7 *Studless Solid Partitions (Multiple-Thickness Gypsum Lath and Plaster)*—Partitions shall be not less than 2 in. (51 mm) thick with three coats on each side. Each side shall be not less than ½ in. (12.7 mm) thick.

10.3.8 *Gypsum Lath Ceilings Attached by Clips*—Plastered ceiling with clip attached gypsum lath shall be covered with three-coat work with the scratch coat not less than 3⁄16 to ¼ in. (4.8 to 6.4 mm) thick over the face of the gypsum lath. The total thickness of scratch and brown coats shall be not less than 7⁄16 in. (11 mm).

10.4 *Application of Finishes*:

10.4.1 Finish coats shall be applied to a partially dry base coat or to a thoroughly dry base coat that has been evenly wetted by brushing or spraying. No water shall be left standing on the surface prior to plaster application (Note 6).

NOTE 6—Precolored plaster is not recommended for smooth-trowel finishes. Where colored plaster is being applied, excessive water causes color variations. See A2.3 and A2.4.

10.4.2 Troweled finishes shall be applied by drawing the first application down tight to the entire base coat surface and doubling back to fill out to a true even surface of from 1⁄16 to ⅛ in. (1.6 to 3.2 mm) thick, free from catfaces and other blemishes or irregularities. Final troweling or texturing shall be done with a minimum of water after the finish coat has become firm.

10.4.2.1 Lime putty-gypsum gauged Keene's cement finish (see 9.6.3 and Note 7) shall be done in accordance with 10.4.2 except that the final troweling shall be continued until the finish has set.

NOTE 7—The thickness of this finish may be increased for decorative work as required.

10.4.2.2 Ready mixed gypsum troweled finishes (see 9.4.2) shall be applied in accordance with the printed directions of the manufacturer.

10.4.3 Textured/float finishes shall be applied in accordance with 10.4.2 except the float applied finish shall also meet the requirements of the specific texture required. The texture required shall be created by the type of float surface used (wood, carpet, cork, rubber, or other) and the length of time between trowel application and floating (take-up).

10.4.3.1 The mixes in 10.4.2.1 and 10.4.2.2 used for a float finish shall be applied in accordance with 10.4.3.

10.4.4 Texture or special finishes shall be applied in accordance with the printed directions of the manufacturer.

10.4.5 Job mixed finishes shall be applied in accordance with 10.4.2 or 10.4.3. The texture or special finish coat shall reduce the total thickness by not more than 1⁄16 in. (1.6 mm) while matching the approved sample.

10.4.5.1 Special finishes shall not reduce the combined thickness of the base coat and finish coat to less than that specified in Table 1. Inorganic coloring material added to the job mix shall be in accordance with A2.4.

10.4.5.2 Acoustical plaster and finish shall be applied in accordance with the printed directions of the manufacturer.

ANNEXES

(Mandatory Information)

A1. GENERAL INFORMATION

A1.1 Surfaces and openings shall be examined before plaster is applied thereto, the proper authorities shall be notified, and unsatisfactory conditions shall be corrected prior to application of plaster.

A2. TECHNICAL INFORMATION

A2.1 *Equivalent Measure for Aggregates*—Six No. 2 shovels of damp loose sand are equivalent to 1 ft^3(0.028 m^3) and 100 lb (45.4 kg). Perlite and vermiculite are normally packed in bags marked with the cubic foot (or cubic metre) content.

A2.2 *Job Addition of Fiber*—Job added fiber, where specified, shall be nonstaining natural or synthetic fiber, well-shredded and free from grease, oil, dirt, or other materials that adversely affect the strength, bond, or setting time of the plaster. Uniform quantities of the fiber, as specified, shall be added to the mixer, batch by batch, after mixing water, aggregate and plaster have been added. The type and amount of fiber to be used is dependent on job specifications or on that quantity of the selected fiber that provides the required application characteristics. Where the type and quantity of fiber is not specified by contractual agreement, gradually increased or decreased quantities shall be used until the required application characteristics are obtained, and that quantity used thereafter.

A2.3 *Ready Mixed Colored Finish Plasters*, shall be mixed and applied in strict accordance with the directions of the manufacturer. Where specified by contractual agreement, sample panels prepared in accordance with the job specifications shall be submitted to the architect or builder for approval of final color prior to the start of any job application.

A2.4 *Job Mixed Colored Finish Plasters*—Job mixed floated or textured colored finish plasters shall be prepared with inorganic or organic water-disperseable, nonbleeding, nonfading, lime-proof coloring materials, dry powdered, paste or liquid. Coloring materials shall be proportioned and thoroughly dispersed into the finish plaster in strict accordance with the directions of the manufacturer of the coloring material. In the absence of specific directions by the manufacturer of the coloring material, uniform quantities, mixer batch by mixer batch, shall be thoroughly dispersed into the mixing water. Uniform, identical proportioning by weight of coloring material, mixing water and dry finish plaster components, and uniform, identical mixing procedure, mixing time and application. Each unbroken area shall be completed in one continuous operation from angle to angle or natural interruption for best uniformity of color. Where specified by contractual agreement, sample panels prepared in accordance with the job specifications, including floating or texturing procedures, shall be submitted to the architect or builder for final color approval prior to the start of any job application. Floating or texturing procedure used for sample preparation shall be strictly followed for job application. The minimum quantity of coloring material necessary to obtain the specified or approved color shall be used, but in no case shall the proportion of coloring material exceed 8 weight % of the cementitious materials used.

A2.5 *Preparation:*

A2.5.1 All surfaces to be plastered shall be free from grease, oil, form release compounds, dirt, dust, paint, laitance, efflorescence or other foreign matter that would inhibit suction or mechanical keying, or cause staining.

A2.5.2 When plastering a cast-in-place or other monolithic wall, bond is dependent on the surface properties. Bond shall be enhanced by one or more of the following techniques to prepare the surface: a) sandblasting; b) wire brushing; c) acid wash; d) chipping; or e) coating with a plaster bonding compound.

A2.5.3 Laitance or efflorescence on concrete and masonry shall be removed by washing first with a 10 % solution of commercial hydrochloric acid (muriatic acid) and water and then with clean water to remove all traces of acid. Grease, oil, and form release compounds shall be removed with cleaning agents compatible with surface and subsequent plastering.

A2.5.4 The use of dressed (smooth) lumber, metal, plastic, or plywood forms, in conjunction with the vibration of concrete, produce bonding surfaces so dense and smooth, that the mechanical key necessary for plaster to bond is absent. In addition, certain kinds of lumber, oiled forms, and exposed reinforcement metals cause staining of the plaster.

A2.6 Bonding compounds that are water re-emulsifiable shall not be used in areas of a building exposed to cyclic or continuous exposure to very humid or wet conditions, or where a dew point condition occurs on the plaster surface. (Dew point conditions frequently occur in commercial laundries, natatoriums, and other wet areas such as showers, hydrotherapy rooms, and where walls are to be washed with water or steam.)

A2.6.1 Applied bonding compound shall be protected from dirt and dust when it will not immediately be covered with plaster. Some bonding compounds require immediate application of plaster to be effective.

www.technobetar.ir

A3. MIXING

A3.1 *Hand Mixing*—Mixing boxes shall be watertight. Where mixing is done in a building, provide water-resistive protection under and around the mixing boxes and water containers.

A3.1.1 *Neat Plaster*—The aggregate shall be added to the plaster and mixed dry to a uniform color, pulled to one end of the box, hoed and chopped into water placed in the other end of the box until thoroughly mixed to the required consistency.

A3.1.2 *Gypsum Ready Mixed Plaster*—Plaster shall be placed at one end of the box without adding aggregate, water shall be placed in the other end and plaster hoed and chopped into water until thoroughly mixed to the required consistency.

A3.1.3 *Gypsum Wood-Fibered Plaster*—Where used without aggregate, the plaster shall be placed at one end of the box, hoed and chopped into water at the other end until thoroughly mixed to the required consistency. Where aggregate is added, it shall be mixed in accordance with A3.1.1.

A3.2 *Mechanical Mixing:*

A3.2.1 *Gypsum Neat Plaster*—Aggregate shall be added at the job while the mixer is in continuous operation, as follows:

A3.2.1.1 Put in less than the total required amount of water.

A3.2.1.2 If sand is used, add half the sand. If vermiculite or perlite is used, add total amount required.

A3.2.1.3 Add all of the plaster.

A3.2.1.4 Add the remainder of the sand.

A3.2.1.5 Adding water as necessary, mix to the proper consistency. Do not overmix.

A3.2.1.6 Dump the entire batch and use. Clean the mixer for the next batch.

A3.2.2 *Gypsum Ready Mixed Plaster*—Aggregate shall be added at the producer's plant. While the mixer is in continuous operation, do as follows:

A3.2.2.1 Put in less than the total required amount of water.

A3.2.2.2 Add the ready mixed plaster.

A3.2.2.3 Adding water or plaster as necessary, mix to the desired consistency.

A3.2.2.4 Dump the entire batch and use. Clean the mixer for the next batch.

A3.2.3 *Gypsum Wood-Fibered Plaster*—Where used with aggregate added, the loading and mixing cycle shall be as prescribed in A3.2.1. Where used without aggregate, the loading and mixing cycle shall be as prescribed in A3.2.2.

A4. BASE COAT PROPORTIONS

A4.1 For job mixed plaster, proportions of sand, perlite, or vermiculite aggregate to 100 lb (45.4 kg) of gypsum neat plaster shall be not more than those specified in Tables 5 and 6.

A4.1.1 Gypsum ready mixed plaster is not prohibited from being used instead of job-prepared mixes of gypsum neat plaster and aggregate provided the proportion of aggregate to plaster is not more than that specified in Tables 5 and 6. Gypsum ready mixed plaster shall be used with the addition of water only, except as otherwise specified.

A4.1.2 *Gypsum Wood-Fibered Plaster*—In no case shall the addition of sand, perlite, or vermiculite be more than 1 ft^3(0.028 m^3) to 100 lb (45.4 kg) of gypsum wood-fibered plaster.

APPENDIXES

(Nonmandatory Information)

X1. GENERAL INFORMATION

X1.1 The work includes all labor, materials, services, equipment, and scaffolding required to complete the plastering on the project in accordance with the drawings and specifications.

X1.2 Scaffolding shall be constructed and maintained in strict conformity with applicable laws and ordinances.

X1.3 The work shall be coordinated with the work of other trades.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X2. VENTILATION INFORMATION

X2.1 Adequate ventilation of attics or similar unheated spaces above gypsum plaster systems is essential to the performance of these systems and shall be designed and provided by others per ASHRAE Fundamentals Handbook or applicable building code.

X3. RECOMMENDED LOCATIONS OF THREE COAT WORK

X3.1 *Use Three-Coat Work on the Following Types of Construction:*

X3.1.1 Over gypsum lath attached to ceiling supports spaced more than 16 in. (406 mm) on center.

X3.1.2 Over gypsum lath attached to ceiling supports by clips.

X3.1.3 Over 3⁄8-in (9.5-mm) thick gypsum lath where a vapor retarder is used adjacent to the back of the lath.

X3.1.4 Over metal plaster bases.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 842 – 99, that may impact the use of this standard. (Approved May 1, 2005)

(*1*) Added Specification C 1489 to 7.4.3 and Referenced Documents.

(*2*) Rewrote 6.1, 10.3.3.1, and A2.5.2 to clarify the intent of those paragraphs.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 843 – 99 (Reapproved 2006)

Standard Specification for Application of Gypsum Veneer Plaster[1]

This standard is issued under the fixed designation C 843; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers the minimum requirements for and methods of applying gypsum veneer plaster.

1.2 Where a specific degree of fire resistance is required for veneer plaster systems, applicable building code regulations shall be followed.

1.2.1 Details of construction for a specific assembly to achieve the required fire resistance shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing laboratories.

1.3 Where a specific degree of sound control is required for veneer plaster assemblies and constructions, details of construction shall be in compliance with official reports of tests conducted in recognized sound testing laboratories in accordance with the applicable sound tests of Test Methods E 90, C 423, or E 492.

NOTE 1—To ensure desirable results, coordinate this specification with Specification C 844.

NOTE 2—General information regarding matters of a contractual nature concerning veneer plaster work is found in Appendix X1. Additional technical information related to veneer plastering is provided in Appendix X2.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.5 The text of this specification references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 423 Test Method for Sound Absorption and Sound Absorption Coefficients by the Reverberation Room Method

C 587 Specification for Gypsum Veneer Plaster

C 588/C 588M Specification for Gypsum Base for Veneer Plasters[3]

C 631 Specification for Bonding Compounds for Interior Gypsum Plastering

C 844 Specification for Application of Gypsum Base to Receive Gypsum Veneer Plaster

C 1047 Specification for Accessories for Gypsum Wallboard and Gypsum Veneer Base

E 90 Test Method for Laboratory Measurement of Airborne Sound Transmission Loss of Building Partitions and Elements

E 492 Test Method for Laboratory Measurement of Impact Sound Transmission Through Floor-Ceiling Assemblies Using the Tapping Machine

3. Terminology

3.1 *Definitions:*

3.1.1 See Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *base coat*, *n*—veneer plaster trowel or machine applied as the first coat of a two-component system.

3.2.2 *finish coat*, *n*—veneer finish plaster trowel or machine applied as the second coat over the base coat plaster in a two-component system.

3.2.2.1 *smooth-trowel finish, n*—a finish resulting from steel troweling with a minimum of water after the plaster has become firm. A smooth finish free of trowel marks, blemishes, or other imperfections.

3.2.2.2 *texture finish, n*—a finish resulting from (*1*) trowel application followed by floating or texturing of the surface with any of a variety of tools using a minimum of water or (*2*) machine application, left as applied or followed by hand texturing.

3.2.3 *joint-reinforcing embedment*, *n*—the cementitious material used to embed the strip material that is compatible with the veneer plaster used.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for Application of Gypsum and Other Products in Assemblies.

Current edition approved May 1, 2006. Published May 2006. Originally approved in 1976. Last previous edition approved in 1999 as C 843 – 99ε1.

www.technobetar.ir

3.2.4 *one-component system*, *n*—a veneer plaster system designed for application directly over approved bases in a single plaster mix applied in a single coat or double-back operation with the same material.

3.2.5 *reinforced joint*, *n*—a joint between gypsum base that is reinforced with strip material embedded in a cementitious material.

3.2.6 *reinforcing*, *n*—joint reinforcing tape or mesh (strip material) that is applied over flat joints and interior angles.

3.2.7 *two-component system*, *n*—a veneer plaster system involving two separate materials mixed and applied separately for base coat and finish coat.

3.2.8 *veneer plaster system*, *n*—gypsum veneer plaster applied to (*1*) a gypsum base in accordance with 10.1 or (*2*) properly prepared masonry or monolithic concrete surfaces, neither side of which is exposed to moisture. The plaster shall be applied with one or more components not exceeding ¼ in. (6.4 mm) in total thickness.

4. Delivery of Materials

4.1 All manufactured materials shall be delivered in the original packages, containers, or cartons bearing the brand name and manufacturer identification.

5. Protection of Materials

5.1 Plasters and other cementitious materials shall be kept dry until ready to be used; they shall be kept off the ground, under cover, and away from damp walls and surfaces.

6. Environmental Conditions

6.1 *Temperature*—When the ambient outside temperature at the building site is less than 55 °F (13 °C), maintain a temperature in the building of not less than 55 °F (13 °C) or not more than 80 °F (27 °C) for not less than 24 h prior to the application of veneer plaster and for one week after the veneer plaster has set or until the veneer plaster has dried. Distribute heat evenly in all work areas, and use deflection or protective screens to prevent concentrated or uneven heat or cold on the veneer plaster.

NOTE 3—The requirements in 6.1 will minimize the cracking of veneer plaster due to structural movements caused by thermal changes from temperature extremes; and dry-outs due to hot spots caused by concentrated heat.

6.2 *Ventilation*—Ventilation shall be provided to remove excess water given off through the drying process.

7. Materials

7.1 *Gypsum Base for Veneer Plasters* (hereinafter referred to as "gypsum base") Specification C 588/C 588M.

7.2 *Veneer Plasters*—Specification C 587.

7.3 *Reinforcing*—Noncorrosive strip providing the joint strength requirements of Specification C 587.

7.4 *Liquid Bonding Compounds*—Specification C 631 (see X2.3).

7.5 *Water*—Water shall be clean, fresh, and of potable water quality.

7.6 *Accessories*—Specification C 1047.

8. Surface Preparation

8.1 *Examination*—Carefully examine all surfaces, including but not limited to, unit masonry, monolithic concrete, gypsum bases of all types, and accessories to receive veneer plaster, before the veneer plaster is applied. Notify the proper authorities promptly of all unsatisfactory conditions. The examination shall determine whether the gypsum base has been exposed to excessive sunlight. Do not apply veneer plaster until after such unsatisfactory conditions are rectified to the satisfaction of the plastering contractor.

NOTE 4—The bond of alkaline veneer plaster to gypsum base may be impaired if the base is exposed to direct light or sunlight for extended periods.

8.1.1 Do not apply veneer plaster over any surfaces of unit masonry or concrete that have been coated with any bituminous compound or other waterproofing or damproofing or form release agent.

8.2 *Conditioning of Surfaces*:

8.2.1 Immediately before the plaster is applied, wet down the masonry surfaces on which suction shall be reduced. Visible water shall not remain on the surface.

8.2.2 Carefully examine accessories, such as corner beads, control joints, casing beads, etc., to ensure that they are straight, curved, plumb, level, square, or true to the required angles and have been applied in a manner to ensure full coverage of flanges before the plaster is applied.

8.3 *Monolithic Concrete Surfaces*—Clean monolithic concrete surfaces of all dust, loose particles, and other foreign matter. Completely remove all grease, oil, noncompatible curing compounds, and form releasing agents. Remove all ridges and protrusions greater that ⅛ in. (3.2 mm) and fill all depressions greater than ¼ in. (6.4 mm) level with portland cement mortar and allow to set and dry. Any further preparation shall be as recommended by the veneer plaster manufacturer.

8.4 *Gypsum Base Joint Reinforcement*—Reinforce all interior angles and flat joints prior to application of the veneer plaster over the base.

8.4.1 *Interior Angles*—Position and secure reinforcement with staples (on 12-in. (305-mm) centers, one side only), veneer plaster, or other cementitious material compatible with the veneer plaster or by using self-adhering strip reinforcement. When stapling, staple along the ceiling edge only for wall-to-ceiling angles and along one edge for wall-to-wall angles. When securing reinforcement with veneer plaster, reinforcement shall be thoroughly embedded so that embedment material is both under and covering reinforcement.

8.4.2 *Flat Joints*—Center reinforcement over the joint line of the gypsum base and secure with staples or veneer plaster if not using self-adhering reinforcement. Keep reinforcement tight and flat against the gypsum base, and when stapling, position the staples no farther than 24 in. (610 mm) apart, staggered along each edge. Embed reinforcement and continue application of the veneer plaster over the field of the base. (**Warning**—This method provides minimum reinforcement of the joints. To minimize incidence and severity of joint ridging and cracking, use one of the following methods (8.4.2.1, 8.4.2.2, or 8.4.2.3) in the absence of any specific method

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:19:33 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

recommended by the veneer plaster manufacturer. Where paper tape and setting-type joint compounds are used, use 8.4.2.3.)

8.4.2.1 *Reinforcement over Set Veneer Plaster*—Tightly trowel veneer plaster over the joint line leaving the plaster feathered out to a width of about 6 in. (152 mm) flush with the face of the gypsum base. Allow the plaster to set; then secure reinforcement over the joint line as described in 8.4.2.

8.4.2.2 *Reinforcement Secured and Embedded with Veneer Plaster*—Apply reinforcement over the joint line as described in 8.4.2. Tightly trowel the plaster over the reinforcement along the joint line to provide thorough embedment of the reinforcement. Allow the joint embedment to set before proceeding with general plastering.

8.4.2.3 *Reinforcement Embedded (no staples)*—Tightly trowel the embedment material to a depth of about 1/32 in. (0.8 mm), working the trowel in both directions along the joint line. Center the reinforcement over the joint line. Firmly and evenly press the reinforcement into the soft embedment material using a little soft material on the trowel to bury it completely, and leave the embedment material feathered out to a width of about 6 in. (152 mm) flush with the face of the gypsum base. Allow the embedment material to set before proceeding with general plastering.

9. Mixing

9.1 Do not use frozen, caked, or lumpy material. Do not retemper or use material that has partially set. Mix each batch separately. Clean mixers thoroughly after each batch so as not to accelerate the following batches. This can be done by spray hosing the mixer paddle and containers immediately after each batch. Water ratios and other techniques used for mixing shall conform to the manufacturer's recommendation for specific veneer plaster products. In the absence of explicit directions, follow the recommendations in X2.1.

9.2 *Setting Time*—Setting times are carefully controlled by the manufacturer. Do not make adjustments to the setting time on the job. If problems with setting develop under unusual job conditions, consult the manufacturer of the veneer plaster for recommendations.

9.2.1 Do not use gauging, molding, or casting plasters, lime, gypsum, Keene's cement, portland cement, etc. to adjust the veneer plaster setting time.

9.3 Occasionally, special textures are desired that require additional sand. Approval of the veneer plaster manufacturer shall be obtained prior to any such additions.

10. Application

10.1 *General*—Veneer plasters have widely differing working properties, physical characteristics, and limitations regarding their compatibility with one another and with various bases. Follow the particular methods, techniques, limitations, and procedures set forth by individual manufacturers for their product. In the absence of manufacturers' directions, follow the recommendations in X2.2.

10.2 *Plaster Thickness*—Measure the plaster thickness from the face of the base to which it is applied, exclusive of joint treatment. The minimum thickness shall be as recommended by the manufacturer of the plaster used but in no case less than shown as follows:

Base coats (trowel applied)	1/16 in. (1.6 mm) min
Base coats (spray applied)	1/16 in. (1.6 mm) min
Finishes (two-component systems)	1/32 in. (0.8 mm) to 1/16 in. (1.6 mm) min
One-component systems	1/16 in. (1.6 mm) min

10.3 Barriers shall be provided to prevent the free circulation of hot, dry winds over the face of freshly applied plaster.

11. Electric Radiant Heat Cable

11.1 Veneer plaster shall be applied to electric heat cable systems in accordance with the veneer plaster manufacturer's directions. In the absence of manufacturer's directions follow the recommendations in X2.5.

11.2 Veneer plaster shall not be applied over heating systems in which the wire temperature will, at any time, be in excess of 125 °F (52 °C).

12. Keywords

12.1 electric heat cable; gypsum; plaster; veneer plaster

APPENDIXES

(Nonmandatory Information)

X1. GENERAL INFORMATION

X1.1 Construct and maintain scaffolding in strict conformity with applicable laws and ordinances so as not to interfere with or obstruct the work of others.

X1.2 Coordinate the work with the work of other trades.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:19:33 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X2. TECHNICAL INFORMATION

X2.1 *Mixing:*

X2.1.1 *Equipment*—A paddle-type agitator fitted to a ½-hp (373-W) heavy-duty, electric drill, rated from 900 to 1000 rpm (no load), and a clean drum of convenient size are recommended for rapid, efficient mixing of veneer plasters.

X2.1.2 *Procedure:*

X2.1.2.1 Put all but 1 or 2 qt (0.94 or 1.89 L) of the proper amount of water in the mixer for each bag of veneer plaster to be mixed.

X2.1.2.2 Add the veneer plaster to the water and immediately mix until uniformly wetted. Veneer plaster may be added while the agitator is turning.

X2.1.2.3 Continue mixing, adding water to obtain the desired lump-free mortar consistency.

X2.1.2.4 When mixing plaster for spray application, mix to a consistency so that 75 to 90 % of the batched mortar will pass a No. 8 (2.36-mm) sieve without shaking. Make sure the plaster is specifically designed for spray application to avoid quick set problems.

X2.1.2.5 Do not overmix. Three to four minutes is usually sufficient to attain fluidity.

X2.2 *Application:*

X2.2.1 *One-Component Plasters*—Apply the plaster with sufficient material and pressure to provide a good bond on the gypsum bases or other bases as approved by the veneer plaster manufacturer. Double back immediately with the same mixer batch of plaster to the desired thickness. Straighten to a true surface without application of water (water will cause blistering when applied at this time). Allow the material to "take-up" and texture with a float or sponge as desired. If a smooth finish is required, allow the plaster to become firm (so that water can be used without blistering) and trowel, using a minimum of water, to achieve a smooth finish, free of catfaces, trowel marks, blemishes, or other imperfections. Complete finishing before the veneer plaster sets.

X2.2.2 *Two-Component Plasters*—The finish component coat may be applied over set but still "green," partially dry, or dry base coat. Avoid application of a second component over a base coat that is damp on joints but dry in the field. It may result in photographing of the joints.

X2.2.3 *Base Coat-Hand Application*—Apply the base coat with sufficient material and pressure to provide a good bond on the gypsum bases or other bases as approved by the veneer plaster manufacturer and straighten to a true surface without application of water. Leave the surface sufficiently rough to provide a mechanical key for the finish coat.

X2.2.4 *Base Coat-Machine Application*—First spray flat joints, beads, and interior angles, and work the material with hand tools to cover the reinforcement, fill the beads, straighten the angles, and feather out the plaster over the joints. Proceed with full areas by spraying with a broad sweeping motion, holding the nozzle close enough to the surface to avoid excessive overspray and buildup in the angles. First apply a light coating while moving in one direction; then immediately double back over the same area, sweeping the nozzle in the opposite direction to obtain a level coat that requires no further working, and that is suitable to receive the finish component coat on setting.

X2.2.5 *Smooth-Trowel Finish*—Apply the plaster by troweling with firm pressure, then doubling back and filling out to a true, even surface. After the plaster has become firm, trowel it well with a minimum amount of water to a smooth finish, free of catfaces, blisters, trowel marks, blemishes, or other imperfections.

X2.2.6 *Texture Finishes*—Apply the plaster over the base coat by troweling thoroughly, building up to an even surface, and then floating with a variety of tools using a minimum of water. It may also be sprayed (depending on the type of texture desired) to a true, even surface free of slick spots or other blemishes.

X2.3 *Bonding Compounds*—Bonding compounds meeting Specification C 631 may be used to bond plaster to portland cement concrete and other sound surfaces. Such bonding agents may be used at the discretion of the specifier who may require performance records from the bonding agent manufacturer. Apply the bonding agent according to the bonding agent manufacturer's directions.

X2.4 *Heating and Ventilation*—A portion of the water used in mixing veneer plaster is necessary for the chemical reaction that rehydrates and hardens the plaster. The excess amount required for mixing and application must be removed from the plaster after set has taken place. Minimum circulation of air is desirable to prevent dry outs.

X2.4.1 Adequate ventilation of attics or similar unheated spaces above gypsum plaster systems is essential to the performance of these systems and shall be designed and provided by others per ASHRAE Fundamentals Handbook or applicable building code.

X2.5 *Electric Radiant Heat Cable*—Apply veneer plaster over electric radiant heat cable according to this specification except as follows:

X2.5.1 Treat flat joints according to 8.4.2 before the electric heating cable is installed,

X2.5.2 Inspect and test the heating system before applying the veneer plaster,

X2.5.3 Apply veneer plaster in a tight scratch coat flush with the cable, working the trowel parallel to the heating cable. Immediately double back before the scratch has set and build up a thickness of veneer plaster over the cable to a minimum of 1/16 in. (1.6 mm) or a maximum of 1/8 in. (3.2 mm),

X2.5.4 Do not turn the heating system on until the veneer plaster has dried completely. Deactivate the heating system and provide supplemental heat as required while paint is being applied. Activating the electric heating cable while the veneer plaster is wet or while paint is being applied may produce photographing of the cables. If the room temperature is more

than 15 °F (8 °C) below the desired temperature after decoration is complete, turn up the heat in 5 °F (3 °C) increments per 24 h period.

Designation: C 844 – 04

Standard Specification for Application of Gypsum Base to Receive Gypsum Veneer Plaster[1]

This standard is issued under the fixed designation C 844; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers the minimum requirements for, and methods of, application of gypsum veneer base for gypsum veneer plasters.

1.2 Gypsum veneer base shall not be used as a base for direct adhesive application of ceramic, metal, or plastic tile in areas exposed to abnormal moisture or humidity or temperature.

1.3 Details of construction for a specific assembly to achieve the required fire resistance shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing laboratories.

1.4 Where a specific degree of sound control is required for veneer plaster assemblies and constructions, details of construction shall be in accordance with official reports of tests conducted in recognized sound testing laboratories in accordance with the applicable sound tests, Test Method C 423, Test Method E 90, or Test Method E 492.

1.5 Where this specification is more stringent (size or thickness of framing; spacing of fasteners) than the fire-rated construction, this specification shall govern; otherwise, the construction described in the fire test report shall govern.

1.6 Unheated spaces above gypsum veneer base ceilings shall be properly ventilated (see Appendix X3).

1.7 The values stated in inch-pound units are to be regarded as the standard. The SI (metric) values given in parentheses are approximate and are provided for information purposes only.

1.8 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

E 492 Test Method for Laboratory Measurement of Impact Sound Transmission Through Floor-Ceiling Assemblies Using the Tapping Machine

2.2 *American Softwood Lumber Standard:*

PS–20 American Softwood Lumber Standard[3]

3. Terminology

3.1 *Definitions*—Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to this Standard:*

3.2.1 *base ply*—first ply of gypsum base in multiple ply application.

3.2.2 *face ply*—outer or visible layer of gypsum base in multiple ply application.

3.2.3 *fastener, n*—nails, screws, or staples used for the application of the gypsum base or backing board.

3.2.4 *framing member, n*—that portion of the framing, furring, blocking, etc., to which the gypsum base is attached. Unless otherwise specified, the surface to which abutting edges or ends are attached shall be not less than 1½ in. (38 mm) wide for wood members, not less than 1¼ in. (32 mm) wide for steel members, and not less than 6 in. (152 mm) wide for gypsum studs. For internal corners or angles, the bearing surface shall be not less than ¾ in. (19 mm).

3.2.5 *parallel application, n*—gypsum base application where the gypsum base edge is applied parallel to the framing members.

3.2.6 *perpendicular application, n*—gypsum base application where the gypsum base edge is applied at right angles to the framing members.

4. Materials

4.1 Materials shall conform to the respective specifications and standards and to the requirements specified herein.

4.2 *Gypsum Base for Veneer Plasters* (hereinafter referred to as "gypsum base")—Specification C 588.

4.3 *Gypsum Backing Board or Coreboard*—Specification C 442.

4.4 *Special Fire-Retardant Gypsum Base*—Specification C 588, Type X.

4.5 *Foil-Backed Gypsum Base*—Specification C 588.

4.6 *Gypsum Veneer Plaster*—Specification C 587.

4.7 *Nails*—Specification C 514.

4.8 *Screws*:

4.8.1 *Non-load bearing steel*—Specification C 1002.

4.8.2 *Load bearing steel*—Specification C 954.

4.9 *Staples*—No. 16 USS gage 0.063 in. (1.6-mm) flattened galvanized wire with 7⁄16-in. (11.1-mm) wide-crown minimum outside measure and divergent points. Staples shall be used only for the base ply of two-ply application over wood framing.

4.10 *Steel Framing, Non-load bearing*—Specification C 645 for the specified design criteria.

4.11 *Accessories*—Specification C 1047.

4.12 *Adhesive*:

4.12.1 For application of gypsum base to steel framing, the adhesive shall be as recommended by the manufacturer of the gypsum base.

4.13 *Steel Framing Load Bearing*—Specification C 955.

4.14 *Wood Framing*—American Lumber Softwood Standard PS–20.

5. Delivery of Materials

5.1 All materials shall be delivered in the original packages, containers, or bundles bearing the brand name and manufacturer (or supplier) identification.

6. Shipping, Handling and Storage

6.1 Gypsum board shall be shipped so as to be kept dry.

6.2 Gypsum board shall be stored so as to be kept dry, preferably inside a building, under a roof. Gypsum board shall be neatly stacked flat with care taken to prevent sagging or damage to edges, ends, and surfaces.

6.3 Where necessary to store gypsum board outside, it shall be stacked flat, off the ground, supported on a level platform and fully protected from weather and direct sunlight exposure.

6.4 Prior to application, the building exterior shall be so enclosed to protect the gypsum base from exposure to weather and direct sunlight.

NOTE 1—The bond of alkaline veneer plaster to gypsum base will be impaired if the base is exposed to direct light or sunlight for extended periods.

7. Environmental Conditions

7.1 *Application of Gypsum Base and Adhesives*—A room temperature of not less than 40 °F (4 °C) shall be maintained during application of gypsum base except when adhesive is used for the attachment of gypsum base. For the bonding of adhesive, a room temperature of not less than 50 °F (10 °C) shall be maintained for 48 h prior to application and continuously thereafter until adhesive is completely dry. When a temporary heat source is used, the temperature shall not exceed 95 °F (35 °C) in any room or area. Adequate ventilation shall be maintained in the working area during the application and adhesive curing process.

8. Application of Gypsum Base

8.1 *General Requirements*:

8.1.1 Installation of steel framing shall be in accordance with applicable Specifications C 754 or C 1007 except where superseded by requirements of Table 1.

NOTE 2—For general wood framing requirements, see Appendix X2.

8.1.2 *Method of Cutting*—The gypsum base shall be cut by scoring and breaking or by sawing, working from the face side. When cutting by scoring, the face shall be cut with a knife or other suitable tool and the gypsum base snapped back away from the cut face. The back shall be broken by snapping the gypsum base in the reverse direction, or by cutting with a knife or other suitable tool.

8.1.3 All cut edges and ends of the gypsum base shall be smoothed to obtain neat jointing. Cut-outs for pipes, fixtures, or other small openings on the face and back of the base shall be scribed in outline before removing or cut out with a saw or

TABLE 1 Maximum Framing Spacing

Single-ply Base (Thickness), in. (mm)		Application to Framing	Maximum On Center Spacing of Framing, in. (mm)
Ceilings:			
	½ (12.7)	parallel	16 (406)
	½ (12.7)[A]	perpendicular	24 (610)
	⅝ (15.9)[B]	perpendicular	24 (610)
Sidewalls:			
	⅜ (9.5)[C]	perpendicular	16 (406)
	½ (12.7)	parallel	16 (406)
	½ (12.7)[A]	perpendicular	24 (610)
	⅝ (15.9)[B]	parallel or perpendicular	24 (610)

[A] ½-in. (12.7-mm) gypsum base applied perpendicular on 24-in. (610-mm) on centers framing shall be considered to be minimum construction.
[B] For ⅝-in. (15.9-mm) base, perpendicular on ceilings and either perpendicular or parallel on sidewalls at 24-in. (610-mm) on centers spacing, only two-component veneer plaster or special joint reinforcement, as recommended by the gypsum veneer plaster manufacturer, shall be used.
[C] ⅜-in. (9.5-mm) gypsum base shall be used over wood framing with two-component veneer plaster systems only.

other suitable tool. The gypsum base shall be scribed where it meets projecting surfaces. Base shall be brought lightly into contact with adjacent panels but not forced into place. Abutting ends and edges shall fit neatly.

8.1.4 When gypsum base is to be applied to both ceiling and walls, the base shall be applied to the ceiling and then to the walls.

8.2 *Fastening, Mechanical*:

8.2.1 The gypsum base shall be held in firm contact with the underlying support while driving any fastener.

8.2.2 Fastener application shall proceed from the center of the field of the gypsum base to the ends and edges or shall begin along one edge and proceed toward the other edge.

8.2.3 Except where required for fire rating, structural performance, or other special considerations, fastening to top or bottom plates shall not be required.

8.2.4 Fasteners shall be spaced not less than ⅜ in. (9.5 mm) from the edges and ends of the gypsum base. Fasteners used at edges or at base ends in horizontal application shall not be more than 1 in. from edges or ends.

8.2.5 Nails and screws shall be driven to a point flush with the gypsum base surface without breaking the surface paper or damaging the surrounding gypsum core and without stripping the framing member around the screws.

8.2.6 Staples shall be driven so that both legs penetrate the support member and the crown bears tightly against the backing board, but does not cut into the face paper. The staple shall be driven with the crown parallel to framing members. Staples shall be used only for the first ply in two-ply gypsum base systems.

8.2.7 Penetration of mechanical fasteners into supporting framing members shall be not less than:

	Nails	Screws	Staples
Wood:	⅞ in. (22 mm)	⅝ in. (15 mm)	⅝ in. (15 mm), each leg
Steel:	...	⅜ in. (9 mm)	...

8.3 *Control Joints*

8.3.1 Control joints shall be installed in ceilings more than 2500 ft^2 (232 m^2) in area that are constructed with perimeter relief. The distance between control joints shall be not more than 50 ft (15 m) in either direction.

8.3.2 Ceilings of more than 900 ft^2 (85 m^2) in area constructed without perimeter relief shall have control joints installed with spacing not to exceed 30 ft (9 m) in either direction.

8.3.3 Control joints shall be installed where ceiling framing or furring changes direction or where construction joints occur in the base building construction. In partitions, walls, or wall furring, the distance between control joints shall be not more than 30 ft (9 m).

8.3.4 A ceiling height door frame, installed in accordance with the spacing requirements set forth in 8.3, functions as a control joint.

9. Application of Single-Ply Gypsum Base

9.1 The maximum spacing of framing members for single-ply gypsum base construction shall be not more than those shown in Table 1.

9.2 In single-ply installation, all ends and edges of gypsum base shall occur over framing members or other solid backing except where treated joints occur at right angles to framing or furring members.

9.3 Joints on opposite sides of a partition shall be arranged to occur on different framing members.

9.4 *Fasteners (Single Ply Application)*:

9.4.1 *Nail Spacing*—Space nails a maximum of 7 in. (178 mm) on centers on the ceiling and a maximum of 8 in. (203 mm) on centers on the walls.

9.4.2 *Double Nailing*—Nails shall be spaced as shown in Fig. 1 and applied as follows:

9.4.2.1 Starting at the center of the base, nails shown as solid dots shall be applied by row starting with row 1, then rows 2 and 2A, 3 and 3A, 4 and 4A. Base shall be kept tight against the framing throughout the procedure.

9.4.2.2 Using the procedure in 9.4.2.1, second nails shown by circles shall be applied.

9.4.2.3 As an alternative procedure, second nails shall be permitted to be applied immediately after all first nails in each individual row have been driven in accordance with 9.4.2.1.

9.4.2.4 Single nails shall be used on the perimeter of the base.

NOTE 3—It may be necessary to reset the first nails in each row after the second nails have been set.

9.4.3 Nails for single-ply application over wood members shall be as follows:

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

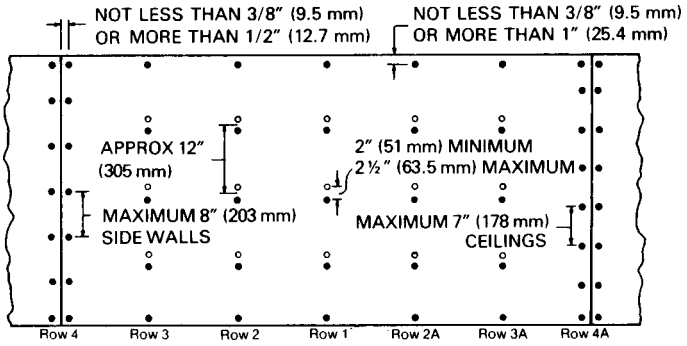

FIG. 1 Double Nailing

Gypsum Base Thickness, in. (mm)	Nails, in. (mm)
⅜ (9.5)	1¼ (32)
½ (12.7)	1⅜ (35)
⅝ (15.9)	1½ (38)

9.4.4 Where a specific degree of fire resistance is required for gypsum board assemblies and constructions, nails of same or larger length, shank diameter, and head bearing area, as those described in the applicable fire test report shall be used.

9.4.5 *Screw Spacing*—Screws shall be spaced not more than 12 in. (305 mm) on center along framing members for wall or ceiling application.

9.5 *Floating Interior Angles*—The floating angle method of application is applicable where single nailing, double nailing, or screw attachment is used, and helps to minimize the possibility of cracking in areas adjacent to a wall and ceiling intersection. When using this method the base shall be applied to ceilings first.

9.5.1 *Ceilings*—Fasteners shall be spaced in accordance with 9.4 except that for single nailing the nail adjacent to the ceiling/wall intersection shall be located 7 in. (178 mm) away from the wall, or 11 to 12 in. (279 mm to 305 mm) away for double nailing or screw application.

9.5.2 *Walls*—The gypsum base shall be fastened to walls to provide a firm support for the floated edges of the ceiling gypsum base. The top attachment shall be located into each stud 8 in. (203 mm) down from the ceiling intersection for single nailing (Fig. 2), and 11 to 12 in. (279 to 305 mm) for double nailing (Fig. 1) or screw application (see Fig. 3 and Fig. 4). At sidewall vertical angles (Fig. 5), the overlapping base shall be applied so as to bring the back of the underlying board into firm contact with the face of the framing member behind it.

10. Adhesive-Mechanical Fastener Application

10.1 Except as modified herein, application shall be in accordance with Section 9.

10.2 Surfaces of gypsum base and framing to receive adhesive shall be free of any foreign matter that impairs the bond.

10.3 A bead of adhesive ⅜ in. (9.5 mm) in diameter shall be applied to the face of all wood framing members, except plates, that support the gypsum base. As pressure is applied to the base the adhesive shall spread to an average width of ¾ in. (19 mm) approximately ⅛ in. (3.2 mm) thick. Application patterns shall be shown as in Fig. 6.

10.3.1 Where two adjacent pieces of gypsum base abut (ends or edges) on a framing member, two parallel beads of adhesive shall be applied to the framing member. Application patterns shall be as shown in Fig. 6.

10.4 Adhesive shall be applied to an area no greater than will be covered with gypsum base within the "open time" of the adhesive.

10.5 *Fastener Spacing:*

10.5.1 Where the properties of the adhesive ensure bridging between the gypsum base and the wood framing, no fastening shall be required in the field of the base for walls. In such cases, perimeter fastening, 16 in. (406 mm) on center, shall be required.

10.5.2 Where the properties of the adhesive achieve no positive bridging between the board and the wood framing, either temporary field nailing or temporary bracing shall be required to ensure contact between the base, the adhesive, and the stud face until the adhesive develops adequate bond strength. Fasteners shall be spaced in accordance with Table 2.

11. Application over Existing Surfaces

11.1 Gypsum base installed over uneven or broken surfaces, on the interior of all exterior masonry or concrete walls or columns, or over reasonably smooth, solid interior surfaces such as concrete or unit masonry shall be applied over furring strips or furring channels in accordance with Section 9 of this specification.

11.2 Over reasonably smooth, sound, existing surfaces, such as gypsum wallboard or plaster in good condition, the gypsum base shall be applied by using fasteners of sufficient length to penetrate into the underlying framing members in accordance with 8.2.7. Fasteners shall be spaced in accordance with Sections 8 and 9 of this specification.

11.3 Fastener and adhesive attachment of gypsum base to existing surfaces shall be in accordance with Section 10 of this specification.

12. Foil-Backed Gypsum Base

12.1 The application of foil-backed gypsum base shall conform to all of the specifications for the application of gypsum base except that it shall not be used as follows:

12.1.1 The face ply on a two-ply laminating system.

12.1.2 Laminated directly to masonry.

12.1.3 Directly over plaster or other existing surfaces.

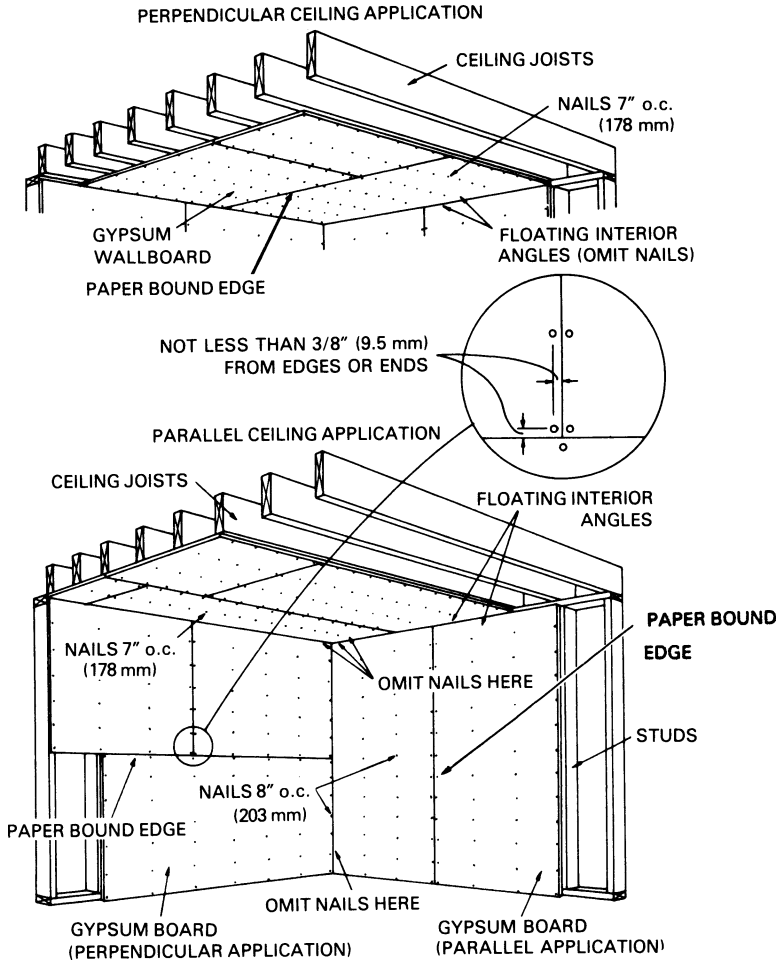

FIG. 2 Single Nailing

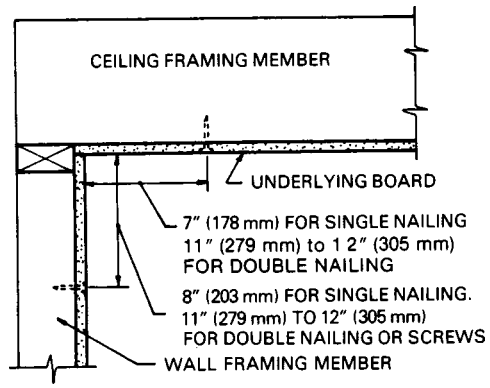

FIG. 3 Vertical Section, Ceiling Framing Perpendicular To Wall

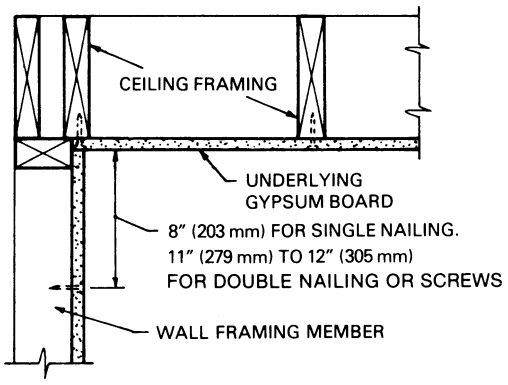

FIG. 4 Vertical Section, Ceiling Framing Parallel to Wall

12.2 The reflective surface of the foil-backed gypsum base shall be placed against the face of the framing members.

13. Application of Two-Ply Gypsum Base to Framing Members

NOTE 4—The base ply in two-ply construction may be gypsum board other than gypsum veneer base (see Section 4).

13.1 Spacing of framing members and the application direction for both plies of two-ply gypsum base construction with no adhesive between plies shall comply with Table 1.

13.2 Spacing of framing members for two-ply gypsum base construction with adhesive between plies shall comply with Table 3.

13.3 The first ply of gypsum base shall be applied using nails, screws, or staples, spaced in accordance with Table 4.

13.4 Where no adhesive is used between plies, the two plies of gypsum base shall be applied either parallel or perpendicular to each other. The face ply shall be applied with the number of nails or screws required for normal single-ply application. Face ply joints that are parallel to framing shall fall over framing

www.technobetar.ir

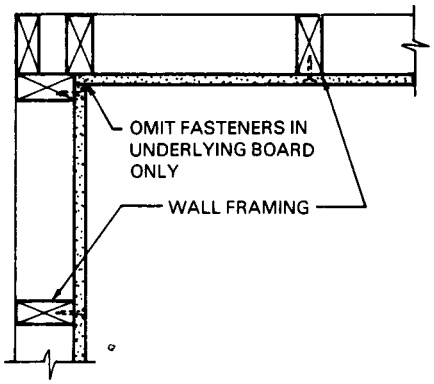

FIG. 5 Horizontal Section Through Interior Vertical Angle

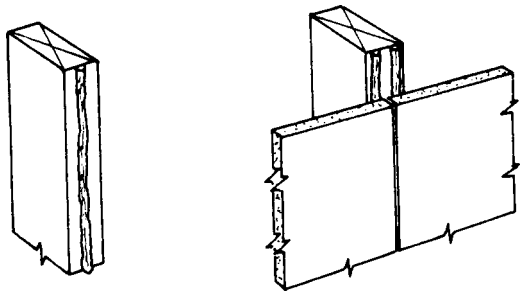

FIG. 6 Adhesive Application Patterns

members and be offset from the base ply joints when two plies of gypsum base are installed parallel to each other.

13.5 Where a laminating adhesive is used between plies, joints in the face ply shall not be required to occur over framing members. Parallel joints of the two plies shall be staggered (offset) at least 8 in. (203 mm).

13.6 Where gypsum base is adhesively installed, the face ply shall be held firmly in place with temporary fasteners or shoring (supports, props, headers, etc.) in sufficient quantity to ensure pressure for bonding. When sufficient bond has developed, supports shall be removed and temporary fasteners removed or driven flush with the surface.

14. Solid Gypsum Base Partitions

14.1 *Face Ply*—shall be ½ in. (12.7 mm), ⅝ in. (15.9 mm), or multiple laminations of gypsum base of 4-ft (1200-mm) width.

14.2 *Core*—shall be 1-in. thick gypsum panel products, either single or multiple layer in 2-ft (610 mm) or 4-ft (1220 mm) width.

14.3 *Runners*—shall be metal not less than 0.0179 in. (0.046 mm) in thickness or construction grade wood.

14.4 Floor and ceiling runners shall be not less than 24 in. (610 mm) on center. Vertical runners shall be installed at required locations, such as exterior walls, exterior corners, and door frames. Partitions shall be secured at the floor and ceiling in accordance with the gypsum base manufacturer's details or as otherwise required.

14.5 Pressure shall be applied to gypsum base laminated to the backing board to ensure a secure, firm bond. Joints between the gypsum base and the backing board shall be staggered. Fasteners shall be used to ensure a continuous bond between the gypsum base and the backing board.

14.6 Veneer plaster shall not be applied until the adhesive is fully set and the gypsum base is firmly bonded.

15. Adhesive Application of Gypsum Base to Interior Masonry or Concrete Walls

15.1 Direct adhesive application shall be used only on interior masonry or concrete walls above grade, or the inside of exterior masonry cavity walls with a cavity not less than 1-in. (25.4-mm) in width between the inside and outside masonry for the full height of the above grade surface to receive gypsum base.

15.2 Foil-backed gypsum base shall not be used for direct adhesive application.

15.3 All surfaces to be adhered shall be free of any foreign matter that impairs the bond. Projections or elevations in the masonry shall be removed by chipping or wire brushing. Large hollows or depressions shall be face-plastered with portland cement and given time to dry.

15.4 For application to monolithic concrete, porous brick, or concrete block, adhesive shall be applied to the back of the gypsum base or on the wall in continuous parallel beads spaced not more than 12 in. (305 mm) on center or daubs spaced not more than 12 in. on center each way.

15.4.1 Beads shall be not less than ⅜ in. (9.5 mm) in diameter to provide a continuous bond between the gypsum base and the wall surface.

15.4.2 Daubs shall be 2 to 3 in. (51 mm to 76 mm) in diameter. (**Warning**—Be sure that the adhesive will bond to monolithic concrete. Form release compounds may cause bond failure.)

15.5 *Gypsum Base Installation*—Gypsum base shall be positioned to provide a tight fit at abutting edges. The base shall not be slid into place. Moderate pressure shall be used to develop a full adhesive bond.

15.5.1 Veneer plaster shall not be applied until the adhesive is fully set and the gypsum base is firmly bonded.

15.6 *Gypsum Base Application over Rigid Plastic Foam*—Gypsum base is capable of being applied over rigid plastic foam insulation panels that have been applied to masonry or concrete walls.

15.6.1 Foam insulation shall be applied to the masonry or concrete in accordance with the foam manufacturer's specifications.

15.6.2 Furring strips or special metal furring members shall be attached using mechanical means to the masonry or concrete wall surface. This shall be done either before or after application of insulation, depending on the system used.

15.6.2.1 Furring members shall be installed in accordance with Table 1 of this specification and at the floor-wall angle, wall-ceiling angle (or at the termination of the gypsum base above suspended ceilings), around door, window, and other openings, and where required for cabinet or fixture attachment.

15.6.3 Gypsum base shall be applied to the furring as described in Section 9 of this specification. Mechanical fasteners shall be of such length that they shall not penetrate completely to the masonry or concrete.

TABLE 4 Attachment Spacing for Base Ply over Wood or Steel Framing

Fastener	Nails	Screws	Staples
Framing	wood	wood or metal	wood
No adhesive between plies	24 in. (610 mm) on centers	24 in. (610 mm) on centers	16 in. (406 mm) on centers
Adhesive between plies	Section 7.2.1	Section 7.2.2	7 in. (178 mm)

16. Gypsum Base Application over Steel Framing and Furring

16.1 *Screw Application*—shall be as specified in Section 9 of this specification.

16.2 *Framing Spacing*—Spacing of steel framing and furring for screw application shall be in accordance with Table 1 for single-ply gypsum base and as specified in Table 3 for two-ply gypsum base.

16.3 *Screw Spacing*:

16.3.1 Screw spacing for single-ply gypsum base and face ply of two-ply gypsum base with no adhesive shall be as specified in 9.4.5 of this specification.

16.3.2 Screw spacing for parallel applied first-ply of two-ply gypsum base over steel framing on side walls with no adhesive between the plies shall be 12 in. (305 mm) on center along the edges of the gypsum base and at third points into each stud or furring channel in the field of the gypsum base.

16.3.3 Screw spacing for a perpendicular applied first-ply of two-ply gypsum base over steel framing on side walls with no adhesive between the plies shall be one screw at each edge at each stud or furring channel intersection and one screw midway between edges at each stud or furring channel.

16.3.4 Screw spacing for perpendicular or parallel applied first-ply of two-ply gypsum base over steel framing with adhesive between plies shall be as specified for single-ply gypsum base in 9.4.5 of this specification.

16.3.5 Screw spacing for the first ply of two-ply gypsum base over steel framing with adhesive between plies on ceilings shall be the same as specified for the face-ply of two-ply gypsum base in 13.4 of this specification. Only a sufficient number of screws to hold the gypsum base in place until the adhesive develops a bond shall be used.

17. Application to Arches

17.1 Gypsum base applied to the soffit of arches (see Table 5) shall be carefully bent into place. If necessary, the base shall first be either dampened or scored 1 in. (25 mm) on center on the back side. In the latter case, after the core has been broken at each cut, the gypsum base shall be applied to the framing member and fastened in place. If the base is dampened, it shall be dry before plastering.

TABLE 5 Bending Radii for Application to Arches

Gypsum Base Thickness, in. (mm)	Bent Lengthwise, ft (m)	Bent Widthwise, ft (m)
½ (12.7)	10 (3.05)	–
⅜ (9.5)	7½ (2.29)	25 (7.62)

www.technobetar.ir

17.2 To apply the base, a stop shall be placed at one end of the curve and the base shall be gently and gradually pushed on the other end, forcing the center against the framing until the curve is complete.

NOTE 5—By moistening the face and back paper thoroughly and allowing the water to soak well into the core, the base may be bent to still shorter radii. When it dries thoroughly, the base will regain its original hardness.

18.1 electric heat cable; gypsum; gypsum base; veneer plastic

APPENDIXES

(Nonmandatory Information)

These Appendixes provide general information and also suggestions for inclusions to be made elsewhere by the specifier, and are not a part of this specification.

X1. GENERAL INFORMATION

X1.1 Scaffolding shall be constructed and maintained in strict conformity with applicable laws and ordinances and shall not interfere with or obstruct the work of others. The work shall be properly coordinated with the work of other trades.

X2. WOOD FRAMING REQUIREMENTS

X2.1 Requirements covering framing, furring, spacing, etc., are essential to provide a proper surface to receive the gypsum base. The following requirements should be included in the project specifications for framing and furring:

X2.1.1 All framing members to which gypsum base will be fastened shall be straight and true and spaced not more than the maximum spacings shown in Table 1. Wood framing, bridging, and furring members shall be the proper grade for the intended use and members 2 by 4 in. nominal size or larger shall bear the grade mark of a recognized inspection agency. Framing, bridging, and furring shall be adequate to carry the design or code loading, or both. In place of an applicable local code, the framing shall meet the minimum requirements of FHA for single or multifamily dwellings. The deflection of members supporting gypsum base shall be not more than L/360 of the span at full design load. Headers shall be provided as necessary for the support of fixtures.

X2.1.2 When the gypsum base is nailed to wood cross furring on ceilings, these members shall have a cross section of not less than 1½ by 1½ in. (38 by 38 mm) and shall be spaced in accordance with the requirements of Table 1. Where screw application is used, the furring member shall have a size of not less than ¾ by 2½ in. (19 by 64 mm) actual size. Lumber shall conform to American Softwood Lumber Standard PS-20.

X2.1.3 All vertical solid surfaces that are furred to receive gypsum base shall be furred with wood framing members not less than ¾ in. (19 mm) thick and 1½ in. (38 mm) wide. (Fastener penetration into the framing member shall be in accordance with 8.2.7 of this specification.)

X2.1.4 Insulating blankets or flanges of blankets shall not be applied over framing members that are to receive gypsum base. Foil-backed gypsum base may be used as a vapor retarder where required.

X3. VENTILATING ABOVE GYPSUM BASE CEILINGS

X3.1 Adequate ventilation of attics or similar unheated spaces above gypsum plaster systems is essential to the performance of these systems and shall be designed and provided by others per ASHRAE Fundamentals Handbook or applicable building code.

X4. CABLE ELECTRIC RADIANT HEATING SYSTEMS FOR CEILINGS

X4.1 The application of gypsum base under this specification shall be performed in accordance with the requirements of this specification except as follows:

X4.1.1 The gypsum base shall have a thickness of ½ in. (12.7 mm). The gypsum base shall be applied perpendicular to framing members by using attachment methods as required in Section 9 of this specification.

X4.1.2 Electric heating cables shall be securely attached to the gypsum base in accordance with the recommendations of the cable manufacturer or supplier.

X4.1.3 Cables shall run at right angles to the gypsum base paperbound edges. Cables shall not be positioned directly over joints that run parallel to the direction of cable run.

X4.1.4 Cables shall be positioned not less than 6 in. (152 mm) from all wall-ceiling intersections and openings.

X4.1.5 All inspections and testing of the heating system shall be completed before application of the veneer plaster.

X4.1.6 Under no conditions shall the heating cable have an operating temperature greater than 125 °F (52 °C).

X4.1.7 Additional information on radiant heating systems is available in Guide C 1546.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 844 – 99, that may impact the use of this specification. (Approved October 1, 2004)

(*1*) Added paragraph X4.1.7.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 845 – 04

Standard Specification for Expansive Hydraulic Cement[1]

This standard is issued under the fixed designation C 845; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers hydraulic cements that expand during the early hardening period after setting.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 33 Specification for Concrete Aggregates

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 114 Test Methods for Chemical Analysis of Hydraulic Cement

C 183 Practice for Sampling and the Amount of Testing of Hydraulic Cement

C 185 Test Method for Air Content of Hydraulic Cement Mortar

C 188 Test Method for Density of Hydraulic Cement

C 465 Specification for Processing Additions for Use in the Manufacture of Hydraulic Cements

C 688 Specification for Functional Additions for Use in Hydraulic Cements

C 806 Test Method for Restrained Expansion of Expansive Cement Mortar

C 807 Test Method for Time of Setting of Hydraulic Cement Mortar by Modified Vicat Needle

3. Terminology

3.1 *Definitions:*

3.1.1 *expansive cement (K)*—an expansive cement containing anhydrous calcium aluminosulfate ($4CaO \cdot 3Al_2O_3 \cdot SO_3$), calcium sulfate, and uncombined calcium oxide.

3.1.2 *expansive cement (M)*—an expansive cement containing calcium aluminate cement and calcium sulfate.

3.1.3 *expansive cement (S)*—an expansive cement containing tricalcium aluminate (C_3A) and calcium sulfate.

3.1.4 *expansive hydraulic cement*—a cement composed essentially of hydraulic calcium silicates, calcium aluminates and calcium sulfates, which, upon being mixed with water, forms a paste that increases significantly in volume during the early hardening period occurring after setting. This volume increase is due principally to the reaction of the calcium aluminates and calcium sulfates.

3.1.5 *shrinkage-compensating concrete*—concrete that is internally restrained with resilient reinforcing and made with expansive cement which induces both compressive stress in the concrete and positive steel strain that approximately off-sets tensile stresses and negative strains induced by drying shrinkage.

4. Classification

4.1 The cement covered by this specification is suitable for use in shrinkage-compensating concrete and shall be designated as Type E-1.

NOTE 1—Three kinds of expansive cement are identified in Section 3 by the letters K, M, and S. The appropriate letter should be used as a suffix to the type designation when one of these kinds is desired. Expansive cement may also be prepared in other ways.

5. Ordering Information

5.1 When it is desired that an optional requirement apply or that the cement be of a particular kind, a specific request to this effect should be made by the purchaser.

6. Chemical Composition

6.1 Expansive cement shall conform to the requirements as to chemical composition prescribed in Table 1.

6.2 The purchaser has the option of specifying that the alkalies ($Na_2O + 0.658K_2O$) shall not exceed 0.60 % (See Table 2).

NOTE 2—This limit should be specified when the cement is to be used in concrete with aggregates that may be reactive. Reference should be made to Specification C 33 for suitable criteria of deleterious reactivity.

7. Physical Properties

7.1 Expansive cement shall conform to the physical requirements prescribed in Table 3.

[1] This specification is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.13 on Special Cements.

Current edition approved July 1, 2004. Published July 2004. Originally approved in 1976. Last previous edition approved in 1996 as C 845–96.

TABLE 1 Standard Chemical Requirements

	Composition, %
Magnesium oxide (MgO), max	6.0
Insoluble residue, max	1.0
Loss on ignition, max	4.0

TABLE 2 Optional Chemical Requirements

Alkalies (Na2O + 0.658 × K2O) max, %	0.60

TABLE 3 Physical Requirements

Time of setting, min, minutes	75
Air content, max, vol %	12.0
Restrained expansion of mortar:	
7-day expansion:	
min, %	0.04
max, %	0.10
28-day, percentage of 7-day expansion, max	115
Compressive strength, min:	
7-day, psi(MPa)	2100(14.7)
28-day, psi(MPa)	3500(24.5)

8. Additions

8.1 The cement covered by this specification shall contain no additions except as follows:

8.1.1 Water, or a functional addition, or both, that has been shown to meet the requirements of Specification C 688, may be added in amounts such that the limits shown in Table 1 for loss on ignition shall not be exceeded.

8.1.2 At the option of the manufacturer, processing additions may be used in the manufacture of the cement, provided such materials in the amounts used have been shown to be not harmful in accordance with Specification C 465.

9. Test Methods

9.1 The cement shall be sampled and the properties enumerated in this specification shall be determined in accordance with the following methods:

9.1.1 *Sampling*—Practice C 183.

9.1.2 *Chemical Analysis*—Test Methods C 114.

9.1.3 *Time of Setting*—Test Method C 807.

9.1.4 *Air Content*—Test Method C 185, using the actual specific gravity of the cement if it differs from 3.15 by more than 0.05 in calculating the air content.

9.1.5 *Restrained Expansion of Mortar*—Test Method C 806.

9.1.6 *Compressive Strength*—Test Method C 109/C109M, except that a water-cement ratio of 0.500 shall be used, the specimens shall be covered with a polyethylene sheet or other suitable material for preventing loss or gain of moisture at the surface of the specimens during the moist storage period in the molds, and the specimens shall remain in the molds for 3 days.

9.1.7 *Density*—Test Method C 188.

10. Inspection

10.1 Every facility shall be provided the purchaser for careful inspection and sampling of the finished cement. The finished cement may be inspected and sampled either at the mill or at the site of the work, as may be specified by the purchaser. The following periods from time of sampling shall be allowed for completion of testing:

7-day test	12 days
28-day test	33 days

10.2 The manufacturer shall provide suitable facilities to enable the inspector to check the intergrinding or blending operation used to produce cement by either means. The plant facilities for intergrinding or blending and inspection shall be adequate to ensure compliance with the provisions of this specification.

11. Rejection

11.1 The cement may be rejected if it fails to meet any of the requirements of this specification.

11.2 Cement remaining in bulk storage at the mill prior to shipment for a period greater than 6 months or cement in bags in local storage in the hands of a vendor for more than 3 months, after completion of the tests, may be retested for expansion and may be rejected if it fails to conform to the requirements of this specification for expansion.

11.3 Packages more than 2 % below the net weight marked thereon, may be rejected. Also, if the average net weight of packages in any shipment, as shown by weighing 50 packages at random, is less than that marked on the packages, the entire shipment may be rejected.

12. Certification

12.1 At the request of the purchaser, the manufacturer shall state in writing the composition of a finished cement.

12.2 The composition of any cement shall conform to that shown in the statement of the manufacturer within the following tolerances:

	Tolerance, ± %
Silicon dioxide (SiO_2)	3
Aluminum oxide (Al_2O_3)	2
Calcium oxide (CaO)	3

12.3 At the request of the purchaser, the manufacturer shall state in writing the nature, amount, and identity of any processing or functional addition that may have been used. Also, if requested, the manufacturer shall supply test data showing compliance of any processing addition with the provisions of Specification C 465, and any functional addition with the provisions of Specification C 688.

12.4 Upon request of the purchaser in the contract or order, a manufacturer's certification that the material during production was tested in accordance with this specification together with a report of the test results shall be furnished at the time of shipment.

13. Packaging and Package Marking

13.1 When the cement is delivered in packages, the words" expansive cement," the type, the kind (if the cement is one of the three kinds defined in Section 3), the name and brand of the manufacturer, and the net weight shall be plainly marked on each package. Similar information shall be provided in the shipping documents accompanying the shipment of packaged or bulk cement. All packages shall be in good condition at the time of inspection.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

14. Storage

14.1 The cement shall be stored in a manner such as to permit easy access for proper inspection and identification of each shipment and in a suitable weathertight building that will protect the cement from dampness and minimize warehouse set.

15. Keywords

15.1 calcium aluminate; calcium aluminosulfate; calcium oxide; calcium silicate; calcium sulfate; cement; expansive; hydraulic; shrinkage-compensated; tricalcium aluminate

Designation: C 847 – 09

Standard Specification for Metal Lath[1]

This standard is issued under the fixed designation C 847; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers sheet lath, expanded metal lath, diamond mesh, flat and self-furring, and rib metal lath, ⅛ and ⅜ in. (3.2 and 9.6 mm), all with or without backing and designed to be used as a base for gypsum or portland cement plaster.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

A 653/A 653M Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process

3. Material

3.1 Metal lath shall be fabricated from cold-rolled carbon steel sheet of commercial quality conforming to Specification A 653/A 653M. Galvanized metal lath shall have a G60 coating in accordance with Specification A 653/A 653M.

3.2 Backing shall be attached to the lath sufficiently enough to prevent accidental removal during shipping, handling, or installation. Attachment of backing shall also allow lapping of metal to metal and backing to backing, 1 in. (25.4 mm) on the ends and ½ in. (12.7 mm) on the sides.

4. Dimensions, Mass, and Permissible Variations

4.1 *Thickness*—The nominal thickness of diamond mesh and flat rib metal lath shall be ⅛ in. (3.2 mm). The nominal thickness of other rib metal lath shall be as designated, ⅜ in. (9.6 mm). The nominal thickness of self-furring diamond mesh shall be 5⁄16 in. (7.9 mm).

4.2 *Width*—The nominal width of metal lath shall be 27 in. (686 mm).

4.3 *Length*—The nominal length of metal lath shall be 96 in. (2438 mm).

4.4 *Weight*—The nominal weight of metal lath shall be as follows:

4.4.1 *U.S. Nominal Weights*:

Type:	Weight, lb/yd^2(kg/m^2)
Diamond mesh	2.5 (1.4); 3.4 (1.8)
Flat rib	1.8 (1.0); 2.75 (1.5); 3.4 (1.8)
⅜-in. rib	3.4 (1.8); 4.0 (2.1)
Sheet	4.5 (2.4)

4.4.2 *Canadian Nominal Weights*:

Type:	Weight, lb/yd^2(kg/m^2)
Diamond mesh	2.5 (1.4); 3.0 (1.6); 3.4 (1.8)
Flat rib	1.8 (1.0); 2.5 (1.4); 3.0 (1.6)
⅜-in. rib	3.0 (1.6); 3.5 (1.9); 4.0 (2.1)

4.5 *Permissible Variations*—The permissible variations shall be as follows:

4.5.1 *Thickness*, ±1⁄64 in. (0.4 mm).

4.5.2 *Width*, ±⅜ in. (9.5 mm).

4.5.3 *Length*, −0 in., + 2½ in. (63.5 mm).

4.5.4 *Weight*, ± 10 %.

5. Finish

5.1 Metal lath shall be fabricated from hot-dipped galvanized steel.

6. Inspection

6.1 Inspection of the material shall be agreed upon between the purchaser and supplier as part of the purchase contract.

7. Rejection and Rehearing

7.1 Any rejection shall be based upon the specific cause of failure to conform to the requirements of this specification, and shall be reported to the seller within 10 working days from the receipt of the shipment by the purchaser.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved May 1, 2009. Published May 2009. Originally approved in 1977. Last previous edition approved in 2006 as C 847 – 06.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

7.2 Claims for rehearing shall be valid only if made within 20 working days from receipt of notice of specific cause for rejection.

8. Certification

8.1 Where specified in the purchase order, a producer's or supplier's certification shall be furnished to the purchaser that the material was in accordance with this specification and has been found to meet the specified requirements.

9. Packaging and Package Marking

9.1 Metal lath shall be packaged ten sheets per bundle, and self-furring lath shall be five or ten sheets per bundle (option of manufacturer).

9.2 When shipped for resale, the name of the manufacturer or the supplier and the brand shall be legibly marked on each lath or package.

10. Keywords

10.1 gypsum cement plaster; lath; metal lath; portland cement plaster; rib lath; self-furring; sheet lath

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 847 – 06, that may impact the use of this specification. (Approved May 1, 2009)

(*1*) Revised the tolerance in 4.5.2 from 3⁄16 in. to 3⁄8 in.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Designation: C 856 – 04

Standard Practice for Petrographic Examination of Hardened Concrete[1]

This standard is issued under the fixed designation C 856; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice outlines procedures for the petrographic examination of samples of hardened concrete. The samples examined may be taken from concrete constructions, they may be concrete products or portions thereof, or they may be concrete or mortar specimens that have been exposed in natural environments, or to simulated service conditions, or subjected to laboratory tests. The phrase "concrete constructions" is intended to include all sorts of objects, units, or structures that have been built of hydraulic cement concrete.

NOTE 1—A photographic chart of materials, phenomena, and reaction products discussed in Sections 7-12 and Tables 1-6 are available as Adjunct C856 (ADJCO856).

1.2 The petrographic procedures outlined herein are applicable to the examination of samples of all types of hardened hydraulic-cement mixtures, including concrete, mortar, grout, plaster, stucco, terrazzo, and the like. In this practice, the material for examination is designated as "concrete," even though the commentary may be applicable to the other mixtures, unless the reference is specifically to media other than concrete.

1.3 Annex A1 outlines an uranyl acetate method for identifying locations where alkali-silica gel may be present. It is a requirement that the substances in those locations must be identified using any other more definitive techniques, such as petrographic microscopy.

1.4 The purposes of and procedures for petrographic examination of hardened concrete are given in the following sections:

	Section
Qualifications of Petrographers and Use of Technicians	3
Purposes of Examination	4
Apparatus	5
Selection and Use of Apparatus	6
Samples	7
Examination of Samples	8
Specimen Preparation	9
Visual and Stereomicroscope Examination	10
Polarizing Microscope Examination	11
Paste Features	12
Report	13

1.5 The values stated in inch-pound units are to be regarded as the standard. The SI units in parentheses are provided for information purposes only.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* A specific hazard statement is given in 5.2.10.1.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 215 Test Method for Fundamental Transverse, Longitudinal, and Torsional Frequencies of Concrete Specimens

C 227 Test Method for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar-Bar Method)

C 342 Test Method for Potential Volume Change of Cement-Aggregate Combinations[3]

C 441 Test Method for Effectiveness of Pozzolans or Ground Blast-Furnace Slag in Preventing Excessive Expansion of Concrete Due to the Alkali-Silica Reaction

C 452 Test Method for Potential Expansion of Portland-Cement Mortars Exposed to Sulfate

C 457 Test Method for Microscopical Determination of Parameters of the Air-Void System in Hardened Concrete

C 496 Test Method for Splitting Tensile Strength of Cylindrical Concrete Specimens

C 597 Test Method for Pulse Velocity Through Concrete

C 803/C 803M Test Method for Penetration Resistance of Hardened Concrete

C 805 Test Method for Rebound Number of Hardened Concrete

C 823 Practice for Examination and Sampling of Hardened Concrete in Constructions

C 1012 Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution

C 1260 Test Method for Potential Alkali Reactivity of Aggregates (Mortar-Bar Method)

E 3 Practice for Preparation of Metallographic Specimens

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.65 on Petrography.

Current edition approved Jan. 1, 2004. Published February 2004. Originally approved in 1977. Last previous edition approved in 2002 as C 856 – 02.

TABLE 1 Visual Examination of Concrete (1)[6]

Coarse Aggregate	+ Fine Aggregate	+ Matrix	+ Air	+ Embedded Items
Composition:				
Maximum dimension,[A] in. or mm, in the range> *d*>				
Type: 1 Gravel 2 Crushed stone 3 Mixed 1 and 2 4 Other (name) 5 Mixed 1 + /or 2 + /or 4 If Type 1, 2, or 4, homogeneous or heterogeneous	Type: 1 Natural sand 2 Manufactured sand 3 Mixed 4 Other (name) 5 Mixed 1 + /or 2 + /or 4 If Type 1, 2, or 4, homogeneous or heterogeneous	color, by comparison with National Research Council *Rock Color Chart* (1963) color distribution: 1 mottled 2 even 3 gradational changes	more than 3 % of total, predominantly in spherical voids? less than 3 % of total, abundant nonspherical voids? color differences between voids and mortar?	Type, size, location; kinds of metal; other items
Lithologic types Coarse aggregate more than 20, 30, 40, or 50 % of total			voids empty, filled, lined, or partly filled	
Fabric:				
Shape Distribution Packing Grading (even, uneven, excess, or deficiency of size or sizes) Parallelism of flat sides or long axes of exposed sections, normal to direction of placement + /or parallel to formed and finished surfaces[B]	distribution particle shape grading preferred orientation } as perceptible	distribution	shape distribution grading (as perceptible) parallelism of long axes of irregular voids or sheets of voids: with each other; with flat sides or long axes of coarse aggregate	voids below horizontal or low-angle reinforcement
Condition:				clean or corroded?
Does it ring when hit lightly with a hammer or give a dull flat sound? Can you break it with your fingers? Cracks? How distributed? Through or around coarse aggregate? With cores or sawed specimens, did the aggregate tear in drilling or sawing? Crack fillings? Surface deposits? If air dry, are there unusually wet or dry looking areas? Rims on aggregate?				Are cracks associated with embedded items?

[A] A substantial portion of the coarse aggregate has maximum dimensions in the range shown as measured on sawed or broken surfaces.

[B] Sections sawed or drilled close to and parallel to formed surfaces appear to show local turbulence as a result of spading or rodding close to the form. Sections sawed in the plane of bedding (normal to the direction of placement) are likely to have inconspicuous orientation. Sections broken normal to placement in conventionally placed concrete with normal bond tend to have aggregate knobs abundant on the bottom of the upper piece as cast and sockets abundant on the top of the lower piece as cast.

2.2 *ASTM Adjuncts:*

Adjunct C856 (ADJCO856) A chart of 27 photos[4]

3. Qualifications of Petrographers and Use of Technicians

3.1 All petrographic examinations of hardened concrete described in this practice shall be performed by or under the technical direction of a full time supervising petrographer with at least 5 years experience in petrographic examinations of concrete and concrete-making materials. The supervising concrete petrographer shall have college level courses that include petrography, mineralogy, and optical mineralogy, or 5 years of documented equivalent experience, and experience in their application to evaluations of concrete-making materials and concrete products in which they are used and in cementitious-based materials. A resume of the professional background and qualifications of all concrete petrographers shall be available.

3.2 A concrete petrographer shall be knowledgeable about the following: concrete-making materials; processes of batching, mixing, handling, placing, and finishing of hydraulic-cement concrete; the composition and microstructure of cementitious paste; the interaction of constituents of concrete; and the effects of exposure of such concrete to a wide variety of conditions of service.

3.3 Sample preparation shall be performed by concrete petrographers or trained technicians pursuant to instructions from and under the guidance of a qualified concrete petrographer. Aspects of the petrographic examination, such as the measurement of sample dimensions, photography of as-received samples, staining of sample surfaces, that do not require the education and skills outlined in 3.1, shall be performed by concrete petrographers or by trained technicians pursuant to instructions and under the guidance of a qualified concrete petrographer. The analysis and interpretation of the features that are relevant to the investigation and evaluation of the performance of the materials represented by the sample shall be made solely by concrete petrographers with qualifications consistent with those outlined in 3.1.

3.4 A concrete petrographer shall be prepared to provide an oral statement, written report, or both that includes a description of the observations and examinations made during the petrographic examinations, and interpretation of the findings insofar as they relate to the concerns of the person or agency

TABLE 2 Outline for Examination of Concrete with a Stereomicroscope (1)

NOTE 1—*Condition*—When it is examined at 6 to 10× under good light, the freshly broken surface of a concrete in good physical condition that still retains most of its natural moisture content has a luster that in mineralogical terms is subtranslucent glimmering vitreous.[A] Thin edges of splinters of the paste transmit light; reflections appear to come from many minute points on the surface, and the quality of luster is like that from broken glass but less intense. Concrete in less good physical condition is more opaque on a freshly broken surface, and the luster is dull, subvitreous going toward chalky. A properly cured laboratory specimen from a concrete mixture of normal proportions cured 28 days that has shown normal compressive or flexural strength and that is broken with a hammer and examined on a new break within a week of the time that it finished curing should provide an example of concrete in good physical condition.

Under the same conditions of examination, when there is reasonable assurance that the concrete does not contain white portland cement or slag cement, the color of the matrix of concrete in good physical condition is definitely gray or definitely tan, except adjoining old cracks or original surfaces.

Coarse Aggregate	Fine Aggregate	Matrix	Voids
Lithologic types and mineralogy as perceptible	Lithologic types and mineralogy as perceptible	Color	Grading
Surface texture	Shape	Fracture around or through aggregate	Proportion of spherical to nonspherical
Within the piece:	Surface texture	Contact of matrix with aggregate:	Nonspherical, ellipsoidal, irregular, disk-shaped
Grain shape	Grading	close, no opening visible on sawed or broken surface; aggregate not dislodged with fingers or probe; boundary openings frequent, common, rare	Color change from interior surface to matrix
Grain size extreme range observed, mm	Distribution	Width	Interior surface luster like rest of matrix, dull, shining
Median within range _ to _ mm		Empty	Linings in voids absent, rare, common, in most, complete, partial, colorless, colored, silky tufts, hexagonal tablets, gel, other
Textureless (too fine to resolve)		Filled	Underside voids or sheets of voids uncommon, small, common, abundant
Uniform or variable within the piece		Cracks present, absent, result of specimen preparation, preceding specimen preparation	
From piece to piece:		Mineral admixtures[C]	
Intergranular bond		Contamination	
Porosity and absorption[B]		Bleeding	
If concrete breaks through aggregate, through how much of what kind?			
If boundary voids, along what kind of aggregate? All? All of one kind? More than 50 % of one kind? Several kinds?			
Segregation			

[A] Dana, E. S., *Textbook of Mineralogy,* revised by W. E. Ford, John Wiley & Sons, New York, N. Y., 4th ed., 1932, pp. 273–274.

[B] Pore visible to the naked eye, or at × _, or sucks in water that is dropped on it.

[C] Dark solid spheres or hollow-centered spheres of glass, or of magnetite, or some of glass and some of magnetite, recognizable at magnification of × 9 on sawed or broken surfaces. Other mineral admixtures with characteristic particles visible at low magnification are recognizable. Ground surface of concrete containing portland blast-furnace slag cement are unusually white near-free surfaces but retain greenish or blue-greenish patches, and slag particles can be seen with the stereomicroscope or polarizing microscope.

for whom the examination was performed. Supplementary information provided to the petrographer on the concrete and concrete materials, conditions of service, or other features of the concrete construction may be helpful in interpreting the data obtained during the petrographic examinations.

3.5 This practice may form the basis for establishing arrangements between a purchaser of the consulting service and the consulting petrographer. In such cases, the purchaser of the consulting service and the consulting petrographer should together determine the kind, extent, and objectives of the examinations and analyses to be made, and may record their agreement in writing. The agreement may stipulate specific determinations to be made, observations to be reported, funds to be obligated, or a combination of these and other conditions.

4. Purposes of Examination

4.1 Examples of purposes for which petrographic examination of concrete is used are given in 4.2-4.5. The probable usefulness of petrographic examination in specific instances may be determined by discussion with an experienced petrographer of the objectives of the investigation proposed or underway.

4.2 *Concrete from Constructions*:

4.2.1 Determination in detail of the condition of concrete in a construction.

4.2.2 Determination of the causes of inferior quality, distress, or deterioration of concrete in a construction.

4.2.3 Determination of the probable future performance of the concrete.

4.2.4 Determination whether the concrete in a construction was or was not as specified. In this case, other tests may be required in conjunction with petrographic examination.

4.2.5 Description of the cementitious matrix, including qualitative determination of the kind of hydraulic binder used, degree of hydration, degree of carbonation if present, evidence of unsoundness of the cement, presence of a mineral admixture, the nature of the hydration products, adequacy of curing, and unusually high water - cement ratio of the paste.

4.2.6 Determination whether alkali - silica or alkali - carbonate reactions, or cement - aggregate reactions, or reactions between contaminants and the matrix have taken place, and their effects upon the concrete.

4.2.7 Determination whether the concrete has been subjected to and affected by sulfate attack, or other chemical attack, or early freezing, or to other harmful effects of freezing and thawing.

4.2.8 Part of a survey of the safety of a structure for a present or proposed use.

4.2.9 Determination whether concrete subjected to fire is essentially undamaged or moderately or seriously damaged.

4.2.10 Investigation of the performance of the coarse or fine aggregate in the structure, or determination of the composition of the aggregate for comparison with aggregate from approved or specified sources.

4.2.11 Determination of the factors that caused a given concrete to serve satisfactorily in the environment in which it was exposed.

www.technobetar.ir

TABLE 3 Effects of Fire on Characteristics of Concrete

Characteristic	Causes and Effects	Ways of Investigation
Surface hardness	Dehydration to 100°C removes free water; dehydration is essentially complete at 540°C; calcium hydroxide goes to CaO at 450–500°C. Paste expands with thermal coefficient effect and then shrinks, cracks, decrepitates, and becomes soft **(4).**	Beneath the softened concrete, which can be tested in accordance with Test Method C 805, the concrete is probably normal if it has not undergone color change. Establish by coring for compressive tests, by wear tests (CRD-C 52) **(4),** and by scratching with a knife.
Cracking	Perpendicular to the face and internal, where heating or cooling caused excess tensile stresses. In some new concrete, resembles large-scale shrinkage cracking; may penetrate up to 100 mm but may heal autogenously **(4).**	Examination of the surface, ultrasonic tests, coring, petrographic examination **(4).**
Color change—When concrete has not spalled, observe depth of pink color to estimate the fire exposure.	Concrete made with sedimentary or metamorphic aggregates shows permanent color change on heating. Color normal to 230°C; goes from pink to red from 290 to 590°C; from 590 to 900°C color changes to gray and then to buff **(4).** For temperatures up to about 500°C temperature distribution is little affected by using carbonate rather than siliceous aggregate **(5).** At 573°C low quartz inverts to high with 0.85 % increase in volume, producing popouts. Spalling over steel to expose one fourth of the bar at 790°C; white powdered decomposed hydration products at 900°C. Surface crazing about 290°C; deeper cracking about 540°C.	Color change is the factor most useful to the investigator; permits recognizing how deeply a temperature of about 300°C occurred **(5).**
Aggregate behavior—Aggregate behavior affects strength, modulus, spalling, cracking, surface hardness, and residual thermal strains **(4).**	Aggregates differ in thermal diffusivity, conductivity, coefficient of expansion. Heat transmission decreases from concrete made with highly siliceous aggregate, sandstone, traprock, limestone, lightweight aggregates **(4).**	Changes on heating are often accompanied by volume change **(4).**
Spalling	Occurs subparallel to free face; followed by breaking off saucer-like pieces especially at corners and edges **(4).**	
Note: Compressive strength and elastic modulus. For concrete at least 1-year old, strength will increase after cooling from 300°C if design strength was attained **(5).**	Reduction in strength of concrete containing siliceous gravel after heating, then cooling and testing: Heated to Temperature ° C / Reduction, % 180 / 25 370 / 50 570 / 80 Reduction in Modulus Temperature,° C / Reduction, % 200 / 25 430 / 50 760 / 70	Determinations by compressive tests and static modulus of cores; Test Method C 805 for qualitative determination; Test Method C 597 **(4).**

4.2.12 Determination of the presence and nature of surface treatments, such as dry shake applications on concrete floors.

4.3 *Test Specimens from Actual or Simulated Service*—Concrete or mortar specimens that have been subjected to actual or simulated service conditions may be examined for most of the purposes listed under Concrete from Constructions.

4.4 *Concrete Products*:

4.4.1 Petrographic examination can be used in investigation of concrete products of any kind, including masonry units, precast structural units, piling, pipe, and building modules. The products or samples of those submitted for examination may be either from current production, from elements in service in constructions, or from elements that have been subjected to tests or to actual or simulated service conditions.

4.4.2 Determination of features like those listed under concrete from constructions.

4.4.3 Determination of effects of manufacturing processes and variables such as procedures for mixing, molding, demolding, consolidation, curing, and handling.

4.4.4 Determination of effects of use of different concrete-making materials, forming and molding procedures, types and amounts of reinforcement, embedded hardware, etc.

4.5 *Laboratory Specimens*—The purposes of petrographic examination of laboratory specimens of concrete, mortar, or cement paste are, in general, to investigate the effects of the test on the test piece or on one or more of its constituents, to provide examples of the effects of a process, and to provide the petrographer with visual evidence of examples of reactions in paste or mortar or concrete of known materials, proportions, age, and history. Specific purposes include:

4.5.1 To establish whether alkali - silica reaction has taken place, what aggregate constituents were affected, what evidence of the reaction exists, and what were the effects of the reaction on the concrete. The technique in Annex A1 is helpful for identifying locations where alkali-silica gel may be present.

4.5.2 To establish whether one or more alkali - carbonate reactions have taken place, which aggregate constituents were affected and what evidence of the reaction or reactions exists, and the effects of the reaction on the concrete properties.

TABLE 4 Outline for Examination of Concrete in Thin Sections

Coarse and Fine Aggregate	Relict Cement Grains and Hydration Products	Characteristics of Cement Paste
Mineralogy, texture, fabric, variable or homogeneous.	In concrete over 2 years old and normally cured, the only residual cement grains are those that were largest, which may be composed of several constituents or be of alite or belite (substituted C_3S and C_2S). The latter two may be bordered by one or two layers of gel having different indexes of refraction, or by a layer of calcium hydroxide. The largest relict grains may be truly unhydrated and retain the low (dark gray) birefringence of alite in distorted quasihexagonal sections and the visible birefringence to first-order yellow of the lamellar twins in rounded grains of belite. Interstitial aluminoferrite appears as prismatic grains ranging in color from brown to greenish brown to reddish brown and having a high refractive index and pleochroism masked by the color of the grain. Tricalcium aluminate is usually not recognized in thin section because the cubic form is isotropic or because it hydrates early in the hydration history of the concrete forming submicroscopic ettringite or tetracalcium aluminum sulfate hydrate or other tetracalcium aluminum hydrates with or without other anions. These may be visible in voids in older concrete but are best discriminated by X-ray diffraction.	Normal cement paste consists in plane transmitted light of pale tan matter varying somewhat in index of refraction and containing relict unhydrated cement grains. In concrete sectioned at early age or not adequately cured, the paste contains unhydrated cement grains ranging down to a few micrometres in maximum size with an upper limit as large as 100 μm in maximum diameter if the cement was ground in open-circuit mills or was deliberately ground to low surface area to reduce the heat of hydration. With crossed polars, normal paste is black or very dark mottled gray with scattered anhedral poikilitic crystals or small segregations of calcium hydroxide and scattered relict grains of cement. In concrete of high water - cement ratio and siliceous aggregate, the calcium hydroxide crystals are as large as the maximum size of residual cement grains, about 100μ m. In concrete of lower water - cement ratio, higher cement content, and either siliceous or carbonate aggregate, the maximum size of calcium hydroxide crystals is considerably smaller. Regardless of water - cement ratio and type of aggregate, calcium hydroxide crystals occupy space tangential to the undersides of aggregate particles. Where all the aggregate is carbonate rock the maximum size of calcium hydroxide is smaller than in comparable concrete with siliceous aggregate. (Calcium hydroxide is probably epitaxial on calcite.)
Grading; excess or deficiency of sand sizes is to be judged after examination of a series of thin sections. Grain size and nature of internal boundaries in aggregate. Classification of coarse and fine aggregate.	Cements from different sources have different colors of aluminoferrite and the calcium silicates have pale green or yellow or white shades. It should be possible to match cements from one source.	Cement paste in concrete that has been subjected to prolonged acid leaching is low in calcium hydroxide which is present as recrystallized virtually anhedral grains precipitated near the exterior surfaces.
Natural mineral aggregate or crushed stone; natural or manufactured fine aggregate.		In concrete over 2 or 3 years old made with Type I, II, or III cement, some ettringite is to be expected as rosettes in air voids. This is a normal phenomenon; to demonstrate sulfate attack it must be established chemically that the SO_3 content of the concrete is greater than would be supplied by the original sulfate content of the cement. Ettringite in voids is not ettringite that has damaged concrete although it may accompany submicroscopic ettringite in the paste that has damaged the concrete.
Bond with matrix; peripheral cracks inside the borders of aggregate grains; internal cracks. General microfractures if one can establish that they existed before thin-sectioning.		
Alkali - carbonate reactions—If the coarse aggregate is a carbonate rock or rocks, are there rims or partial rims depleted in calcium hydroxide? Partly dolomitic rocks that have reacted sometimes are bordered with paste free from calcium hydroxide along the dolomitic portion while the paste along the limestone portion is normal. See other comments in Column 3.		
Alkali - silica reaction—Does the aggregate contain particles of types known to be reactive (chert, novaculite, acid volcanic glass, cristobalite, tridymite, opal, bottle glass)? If quartzite, metamorphosed subgraywacke, argillite, phyllite, or any of those listed in the sentence above, are there internal cracks inside the periphery of the aggregate? Has the aggregate been gelatinized so that it has pulled off during sectioning leaving only a peripheral hull bonded to the mortar? (This last phenomenon also occurs in concrete with air-cooled slag aggregate, where it indicates reaction between cement and slag.) Cracks that appear to be tensile and to narrow from the center toward the border of the particle are also evidence of alkali - silica reaction **(6).**		

4.5.3 To establish whether any other cement - aggregate reaction has taken place. In addition to alkali - silica and alkali - carbonate reactions, these include hydration of anhydrous sulfates, rehydration of zeolites, wetting of clays and reactions involving solubility, oxidation, sulfates, and sulfides (see Refs **1, 2,** and **3**).[5]

4.5.4 To establish whether an aggregate used in a test has been contaminated by a reactive constituent when in fact the aggregate was not reactive.

4.5.5 To establish the effects of a freezing and thawing test or other physical or mechanical exposure of concrete on the aggregate and the matrix.

4.5.6 To establish the extent of reaction, the nature of reaction products, and effects of reaction produced in exposure to a chemically aggressive environment such as in Test Method C 452 or Test Method C 1012.

4.5.7 To determine the characteristics of moist-cured concrete that has not been subjected to chemical attack or cement - aggregate reaction or freezing and thawing.

4.5.8 By comparison with appropriate laboratory specimens, a petrographer may be able to substantiate the existence of a particular reaction in concrete or determine that the reaction cannot be detected.

5. Apparatus

5.1 The apparatus and supplies employed in making petrographic examinations of hardened concrete depend on the procedures required. The following list includes the equipment generally used. Equipment needed to perform the examinations in Annex A1 is listed therein. Equipment required for field sampling is not listed. Any other useful equipment may be added.

5.2 *For Specimen Preparation*:

5.2.1 *Diamond Saw*—Slabbing saw with an automatic feed and blade large enough to make at least a 7-in. (175-mm) cut in one pass.

[5] The boldface numbers in parentheses refer to the list of references at the end of this practice.

[A] Secondary ettringite can sometimes be recognized by crystal habit and silky luster.
[B] Fly ash can be detected by color and shape when dark spheres are present. In concrete that has not oxidized the presence of slag may be inferred from the green or blue color of the paste.
[C] Ettringite and calcium hydroxide in voids may be recognized by their crystal habits.
[D] Magnesium oxide and calcium oxide should be identifiable in polished section.

5.2.2 *Cutting Lubricant*, for diamond saw.

5.2.3 *Horizontal Lap Wheel or Wheels*, steel, cast iron, or other metal lap, preferably at least 16 in. (400 mm) in diameter, large enough to grind at least a 4 by 6-in. (100 by 152-mm) area.

5.2.4 *Free Abrasive Machine*, using abrasive grit in lubricant, with sample holders rotating on a rotating table. This type of grinding machine greatly increases the speed of preparation of finely ground surfaces.

5.2.5 *Polishing Wheel*, at least 8 in. (200 mm) in diameter and preferably two-speed, or a vibratory polisher.

5.2.6 *Hot Plate or Oven*, thermostatically controlled, to permit drying and impregnating specimens with resin or wax for preparing thin sections, ground surfaces, and polished sections.

5.2.7 *Prospector's Pick or Bricklayer's Hammer*, or both.

5.2.8 *Abrasives*—Silicon carbide grits, No. 100 (150-µm), No. 220 (63-µm), No. 320 (31-µm), No. 600 (16-µm), No. 800

TABLE 6 Secondary Deposits in Concrete[A]

Compound and Mineral Equivalent	Indexes of Refraction	Form and Occurrence
Calcium carbonate ($CaCO_3$); calcite	ω = 1.658 ϵ = 1.486	Fine-grained, white or gray masses or coatings in the cement paste, in voids, along fractures, or on exposed surfaces; very common
Calcium carbonate ($CaCO_3$); aragonite	α = 1.530 β = 1.680 γ = 1.685	Minute, white prisms or needles in voids or fractures in concrete; rare
Calcium carbonate ($CaCO_3$); vaterite	o = 1.544–1.550 E = 1.640–1.650	Spherulitic, form-birefringent, white encrustations on moist-stored laboratory specimens (vaterite A); also identified in sound concrete from structures by X-ray diffraction (α-vaterite); common **(7)**
6-calcium aluminate trisulfate-32 hydrate $\{Ca_6[Al(OH)_6]_2 \cdot 24H_2O\}(SO_4)_3 \cdot 2H_2O$ **(8)**; ettringite	ω = 1.464–1.469[B] ϵ = 1.458–1.462	Fine, white fibers or needles or spherulitic growths in voids, in the cement paste, or in fractures; very common **(1, 7)**
Tetracalcium aluminate monosulfate-12-hydrate ($3CaO \cdot Al_2O_3 \cdot CaSO_4 \cdot 12H_2O$)	ω = 1.504 ϵ = 1.49	White to colorless, minute, hexagonal plates in voids and fractures; very rare **(7)**
Tetracalcium aluminate-13-hydrate ($Ca_4Al_2(OH)_{14} \cdot 6H_2O$)	ω = 1.53 ϵ = 1.52	Micalike, colorless, pseudohexagonal, twinned crystals in voids; very rare **(9)**
Hydrous sodium carbonate ($Na_2O \cdot CO_2 \cdot H_2O$); thermonatrite	α = 1.420 β = 1.506 γ = 1.524	Minute inclusions in alkalic silica gel; rare **(7)**
Hydrated aluminum sulfate ($2Al_2O_3 \cdot SO_3 \cdot 15H_2O$); paraluminite	α = 1.463 ± 0.003 β = 1.471 γ = 1.471	Occurring in cavities in intensely altered concrete; very rare **(9)**
Calcium sulfate dihydrate ($CaSO_4 \cdot 2H_2O$); gypsum	α = 1.521 β = 1.523 γ = 1.530	White to colorless crystals in voids, in the cement paste, or along the surfaces of aggregate particles in concrete or mortar affected by sulfate or seawater attack; unusual
Calcium hydroxide ($Ca(OH)_2$); portlandite	ω = 1.574 ϵ = 1.547	White to colorless, hexagonal plates or tablets in the cement paste, in voids, along fractures; ubiquitous in concrete
Magnesium hydroxide ($Mg(OH)_2$); brucite	ω = 1.559 ϵ = 1.580	White to yellow, fine-grained encrustations and fillings in concrete attacked by magnesian solutions or seawater; unusual **(10, 11)**
Hydrous silica ($SiO_2 \cdot nH_2O$); opal	η = 1.43 varies with water content	White to colorless, finely divided, amorphous; resulting from intense leaching or carbonation of cement paste; unusual in recognizable proportions
Alkalic silica gel ($Na_2O \cdot K_2O \cdot CaO \cdot SiO_2$)	η = 1.46–1.53	White, yellowish, or colorless; viscous, fluid, waxy, rubbery, hard; in voids, fractures, exudations, aggregate; common **(12, 13)**
Hydrated iron oxides ($Fe_2O_3 \cdot nH_2O$); Limonite	opaque or nearly so	Brown stain in fractures and on surfaces; common
Thaumasite $\{Ca_6[Si(OH)_6]_2 \cdot 24H_2O\}(SO_4)_2(CO_3)_2$ **(8)**	ω = 1.504 ϵ = 1.468± 0.002[B]	Prismatic, hexagonal; capable of growing in continuity with ettringite; in sewer pipe subject to sulfate attack, in grout, in some pavement **(14)**
Syngenite $(K_2Ca(SO_4)_2) \cdot H_2O$	α = 1.501 **(15)** β = 1.51 γ = 1.51	Found in cavities and zones peripheral to slate particles, in fibrous form **(16)**
Hydrotalcite $Mg_{3/4}Al_{1/4}(OH)_2(CO_3)_{1/8}(H_2O)_{1/2}$ **(8)**	ω = 1.510 ± 0.003 ϵ = 1.495± 0.003	Foliated platy to fibrous masses **(17, 8)**

[A] The literature and private reports include data on many unidentified secondary compounds in concrete; these are not included in the tabulation. Indexes of refraction of common mineralogic types are taken from standard works on mineralogy.

[B] Higher and lower indexes of refraction have been recorded for naturally occurring ettringite **(15)** and thaumasite **(14)**, but it is not known that the naturally occurring minerals and compounds found in hydrated cement are of the same composition.

(12-µm); optical finishing powders, such as M-303, M-204, M-309; polishing powders as needed.

5.2.9 *Plate-glass Squares*, 12 to 18-in. (300 to 450-mm) on an edge and at least ⅜ in. (10 mm) thick for hand-finishing specimens.

5.2.10 *Suitable Medium or Media*, for impregnating concrete and mounting thin sections plus appropriate solvent. Canada balsam, Lakeside 70 cement, and flexibilized epoxy formulations have been used.

5.2.10.1 **Warning**—Flexibilized epoxies form strong bonds but have higher indexes of refraction than Canada balsam or Lakeside 70 and are toxic. Do not allow to touch the skin; plastic gloves shall be worn, and the work shall be done under a hood so as not to breathe the fumes.

5.2.11 *Microscope Slides*—Clear, noncorrosive, glass approximately 24 mm wide and at least 45 mm long. Thickness may need to be specified to fit some thin section machines.

5.2.12 *Cover Glasses*, noncorrosive and preferably No. 1 (0.18-mm) thickness.

5.3 *For Specimen Examination*:

5.3.1 *Stereomicroscope*, providing magnifications in the range from 7× to 70× or more.

5.3.2 *Dollies*—Small, wheeled dollies with flat tops and with tops curved to hold a section of core assist in manipulating concrete specimens under the stereomicroscope.

5.3.3 *Petrographic Microscope or Polarizing Microscope*, for examinations in transmitted light, with mechanical stage; low-, medium-, and high-power objectives such as 3.5×, 10×,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:39:44 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

and 20 to 25×; 43 to 50× with numerical aperture 0.85 or more; assorted eyepieces having appropriate corrections and magnifications for use with each of the objectives; micrometer eyepiece; condenser adjustable to match numerical aperture of objective with highest numerical aperture to be used; full-wave and quarter-wave compensators, quartz wedge, and other accessories.

5.3.4 *Metallographic Microscope*, with vertical illuminator, mechanical stage, metallographic objectives of low, medium, and high magnification, and appropriate eyepieces to provide a range of magnifications from about 25× to 500×. Reflected polarized light should be available and appropriate compensators provided. Some polarizing microscopes can be equipped with accessories for metallographic examination, if the tube can be raised or the stage lowered to give adequate clearance for the vertical illuminator and the thicker specimens usually employed.

5.3.5 *Eyepiece Micrometer*—Eyepiece micrometers calibrated using a stage micrometer are useful for measuring particles of aggregate, cement grains, calcium hydroxide and other crystals, and crack widths.

5.3.6 *Stage Micrometer*, to calibrate eyepiece micrometers.

5.3.7 *Microscope Lamps*—Many modern polarizing microscopes have built-in illuminators which are convenient and satisfactory if, with the condenser, they can be adjusted to fill the back lens of the objective of highest numerical aperture with light. If the microscope requires a separate illuminator, tungsten ribbon-filament bulbs in suitable adjustable housings are satisfactory. Many kinds of illuminators are available for stereomicroscopes; some can be mounted on the microscope, some stand on their own bases; choice is a question of adequacy of illumination for the tasks intended. Focusable illuminators are preferred.

5.3.8 *Needleholders and Points*—In addition to pin vises and needles from laboratory supply houses, a No. 10 sewing needle mounted in a handle or a selection of insect pins from size 00 to size 4 are useful for prying out reaction products.

5.3.9 *Bottles with Droppers*, for acid, water, and other reagents applied during examination.

5.3.10 *Assorted Forceps*, preferably stainless steel, including fine-pointed watchmaker's forceps.

5.3.11 *Lens Paper*.

5.3.12 *Refractometer, and Immersion Media*, covering the range of refractive indexes from 1.410 to at least 1.785, in steps not larger than 0.005. Stable immersion media, calibrated at a known temperature and of known thermal coefficient, are preferable and should be used in a temperature-controlled room. A thermometer graduated in tenths of a degree Celsius should be used to measure air temperature near the microscope stage so that thermal corrections of refractive index can be made if needed.

6. Selection and Use of Apparatus

6.1 Laboratories should be equipped to provide photographs, photomacrographs, and photomicrographs to illustrate significant features of the concrete. While ordinary microscope lamps are sometimes satisfactory for photomicrography in transmitted and reflected light, lamps providing intense point or field sources, such as tungsten ribbon-filament bulbs, or zirconium or carbon arcs, are highly desirable. For much useful guidance regarding photomicrography, especially using reflected light, see Guide E 883.

6.2 The minimum equipment for petrographic examination of concrete where both specimen preparation and examination are completed within the laboratory consists of a selection of apparatus and supplies for specimen preparation, a stereomicroscope preferably on a large stand so that 6-in. (152-mm) diameter cores can be conveniently examined, a polarizing microscope and accessories, lamps for each microscope, and stable calibrated immersion media of known thermal coefficient. Specimens for petrographic examination may be obtained by sending samples to individuals or firms that offer custom services in preparing thin or polished sections and finely ground surfaces. It is more convenient to prepare specimens in house, and their prompt availability overrides their probably greater cost.

6.3 X-ray diffraction, X-ray emission, differential thermal analysis, thermogravimetric analysis, analytical chemistry, infrared spectroscopy, scanning electron microscopy, energy or wavelength dispersive analysis, and other techniques may be very useful in obtaining quick and definite answers to relevant questions where microscopy will not do so. Some undesirable constituents of concrete, some hydration products of cement, and some reaction products useful in defining the effects of different exposures, and many contaminating materials may not be identified unless techniques that supplement light microscopy are used. (**18, 19**). The uranyl-acetate technique given in Annex A1 can be helpful in locating sites where alkali-silica gel may be present.

7. Samples

7.1 The minimum size of sample should amount to at least one core, preferably 6 in. (152 mm) in diameter and 1 ft (305 mm) long for each mixture or condition or category of concrete, except that in the case of pavement the full depth of pavement shall be sampled with a 4 or 6-in. (102 or 152-mm) core. Broken fragments of concrete are usually of doubtful use in petrographic examination, because the damage to the concrete cannot be clearly identified as a function of the sampling technique or representative of the real condition of the concrete. Cores smaller in diameter than 6 in. can be used if the aggregate is small enough; in deteriorated concrete, core recovery is much poorer with 2⅛-in. (54-mm) diameter core than with 6-in. diameter core. While it is desirable in examination and testing to have a core three times the maximum size of aggregate, this circumstance is a rare occurrence when concrete with aggregate larger than 2 in. is sampled, because of the cost of large bits and the problems of handling large cores.

7.2 *Samples from Constructions*—The most useful samples for petrographic examination of concrete from constructions are diamond-drilled cores with a diameter at least twice (and preferably three times) the maximum size of the coarse aggregate in the concrete. If 6-in. (152-mm) aggregate is used, a core at least 10 in. (250 mm) in diameter is desirable; usually a 6-in. diameter core is the largest provided.

7.2.1 The location and orientation of all cores, including cores or core lengths not sent to the laboratory, should be clearly shown; and each core should be properly labeled. For

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

vertically drilled cores, the elevation or depth at top and bottom of each section should be shown, and core loss and fractures antedating the drilling should be marked. For cores taken horizontally or obliquely, the direction of the vertical plane and the tops and bottoms should be marked. A field log should be provided.

7.2.2 Broken pieces of concrete from extremely deteriorated structures or pieces removed while preparing for repair work are sometimes used for petrographic examination. The samples will be more useful if their original locations in the structure are clearly described or indicated in a sketch or photographs.

7.2.3 The information provided with the samples should include:

7.2.3.1 The location and original orientation of each specimen (see Practice C 823),

7.2.3.2 The mixture proportions of the concrete or concretes,

7.2.3.3 Sources of concrete-making materials and results of tests of samples thereof,

7.2.3.4 Description of mixing, placing, consolidation, and curing methods,

7.2.3.5 Age of the structure, or in case of a structure that required several years to complete, dates of placement of the concrete sampled,

7.2.3.6 Conditions of operation and service exposure,

7.2.3.7 The reason for and objectives of the examination,

7.2.3.8 Symptoms believed to indicate distress or deterioration, and

7.2.3.9 Results of field tests such as measurements of pulse velocity (Test Method C 215), rebound hammer numbers (Test Method C 805) or probe readings (Test Method C 803/C 803M).

7.3 *Samples from Test Specimens from Natural Exposures, Concrete Products, and Laboratory Specimens*:

7.3.1 Information provided should include: materials used, mixture proportions, curing, age of concrete when placed in service or test, orientation in exposure, present age, condition surveys during exposure, characteristics of the natural or laboratory exposure, and method of manufacture of concrete products. Large concrete products may be sampled like constructions; smaller ones may be represented by one or more showing the range of condition from service or fabrication or both.

7.3.2 The exposure of laboratory specimens should be described with test results, age at test and available test results on the aggregates, hydraulic binders, and admixtures used. This information should accompany test specimens from natural exposures and concrete products or samples therefrom, if available.

8. Examination of Samples

8.1 *Choice of Procedures*—Specific techniques and procedures employed in examination of a sample depend on the purpose of the examination and the nature of the sample. Procedures to be used should be chosen after the questions that the examination is intended to answer have been clearly formulated. The procedures should be chosen to answer those questions as unequivocally and as economically as possible. The details that need to be resolved will be dictated by the objectives of the examination and will vary for different situations. Consequently, the selection and location of specimens from the samples submitted for examination should be guided by the objectives of the study. Test Method C 457 should be referred to for those relevant subjects not described here.

8.2 *Visual Examination and Outline of Additional Examination*—A petrographic examination of concrete, mortar, or cement paste should begin with a review of all the available information about the specimen or specimens, followed by a visual examination of each sample. An outline of information that can be obtained is given in Table 1. That study should be followed by an examination using a stereomicroscope (see Table 2 and the section on Visual and Stereomicroscopic Examination). In some cases, further study is unnecessary, and a report can be prepared. In other cases, specimens are chosen during the visual and stereomicroscope examination for further processing and additional stereomicroscope study, more detailed examination using the petrographic or metallographic microscopes or by X-ray diffraction and other instrumental methods, and for other chemical or physical tests. Methods for specimen preparation are outlined in the Specimen Preparation Section. Tables 2-4 summarize characteristics of concrete conveniently observed with stereomicroscopic, petrographic, and metallographic microscopes. Examination using a stereomicroscope is outlined in the Visual and Stereomicroscopic Examination Section. Examination of fire-damaged concrete is outlined in Table 3; using a polarizing microscope in the Polarizing Microscope Examination Section and Table 4; and using a metallographic microscope in the Metallographic Microscope Examination Section. During each kind of study, the petrographer should note specific examinations to be made in detail, later, and may recognize the need to reexamine specimens. Observations possible using different kinds of microscopes are shown in Table 5; properties of some relevant compounds are listed in Table 6. A broad overview of possible locations where alkali-silica gel may be present can be obtained using the uranyl-acetate method outlined in Annex A1.

8.3 *Photography*[6]—It is frequently desirable to maintain a photographic record as illustrations for the report and for future reference. Photographs which may be useful include:

8.3.1 Overlapping close-ups of a core or cores, laid out in sequence, including a dimensional scale. It is convenient to use a view camera at a constant distance using the same lighting in all photographs.

8.3.2 Photographs and photomacrographs of features of interest on a core surface, a ground surface, or an old or new crack surface, at magnifications of 0.7× to 3× are particularly useful if the specimen will be destroyed during subsequent studies. A camera equipped with a long extension bellows and lenses of focal length from 6.5 to 2.9 in. (165 to 74 mm), and a ground-glass back, is desirable.

8.3.3 Photomacrographs at magnifications of at least 3× to 10×, and sometimes at higher magnifications, may be used to illustrate reaction products or growths on the specimen or significant crack patterns. Black and white photographs such as

[6] *Annual Book of ASTM Standards*, Vol 04.02.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

4 by 5 in. (102 by 127 mm) taken at 1× magnification on fine-grained film with a long gray scale, convey a great deal of information and may be more useful than a photograph taken at a higher magnification on smaller format. As a general guide, the subject should be illuminated by oblique lighting at a low angle if the relief on the subject surface is low, and at a higher angle if the relief is high. The object of the oblique illumination is to reveal detail and contrast without obscuring features by long shadows. Details can also be enhanced by the use of colored filters such as Wratten G or other yellow filters. Cross lighting from two sides is sometimes successful in revealing detail and obliterating confusing shadows.

8.3.4 Photomicrographs of thin sections, immersion mounts, and polished sections at magnifications from 2× to an upper limit appropriate to the subject and dependent on the quality of the equipment and the skill of the photographer may be used to illustrate textures, compounds, and crack patterns.

8.3.5 The range of photographic techniques used should be adequate to provide a choice useful for illustrations for the report and for the record. The subjects may usually be selected during the visual and stereomicroscopic examinations.

9. Specimen Preparation

9.1 *Preparation for Visual and Stereomicroscope Examination*:

9.1.1 Diamond-drilled cores, formed or finished surfaces, freshly broken surfaces, or old crack surfaces should be examined in the condition received. It is sometimes helpful to have drilled surfaces and formed and finished surfaces wetted to increase contrast.

9.1.2 Diamond saw cuts should be oriented with relation to significant features of the concrete, either normal to the bedding directions in conventional concrete, or normal to a formed or finished surface, or to a crack or crack system, in order to reveal the structure and fabric of the concrete and the extent of alteration outward from the crack.

9.1.3 It is useful to prepare at least one sawed surface by grinding it with progressively finer abrasives (as described in Test Method C 457) until a smooth matte finish is achieved and to select areas on the matching opposing surface for preparation of thin sections and specimens for optical, chemical, X-ray diffraction, or other examinations.

9.1.4 Specimens obtained by diamond drilling are not ordinarily damaged in the process; however, weak concrete damaged by chemical attack, an alkali - aggregate reaction, freezing and thawing, or several of these, will give poor core recovery with many fractures if it is drilled with a 2⅛-in. or 54-mm bit and barrel while it will give essentially complete recovery if drilled with a 6-in. (152-mm) diameter bit and barrel. This difference is particularly important in petrographic examinations made during condition surveys of old structures. Weakened concrete may also break during sawing. The removal and preparation of specimens for laboratory studies usually involves the application of force and sometimes the application of heat to the specimen.

9.1.5 The effects of force can be minimized during specimen preparation by using thicker slices and making only one cut parallel to the long axis of a core section. Fractured or fragile concrete can be supported by partially or completely encasing it in plaster, epoxy resin, or other reinforcing media before sawing.

9.1.6 Heat used while impregnating concrete with thermoplastic wax or resin will cause cracking if the concrete is heated while it is wet, and will alter the optical properties of some compounds, such as ettringite. Artifacts may therefore be produced and compound identification made difficult. These artifacts may be mistaken as original features. Care must therefore be used in evaluating a particular feature and indexing it as original in the specimen, or produced during the removal of the specimen from the structure or during laboratory processing.

9.1.7 When alkali - carbonate reactions are suspected and rims around crushed carbonate aggregate are seen, it is useful to etch a sawed or ground surface in 6 *N* or weaker hydrochloric acid to see if peripheral rims on coarse aggregate particles are more or less susceptible to etching than the interior of the particle. Since etching destroys the surface, this step should not be taken until all other examinations of the surface have been completed. Etching the ground surface for 30 s in 10 % hydrochloric acid is an appropriate procedure.

9.2 *Preparation of Immersion Mounts*— Immersion mount samples are prepared for examinations using the petrographic microscope. This type of examination provides versatility because materials can be immersed in liquids having different refractive indices. Detailed knowledge of the use of the capabilities of the petrographic microscope is required to properly examine immersion mounts.

9.2.1 Immersion mounts are useful for observing and identifying a variety of aggregate components, residual and relict portland cement particles, the calcium hydroxide component of cement hydration, components of blended cements, mineral admixtures, components resulting from chemical alteration of cementitious components and of aggregates, secondary deposits from exposure of concrete to a variety of chemicals, and for confirming identifications by other methods.

9.2.2 Powders and fine chips for immersion mounts can be prepared by: (1) pulverization of samples from which specimens may be taken; (2) using a sharply pointed probe for removing specimens from small areas of aggregate and paste, material in aggregate sockets, voids, and cracks; and (3) scrapings from fracture and formed surfaces.

9.2.3 In immersion mounts, individual fragments are usually in random orientation so that the identification of principal refractive indices of a material can be determined in addition to data about other optical characteristics. Portions of powdered material, chips, or scraping are placed on a glass slide and immersed in an immersion liquid of known refractive index. A cover slip is used on top of the preparation. Based upon refractive indices and other optical properties, specific identifications can be made of unknown compounds.

9.2.4 Refractive index liquids available provide refractive index values to at least three decimal places (see 5.3.12). Liquids accurate to two decimal places can be used if the petrographer is knowledgeable about Becke line colors or other techniques.

www.technobetar.ir

9.3 *Preparation of Thin Sections*—The detailed description of thin-section preparation is beyond the scope of this practice. There are many laboratories that provide this service if in-house facilities are not available. The procedure includes slicing the concrete into 1⁄16-in. (2-mm) thick wafers if the concrete is strong and thicker slices if it is not. It may be necessary to impregnate the concrete with a resin before slicing to prevent disintegration. Diluted flexibilized epoxy resins or thermoplastic resins have been used successfully. The thin concrete slices are then mounted on glass slides with either flexibilized epoxy, Canada balsam, or Lakeside 70, and ground on laps using progressively finer abrasive until a thickness of 30 µm or less is obtained; thickness not greater than 20 µm is required for detailed examination of the paste in transmitted light. It is usually necessary to check the thickness of the section by the use of birefringent colors of common minerals in the aggregate, such as quartz or feldspar, during the final grinding stages. A cover glass is placed on the cleaned, prepared section and secured with Canada balsam or other media.

9.3.1 Semiautomatic thin-section making machines are available which prepare the original surface of the blank for mounting, trim the excess thickness of the blank after mounting, and grind the section to 50 to 100 µm, leaving little thickness to be removed by hand lapping.

9.4 *Preparation for Examination with the Metallographic Microscope*:

9.4.1 The preparation of specimens for examination with the metallographic microscope is described in Practice E 3.

9.4.2 The procedures described here are intended as guides only. Methods should be used that are appropriate to the varieties of microscopical techniques to be employed, and to specimen condition and composition. It is impossible to provide instructions to suit every possible situation.

9.5 The preparation of the specimens for the uranyl-acetate method given in Annex A1 is provided therein.

10. Visual and Stereomicroscope Examination

10.1 If there is more than one specimen, arrange them in logical order to represent: position in the structure and differences in materials, proportions, and exposure, or combinations of these. Photographs and sketches of significant features should be made before specimens are altered. Tables 1 and 2 list some features to be observed during visual and stereomicroscopic examination.

10.2 *Concrete from Constructions* (Core Log):

10.2.1 Fit fragmented cores together and determine if any pieces are missing. Measure cores to verify field data and prepare a diagramatic log of each core, if necessary. The log should be made to a scale to show relevant features. The log may be used to show fresh and old fractures, reacted particles, reaction products, changes in size or type of coarse and fine aggregates, distribution of coarse aggregate, honeycomb, segregation of components, cold joints or lift or course boundaries, location and direction of steel or other embedded items, changes in color of paste, and other significant features. Notes should be taken and suitably referenced in the log. If cores have been suitably packed so as to preserve the moisture content as drilled (which may or may not be the actual in-place moisture content), specimens should be carefully handled to preserve the moisture content and avoid breakage. Tests that may be made of specimens in the as-received moisture condition include compressive strength, static or dynamic modulus of elasticity, air content by high-pressure meter, permeability, and freezing and thawing.

10.2.2 During the visual examination, general comparison of cores representing different conditions, materials, and extent and nature of deterioration should be made and recorded. The specimens should be sorted into comparable groups based on condition or location of regions designated for more detailed examination. In some cases, during the visual examination or the stereomicroscope examination, one or more specimens from each group may be selected for more detailed studies. If a reduced number of specimens is to be selected for detailed examination, the selection should be made after careful visual and stereomicroscope examinations have been used to define one or more factors that characterize each group.

10.3 *Specimens from Natural Exposures*— These specimens should be laid out in logical order, either by materials, proportions, age, or combinations of these, and compared with respect to composition and condition. Significant features for more detailed examination should be marked and noted. Table 3 shows features of fire-damaged concrete.

10.4 *Concrete Products*:

10.4.1 The samples may consist of complete units when they have relatively small dimensions (such as tile, block, or brick), or portions removed from units by coring or sawing. The samples should be organized and oriented in a manner appropriate to the objectives of the examination. So, for example, portions taken from a single product unit should be grouped together, and each sample should be described by visual observation and measurement of dimensions in relation to markings or labels. The following information should be recorded or clearly marked on the samples: location in the product unit (top, side, end, interior, etc.); vertical and horizontal directions as cast or molded; outer and inner ends; position in the product unit during curing period; position of the sample relative to highly stressed portions of the concrete adjacent to tendon anchorages; and location in the unit as put in place in construction, etc. Sketches or photographs of pertinent features should be recorded to show such conditions as cracking, staining, chemical deposits, presence of foreign matter, segregation, surface defects, and the like.

10.4.2 Procedures such as those set forth in 10.1 and 10.2 are applicable in the examination of concrete products. The investigation may be directed toward features resulting from the specific manufacturing operations involved, such as mixing, molding, demolding, curing, and any prestressing procedures. For example, lack of uniformity might originate in incomplete mixing, improper consolidation during molding, or incomplete or nonuniform curing. Surface defects and poor appearance may result from improper application of form-release agents, possibly giving rise to inhibition of hydration of the cement in a near-surface zone. Features like these can be detected and described by visual and microscopical examination of formed or molded surfaces, sawed and lapped surfaces, or fracture surfaces across the sample.

www.technobetar.ir

10.5 *Laboratory Specimens*—These should be laid out in logical order and compared with respect to composition and condition, and to features influenced or expected to be influenced by the test process.

10.6 *Stereomicroscope Examination*—The stereomicroscope examination reveals additional details at magnifications from 5× to 150× (see Tables 1 and 2). The stereomicroscope examination and visual examination are often carried on alternately. Examinations at low magnifications reveal characteristics of formed, finished, deteriorated, broken, sawed, or ground surfaces. Old cracks may be opened and their surfaces examined to detect reaction products and secondary alteration. Old cracks are frequently of different color than the mass of the concrete, and appear blurred by secondary deposits.

10.6.1 Freshly broken surfaces may follow structural weaknesses and reveal significant features that have not been masked by secondary alteration.

10.6.2 Sawed and ground surfaces are examined to detect fine cracks and trace networks of cracks that are not perceptible on drilled or sawed surfaces, to examine filling and partial filling in voids and cracks, and to detect rims on aggregate particles that may indicate chemical reactions between the cement and the aggregate. Rims on gravel or natural sand should be presumed to be a result of weathering in the deposit, unless samples of aggregates used are available and show that rims were not present before the aggregate was used in the concrete. Rims produced in the concrete on particles of sand and gravel are absent or relatively thin and faint at locations where the particle is in contact with an air void. Rims produced by weathering may mask rims produced by alkali - silica reaction. Rimmed crushed stone in concrete usually indicates alteration in the concrete, as alkali - silica reaction or alkali - carbonate reaction (**12, 20, 21**). Pale rims in mortar bordering coarse aggregate (**7, 19**) and pale areas in the mortar may be gel-soaked paste (**6**) or highly carbonated paste adjoining carbonate aggregate that has undergone an alkali - carbonate reaction. The method in Annex A1 is helpful in locating deposits of alkali-silica gel.

10.6.3 Deposits in old cracks may include calcite or ettringite or calcium hydroxide, or combinations of these compounds, or more unusual crystalline substances, but sometimes include sand, silt, clay, and freshwater or saltwater organisms. Such organisms may provide evidence that a part of a structure that is not ordinarily submerged has been submerged.

10.6.4 Quantitative determination of constituents of concrete can be made by microscopical point-count or linear-traverse procedures in general accord with the requirements of Test Method C 457. A total analysis may include the proportional amounts of coarse aggregate, fine aggregate, cementitious matrix, and air voids. The differentiation of coarse and fine aggregate is not accurate unless the two fractions are distinguishable lithologically, since the maximum dimension of the particles usually is not intersected by the prepared surface. Likewise, the proportion of individual rock types can be determined quantitatively by these methods, such as, the content of unsound or reactive constituents in the coarse or fine aggregate or both; proportions of lightweight and normal weight aggregate; and the abundance of granular contaminating substances.

11. Petrographic Microscope Examination

11.1 *Characteristics of Good Concrete Thin Sections*—Features that characterize good, thin sections of concrete or mortar are as follows: the mounted lower surface is free of abrasive and has been ground to a smooth matte finish ordinarily obtained by finishing the surface with optical alumina or equivalent; the lower surface of the blank is entire; air voids have complete peripheries; there is a sharp boundary between the void and surrounding mortar; deposits in voids are preserved; and aggregate that has been observed under the stereomicroscope to be entire when the blank was selected has remained entire and microfractures have not been produced in micro fsectioning. It is very difficult to avoid production of micro fsectioning when the aggregate is principally quartzite and quartz, if it is desired to reduce the section to a thickness of 30 µm so that the brightest birefringence color of quartz is first-order white. Some cracks will be formed and some loss of paste which is softer than quartz aggregate will occur.

11.1.1 The desirable thickness of the thin sections ranges from about 40 to 20 µm. Thinner sections may be required for detailed examination of the cement paste matrix. It is sometimes necessary to give up normal thickness and use a thicker section to preserve fragile deposits in voids such as alkali - silica gel, ettringite, calcium hydroxide, calcite, aragonite, or thaumasite. When it is desired to preserve the contacts between mortar and coarse aggregate, it may be preferable to leave the section thicker than normal with the highest birefringence color of the quartz pale first-order yellow. In normal concrete, the material bordering the aggregate consists of amorphous cement gel, with calcium hydroxide crystals quite evenly distributed but with slight concentrations along the undersides of coarse aggregate and fine aggregate, if the section is cut parallel to the placement direction. In cases of alkali - silica reaction, there is usually a zone depleted in or free of calcium hydroxide surrounding reacted aggregate particles; sometimes gel is present surrounding the aggregate or soaking the paste so that it is completely dark with crossed polars and brown grading hazily to more normal paste in plane polarized light. It is fairly easy to recognize gel-soaked paste; it is possible with experience to recognize depleted calcium hydroxide around a reacted aggregate particle, so long as the fine aggregate or any crusher dust present does not contain much colorless mica. Thin flakes of muscovite can be confused with thin tablets of calcium hydroxide when both are viewed on edge; they can be distinguished if the higher index of the mica is observed.

11.1.2 It is sometimes preferable to lose part of the section or crack the quartz in order to distinguish among quartz (birefringence 0.009), calcium hydroxide (birefringence 0.027), and calcite (birefringence 0.172). When the three materials occur together, the quartz particles will be shaped like sand grains or rock fragments, while calcium hydroxide will be present either as tablets tangential to aggregate or as poikilitic crystals in the paste enclosing residual cement grains or areas of gel. The birefringence of calcium hydroxide is three times that of quartz; the birefringence of calcite is 6.4 times

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:39:44 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

that of calcium hydroxide; and birefringence of aragonite is 5.7 times that of calcium hydroxide. While aragonite is fairly uncommon in concrete, calcite is common as a product of carbonation and as an ingredient of aggregate. At normal thickness of 30 µm, the highest birefringence of calcium hydroxide viewed parallel to the cleavage is bright first-order yellow with an occasional orange or first-order red area. Calcite in the same section has high-order white birefringence except in very minute grains in which it is very thin, approximately rhombic in shape, and the birefringence color is first-order white. The birefringence relations discussed in this paragraph are the basis that makes possible much of the interpretation of concrete thin sections.

11.2 *Choice of Areas for Thin Sections of Concrete*—Areas from which thin sections are to be prepared usually should be chosen after examining the sawed or sawed and ground surface with a stereomicroscope. Selection of the area may depend on the features to which the examination is directed, or the choice may be affected in the case of highly deteriorated concrete by the desire to choose a volume strong enough to endure sectioning even after impregnation. In that second case, an area of mortar with coarse aggregate at the corners or along the sides may be the successful choice. If it is desired to examine the aggregate to compare it with aggregate of a known source to establish whether the two probably came from the same deposit or quarry, coarse aggregate should be chosen in sufficient number to cover the range of varieties present and their physical condition. If the concrete has been subjected to alkali - silica or alkali - carbonate reactions, areas selected for sectioning should include coarse aggregate with cracks inside the periphery but surrounding the center and cracks in the middle of the particle which narrow toward the border which may or may not contain gel in the case of alkali - silica reaction. Reaction-rimmed particles may be chosen for sectioning in the case of either kind of reaction, but it is ordinarily a futile effort; the rims distinct to the naked eye or the low power of the stereomicroscope may not be visible in thin section.

11.2.1 Features visible in the examination of thin sections of concrete are shown in Table 4.

12. Paste Features

12.1 Many physical and mineralogical properties of the paste are influenced, or are in part governed by, *w/c* and *w/cm*, extent of curing, fineness and composition of the portland cement and other cementitious materials, pozzolans, mineral and chemical admixtures, and fine material from aggregates. Among these properties, with respect to the evaluation of unaltered paste, are: (a) color, hardness density, and porosity **(22, 23, 24, 25)**; (b) texture of fracture surfaces **(22, 23)**; (c) size, abundance, color, and mineralogy of non-pozzolanic, and residual and relict pozzolanic and cementitious materials **(22, 23, 24, 26)**; (d) size, abundance, and morphology of the calcium hydroxide component of cement hydration as may be affected by pozzolanic materials **(22, 23, 26)**; (e) degree of hydration of cementitious materials **(22, 23, 24, 25, 26, 27, 28)**; (f) color intensity of dye-impregnated pastes **(24,26)**; (g) nature of aggregate-paste bond; (h) rate of absorption of water droplets **(24)**; (i) depth of carbonation **(23)**; (j) magnitude of bleeding and segregation of concrete-making components **(23, 27)**; and (k) paste micro hardness **(25)**.

12.2 The *w/c* and *w/cm* and their uniform distribution throughout concrete may be affected by a number of influences that include: (a) the amount of original water, free water introduced by aggregates, and tempering and retempering water; (b) absorption of water by aggregates; (c) efficiency of mixing batch water and free water from aggregates; (d) bleeding and vibration after concrete placement; and (e) water lost due to evaporation and to absorption by the subbase.

12.3 Because of the variable nature of pastes, age of pastes, and exposure to a variety of external influences, there is no generally accepted standard procedure that employs microscopical methods for determining the *w/c* or *w/cm* of hardened concrete. A procedure for estimating *w/c* and *w/cm* **(29)** was critically evaluated in a SHRP study, but was not recommended by SHRP for inclusion in Practice C 856.

13. Report

13.1 The report of the examination should include the following:

13.1.1 Location and orientation of the samples in the construction or products or type of specimen,

13.1.2 History of the samples insofar as is available,

13.1.3 Physical and chemical tests made on the samples, with their results,

13.1.4 Description of the samples and a report on mixture proportions, if available or if estimated, workmanship, construction practice, and original quality of the concrete in the constructions, insofar as such information is available, and

13.1.5 Interpretation, insofar as possible, of the nature of the materials and the chemical and physical events that have led to the success or distress of the concrete.

14. Keywords

14.1 aggregates; air voids; alkali-silica reaction; analysis; deterioration; examination; fire effects; hardened concrete; microscopy; paste; petrographic; secondary deposits

ANNEX

(Mandatory Information)

A1. A TECHNIQUE FOR DETECTING ALKALI-SILICA GEL SUBJECT TO CONFIRMATION BY OTHER METHODS

A1.1 Scope

A1.1.1 This technique has been used for detecting alkali-silica gel resulting from reactions of forms of silica in aggregates with alkalies in portland-cement paste. The technique involves treating the surface of conditioned concrete with a solution of uranyl-acetate and observing the treated surface exposed to short-wave ultraviolet light.

A1.1.2 This technique is one of a number of procedures that may be used to identify if alkali-silica reactions have occurred in hardened concrete. The test is ancillary to more definitive petrographic examinations and physical tests for determining concrete expansion. The petrographic examinations include identification of alkali-silica gel and the reactive aggregate component(s), as may be supplemented by electron microscopy and ancillary elemental probe analysis. The physical tests may include length change tests of prisms from the concrete.

A1.1.3 Fly ash, silica fume, and other materials that possess pozzolanic properties can react and produce secondary products similar to the gel produced by alkali-silica reaction (ASR). If these products are uniformly distributed, their effect is to create a uniform background on which the more localized and concentrated alkali-silica gel usually can be distinguished. Opal-containing materials and possibly other components of rocks, however, will also be detected. Localized concentrations of secondary ettringite have also been reported to fluoresce. Secondary ettringite is widespread as a component of concrete affected by many processes.

A1.2 Cautions

A1.2.1 Uranyl-acetate is a hazardous material that requires special handling and disposition. Ultraviolet light is hazardous to eyes and skin. Annex A1 does not address the safety problems of handling, use, and disposition of uranyl-acetate and uranyl-acetate-treated concrete. Annex A1 does not address the use and all cautions to be used regarding ultraviolet light applications and exposure to the eyes and skin.

A1.2.2 Before using uranyl-acetate and ultraviolet light involved in this technique, it is the responsibility of the user to establish adequate safety, health, and disposition of materials practices and procedures for handling uranyl-acetate and ultraviolet radiation. It is also the responsibility of the user to conform to all local, state, and federal regulatory requirements.

A1.2.3 Protective clothing, including polyethylene gloves, laboratory coat, and other clothing as may be needed should be used when handling uranyl-acetate and other chemicals.

A1.2.4 Short-wave ultraviolet light can be harmful to the eyes and skin. Ultraviolet-filtering goggles or face shields that will absorb the ultraviolet radiation should be used.

A1.2.5 Uranyl-acetate is classed by the United States Government as a hazardous material requiring special handling and disposition. Handling, storage, and disposition of the uranyl-acetate solution and materials to which it is applied and contacts must be in conformance to applicable regulations.

A1.3 Qualification

A1.3.1 This technique can be used by an adequately trained technician.

A1.4 Apparatus, Reagents, and Materials

A1.4.1 *Specimen Conditioning Apparatus*:

A1.4.1.1 *Plastic Beaker*— 500-mL capacity or larger,

A1.4.1.2 *Plastic Squeeze Bottle (for Water)*—Nominal 250-mL capacity,

A1.4.1.3 *Disposable Polyethylene Gloves*,

A1.4.1.4 *Protective Clothing* (for example, laboratory coat),

A1.4.1.5 *Absorbent Paper Towels*, and

A1.4.1.6 *Enclosed Space for Applying the Reagent*—A fume hood, glove box, or disposable glove bags have been found to be suitable for this purpose.

A1.4.2 *Specimen Treatment Apparatus*:

A1.4.2.1 *Non-Atomized or Non-Misting Type Applicator Unit for Reagent* (for example, a small, hand-held squeeze bottle for applying dilute reagent solutions), and

A1.4.2.2 *Applicator for Water*—A small hand-held squeeze bottle for applying dilute solutions.

A1.4.3 *Reagent (Uranyl-Acetate Solution)*,

A1.4.3.1 *Acetic Acid Solution (1N)*,

A1.4.3.2 *Boiling Flask*— Nominal 250-mL capacity,

A1.4.3.3 *Distilled or Deionized Water*,

A1.4.3.4 *Volumetric Flask*—Nominal 100-mL capacity,

A1.4.3.5 *Polyethylene Storage Bottle with Tight Fitting Cap*—Nominal 100-mL capacity,

A1.4.3.6 *Uranyl-Acetate Powder (ACS Reagent Grade)*,

A1.4.3.7 *Balance*—Capable of weighing up to 10 g within 0.05 g, and

A1.4.3.8 *Uranyl-Acetate Solution (prepared as follows)*—Weigh 5 g of powdered uranyl-acetate. Measure 100 mL of acetic acid solution using a 100-mL volumetric flask. (**Warning**—Use proper safety precautions in handling the uranyl-acetate and the acetic acid. Transfer the measured acetic acid solution from the volumetric flask to the boiling flask. Add 5 g of powdered uranyl-acetate to the boiling flask. Warm the mixture over a low flame until the powder is dissolved. Do not bring the mixture to a rolling boil. Remove the flask from the burner, cover, and let it cool to room temperature. Store the cooled solution at room temperature in a tightly capped polyethylene storage bottle. The reagent, when stored as described, will keep for at least one year.)

A1.4.4 *Short-Wave (254-nm) Ultraviolet (UV) Lamp*,

A1.4.5 *Viewing Cabinet or a Dark Room*, and

A1.4.6 *Goggles*—for shielding short-wave ultraviolet light.

A1.5 Specimens

A1.5.1 Samples to be evaluated can be of any size or shape. The surface area for testing should have a nominal area of 155 cm^2 (24 $in.^2$) or sufficiently large to be representative of the concrete. The size will be dictated in part by the maximum size of the aggregate. The method is applicable to field and laboratory-prepared samples. The latter includes samples tested using Test Methods C 227, C 342, C 441, and C 1260.

A1.5.2 Break the specimen to expose the interior of the concrete using any suitable method, such as the splitting techniques of Test Method C 496. Immediately conduct the test on the freshly exposed surfaces.

A1.6 Conditioning and Pre-Screening Procedure

A1.6.1 *Conditioning and Pre-Screening*:

A1.6.1.1 Dampen the freshly broken specimen surface using the squeeze bottle filled with distilled or deionized water. Proceed with the test while the specimen is still damp.

A1.6.2 Pre-screen the specimen for natural fluorescence.

A1.6.2.1 Wear protective clothing including polyethylene gloves, laboratory coat, and UV-filtering goggles. Short-wave UV light can be harmful to the eyes and skin. Normal eyeglasses or plastic goggles or face shield will absorb the harmful rays.

A1.6.2.2 If a viewing cabinet is being used, place the UV lamp in the proper place on the viewing cabinet. Place the damp specimen inside the viewing cabinet. If a darkened room is being used, place the damp specimen on the table and turn off the lights.

A1.6.2.3 Turn on the short-wave UV light in the viewing cabinet or the darkened room, and shine it on the damp specimen. Use UV-filtering goggles and observe and note for future comparison whether any of the aggregates or other components fluoresce. Non-fluorescent aggregates will appear dark, while cement paste and naturally fluorescent aggregates, such as opal and some slags, will fluoresce mildly. Note the location and nature of any fluorescence.

A1.7 Uranyl-Acetate Treatment Procedure:

A1.7.1 Wear protective clothing including polyethylene gloves, laboratory coat, and UV filtering goggles.

A1.7.2 The test should be conducted only on freshly fractured interior surfaces. If the interior surface of the specimen is not damp, dampen it using the squeeze bottle filled with distilled or deionized water.

A1.7.3 Fill the squeeze bottle to about half its capacity with the prepared uranyl-acetate solution.

A1.7.4 Line the bottom of the glove box, glove bag, or fume hood with absorbent paper towels. Place the squeeze bottles containing the distilled or deionized water and reagent, the 500-mL plastic beaker, and the dampened specimen inside the glove box, glove bag, or fume hood.

A1.7.5 Place the specimen in a horizontal position on a paper towel. Apply the uranyl-acetate solution to the wet interior surface of the specimen. Direct the squeeze bottle nozzle on the specimen surface at all times. The nozzle should be kept approximately 25 mm (1 in.) away from the surface. The bottle pressure should be kept to a minimum to avoid misting and rebound from the specimen surface.

A1.7.6 Allow the uranyl-acetate to absorb on the interior surface of the concrete for 1 min.

A1.7.7 After 1 min, hold the specimen in a vertical position over the 500-mL plastic beaker and wash the treated surface three times with distilled or deionized water to remove excess uranyl-acetate. Collect the wash water from the specimen in the plastic beaker.

A1.7.8 Remove the specimen from the glove box, glove bag, or fume hood, and place it on a paper towel. Proceed with observation of the specimen immediately after the uranyl-acetate treatment is completed.

A1.8 Ultraviolet Exposure of Treated Surface

A1.8.1 If a viewing cabinet is being used, place the UV lamp at the proper place in the viewing cabinet. Line the bottom surface of the viewing cabinet with paper towels. If a dark room is being used, line an area of a table top with paper towels.

A1.8.2 Dampen the specimen again using the squeeze bottle filled with distilled or deionized water. Place the specimen inside the viewing cabinet on the paper towel. If a dark room is being used, place the wet specimen on the paper towel on the table top in the dark room and turn off the lights.

A1.8.3 Shine the UV light on the treated surface. Do not view, and do not allow anyone to view the UV light without eye protection.

A1.9 Identification of Alkali-Silica Gel

A1.9.1 Alkali-silica gel will fluoresce bright greenish-yellow, and usually occurs in and around aggregate particles, in voids, and in cracks. It has been reported that ettringite may similarly fluoresce.

A1.9.2 Carbonated areas of concrete also may fluoresce. The fluorescence due to carbonation products, however, is usually uniform and normally present along concrete surfaces exposed to the atmosphere. Carbonation may also be present where there is extensive deterioration or cracks, or both, which allow atmospheric carbon dioxide into the interior of the specimen.

A1.9.3 Some fly ash, silica fume, slag, and natural pozzolans can react and form reaction products that fluoresce. Well dispersed fly ash and silica fume and fine ground slag and natural pozzolans, however, cause only an increase in the generally uniform background fluorescence intensity of the paste. If these materials are not well dispersed or are clumped together, the fluorescence will be observed as discrete fine areas. The size of these areas is normally very small and usually is distinguishable from the bright fluorescence of gel derived from the coarse and fine aggregates.

A1.9.4 Identification of the presence of alkali-silica gel using this technique must be confirmed by other petrographic techniques, such as microscopical examinations of thin sections or powder mounts, or both.

A1.9.5 Literature on the development and use of this technique is given in Refs **(31-37)**.

Designation: C 869 – 91 (Reapproved 2006)

Standard Specification for Foaming Agents Used in Making Preformed Foam for Cellular Concrete[1]

This standard is issued under the fixed designation C 869; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers foaming agents specifically formulated for making preformed foam for use in the production of cellular concrete.

1.2 The function of this specification is to provide the means for evaluating the performance of a specific foaming agent. This is accomplished by using the foaming agent in making a standard cellular concrete test batch (see Test Method C 796) from which test specimens are cast. Then, significant properties of the concrete are determined by tests and compared with the requirements of Section 3.

1.3 The values stated in inch-pound units are to be regarded as the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 796 Test Method for Foaming Agents for Use in Producing Cellular Concrete Using Preformed Foam

3. Performance Requirements

3.1 The test batch shall conform to the requirements prescribed in Table 1.

TABLE 1 Physical Requirements

Property	Requirement
Density—The density shall satisfy either of the following:	
Density after pumping (see Test Method C 796)	40 ± 3 lb/ft^3 (641 ± 48 kg/m^3)
Oven dry density[A] (see Test Method C 796)	
For Type I cement	30.4 ± 2.5 lb/ft^3 (487± 40 kg/m^3)
For Type III cement	29.3 ± 2.5 lb/ft^3 (469± 40 kg/m^3)
Compressive Strength (see Test Method C 796), min	200 psi (1.4 MPa)
Tensile Splitting Strength (see Test Method C 796), min	25 psi (0.17 MPa)
Water Absorption (see Test Method C 796), max	25 % by volume
Loss of Air During Pumping(see Test Method C 796), max[B]	4.5 % by volume

[A] For this comparison, the calculated oven-dry density of the test batch may be determined by assuming that the water of hydration is 20 % of the weight of the cement. Then the oven−dry density $= \frac{W_c + (0.2\ W_c)}{V_{batch}}$, where W_c = weight of cement; and V_{batch} = volume of batch.

For example: using the test batch specified in Test Method C 796, for Type I cement (W_c = 100 lb; W_{TW}/W_c = 0.58, where W_{TW} = total weight of water), the total weight of materials is 100 + 0.58 × 100 = 158 lb (71.67 kg). For a wet density, after pumping, of 40 lb/ft^3(641 kg/m^3), the batch volume is 158/40 = 3.95 ft $_3$(0.11185 m^3). The calculated oven dry density is then (100 + 0.2 × 100)/3.95 = 30.4 lb/ft^3 or (45.36 + 0.2 × 45.36)/0.11185 = 487 kg/m^3. Finally, the oven-dry density as determined by Test Method C 796 shall be 30.4 ± 2.5 lb/ft^3 (487 ± 40 kg/m^3).

[B] The loss of air during pumping includes air that is accidently entrapped during mixing of the concrete.

4. Test Methods

4.1 The foaming agent being tested shall be used in making the test specimens required.

4.2 For each of the properties listed in Table 1, the test procedure, the number and type of test specimens, and the method of molding, curing, and testing shall be as described in Test Method C 796.

5. Keywords

5.1 cellular concrete; foaming agents

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates, and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

Current edition approved July 1, 2006. Published August 2006. Originally approved in 1977. Last previous edition approved in 1999 as C 869 – 91 (1999).

Designation: C 869 – 91 (Reapproved 2006)

Standard Specification for Foaming Agents Used in Making Preformed Foam for Cellular Concrete[1]

This standard is issued under the fixed designation C 869; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers foaming agents specifically formulated for making preformed foam for use in the production of cellular concrete.

1.2 The function of this specification is to provide the means for evaluating the performance of a specific foaming agent. This is accomplished by using the foaming agent in making a standard cellular concrete test batch (see Test Method C 796) from which test specimens are cast. Then, significant properties of the concrete are determined by tests and compared with the requirements of Section 3.

1.3 The values stated in inch-pound units are to be regarded as the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 796 Test Method for Foaming Agents for Use in Producing Cellular Concrete Using Preformed Foam

3. Performance Requirements

3.1 The test batch shall conform to the requirements prescribed in Table 1.

TABLE 1 Physical Requirements

Property	Requirement
Density—The density shall satisfy either of the following:	
Density after pumping (see Test Method C 796)	40 ± 3 lb/ft^3 (641 ± 48 kg/m^3)
Oven dry density[A] (see Test Method C 796)	
For Type I cement	30.4 ± 2.5 lb/ft^3 (487± 40 kg/m^3)
For Type III cement	29.3 ± 2.5 lb/ft^3 (469± 40 kg/m^3)
Compressive Strength (see Test Method C 796), min	200 psi (1.4 MPa)
Tensile Splitting Strength (see Test Method C 796), min	25 psi (0.17 MPa)
Water Absorption (see Test Method C 796), max	25 % by volume
Loss of Air During Pumping(see Test Method C 796), max[B]	4.5 % by volume

[A] For this comparison, the calculated oven-dry density of the test batch may be determined by assuming that the water of hydration is 20 % of the weight of the cement. Then the oven−dry density $= \frac{W_c + (0.2\ W_c)}{V_{batch}}$, where W_c = weight of cement; and V_{batch} = volume of batch.

For example: using the test batch specified in Test Method C 796, for Type I cement (W_c = 100 lb; W_{TW}/W_c = 0.58, where W_{TW} = total weight of water), the total weight of materials is 100 + 0.58 × 100 = 158 lb (71.67 kg). For a wet density, after pumping, of 40 lb/ft^3(641 kg/m^3), the batch volume is 158/40 = 3.95 ft$_3$(0.11185 m^3). The calculated oven dry density is then (100 + 0.2 × 100)/3.95 = 30.4 lb/ft^3 or (45.36 + 0.2 × 45.36)/0.11185 = 487 kg/m^3. Finally, the oven-dry density as determined by Test Method C 796 shall be 30.4 ± 2.5 lb/ft^3 (487 ± 40 kg/m^3).

[B] The loss of air during pumping includes air that is accidently entrapped during mixing of the concrete.

4. Test Methods

4.1 The foaming agent being tested shall be used in making the test specimens required.

4.2 For each of the properties listed in Table 1, the test procedure, the number and type of test specimens, and the method of molding, curing, and testing shall be as described in Test Method C 796.

5. Keywords

5.1 cellular concrete; foaming agents

Designation: C 869 – 91 (Reapproved 2006)

Standard Specification for Foaming Agents Used in Making Preformed Foam for Cellular Concrete[1]

This standard is issued under the fixed designation C 869; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers foaming agents specifically formulated for making preformed foam for use in the production of cellular concrete.

1.2 The function of this specification is to provide the means for evaluating the performance of a specific foaming agent. This is accomplished by using the foaming agent in making a standard cellular concrete test batch (see Test Method C 796) from which test specimens are cast. Then, significant properties of the concrete are determined by tests and compared with the requirements of Section 3.

1.3 The values stated in inch-pound units are to be regarded as the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 796 Test Method for Foaming Agents for Use in Producing Cellular Concrete Using Preformed Foam

3. Performance Requirements

3.1 The test batch shall conform to the requirements prescribed in Table 1.

TABLE 1 Physical Requirements

Property	Requirement
Density—The density shall satisfy either of the following:	
Density after pumping (see Test Method C 796)	40 ± 3 lb/ft^3 (641 ± 48 kg/m^3)
Oven dry density[A] (see Test Method C 796)	
For Type I cement	30.4 ± 2.5 lb/ft^3 (487± 40 kg/m^3)
For Type III cement	29.3 ± 2.5 lb/ft^3 (469± 40 kg/m^3)
Compressive Strength (see Test Method C 796), min	200 psi (1.4 MPa)
Tensile Splitting Strength (see Test Method C 796), min	25 psi (0.17 MPa)
Water Absorption (see Test Method C 796), max	25 % by volume
Loss of Air During Pumping(see Test Method C 796), max[B]	4.5 % by volume

[A] For this comparison, the calculated oven-dry density of the test batch may be determined by assuming that the water of hydration is 20 % of the weight of the cement. Then the oven−dry density $= \frac{W_c + (0.2\ W_c)}{V_{batch}}$, where W_c = weight of cement; and V_{batch} = volume of batch.

For example: using the test batch specified in Test Method C 796, for Type I cement (W_c = 100 lb; W_{TW}/W_c = 0.58, where W_{TW} = total weight of water), the total weight of materials is 100 + 0.58 × 100 = 158 lb (71.67 kg). For a wet density, after pumping, of 40 lb/ft^3(641 kg/m^3), the batch volume is 158/40 = 3.95 ft$_3$(0.11185 m^3). The calculated oven dry density is then (100 + 0.2 × 100)/3.95 = 30.4 lb/ft^3 or (45.36 + 0.2 × 45.36)/0.11185 = 487 kg/m^3. Finally, the oven-dry density as determined by Test Method C 796 shall be 30.4 ± 2.5 lb/ft^3 (487 ± 40 kg/m^3).

[B] The loss of air during pumping includes air that is accidently entrapped during mixing of the concrete.

4. Test Methods

4.1 The foaming agent being tested shall be used in making the test specimens required.

4.2 For each of the properties listed in Table 1, the test procedure, the number and type of test specimens, and the method of molding, curing, and testing shall be as described in Test Method C 796.

Designation: C 873/C 873M – 04$^{\epsilon 1}$

Standard Test Method for Compressive Strength of Concrete Cylinders Cast in Place in Cylindrical Molds[1]

This standard is issued under the fixed designation C 873/C 873M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

ε[1] NOTE—The designation was changed editorially to agree with the existing values statement in the Scope in March 2008.

1. Scope*

1.1 This test method covers the determination of strength of cylindrical concrete specimens that have been molded in place using special molds attached to formwork. This test method is limited to use in slabs where the depth of concrete is from 5 to 12 in. [125 to 300 mm].

1.2 The values stated in either inch-pounds or SI units shall be regarded separately as standard. SI units are shown in brackets. The values stated may not be exact equivalents, therefore each system must be used independently of the other. Combining values of the two units may result in nonconformance.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 470/C 470M Specification for Molds for Forming Concrete Test Cylinders Vertically

C 617 Practice for Capping Cylindrical Concrete Specimens

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Summary of Test Method

3.1 A concrete cylinder mold assembly consisting of a mold and a tubular support member is fastened within the concrete formwork prior to placement of the concrete as shown in Fig. 1. The elevation of the mold upper edge is adjusted to correspond to the plane of the finished slab surface. The mold support prevents direct contact of the slab concrete with the outside of the mold and permits its easy removal from the hardened concrete. The mold is filled at the time its location is reached in the normal course of concrete placement. The specimen in the "cured-in-place" condition is removed from its in-place location immediately prior to de-molding, capping, and testing. The reported compressive strength is corrected on the basis of specimen length-diameter ratio using correction factors provided in the section on calculation of Test Method C 42/C 42M.

4. Significance and Use

4.1 Cast-in-place cylinder strength relates to the strength of concrete in the structure due to the similarity of curing conditions since the cylinder is cured within the slab. However, due to differences in moisture condition, degree of consolidation, specimen size, and length-diameter ratio, there is not a constant relationship between the strength of cast-in-place cylinders and cores. When cores can be drilled undamaged and tested in the same moisture condition as the cast-in-place cylinders, the strength of the cylinders can be expected to be on average 10 % higher than the cores at ages up to 91 days for specimens of the same size and length-diameter ratio.[4]

4.2 Strength of cast-in-place cylinders may be used for various purposes, such as estimating the load-bearing capacity

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved June 1, 2004. Published July 2004. Originally approved in 1977. Last previous edition approved in 1999 as C 873 – 99.

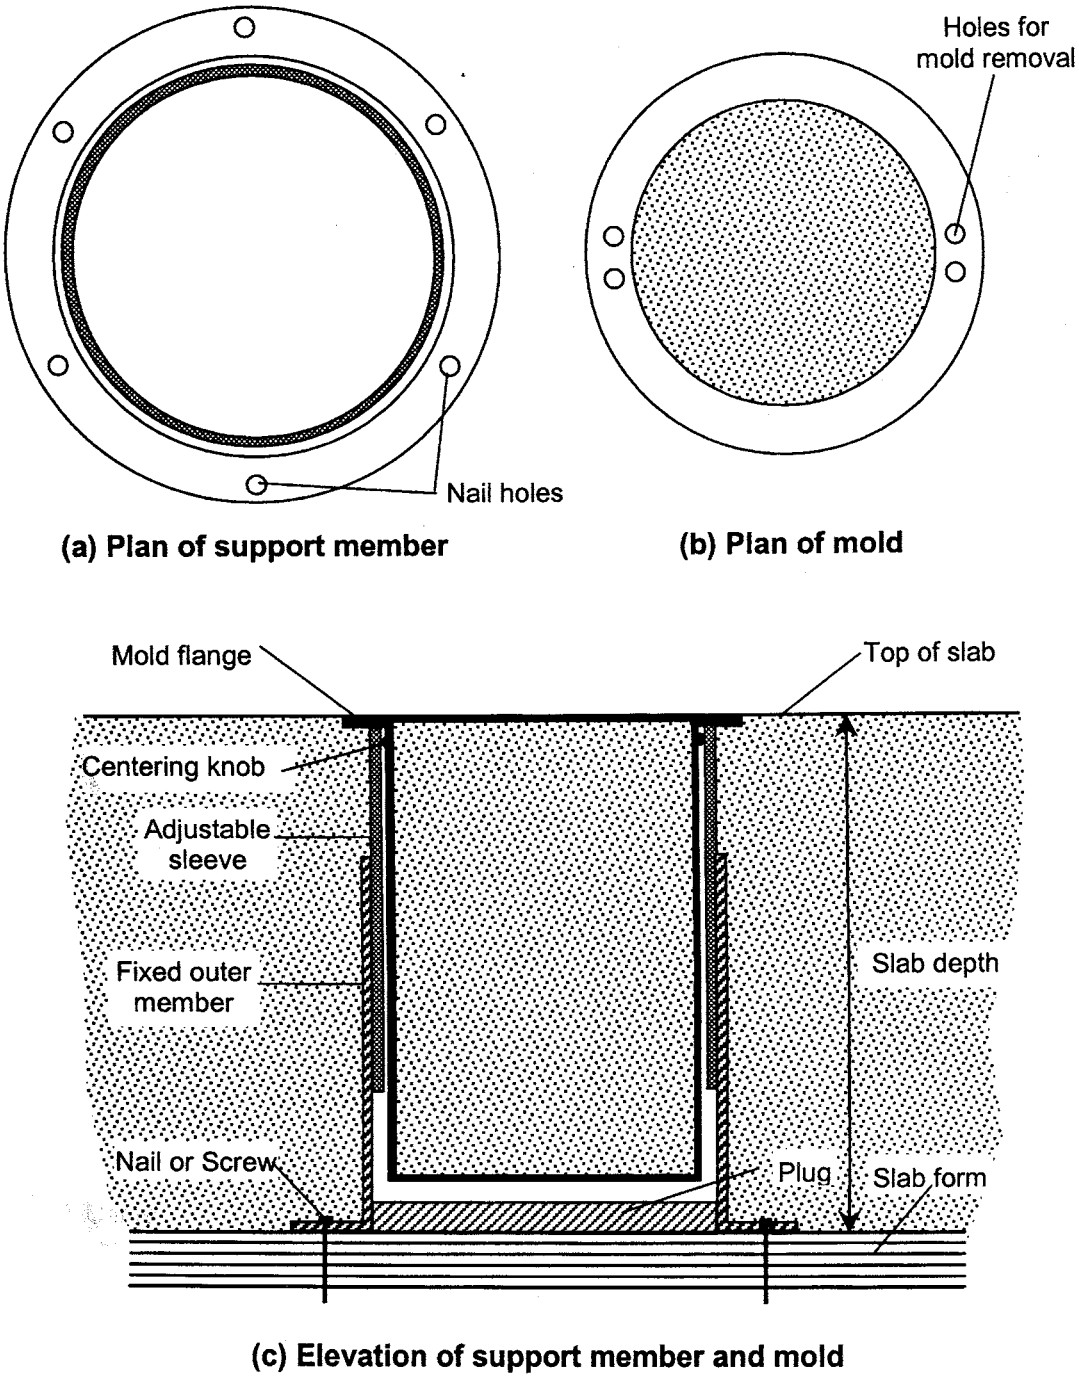

FIG. 1 Schematic of Cast-in-Place Cylinder Mold Assembly

of slabs, determining the time of form and shore removal, and determining the effectiveness of curing and protection.

5. Apparatus

5.1 Cast-in-place molds shall have a diameter at least three times the nominal maximum aggregate size. The length-diameter ratio (*L/D*) of the specimen after capping shall not be less than 1.0 and should preferably be between 1.5 and 2.0. Molds (inner member) shall be constructed in one piece in the form of right circular cylinders at least 4 in. [100 mm] in inside diameter with the average diameter not differing from the nominal diameter by more than 1 % and no individual diameter differing from any other diameter by more than 2 %. The plane of the rim of the mold and the bottom shall be perpendicular to the axis of the mold within 0.5° (approximately equivalent to ⅛ in. in 12 in. [1 mm in 100 mm]).

5.2 Molds shall be watertight and meet the criteria of the section on water leakage of Specification C 470/C 470M. Molds and auxiliary apparatus shall be made of nonabsorbent material that does not react with concrete containing portland

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

or other hydraulic cements. They shall be sufficiently strong and tough to permit use under normal construction conditions without tearing, crushing, or otherwise deforming when filled with fresh concrete. They shall resist deformation to the extent that they produce hardened concrete cylinders such that two diameters measured at right angles to each other in any horizontal plane do not differ by more than 1/16 in. [2.0 mm].

5.3 The exterior top of the mold shall have outwardly extending centering knobs and an annular flange to rest on top of the support member (5.4) and to seal the annular ring space between the mold and that support member. Means for twisting and vertical withdrawal of molds shall be provided in the annular flange (see Fig. 1).

5.4 Support members shall be right circular cylinders and shall be rigid tubes of diameter required to accommodate molds stipulated in 5.1 and to concentrically contact and support the annular flange of the mold. Support members shall be provided with a means for height adjustment and shall be fitted with exterior means to permit nailing or other firm attachment to slab forms or reinforcing steel in a manner preventing entry of concrete or mortar into the annular ring space between the support member and the mold.

6. Installation of Apparatus

6.1 After completion of reinforcing steel placement and other formwork preparation, fasten the support member to slab forms using nails or screws. Adjust the support member so that the tops of the molds are aligned with the elevation of other screeds. The location of mold assemblies should be noted on the project plans for easy location after concrete placement, and for identification.

6.2 Place the mold in the support member so that the flange of the mold is uniformly supported by the sleeve to prevent concrete or mortar from penetrating into the space between the mold and support member.

NOTE 1—Insertion of compressible material between the support member and the mold is permitted to prevent mortar seepage into the annular space.

7. Procedure

7.1 Inspect the molds to ensure they are clean and free of any debris or foreign matter. Fill the molds when the concrete placement progresses to the vicinity of mold location.

7.2 Consolidation of concrete in the mold may be varied to simulate the conditions of placement. In normal field construction practice, if the surrounding concrete is consolidated by internal vibration, use the vibrator externally, briefly touching the exterior of the mold support member. Internal vibration of concrete in the mold is prohibited except under special circumstances, which shall be explained in the report of test results. Subject the specimen surface to the same finishing as the surrounding concrete.

7.3 *Curing of Specimens*—Subject the specimens to the same curing and treatment as provided to the surrounding concrete. Record maximum and minimum slab surface temperatures during the curing period for inclusion in the report. Specimen molds shall remain fully seated in place until time of removal for transportation to the testing location.

7.4 Remove molds from support members, exercising care so as not to physically damage specimens. From the time of removal from the structure until time of test, maintain test specimens at a temperature within ±10 °F [±6 °C] of the slab surface temperature at the time of removal. Transport specimens to the laboratory within 4 h after removal. During transportation protect the specimens with suitable material to prevent damage from jarring, freezing temperatures or moisture loss, or combination thereof.

7.5 *Testing of Specimens*—Remove specimens from molds. Determine the average diameter of each specimen to the nearest 0.01 in [0.2 mm] by averaging two diameters measured at right angles to each other at about the midheight of the specimen. Cap specimens in accordance with Practice C 617, measure the length of the capped specimens to the nearest 0.1 in. [2 mm], and test in accordance with Test Method C 39/C 39M. Test the specimens for compressive strength in the "as-received" moisture condition unless required otherwise by project specifications.

8. Calculation

8.1 Calculate the compressive strength of each specimen using the computed cross-sectional area based on the average diameter of the specimen. If the length-diameter ratio of the specimen is 1.75 or less, correct the calculated strength by multiplying by the applicable strength correction factor given in Test Method C 42/C 42M.

9. Report

9.1 Report the following information:

9.1.1 Identification of structure in which specimens were cast, identification of specimen, and location of the mold in the structure,

9.1.2 Diameter and length, in. [mm],

9.1.3 Maximum load, lbf [N],

9.1.4 The *L/D* strength correction factor used,

9.1.5 Compressive strength calculated to the nearest 10 psi [0.1 MPa] after multiplying by the applicable *L/D* strength correction factor, if required,

9.1.6 Type of fracture (see Test Method C 39/C 39M),

9.1.7 Defects in specimen, or caps, if observed,

9.1.8 Age of specimen,

9.1.9 Curing methods used,

9.1.10 Initial concrete temperature,

9.1.11 Maximum and minimum temperature information obtained at job site to define curing conditions of specimens in place,

9.1.12 Detailed descriptions of any internal vibration or other internal manipulations of the fresh concrete in the mold (7.2), and

9.1.13 Other information pertaining to job conditions that could affect the results.

www.technobetar.ir

10. Precision and Bias

10.1 *Precision*—The single-operator coefficient of variation has been found to be 3.5 %[5] for a range of compressive strength between 1500 and 6000 psi [10 and 41 MPa].[6] Therefore, results of two properly conducted tests by the same operator on the same sample of concrete should not differ from each other by more than 10.0 %[5] of their average. Larger differences may be due to improperly prepared specimens or actual strength differences because of different batches of concrete or different curing conditions.

10.2 *Bias*—The bias of this test method cannot be determined because the strength of a cast-in-place cylindrical specimen can only be obtained by using this test method.

11. Keywords

11.1 compressive strength; concrete; cylinder molds; in-place strength

[5] These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

[6] This statement was derived from research data reported by Nicholas J. Carino, H. S. Lew, and Charles K. Volz in "Early Age Temperature Effects on Concrete Strength Prediction by the Maturity Method," *ACI Journal*, Vol 80, No. 2, March–April 1983.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 873 – 99, that may impact the use of this test method. (Approved June 1, 2004)

(*1*) Simplified the wording in 1.1.
(*2*) Added a warning about chemical burns in 1.3.
(*3*) Added a step to the procedure in 7.5 to measure the diameter and length of the test specimens.
(*4*) Clarified the application of the *L/D* strength correction factor in 8.1.

Designation: C 878/C 878M – 09

Standard Test Method for Restrained Expansion of Shrinkage-Compensating Concrete[1]

This standard is issued under the fixed designation C 878/C 878M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the expansion of concrete made with shrinkage-compensating cement.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 219 Terminology Relating to Hydraulic Cement

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 806 Test Method for Restrained Expansion of Expansive Cement Mortar

C 845 Specification for Expansive Hydraulic Cement

2.2 *ACI Standards and Committee Reports:*[4]

116-R-90 Cement and Concrete Terminology

223-83 Standard Practice for the Use of Shrinkage-Compensating Concrete

3. Terminology

3.1 Terms used in this test method are defined in Terminology C 219, Terminology C 125, and ACI 116-R-90.

4. Significance and Use

4.1 Since the potential for expansion, under conditions of controlled restraint, of concrete made with shrinkage-compensating cement cannot always be satisfactorily predicted from tests of mortars made in accordance with Test Method C 806, a need has been recognized for a test method in which concrete specimens are tested.

4.2 This test method can also be adapted readily to studies of expansion involving degrees of restraint, comparisons of cements, effects of cement contents, mixture proportions, schedules, or environmental treatments that differ from the standard procedures prescribed by this test method.

5. Apparatus

5.1 *Molds*, for casting test specimens, when used in conjunction with the restraining cage described in 4.2, shall provide for forming prisms 76 mm [3 in.] square with a gage length of 250 mm [10 in.]. The molds shall otherwise conform to the requirements for molds in Practice C 490, except that the stud holder, gage studs, and spacer screws described in that practice will not be used.

5.2 *Restraining Cage*, consisting of a threaded low-carbon steel rod (plain or zinc-coated) with steel end plates held in place by hex nuts as shown in Fig. 1. The hex nuts outside the cage shall be of stainless steel. Stainless steel cap nuts shall be put on each end of the rod. When tested in tension, within the elastic range, the rod shall have a strain of 2800 kN [0.0012 ± 0.0001/630 lbf] of load (Note 1).

NOTE 1—It is intended that all rods used meet the indicated requirement for strain. When a large number of rods are obtained as a single lot,

FIG. 1 Restraining Cage

exercise judgment as to whether or not all must be tested. The designation "10-24" is used in ordinary rods having the desired properties.

5.3 *Length Comparator*, conforming to and to be used in accordance with the requirements of Practice C 490. Use a reference bar complying with the description given in Practice C 490. If the terminals of the comparator are fitted with collars, they shall be such that the cap nuts on the ends of the threaded rod of the specimen do not rest on the collar during the measuring (see Figs. 2 and 3).

5.4 *Tamping Rod*—The tamping rod shall be a straight steel rod, 10 mm [3/8 in.] in diameter, and no less than 250 mm [10 in.] in length, having at least the tamping end rounded to a hemispherical tip of the same diameter.

5.5 *Vibrators*, conforming to the requirements for external vibrators prescribed in Practice C 192/C 192M.

6. Test Specimen

6.1 The test specimen shall be a prism: 75 mm [3 in.] square with a gage length of 250 mm [10 in.] and an overall length (including the length of the rod and cap nuts) of approximately 290 mm [11.5 in.]. At least three specimens shall be prepared for each test.

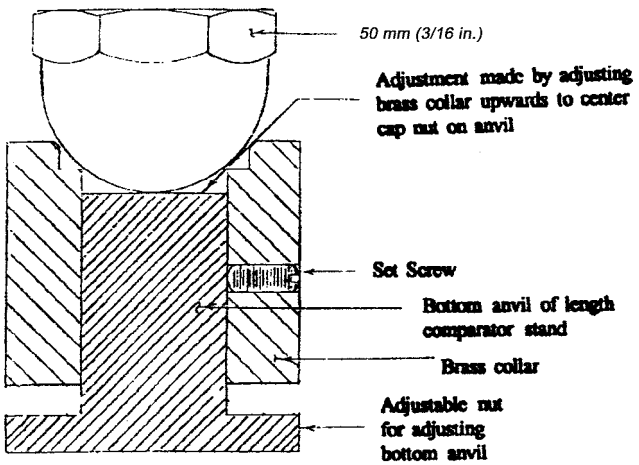

FIG. 3 Cross Section of Restraining Collar Showing Positioning of Cap Nut for Measurement

NOTE 2—Use of aggregates of nominal maximum size greater than 25.0 mm [1 in.] may adversely affect the test results.

7. Preparation and Assembly of Specimen Molds and Restaining Cage

7.1 Install the cap nuts firmly in place on the ends of the restraining rods using a suitable adhesive to keep them from loosening when comparator readings are made (Note 3). The cap nuts should not be removed after the initial comparator reading of a specimen is made. Measure the restraining cage assembly length, including the cap nuts, while it is at 23.0 ± 2 °C [73.5 ± 3.5 °F]. This is to ensure it is 30 ± 2 mm [11⁹⁄₁₆ ± 1⁄16 in.]. The measurement taken at this time is used only to ensure that comparator readings can be made.

NOTE 3—A rapid-setting epoxy has been found suitable.

7.2 Thinly cover the edges of the restraining cage end plates that contact the sides and bottom of the mold with a heavy mineral oil or light cup grease such as petrolatum. After assembly of the molds, place a restraining cage in each mold compartment. Seal the contact lines between the outer sides and base plate of the molds with paraffin or micro-crystalline wax. Thinly cover the interior faces of the molds with mineral oil and remove any oil or grease from the restraining cage rod and end plates.

8. Procedure

8.1 *Preparation and Mixing of Materials*—Mixtures using job materials shall be made in the laboratory as described in Practice C 192/C 192M, except that the material temperatures shall be approximately those anticipated in the field. Mixing procedures shall also reflect the actual mixing and delivery times expected for the particular work. Remove aggregate retained on the 25.0 mm [1 in.] sieve from that used in the mixture from which the specimens are to be molded. Select the mixture proportions according to applicable provisions of ACI 223-83.

8.2 *Molding Specimens*—Place the concrete in the mold in two approximately equal layers (the first layer shall just cover the threaded restraining rod) in accordance with the general instructions given for placing concrete in specimen molds given in Practice C 192/C 192M. Consolidate each layer by rodding or by external vibration in accordance with the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:39:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

instructions for consolidation of flexure test specimens given in Practice C 192/C 192M, except use the same method of consolidation for all specimens to be compared. The top layer shall slightly overfill the mold. After consolidation is complete, strike off the excess material with a straightedge and finish the exposed surface with a few strokes of a straight-edged trowel.

8.3 *Curing Specimens*—Cover the specimens with a polyethylene sheet or other suitable material to prevent loss or gain of moisture at the surface of the specimens.

8.4 Remove the specimens from the molds at the age of 6 h. In unusual cases the specimens may not be strong enough to demold at the age of 6 h. If this is the case, select a later time but demold as soon as practicable and report the demolding age with the results. Remove the specimens from the molds by loosening or removing the mold-fastening devices and gently tapping the base plate and side plates so as to free them from the specimens. Exercise great care in this operation, because of the fragility of the concrete at this age and in all later handling of specimens. Do not place specimens directly on hard wood or metal table tops. Placing a soft rubber mat over table tops to lessen impact force on specimens has been found to reduce scatter in data. Limit any marks placed on the specimens for identification or positioning to those made by graphite applied either by a soft pencil or as a liquid that deposits essentially graphite without binder, to those made with waterproof indelible ink, or to light scratchings in the surface of the concrete made with a sharp instrument.

8.5 *Measuring Specimens*—Take the initial comparator readings 30 ± 2 min after demolding. After the initial comparator reading, cure the specimens in lime-saturated water at 23 ± 2 °C [73.5 ± 3.5 °F] until they have reached an age of 7 days. At the end of the curing period take another comparator reading. It is permitted for comparator readings to be taken at intermediate ages between the initial comparator reading and the comparator reading at 7 days (Note 4).

NOTE 4—It is permitted to provide further water-curing, or alternatively the specimens shall be allowed to air-dry under any desired condition in order to determine later age length change data. Comparator readings shall be taken at any appropriate interval.

9. Calculation

9.1 Calculate the length changes as percent expansion or shrinkage as follows:

$$\text{Length change, \%} = [(\text{corrected comparator reading} - \text{corrected initial comparator reading})/\text{gage length}] \times 100 \quad (1)$$

where the corrected comparator reading is equal to the specimen comparator reading minus the reference bar comparator reading.

10. Report

10.1 Report the following information:

10.1.1 Identification of specimens, number of specimens for each condition, and date molded,

10.1.2 Source and identification of each material employed,

10.1.3 Type, nominal maximum size, moisture condition, and proportions of each aggregate used,

10.1.4 Concrete mixture data,

10.1.5 Consolidation method, whether rodding or external vibration was used,

10.1.6 Conditions and periods of moist curing prior to and subsequent to removal of molds, if different from those specified.

10.1.7 Description of storage conditions,

10.1.8 Total length of the period of storage and total age of the specimen, or total length of curing and storage if the same condition was used for both, for each observation, and

10.1.9 Report length change data, in % , recorded as linear expansion during moist-curing and moist storage and as linear contraction during dry storage both based on the initial comparator reading made at the time of removal from the molds, as the average percent change in linear dimension to the nearest 0.001 %.

10.1.10 Any other pertinent information.

11. Precision and Bias

11.1 *Precision*:

11.1.1 The following precision statements are applicable when a test result is the average percent restrained expansion of 3 prisms molded from a single batch of concrete and tested at the same age. It is applicable for concrete made from Type K, Type S, or Type M shrinkage-compensating cements (C 845) and tested at 3, 7, or 28 days.

11.2 The multilaboratory standard deviation has been found to be 0.015 % expansion. Therefore, the results of properly conducted tests of a single batch by two different laboratories should not differ from each other by more than 0.043 %[5].

11.3 Data necessary to determine single-laboratory precision are not available at this time.

11.4 *Bias*—Data to determine bias are not available; no standards are known to exist.

12. Keywords

12.1 expansion; restrained expansion; shrinkage compensating concrete

[5] These numbers represent, respectively, the (1s) ands (d2s) limits as described in Practice C 670.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 878/C 878M – 03, that may impact the use of this test method. (Approved June 15, 2009)

(*1*) Added a warning on hydraulic cementitious mixtures in accordance with ASTM Form and Style. Added new Footnote 2 and renumbered subsequent footnotes.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 881/C 881M – 02

Standard Specification for Epoxy-Resin-Base Bonding Systems for Concrete[1]

This standard is issued under the fixed designation C 881/C 881M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers two-component, epoxy-resin bonding systems for application to portland-cement concrete, which are able to cure under humid conditions and bond to damp surfaces.

1.2 The values stated in either inch-pound units or SI units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system are not exact equivalents, therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with this specification.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific hazards statements, see Section 9.

2. Referenced Documents

2.1 *ASTM Standards:*

C 882 Test Method for Bond Strength of Epoxy-Resin Systems Used with Concrete by Slant Shear[2]

C 884 Test Method for Thermal Compatibility Between Concrete and an Epoxy-Resin Overlay[2]

D 570 Test Method for Water Absorption of Plastics[3]

D 638 Test Method for Tensile Properties of Plastics[3]

D 648 Test Method for Deflection Temperature of Plastics Under Flexural Load[3]

D 695 Test Method for Compressive Properties of Rigid Plastics[3]

D 1259 Test Methods for Nonvolatile Content of Resin Solutions[4]

D 1652 Test Method for Epoxy Content of Epoxy Resins[5]

D 2393 Test Method for Viscosity of Epoxy Resins and Related Compounds[6]

D 2566 Test Method for Linear Shrinkage of Cured Thermosetting Casting Resins During Cure[6]

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *binder*, *n*—the cementitious part of a grout, mortar, or concrete that binds the aggregate or filler into a cohesive mass.

3.1.2 *bonding system*, *n*—the product resulting from the combination of all the components supplied for use as a bonding material.

3.1.3 *component*, *n*—a constituent that is intended to be combined with one or more other constituents to form a bonding system.

3.1.4 *contact strength*, *n*—bond strength measured by slant shear after a specified contact and cure time.

3.1.5 *contact time*, *n*—specified time between when the epoxy system is applied and when the two segments are bonded together and still achieve a specified bond strength after a specified curing time and temperature.

3.1.6 *curing agent*, *n*—a substance that causes the conversion of a fluid resin system to a solid cured resin by means of a chemical reaction.

3.1.7 *epoxy equivalent*, *n*—the weight of resin containing one molecular weight of epoxy groups.

3.1.8 *epoxy resin*, *n*—a resin that contains or did contain epoxy groups principally responsible for its polymerization.

3.1.9 *filler*, *n*—a finely divided solid, predominantly passing the No. 200 [75-µm] sieve, that is used to improve certain properties of the bonding system or to reduce cost.

3.1.10 *formulator*, *n*—the agency responsible for preparing the separate components and for recommending the proportions to be used in preparing the final bonding system.

3.1.11 *lot or batch*, *n*—that quantity of manufactured material which has been subjected to the same unit chemical or physical processes intended to make the final product substantially uniform.

3.1.12 *manufacturer*, *n*—a producer of a basic constituent part of a component.

3.1.13 *reactive diluent*, *n*—a relatively free flowing liquid

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates, and is the direct responsibility of Subcommittee C09.25 on Organic Materials for Bonding.

Current edition approved July 10, 2002. Published August 2002. Originally published as C 881 – 78. Last previous edition C 881 – 99.

www.technobetar.ir

used to reduce the viscosity of the liquid resin or resin mixture, and which contains reactive groups that cause it to become an integral part of the cured resin.

3.1.14 *working (pot) life, n*—the time after mixing during which a bonding system or mixture containing it retains sufficient workability for proper use.

4. Classification

4.1 This specification provides for the classification of epoxy-resin bonding systems by type, grade, class, and color.

4.2 *Types*—Seven types of systems that are distinguished by the requirements of Table 1 are recognized:

4.2.1 *Type I*—For use in non-load bearing application for bonding hardened concrete to hardened concrete and other materials, and as a binder in epoxy mortars or epoxy concretes.

4.2.2 *Type II*—For use in non-load bearing applications for bonding freshly mixed concrete to hardened concrete.

4.2.3 *Type III*—For use in bonding skid-resistant materials to hardened concrete and as a binder in epoxy mortars or epoxy concretes used on traffic bearing surfaces (or surfaces subject to thermal or mechanical movements).

4.2.4 *Type IV*—For use in load bearing applications for bonding hardened concrete to hardened concrete and other

TABLE 1 Physical Requirements of Bonding Systems

Property	Type						
	I	II	III	IV	V	VI	VII
Viscosity, P [Pa·s]:							
Grade 1, max	20[2.0]	20[2.0]	20[2.0]	20[2.0]	20[2.0]	...	...

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

materials and as a binder for epoxy mortars and concretes.

4.2.5 *Type V*—For use in load bearing applications for bonding freshly mixed concrete to hardened concrete.

4.2.6 *Type VI*—For bonding and sealing segmental precast elements with internal tendons and for span-by-span erection when temporary post tensioning is applied.

4.2.7 *Type VII*—For use as a nonstress carrying sealer for segmental precast elements when temporary post tensioning is not applied as in span-by-span erection.

NOTE 1— Epoxy resin systems will adhere to a wide variety of materials, including wood, metals, masonry, and most plastics. Polyethylene, TFE-fluorocarbon, cellophane, and greased or waxed surfaces are among the few materials to which these systems will not adhere.

4.3 *Grades*—Three grades of systems are defined according to their flow characteristics and are distinguished by the viscosity and consistency requirements of Table 1.

4.3.1 *Grade 1*—Low viscosity.

4.3.2 *Grade 2*—Medium viscosity.

4.3.3 *Grade 3*—Non-sagging consistency.

4.4 *Classes*—Classes A, B, and C are defined for Types I through V, and Classes D, E, and F are defined for Types VI and VII, in accordance with the range of temperatures for which they are suitable (Note 2).

4.4.1 *Class A*—For use below 40°F [4.0°C] the lowest allowable temperature to be defined by the manufacturer of the product.

4.4.2 *Class B*—For use between 40 and 60°F [4.0 and 15.0°C].

4.4.3 *Class C*—For use above 60°F [15.0°C] the highest allowable temperature to be defined by the manufacturer of the product.

4.4.4 *Class D*—For use between 40 and 65°F [4.0 and 18.0°C].

4.4.5 *Class E*—For use between 60 and 80°F [15.0 and 30.0°C].

4.4.6 *Class F*—For use between 75 and 90°F [25.0 and 30.0°C].

NOTE 2—The temperature in question is usually that of the surface of the hardened concrete to which the bonding system is to be applied. This temperature may be considerably different from that of the air. Where unusual curing rates are desired it is possible to use a class of bonding agent at a temperature other than that for which it is normally intended. For example, a Class A system will cure rapidly at room temperature.

4.5 *Color*—Epoxy resin systems are normally unpigmented, but they can be colored or darkened. If a specific color is desired, it should be so stated by the purchaser.

5. Ordering Information

5.1 The purchaser shall specify the type, grade, class, and color of bonding system desired and the size of units in which the components shall be furnished. Special requirements regarding filling of either the components or the final bonding system should be stated. The product furnished under this specification is intended to be resistant to moisture and therefore should be suitable for either indoor or outdoor exposure.

5.2 The purchaser may specify a minimum gel time of 5 min for Types I and IV when automatic proportioning, mixing, and dispensing equipment are used.

6. Materials and Manufacture

6.1 The systems covered by this specification shall be furnished in two components for combining immediately prior to use in accordance with written instructions of the formulator. Component A shall contain an epoxy resin with or without a reactive diluent. Component B shall contain one or more curing agents, which on mixing with Component A shall cause the mixture to harden. A suitable inert filler may be uniformly incorporated in one or both components. The filler shall be either nonsettling or readily dispersible in any component in which it is incorporated. All systems shall cure under humid conditions, and bond to damp surfaces.

7. Chemical Composition

7.1 The epoxy resin constituent of Component A shall have an epoxy equivalent of 155 to 275.

8. Physical Properties

8.1 A mixture of Components A and B in the proportions recommended by the formulator shall conform to the properties prescribed in Table 1.

9. Safety Hazards

9.1 **Caution:** Epoxy resins contain irritants, especially to the skin, eyes, and respiratory system. Persons handling these materials shall use appropriate protective clothing, including rubber or plastic gloves. If an epoxy resin should contact the skin, it shall be removed immediately with a dry cloth or paper towel, and the area of contact washed thoroughly with soap and water. Solvents shall *not* be used, because they carry the irritant into the skin. Cured epoxy resins are innocuous.

10. Sampling

10.1 Take a representative sample of each of the two components from a well-blended lot prior to packaging or by withdrawing samples from no fewer than 5 % of the containers comprising the lot or shipment. Unless the samples of the same component taken from containers show visual evidence of variability, they may be combined into a single composite sample. In place of the foregoing, packaged materials may be sampled by a random selection of containers of each component from each lot, provided such a procedure is acceptable to the purchaser.

11. Test Methods

11.1 *Consistency*—Test Method to Determine The Consistency of an Epoxy Resin System.

11.1.1 *Scope*—This test provides a method for determining the consistency of Grade 3 epoxy resin systems.

11.1.2 *Significance and Use*—This test method is used to determine compliance with the requirements of the specification.

11.1.3 *Apparatus*:

11.1.3.1 *Paper cup*—Approximately 3 oz. [approximately 0.100L] unwaxed paper cup.

11.1.3.2 *Mixing blade*—Ordinary wooden tongue depressor or stick of similar size.

11.1.3.3 *Glass panel*.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:39:51 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11.1.4 *Conditioning*—Condition the individual components and any equipment with which they will come in contact to the following temperatures: Class A, 32 ± 2°F [0 ± 1°C]; Class B, 50 ± 2°F [10 ± 1°C]; Class C, 73 ± 2°F [23 ± 1°C], Class D, 65° ± 2°F [18° ± 1°C]; Class E, 80° ± 2°F [27°± 1°C]; Class F, 90° ± 2°F [32° ± 1°C] or to the temperature at which the material will be used (Note 2).

11.1.5 *Procedure*—Prepare approximately 30 cm^3 of the bonding system. Weigh the necessary amounts of the components to an accuracy of 1 % into a single 3-oz [approximately 100-cm^3] unwaxed paper cup. Mix immediately with a wooden tongue depressor or stick of similar size. Note the time at which mixing begins. Mix for 3 min, taking care to scrape the side and bottom of the cup periodically. Immediately apply about 2 cm^3 of the mixture to a glass panel. Form a semicylindrical bead of the bonding system by drawing the applicator blade through the sample in a straight line with the panel horizontal. Immediately raise the panel to a position inclined at no greater than 10° from vertical and with the bead horizontal. Maintain the panel and sample at their original temperature until the bonding system has cured, as determined by an inability to indent it appreciably with a pencil point or fingernail. Determine the consistency by measuring the flow of the lower edge of the bead from its original position at three points along its length.

11.1.6 *Report*—Report the average value to the nearest ⅛in. [1 mm].

11.1.7 *Precision and Bias*:

11.1.7.1 *Precision*—The precision of the procedure in this test method for consistency is being determined.

11.1.7.2 *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

11.2 *Gel Time*:

11.2.1 Test Method to Determine the Gel Time of an Epoxy Resin System.

11.2.2 *Scope*—This test method determines the time after mixing when an epoxy resin system gels.

11.2.3 *Significance and Use*—This test method is used to determine compliance with the requirements of the specification.

11.2.4 *Apparatus*:

11.2.4.1 *Paper cup*—8 oz. [approximately 250 cm^3] unwaxed paper cup

11.2.4.2 *Mixing blade*—Ordinary wooden tongue depressor or stick of similar size.

11.2.5 *Conditioning*—Condition the individual components and any equipment with which they will come in contact to the temperatures set forth in 11.1, depending on the class of system in question, or to the temperature at which the material will be used, providing that temperature is within the ranges established in 4.4 for Types I, II, III, and V. For Type VI and VII use the highest temperature of the specified class (Note 2). Prepare 60 g of the bonding system for Types I through V and 1 gal [4.0 L] for Types VI and VII using the procedures set forth in 11.1.

11.2.6 *Procedure*—Transfer as much as possible of the sample into an 8-oz [approximately 250-cm^3] unwaxed paper cup and set it on a wooden surface in a location maintained at the original conditioning temperature and not subject to abnormal room air movement. Determine the time at which a soft, gelatinous mass forms in the center of the sample by probing every 2 min with a wooden tongue depressor or similar device, starting 8 min after the beginning of mixing.

11.2.7 *Report*—The gel time is the interval between the beginning of mixing and the formation of the gelatinous mass.

11.2.8 *Precision and Bias*:

11.2.8.1 *Precision*—The precision of the procedure in this test method for gel time is being determined.

11.2.8.2 *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

11.3 *Filler Content*:

11.3.1 Test Method to Determine the Filler Content of Epoxy Resin Systems.

11.3.2 *Scope*—This test method is a quantitative test to determine the filler content of epoxy resin systems.

11.3.3 *Significance and Use*—the filler content of an epoxy resin system must be known in order to determine the epoxy equivalent.

11.3.4 *Apparatus*:

11.3.4.1 150 mL beaker.

11.3.4.2 Medium porosity, fritted disk filtering crucible.

11.3.4.3 *Mixing blade*—Ordinary wooden tongue depressor or stick of similar size.

11.3.5 *Reagents*:

11.3.5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society where such specifications are available.[7] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

11.3.5.2 Methyl ethyl ketone (MEK).

11.3.5.3 Benzene.

11.3.6 *Procedure*—Weigh, to the nearest 0.1 mg, approximately 10 g of the epoxy resin component into a 150-mL beaker. Add 50 mL of methyl ethyl ketone (MEK) to the beaker, and stir the contents until all the soluble matter is dissolved. If the sample is black, owing to the presence of bituminous material, the solvent used shall be a mixture of 1+1 MEK and benzene, by volume. Dry a medium-porosity, fritted-disk filtering crucible to constant weight at 230 ± 9°F [110 ± 5°C]. Wet the filter with MEK, then filter the contents of the beaker through the filtering crucible with the aid of a vacuum. Transfer the contents of the beaker entirely to the crucible, and wash the beaker and the residue on the filter with MEK. The total volume of solvent used to transfer and wash the residue should be about 200 mL. Dry the filter and residue to constant weight at 230 ± 9°F [110 ± 5°C].

11.3.7 *Report*—Calculate the percentage of filler in the component, and report the value to the nearest 0.1 %.

www.technobetar.ir

11.3.8 *Precision and Bias*

11.3.8.1 *Precision*—The precision of the procedure in this test method for filler content is being determined.

11.3.8.2 *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

11.4 *Epoxy Equivalent*—Determine the epoxy equivalent of Component A in accordance with Test Method D 1652. Calculate the epoxy equivalent after correcting for any filler and volatile contents of the component as follows:

$$x = y(1 - f - v) \quad (1)$$

where:

x = corrected weight per epoxy equivalent of the component,
y = weight per epoxy equivalent of the total component as determined by Test Method D 1652,
f = weight fraction of filler in the component, and
v = weight fraction of volatile matter in the component.

11.5 *Viscosity*—Determine the viscosity of the freshly mixed resin system by means of Test Method D 2393, except that the determination shall be made at the temperature given in 11.1 for the class of material in question.

11.6 *Absorption*—Determine the absorption by means of Test Method D 570. The test specimens shall have the shape and dimensions specified for molded plastics, shall be cured for 14 days at a temperature of 73 ± 2°F [23 ± 1°C], shall be tested in accordance with the procedure for 24-h immersion and shall be reconditioned, if necessary, as directed in Test Method D 570.

11.7 *Bond Strength*—Determine the bond strength in accordance with Test Method C 882.

11.8 *Thermal Compatibility*—Determine the thermal compatibility in accordance with Test Method C 884.

11.9 *Heat Deflection Temperature*—Determine the heat deflection temperature in accordance with Test Method D 648, except condition, mix, cure, and start testing the resin components at 73 ± 2°F [23 ± 1°C].

11.10 *Linear Coefficient of Shrinkage*— Determine the linear coefficient of shrinkage in accordance with Test Method D 2566, except condition, mix, cure, and test the resin components at 73 ± 2°F [23 ± 1°C].

11.11 *Compressive Yield Strength and Modulus*—Determine the compressive yield strength and modulus in accordance with Test Method D 695, except condition, mix, and cure the resin components at the lowest application temperature of the specified class. Test at 73 ± 2°F [23 ± 1°C] without delay. Use of a 1 × 1 × 2-in. [25.4 × 25.4 × 50.8-mm] specimen is also acceptable.

11.12 *Tensile Strength and Elongation at Break*—Determine the tensile strength and elongation at break in accordance with Test Method D 638, except condition, mix, and cure at the lowest application temperature of the specified class. Test at 73 ± 2°F [23 ± 1°C] without delay.

11.13 *Contact Strength*—Determine the contact strength in accordance with Test Method C 882 except condition the material and the specimens at the highest application temperature of the specified class and apply the bonding system at a thickness of 1/16 in. [2 mm] on the slanted surface of each half cylinder. Maintain at the highest application temperature and assemble the two half cylinders after 1 h for Type VI and 8 h for Type VII. Cure at the assembly temperature and test at 73 ± 2°F [23± 1°C]. Contact strength is expressed in terms of pounds per square inch obtained after a specified time of cure.

12. Rejection and Rehearing

12.1 The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the test, the producer or supplier has the right to a rehearing.

12.2 If all requirements of this specification are met, except those pertaining to bond strength, the bond tests shall be repeated. If the sample again fails to meet the bond strength requirements, the entire lot shall be rejected.

12.3 *Retest*—Lots of material that have been rejected may be reworked by the producer to correct the defects and resubmitted for test provided specific approval of the purchaser has been obtained for such resubmission. Before resubmission of the material, full particulars concerning the action taken to correct the defects in the original material shall be made available to the purchaser.

13. Packaging and Package Marking

13.1 *Packaging*—The two components furnished under this specification shall be supplied in separate containers that are nonreactive with the contents. They are usually supplied in amounts such that the recommended proportions of the final mixture can be obtained by combining one container of Component A with one container of Component B.

13.2 *Marking*—Containers shall be identified as "Component A—Contains Epoxy Resin'' and "Component B—Contains Curing Agent'' and shall show the type, grade, class, and color. Each container shall be marked with the name of the formulator, the lot number, the date of packaging, the quantity contained therein, and the recommended mixing ratio, by both weight and volume.

14. Keywords

14.1 bonding; bonding systems; contact strength; contact time; epoxy resin

Designation: C 882/C 882M – 05$^{\epsilon 1}$

Standard Test Method for Bond Strength of Epoxy-Resin Systems Used With Concrete By Slant Shear[1]

This standard is issued under the fixed designation C 882/C 882M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

ε[1] NOTE—The designation was changed editorially to agree with the existing values statement in the Scope in March 2008.

1. Scope

1.1 This test method covers the determination of the bond strength of epoxy-resin-base bonding systems for use with portland-cement concrete. This test method covers bonding hardened concrete to hardened or freshly-mixed concrete.

1.2 The values stated in either inch-pound units or SI units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with this test method.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* A specific hazard statement is given in Section 8.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 150 Specification for Portland Cement

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 617 Practice for Capping Cylindrical Concrete Specimens

C 881/C 881M Specification for Epoxy-Resin-Base Bonding Systems for Concrete

3. Terminology

3.1 See Section on Terminology of Specification C 881/C 881M.

4. Summary of Test Method

4.1 The bond strength is determined by using the epoxy system to bond together two equal sections of a 3 by 6-in. [75 by 150-mm] portland-cement mortar cylinder, each section of which has a diagonally cast bonding area at a 30° angle from vertical. After suitable curing of the bonding agent, the test is performed by determining the compressive strength of the composite cylinder.

5. Significance and Use

5.1 The strength developed by a bonding system that joins two regions of concrete is its most important property.

6. Apparatus

6.1 *Apparatus to Mix Portland-Cement Mortar*—This apparatus shall be as described in Test Method C 109/C 109M, except for the sections on specimen molds, tamper, and testing machine.

6.2 *Specimen Molds*—The molds shall be constructed in the form of right cylinders, 3 ± 1/16 in. [75 ± 2 mm] in inside diameter and 6 ± 1/16 in. [150 ± 2 mm] high. All molds shall be either selected or machined so that the maximum range of the differences in each of the dimensions of the group of molds is less than 1/64 in. [0.5 mm]. The molds shall be made of metal not attacked by portland-cement mortar. The side of the mold shall be sufficiently rigid to prevent spreading or warping. The molds shall be made watertight before use. A satisfactory

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.25 on Organic Materials for Bonding.

Current edition approved Nov. 1, 2005. Published November 2005. Originally approved in 1978. Last previous edition approved in 1999 as C 882 – 99.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

material for this purpose is the paraffin-rosin mixture described in Test Method C 109/C 109M.

6.3 *Dummy Section*—A dummy section (Fig. 1) shall be machined of a hard material that is not attacked by portland-cement mortar. It shall fit the mold and be equal to half the volume of the cylinder, but at an angle of 30° from the vertical. Additional dummy sections can be made by casting an epoxy-resin mortar against the machined dummy section contained in a specimen mold. Due precautions, such as waxing, shall be taken to prevent the bonding of the epoxy-resin mortar to the machined dummy section or the mold.

6.4 *Tamping Rod*—The tamping rod shall be a round rod of brass or plastic, ⅜ in. [10 mm] in diameter and approximately 12 in. [300 mm] long, having both ends rounded to hemispherical tips.

6.5 *Apparatus for Mixing Epoxy-Resin Bonding System*—A glass, plastic, or metal container of approximately 3 oz. [0.1 L] capacity shall be used to hand-mix the bonding system. A tongue depressor or wooden stick of similar dimensions shall be used as a paddle.

6.6 *Testing Machine*—The testing machine shall be as described in Test Method C 39/C 39M.

6.7 *Moist Room*—The moist room shall conform to the requirements of Specification C 511.

6.8 *Temperature-Conditioning Chambers*— Rooms or chambers in which the temperature is maintained appropriate to the class of the resin system being tested, in accordance with Specification C 881/C 881M.

7. Materials

7.1 Laboratory conditions, materials, proportions, and procedures for mixing the portland-cement mortar shall be in accordance with Test Method C 109/C 109M. A Type III cement (Specification C 150) shall be used.

7.2 Lightly oil the dummy section and the cylinder mold. Position the dummy section in the mold with the slant side up. Place the portland-cement mortar in the mold in three layers of approximately equal volume. Rod each layer with 25 strokes of the tamping rod. Distribute the strokes uniformly over the section and rod deeply enough to penetrate into any underlying layer. Rod the bottom layer as deeply as possible. Strike off the surface of the top layer with the trowel, and cover the specimen and mold with a glass or metal plate. Cure the mortar half-cylinder in accordance with Practice C 192/C 192M for at least 28 days. Then dry the half-cylinder in laboratory air for at least 7 days. As an alternative, a complete 3 by 6-in. [75 by 150 mm] cylinder shall be cast and, after cure, may be saw-cut at an angle of 30°.

	Dimensions	
	in.	mm
A—Diameter	3.000	[75±2]
B—Height	5.598	[140±2]
C—Slant height	6.000	[150±2]
D—Base height	0.402	[10±2]

FIG. 1 Dummy Section

7.3 A 3 by 6-in. [75 by 150-mm] cylinder of the mortar shall have a compressive strength, when tested in accordance with 11.3, of at least 4500 psi [31 MPa] at 28-days age.

8. Hazards

8.1 **Warning**—Epoxy resins contain irritants, especially to the skin, eyes, and respiratory system. Persons handling these materials shall use appropriate protective clothing, including rubber or plastic gloves. If an epoxy resin should contact the skin, it shall be removed immediately with a dry cloth or paper towel, and the area of contact shall be washed thoroughly with soap and water. Solvents shall *not* be used, because they carry the irritant into the skin. Cured epoxy resins are innocuous.

9. Sampling

9.1 Take samples in accordance with Specification C 881/C 881M.

10. Test Specimens

10.1 Three composite test specimens are required for all Types of resin systems.

10.2 *Conditioning*:

10.2.1 *Types I, III, IV, VI, and VII Systems*—Condition the resin system components, the mortar sections, and all equipment that will contact the resin to the temperatures specified in Specification C 881/C 881M.

10.2.1.1 Prepare the test specimens and make provision for maintaining them at the appropriate temperature during the entire cure time. Prepare the surface to be bonded by sand-blasting and dry brushing to remove all loose surface material.

10.2.1.2 Use mortar sections and assemblies that have been soaked in water for 24 h. Place the face of the mortar sections to be bonded on an absorbent material for 10 min prior to applying the adhesive. For assembled test specimens, remove all water by shaking. Allow to air dry for 15 min.

10.2.2 *Type II and Type V Systems*—Since Type II and Type V resins are appropriate for use only at temperatures that permit strength gain of the freshly prepared concrete, only the conditioning temperature for a Class C resin, 73 ± 2 °F [23 ± 1 °C], need be provided.

10.3 *Specimen Preparation*:

10.3.1 *Type I, III, IV, VI, and VII, Grade 2 or 3 Systems*—Two mortar sections will be needed for each test specimen. Wrap 4 mil (100 μm) of polyethylene film 6 by 20 in. [150 by 500 mm] around one section of each pair, even with the base and secure with masking tape. Thoroughly mix the components of the bonding system in the proportions recommended by the formulator. A mixing time of 3 min should suffice. Support the film-wrapped mortar section so that the prepared bonding surface is horizontal.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:39:58 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.3.1.1 To test Grade 2 systems, apply a 0.02 in. [0.5 mm] layer of the bonding systems to the prepared elliptical surface of the film wrapped mortar section. Using Grade 3 systems, apply a 0.02 in. [0.5 mm] layer of bonding system on the prepared elliptical surface of the mortar section not film wrapped. For the determination of contact strength (Specification C 881/C 881M) of Type VI and VII systems, apply a 1/16-in. [2.0-mm] layer to the prepared elliptical surface of both mortar sections.

10.3.1.2 Insert mortar sections not film wrapped into the cylinder formed by film surrounding other mortar sections and squeeze out the excess resin through a hole, or holes, punched in the film at the bondline, while keeping the joint horizontal. Secure the assembly with sufficient additional masking tape placed around the film. Be sure the joint is entirely filled. Keep the bonded joint horizontal for 48 h, then remove all the masking tape.

10.3.2 *Type I, III, and IV, Grade 1 Systems*—Two mortar sections will be needed for each test specimen. Prepare the elliptical bonding surface as described in 10.2. Place the two halves of the specimen together, forming a gap approximately 0.02 in. [0.5 mm]. Wrap masking tape around the periphery of the specimen close to each end. Place additional tape along the joint. Coat the tape over the joint with hot paraffin to help contain the epoxy when it is poured into the slit. Support the specimen so that the taped joint is vertical. Cut a slit in the tape to expose approximately ¾ in. (20 mm) of the upper portion of the joint. Slowly pour the resin bonding system into the exposed joint until it is completely filled. Keep the joint vertical for 48 h, then remove all masking tape.

10.3.3 *Type II and V Systems*—One hardened mortar section will be needed for each test specimen. Prepare the mortar surface as described in 10.2, but do not tape around the edge. Mix the components of the bonding system as described in 10.3. Brush the bonding system on the prepared surface. Place the primed mortar section in the cylinder mold that has previously been lined with a 4-mil (100-μm) polyethylene sheet. Support the mold so that the bonding surface of the mortar section is horizontal. Place a layer of freshly mixed portland-cement mortar over the primed surface to a depth of approximately ½ in. [15 mm]. Rod the layer with the tamping rod gently, so as to disturb the layer of resin as little as possible. Place the mold in its normal vertical position, and place additional mortar into the mold in two layers of approximately equal volume. Rod each layer with 25 strokes of the tamping rod. Distribute the strokes over the cross section, and make them deep enough to penetrate into the underlying layer. Strike off the surface of the top layer with the trowel, and cover the mold with a glass or metal plate.

10.4 *Curing*:

10.4.1 *Type I, III, IV, VI, and VII Systems*—Maintain all specimens at the preparation temperature in a moist room for the specified period of time.

10.4.2 *Type II and V Systems*—Demold the test specimens and cure in accordance with the curing section of Practice C 192/C 192M.

11. Procedure

11.1 Remove the specimens from the cure environment after the specified time.

11.2 *Capping*—Cap the specimens immediately after removal from curing in accordance with Practice C 617.

11.3 *Strength Testing*—Test the specimens at 73 ± 2 °F [23 ± 1 °C] in compression after capping in accordance with Test Method C 39/C 39M.

12. Calculation

12.1 Calculate the bond strength of the resin bonding system by dividing the load carried by the specimen at failure by the area of the bonded surface (Note 1). Reduce the area of the bonded surface by that of any voids found in the bond on inspection after test. Only voids larger than ⅛ in. [3 mm] should be counted in reducing the area. Report the results to the nearest 10 psi (0.1 MPa).

NOTE 1—The area of the elliptical bonding surface of the test cylinders specified in this test method is 14.13 in.^{2} [9116 mm^2]. The actual area should be based on measuring the lengths of the two axes for the areas of an ellipse [0.7854 a b]

13. Report

13.1 Report the following information:

13.1.1 Identification number,

13.1.2 Bond strength,

13.1.3 Bonding area,

13.1.4 Number and total area of voids in the bond,

13.1.5 Type and position of the fracture (in the bonding material, in the mortar, or in the interface between them), and

13.1.6 Defects in either the specimen or the cap.

14. Precision and Bias

14.1 *Precision*—The standard deviation was found to be 365 psi for the 14 day bond strength average of 1790 psi. Therefore, results of two properly conducted tests from two laboratories on similar batches should not differ from each other by more than 1022 psi.

14.2 *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

15. Keywords

15.1 adhesives; bonding agents; bond strength; shear bond

Designation: C 884/C 884M – 98 (Reapproved 2005)

Standard Test Method for Thermal Compatibility Between Concrete and an Epoxy-Resin Overlay[1]

This standard is issued under the fixed designation C 884/C 884M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the determination of which epoxy-resin formulations are subject to debonding when used as overlays for concrete when the combination of the two is subjected to temperature changes that may be met in the field.

1.2 The values stated in either inch-pound units or SI units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* A specific hazard statement is given in Section 7.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 33 Specification for Concrete Aggregates

C 150 Specification for Portland Cement

C 260 Specification for Air-Entraining Admixtures for Concrete

C 672/C 672M Test Method for Scaling Resistance of Concrete Surfaces Exposed to Deicing Chemicals

C 778 Specification for Sand

C 881/C 881M Specification for Epoxy-Resin-Base Bonding Systems for Concrete

3. Summary of Test Method

3.1 A layer of epoxy-sand mortar is applied to a slab of cured and dried concrete. After the epoxy has cured, the sample is subjected to five cycles of temperature change between 77°F [25°C] and – 6°F [–21°C]. Cracks near the bond line between the concrete and the epoxy mortar constitute failure of the test.

4. Significance and Use

4.1 This test method applies to materials used in making epoxy-mortar overlays for concrete pavement. When debonding occurs between the overlay and the pavement, the material is unsuitable.

5. Apparatus

5.1 *Molds*, in conformance with Test Method C 672.

5.2 *Freezer*, in conformance with Test Method C 672, except that the temperature of the freezer shall be – 6 ± 3°F [–21 ± 2°C].

5.3 *Retaining strips*, to retain the epoxy-mortar overlay. Pieces of wood or steel that can be attached to the 12 by 12 by 3-in. [300 by 300 by 75-mm] concrete block so as to enclose completely the top surface of the block and rise above it a uniform distance of 0.5 in. [15 mm].

6. Materials

6.1 *Portland Cement*, Type I or Type II, meeting the requirements of Specification C 150.

6.2 *Standard Sand*, meeting the requirements of Specification C 778.

6.3 *Aggregates*—Fine and coarse aggregate meeting the requirements of Specification C 33. The coarse aggregate shall be durable under freezing exposure and shall have a maximum size of 1 in. [25 mm]. The fine aggregate shall be a natural sand.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates, and is the direct responsibility of Subcommittee C09.25 on Organic Materials for Bonding, Patching, and Sealing.

Current edition approved Nov. 1, 2005. Published January 2006. Originally approved in 1978. Last previous edition approved in 1998 as C 884/C 884M – 98.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

6.4 *Air-Entraining Admixture*, meeting the requirements of Specification C 260.

7. Hazards

7.1 **Warning**—Epoxy resins contain irritants, especially to the skin, eyes, and respiratory system. Persons handling these materials shall use appropriate protective clothing, including rubber or plastic gloves. If an epoxy resin should contact the skin, it shall be removed immediately with a dry cloth or paper towel, and the area of contact shall be washed thoroughly with soap and water. Solvents shall not be used, because they carry the irritant into the skin. Cured epoxy resins are considered innocuous.

8. Sampling

8.1 Take samples in accordance with Specification C 881.

9. Preparation of Concrete Blocks

9.1 *Proportions*—Proportion an air-entrain concrete in accordance with Test Method C 672. Prepare two blocks.

9.2 *Fabrication of Concrete Block*—Fabricate the concrete block in accordance with Test Method C 672, except end the fabrication operations after the strike-off operation.

9.3 *Curing*—Cure the concrete blocks in accordance with Test Method C 672, except that air-drying shall be at least 14 days.

9.4 *Surface Preparation*—Prior to the application of the epoxy mortar, sand-blast the top surface of the concrete block, and then remove any loose material with a bristle-brush.

10. Fabrication of Test Specimen

10.1 Assemble the retaining strips to the concrete blocks. Coat their inner surfaces with a suitable bond breaker.

10.2 *Preparation of Epoxy Mortar*—Prepare enough epoxy mortar to cover two concrete blocks. Mix the epoxy resin under test in accordance with the instructions of the manufacturer or formulator. To 1 part by volume of the mixed system add the following bulk or "loose" volumes (that is, that of the container in which it is) of standard sand and mix thoroughly:

	Unfilled	*Filled*
Grade 1	3 parts	2.5 parts
Grade 2	2.5 parts	2 parts
Grade 3		1 part

10.3 *Application of Epoxy Mortar*—Prime the surface of the concrete blocks with the recommended primer. Thoroughly brush on the primer in a thin coat. Apply the epoxy mortar in a layer flush with the tops of the retaining strips. Remove the retaining strips after 24 h and allow the epoxy mortar to cure an additional 6 days at 73 ± 2°F [23 ±1°C]. It may be necessary to grind or saw cut the vertical faces so as to have a visible bond line.

11. Procedure

11.1 After the completion of the curing period of the epoxy mortar, place the two specimens in the freezer for 24 h. Then remove them to room temperature (73 ± 2°F [23 ±1°C]) for 24 h. This is one test cycle. Continue for four additional cycles.

12. Interpretation of Results

12.1 Delamination of the epoxy-mortar layer from the concrete test block or the presence of horizontal cracks in the concrete near the interface shall constitute failure. If either of the companion specimens has failed, the epoxy-resin system under test shall be considered to have failed the test.

13. Report

13.1 The report shall state whether the resin system has passed or failed the test.

14. Precision and Bias

14.1 No statement is made about either precision or the bias of this test method for measuring thermal compatibility between concrete and an epoxy-resin overlay since the result merely states whether there is conformance to the criteria for success specified in the procedure.

15. Keywords

15.1 epoxy-resin overlay; thermal compatibility

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 897 – 05 (Reapproved 2009)

Standard Specification for Aggregate for Job-Mixed Portland Cement-Based Plasters[1]

This standard is issued under the fixed designation C 897; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers natural or manufactured aggregate for use in job-mixed base and finish-coat full thickness portland cement, portland cement-lime and modified portland cement plasters.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 The text of this specification references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 40 Test Method for Organic Impurities in Fine Aggregates for Concrete

C 87 Test Method for Effect of Organic Impurities in Fine Aggregate on Strength of Mortar

C 88 Test Method for Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate

C 117 Test Method for Materials Finer than 75-μm (No. 200) Sieve in Mineral Aggregates by Washing

C 123 Test Method for Lightweight Particles in Aggregate

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 142 Test Method for Clay Lumps and Friable Particles in Aggregates

D 75 Practice for Sampling Aggregates

3. Terminology

3.1 *Definitions*—Definitions used in this standard shall be in accordance with Terminologies C 11 and C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *aggregate*, *n*—a granular material such as natural or manufactured sand used with a cementing medium to form plaster (stucco).

3.2.2 *manufactured sand*, *n*—the fine material resulting from the crushing and classification by screening, or otherwise, of rock, gravel, or blast furnace slag.

3.2.3 *natural sand*, *n*—the fine granular material resulting from the natural disintegration of rock.

4. Composition

4.1 *Deleterious Substances*—The amount of deleterious substances in aggregates, each determined on independent samples complying with the grading requirements of Section 6, shall not be more than the following:

Item	Maximum Permissible Weight, %
Friable particles	1.0
Light weight particles, floating on liquid having a specific gravity of 2.0	0.5

4.2 *Organic Impurities*:

4.2.1 The aggregate shall be free of injurious amounts of organic impurities. Except as herein provided, aggregates subjected to the test for Organic Impurities, Test Method C 40, and producing a color darker than the standard shall be rejected.

4.2.2 Aggregate failing the test for organic impurities may be used provided that, when tested for the effect of organic impurities on strength in accordance with Test Method C 87, the relative strength at 7 days is not less than 95 %.

5. Physical Properties

5.1 *Soundness* (see 7.1.7):

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved Sept. 1, 2009. Published September 2009. Originally approved in 1978. Last previous edition approved in 2005 as C 897 – 05.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

5.1.1 Except as herein provided, aggregate subjected to five cycles of the soundness test shall show a loss, when weighed in accordance with the grading of a sampling complying with the limitations set forth in Section 6, not greater than 20 % when sodium sulfate is used, or 15 % when magnesium sulfate is used.

5.1.2 Aggregates failing to meet the requirements of 5.1.1 shall be accepted, provided there is evidence that plasters of comparable properties made from similar aggregates from the same source has been exposed to weathering, similar to that to be encountered, for a period of more than 5 years without appreciable disintegration.

6. Dimensions, Mass, and Permissible Variations

6.1 *Aggregate for Base Coat*—Aggregate for use in base coat portland cement-based plasters shall be graded as follows:

U.S. Standard Sieve	Percent Retained (by Weight)			
	Natural Sand		Manufactured Sand	
	max	min	max	min
No. 4 (4.75 mm)	0	0	0	0
No. 8 (2.36 mm)	10	0	10	0
No. 16 (1.18 mm)	40	10	40	10
No. 30 (600 µm)	65	30	65	30
No. 50 (300 µm)	90	70	80	60
No. 100 (150 µm)	100	95	90	75
No. 200 (75 µm)	100	97	100	90

6.1.1 Not more than 50 % shall be retained between any two consecutive sieves shown in the above table, nor more than 25 % between No. 50 (300-µm) and No. 100 (150-µm) sieves. The amount of material finer than a No. 200 (75-µm) sieve shall not exceed 3 %.

6.1.2 The fineness modulus shall fall between 2.05 and 3.05. If the fineness modulus varies by more than 0.25 from the value assumed in selecting proportions for the plaster, the aggregate shall be rejected unless adjustments are made in proportions to compensate for change in grading.

NOTE 1—The gradation of aggregate used in portland cement-based plaster affects the workability, shrinkage characteristic porosity, and durability of the plaster.

6.1.3 Aggregate failing to meet only the gradation limits of this specification shall be permitted to be used, provided the supplier furnishes satisfactory documentation to the specifier that the plaster made with the aggregate has an acceptable demonstrated performance record.

6.2 *Aggregate for Finish Coat Plaster*— Aggregate for finish coat plaster shall all pass the No. 8 (2.36 mm) sieve and meet the remaining gradation requirements of 6.1, except where special texture finishes require gradation of aggregate outside of these limits.

6.2.1 When special texture finishes require gradation of the aggregate outside of the limits of 6.1, sample panels shall be required and evaluated in accordance with criteria defined in the purchase agreement.

NOTE 2—Special texture finishes may require modification of the plaster formulation and application to compensate for the effect of aggregate gradation.

7. Sampling and Testing

7.1 The aggregate shall be sampled and tested as specified in the following methods, except as otherwise specified in this specification:

7.1.1 *Sampling*, Practice D 75.

7.1.2 *Fineness Modulus*, Terminology C 125, is obtained by adding the total percentages shown by the sieve analysis to be retained on each of the sieves in 6.1, except the No. 200 (75 µm) sieve, and dividing the sum by 100.

7.1.3 *Materials Finer than No. 200 (75-µm) Sieve*, Test Method C 117 by washing.

7.1.4 *Friable Particles*, Test Method C 142.

7.1.5 *Light Constituents*, Test Method C 123.

7.1.6 *Organic Impurities*, Test Method C 40.

7.1.7 *Soundness*, Test Method C 88.

7.1.8 *Sieve Analysis*, Test Method C 136.

8. Inspection

8.1 Inspection of the material shall be agreed upon between the purchaser and supplier as part of the purchase contract.

9. Rejection and Rehearing

9.1 Any rejection shall be based upon the specific cause of failure to conform to the requirements of this specification, and shall be reported to the seller within ten working days from the receipt of the shipment by the purchaser.

9.2 Claims for rehearing shall be valid only if made within 20 working days from receipt of notice of specific cause for rejection.

10. Certification

10.1 When specified in the purchase order a producer's or supplier's certification shall be furnished to the purchaser that the material was prepared or manufactured in accordance with this specification and has been found to meet the specified requirements.

11. Packaging and Package Marking

11.1 Where packaged, the materials shall be packaged in substantial commercial containers of the type, size, and kind commonly used for the purpose, so constructed as to preserve the contents in good condition, and to ensure acceptance and safe delivery by common or other carriers, at the lowest rate, to the point of delivery.

11.2 The containers shall be so made that the contents can be partially removed without destroying the container's ability to serve as a receptacle for the remainder of the contents.

11.3 The containers shall be labeled to show the content, weight, and the name of the manufacturer or supplier.

11.4 Where delivered in bulk quantities, the bill of lading shall show the quantity by weight, or cubic yards, and the name of the manufacturer or supplier.

11.5 Each package or container shall be marked with the name of manufacturer, description of contents, and amount.

12. Keywords

12.1 aggregate; fine aggregate; gradation; natural and manufactured sand; particle shape and size; plaster stucco; soundness

Designation: C 900 – 06

Standard Test Method for Pullout Strength of Hardened Concrete[1]

This standard is issued under the fixed designation C 900; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers determination of the pullout strength of hardened concrete by measuring the force required to pull an embedded metal insert and the attached concrete fragment from a concrete test specimen or structure. The insert is either cast into fresh concrete or installed in hardened concrete. This test method does not provide statistical procedures to estimate other strength properties.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 The text of this test method references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this test method.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**WARNING**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

E 4 Practices for Force Verification of Testing Machines

E 74 Practice of Calibration of Force-Measuring Instruments for Verifying the Force Indication of Testing Machines

3. Summary of Test Method

3.1 A metal insert is either cast into fresh concrete or installed into hardened concrete. When an estimate of the in-place strength is desired, the insert is pulled by means of a jack reacting against a bearing ring. The pullout strength is determined by measuring the maximum force required to pull the insert from the concrete mass. Alternatively, the insert is loaded to a specified load to verify whether a minimum level of in-place strength has been attained.

4. Significance and Use

4.1 For a given concrete and a given test apparatus, pullout strengths can be related to compressive strength test results. Such strength relationships depend on the configuration of the embedded insert, bearing ring dimensions, depth of embedment, and level of strength development in that concrete. Prior to use, these relationships must be established for each system and each new combination of concreting materials. Such relationships tend to be less variable where both pullout test specimens and compressive strength test specimens are of similar size, compacted to similar density, and cured under similar conditions.

NOTE 1—Published reports (**1-17**)[4] by different researchers present their experiences in the use of pullout test equipment. Refer to ACI 228.1R (**14**) for guidance on establishing a strength relationship and interpreting test results. The Appendix provides a means for comparing pullout strengths obtained using different configurations.

4.2 Pullout tests are used to determine whether the in-place strength of concrete has reached a specified level so that, for example:

(1) post-tensioning may proceed;

(2) forms and shores may be removed; or

(3) winter protection and curing may be terminated.

In addition, post-installed pullout tests may be used to estimate the strength of concrete in existing constructions.

4.3 When planning pullout tests and analyzing test results, consideration should be given to the normally expected decrease of concrete strength with increasing height within a

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.64 on Nondestructive and In-Place Testing.

Current edition approved Dec. 15, 2006. Published January 2007. Originally approved in 1978. Last previous edition approved in 2001 as C 900 – 01.

www.technobetar.ir

given concrete placement in a structural element. The measured pullout strength is indicative of the strength of concrete within the region represented by the conic frustum defined by the insert head and bearing ring. For typical surface installations, pullout strengths are indicative of the quality of the outer zone of concrete members and can be of benefit in evaluating the cover zone of reinforced concrete members.

4.4 Cast-in-place inserts require that their locations in the structure be planned in advance of concrete placement. Post-installed inserts can be placed at any desired location in the structure provided the requirements of 6.1 are satisfied.

4.5 This test method is not applicable to other types of post-installed tests that, if tested to failure, do not involve the same failure mechanism and do not produce the same conic frustum as the cast-in-place test described in this test method (**16**).

5. Apparatus

5.1 The apparatus requires three basic sub-systems: a pull-out insert, a loading system, and a load-measuring system (Note 2). For post-installed inserts, additional equipment includes a core drill, a grinding wheel to prepare a flat bearing surface, a milling tool to undercut a groove to engage the insert, and an expansion tool to expand the insert into the groove.

NOTE 2—A center-pull hydraulic jack with a pressure gauge calibrated according to Annex A1 and a bearing ring have been used satisfactorily.

5.1.1 Cast-in-place inserts shall be made of metal that does not react with cement. The insert shall consist of a cylindrical head and a shaft to fix embedment depth. The shaft shall be attached firmly to the center of the head (see Fig. 1). The insert shaft shall be threaded to the insert head so that it can be removed and replaced by a stronger shaft to pullout the insert, or it shall be an integral part of the insert and also function as the pullout shaft. Metal components of cast-in-place inserts and attachment hardware shall be of similar material to prevent galvanic corrosion. Post-installed inserts shall be designed so that they will fit into the drilled holes, and can be expanded subsequently to fit into the grooves that are undercut at a predetermined depth (see Fig. 2).

NOTE 3—A successful post-installed system uses a split ring that is coiled to fit into the core hole and then expanded into the groove.

5.1.2 The loading system shall consist of a bearing ring to be placed against the hardened concrete surface (see Figs. 1 and 2) and a loading apparatus with the necessary load-measuring devices that can be readily attached to the pullout shaft.

5.1.3 The test apparatus shall include centering features to ensure that the bearing ring is concentric with the insert, and that the applied load is axial to the pullout shaft, perpendicular to the bearing ring, and uniform on the bearing ring.

5.2 Equipment dimensions shall be determined as follows (see Fig. 1):

5.2.1 The diameter of the insert head (d_2) is the basis for defining the test geometry. The thickness of the insert head and the yield strength of the metal shall be sufficient to prevent yielding of the insert during test. The sides of the insert head shall be smooth (see Note 5). The insert head diameter shall be greater than or equal to ⅔ of the nominal maximum size of aggregate.

NOTE 4—Typical insert diameters are 25 and 30 mm, but larger

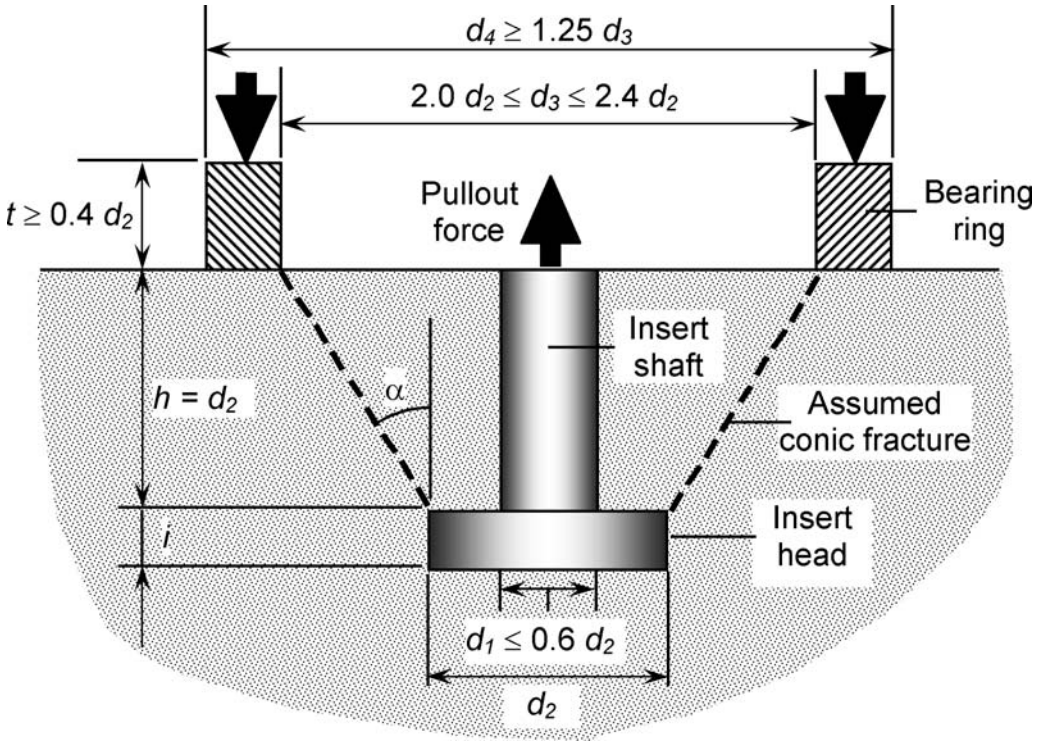

FIG. 1 Schematic Cross Section of Cast-in-Place Pullout Test

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

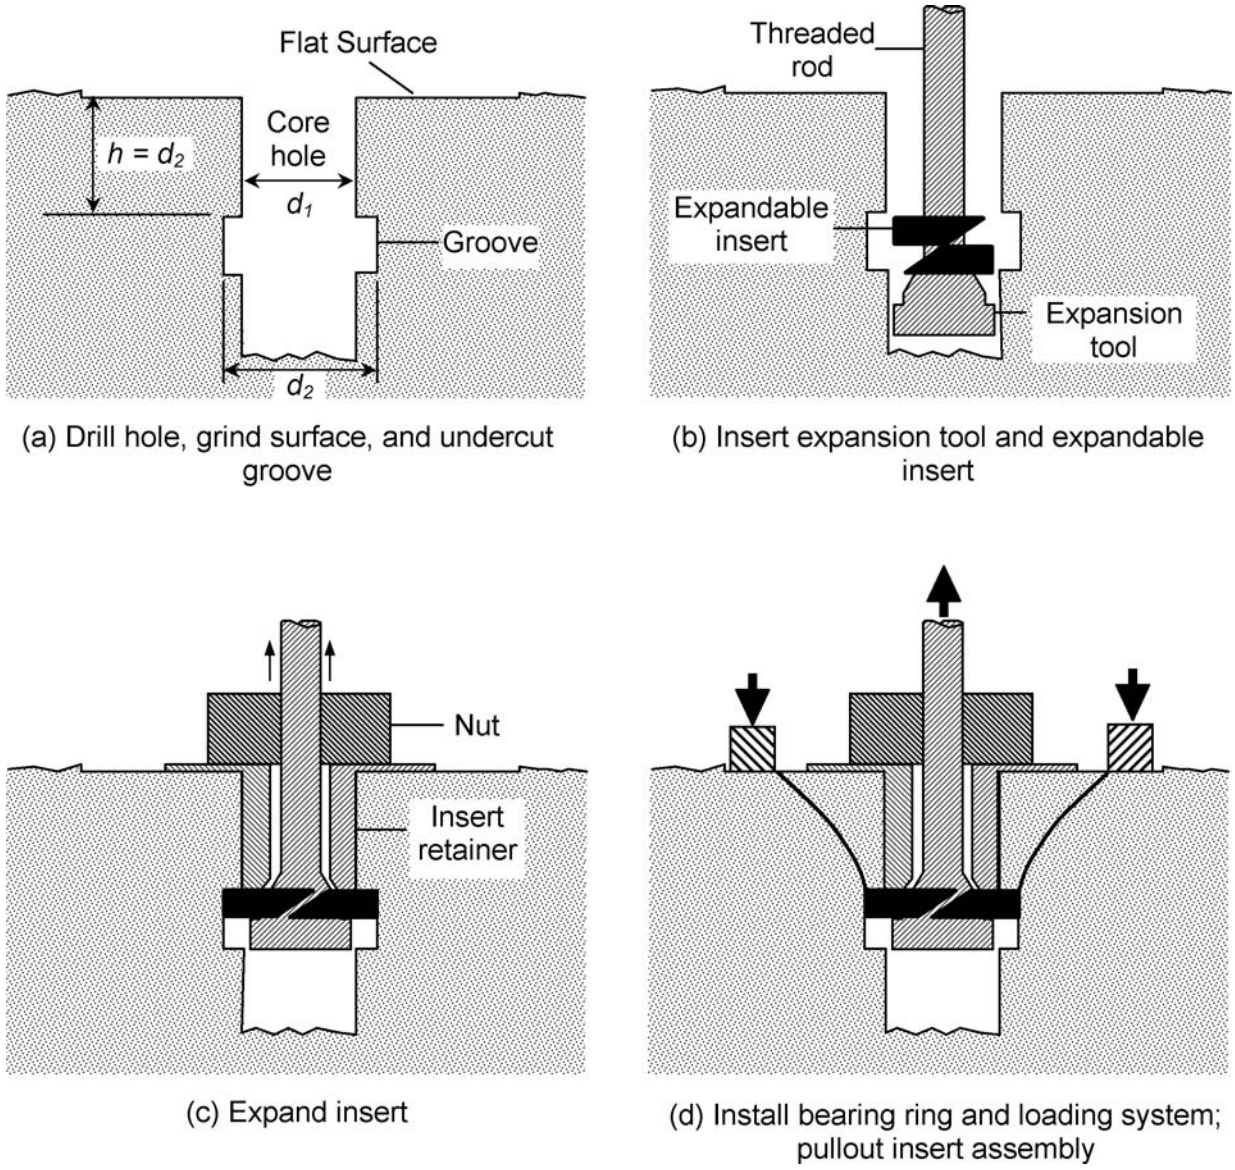

FIG. 2 Schematic of Procedure for Post-Installed Pullout Test

diameters have been used (**1, 3**). Tests (**15**) have shown that nominal maximum aggregate sizes up to 1.5 times the head diameter do not have significant effects on the strength relationships. Larger aggregate sizes may result in increased scatter of the test results because the large particles can interfere with normal pullout of the conic frustum.

NOTE 5—Cast-in–place inserts may be coated with a release agent to minimize bonding with the concrete, and they may be tapered to minimize side friction during testing. The insert head should be provided with the means, such as a notch, to prevent rotation in the concrete if the insert shaft has to be removed prior to performing the test. As a further precaution against rotation of the insert head, all threaded hardware should be checked prior to installation to ensure that it is free-turning and can be easily removed. A thread-lock compound is recommended to prevent loosening of the insert head from the shaft during installation and during vibration of the surrounding concrete.

5.2.2 For cast-in–place inserts, the length of the pullout insert shaft shall be such that the distance from the insert head to the concrete surface (h) equals the diameter of the insert head (d_2). The diameter of the insert shaft at the head (d_1) shall not exceed 0.60 d_2.

5.2.3 For post-installed inserts, the groove to accept the expandable insert shall be cut so that the distance between the bearing surface of the groove and concrete surface equals the insert diameter after expansion (d_2). The difference between the diameters of the undercut groove (d_2) and the core hole (d_1) shall be sufficient to prevent localized failure and ensure that a conic frustum of concrete is extracted during the test (see Note 6). The expanded insert shall bear uniformly on the entire bearing area of the groove.

NOTE 6—A core hole diameter of 18 mm and an undercut groove diameter of 25 mm have been used successfully.

5.2.4 The bearing ring shall have an inside diameter (d_3) of 2.0 to 2.4 times the insert head diameter (d_2), and shall have an outside diameter (d_4) of at least 1.25 times the inside diameter. The thickness of the ring (t) shall be at least 0.4 times the pullout insert head diameter.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

5.2.5 Tolerances for dimensions of the pullout test inserts, bearing ring and embedment depth shall be ±2 % within a given system.

NOTE 7—The limits for dimensions and configurations for pullout test inserts and apparatus are intended to accommodate various systems.

5.2.6 The loading apparatus shall have sufficient capacity to provide the loading rate prescribed in 7.4 and exceed the maximum load expected.

NOTE 8—Hydraulic pumps that permit continuous loading may give more uniform test results than pumps that apply load intermittently.

5.2.7 The gauge to measure the pullout force shall have a least division not larger than 5 % of the minimum value in the intended range of use.

5.2.8 The force gauge shall have a maximum value indicator that preserves the value of the maximum load during testing.

5.2.9 Pullout apparatus shall be calibrated in accordance with Annex A1 at least once a year and after all repairs. Calibrate the pullout apparatus using a testing machine verified in accordance with Practices E 4 or a Class A load cell as defined in Practice E 74. The indicated pullout force based on the calibration relationship shall be within ±2 % of the force measured by the testing machine or load cell.

6. Sampling

6.1 Pullout test locations shall be separated so that the clear spacing between inserts is at least seven times the pullout insert head diameter. Clear spacing between the inserts and the edges of the concrete shall be at least 3.5 times the head diameter. Inserts shall be placed so that reinforcement is outside the expected conical failure surface by more than one bar diameter, or the maximum size of aggregate, whichever is greater.

NOTE 9—A reinforcement locator is recommended to assist in avoiding reinforcement when planning the locations of post-installed tests. Follow the manufacturer's instructions for proper operation of such devices.

6.2 When pullout test results are used to assess the in-place strength in order to allow the start of critical construction operations, such as formwork removal or application of post tensioning, at least five individual pullout tests shall be performed as follows:

6.2.1 For a given placement, every 115 m^3, or a fraction thereof, or

6.2.2 For slabs or walls, every 470 m^2 , or a fraction thereof, of the surface area of one face.

NOTE 10—More than the minimum number of inserts should be provided in case a test result is not valid or testing begins before adequate strength has developed.

6.2.3 Inserts shall be located in those portions of the structure that are critical in terms of exposure conditions and structural requirements.

6.3 When pullout tests are used for other purposes, the number of tests shall be determined by the specifier.

7. Procedure

7.1 *Cast-in-Place Inserts*:

7.1.1 Attach the pullout inserts to the forms using bolts or by other acceptable methods that firmly secure the insert in its proper location prior to concrete placement. All inserts shall be embedded to the same depth. The axis of each shaft shall be perpendicular to the formed surface.

7.1.2 Alternatively, when instructed by the specifier of tests, manually place inserts into unformed horizontal concrete surfaces. The inserts shall be embedded into the fresh concrete by means that ensure a uniform embedment depth and a plane surface perpendicular to the axis of the insert shaft. Installation of inserts shall be performed or supervised by personnel trained by the manufacturer or manufacturer's representative.

NOTE 11—Experience indicates that pullout strengths are of lower value and more variable for manually-placed surface inserts than for inserts attached to formwork (12).

7.1.3 When pullout strength of the concrete is to be measured, remove all hardware used for securing the pullout inserts in position. Before mounting the loading system, remove any debris or surface abnormalities to ensure a flat bearing surface that is perpendicular to the axis of the insert.

7.2 *Post-Installed Inserts*:

7.2.1 The selected test surface shall be flat to provide a suitable working surface for drilling the core and undercutting the groove. Drill a core hole perpendicular to the surface to provide a reference point for subsequent operations and to accommodate the expandable insert and associated hardware. The use of an impact drill is not permitted.

7.2.2 If necessary, use a grinding wheel to prepare a flat surface so that the base of the milling tool is supported firmly during subsequent test preparation and so that the bearing ring is supported uniformly during testing. The ground surface shall be perpendicular to the axis of the core hole.

7.2.3 Use the milling tool to undercut a groove of the correct diameter and at the correct depth in the core hole. The groove shall be concentric with the core hole.

NOTE 12—To control the accuracy of these operations, a support system should be used to hold the apparatus in the proper position during these steps.

7.2.4 If water is used as a coolant, remove free-standing water from the hole at the completion of the drilling and undercutting operations. Protect the hole from ingress of additional water until completion of the test.

NOTE 13—Penetration of water into the failure zone could affect the measured pullout strength; therefore, water must be removed from the hole immediately after completion of drilling, grinding, and undercutting operations. If the test will not be completed immediately after preparation of the hole, water must not be allowed to enter the hole before completing the test.

7.2.5 Use the expansion tool to position the expandable insert into the groove and expand the insert to its proper size.

7.3 *Bearing Ring*—Place the bearing ring around the pullout insert shaft, connect the pullout shaft to the hydraulic ram, and tighten the pullout assembly snugly against the bearing surface. Ensure that the bearing ring is centered around the shaft and flush against the concrete.

7.4 *Loading Rate*—Apply load at a uniform rate so that the nominal normal stress on the assumed conical fracture surface increases at a rate of 70 ± 30 kPa/s (Note 14). If the insert is to be tested to rupture of the concrete, load at the specified uniform rate until rupture occurs. Record the maximum gauge

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

reading to the nearest half of the least division on the dial. If the insert is to be tested only to a specified load to verify whether a minimum in-place strength has been attained, load at the specified uniform rate until the specified pullout load is reached. Maintain the specified load for at least 10 s.

NOTE 14—The loading rate is specified in terms of a nominal stress rate to accommodate different sizes of pullout test systems. See Appendix X1 for the formula relating the nominal normal stress and the pullout load. For a pullout test system in which d_2 = 25 mm and d_3 = 55 mm, the specified stress rate corresponds to a loading rate of approximately 0.5 ± 0.2 kN/s. If this system is used, the ranges of the times to complete a test for different anticipated ultimate pullout loads would be as follows:

Anticipated Pullout Load, kN	Minimum Time, s	Maximum Time, s
10	14	33
20	29	67
30	43	100
40	57	133
50	71	167
60	86	200
70	100	233
80	114	267
90	129	300
100	143	333

7.4.1 Do not test frozen concrete.

7.5 *Rejection*—Reject a test result if one or more of the following conditions are encountered:

7.5.1 The large end of the conic frustum is not a complete circle of the same diameter as the inside diameter of the bearing ring;

7.5.2 The distance from the surface to the insert head (*h* in Fig. 1 or Fig. 2) is not equal to the insert diameter;

7.5.3 The diameter of the groove in a post-installed test is not equal to the design value;

7.5.4 The expanded insert diameter in a post-installed test is not equal to the design value; or,

7.5.5 A reinforcing bar is visible within the failure zone after the conic frustum is removed.

8. Calculation

8.1 Convert gauge readings to pullout force on the basis of calibration data.

8.2 Compute the average and standard deviation of the pullout forces that represent tests of a given concrete placement.

9. Report

9.1 Report the following information:

9.1.1 Dimension of the pullout insert and bearing ring (sketch or define dimensions),

9.1.2 Identification by which the specific location of the pullout test can be identified,

9.1.3 Date and time when the pullout test was performed.

9.1.4 For tests to failure, maximum pullout load of individual tests, average, and standard deviation, kN. For tests to a specified load, the pullout load applied in each test, kN.

9.1.5 Description of any surface abnormalities beneath the reaction ring at the test location,

9.1.6 Abnormalities in the ruptured specimen and in the loading cycle,

9.1.7 Concrete curing methods used and moisture condition of the concrete at time of test, and

9.1.8 Other information regarding unusual job conditions that may affect the pullout strength.

10. Precision and Bias

10.1 *Single Operator Precision*—Based on the data summarized in ACI 228.1 R (**14**) for cast-in-place pullout tests with embedment of about 25 mm, the average coefficient of variation for tests made on concrete with maximum aggregate of 19 mm by a single operator using the same test device is 8 %.[5] Therefore, the range in individual test results, expressed as a percentage of the average, should not exceed the following:

Number of Tests	Acceptable range, (percent of average)
5	31 %
7	34 %
10	36 %

Similar values of within-test variability have been reported for post-installed pullout tests of the same geometry as cast-in-place tests (**15**).

NOTE 15—If the range of tests results exceeds the acceptable range, further investigation should be carried out. Abnormal test results could be due to improper procedures or equipment malfunction. The user should investigate potential causes of outliers and disregard those test results for which reasons for the outlying results can be identified positively. If there are no obvious causes of the extreme values, it is probable that there are real differences in concrete strength at different test locations. These differences could be due to variations in mixture proportions, degree of consolidation, or curing conditions.

10.2 *Multi-Operator Precision*—Test data are not available to develop a multi-operator precision statement.

10.3 *Bias*—The bias of this test method cannot be evaluated since pullout strength can only be determined in terms of this test method.

11. Keywords

11.1 concrete strength; in-place strength; in-place testing; pullout test

[5] This number represents the (1s%) limit as described in Practice C 670.

ANNEX

(Mandatory Information)

A1. CALIBRATION OF PULLOUT-HYDRAULIC LOADING SYSTEM

A1.1 The objective of the calibration procedure is to establish a relationship between the reading of the pullout force measuring system and the tensile force in the shaft used to pullout the insert. This relationship is established using alternative approaches as indicated in Fig. A1.1. In general, calibration is achieved by correlating the gauge reading of the pullout loading system with the force measured by a testing machine that has been verified in accordance with Practices E 4 or measured with a Class A load cell that has been calibrated in accordance with Practice E 74. The time interval between testing machine verifications or load cell calibrations shall be as defined in Practices E 4 or E 74.

A1.2 Position the pullout loading system on the force measurement apparatus. Align all components so that the pullout force is concentric with the loading system and the force measurement system. Use spherical seats or other similar means to minimize bending effects in the loading system.

NOTE A1.1—When a compression-testing machine is used to measure the force, the bearing blocks should be protected against damage.

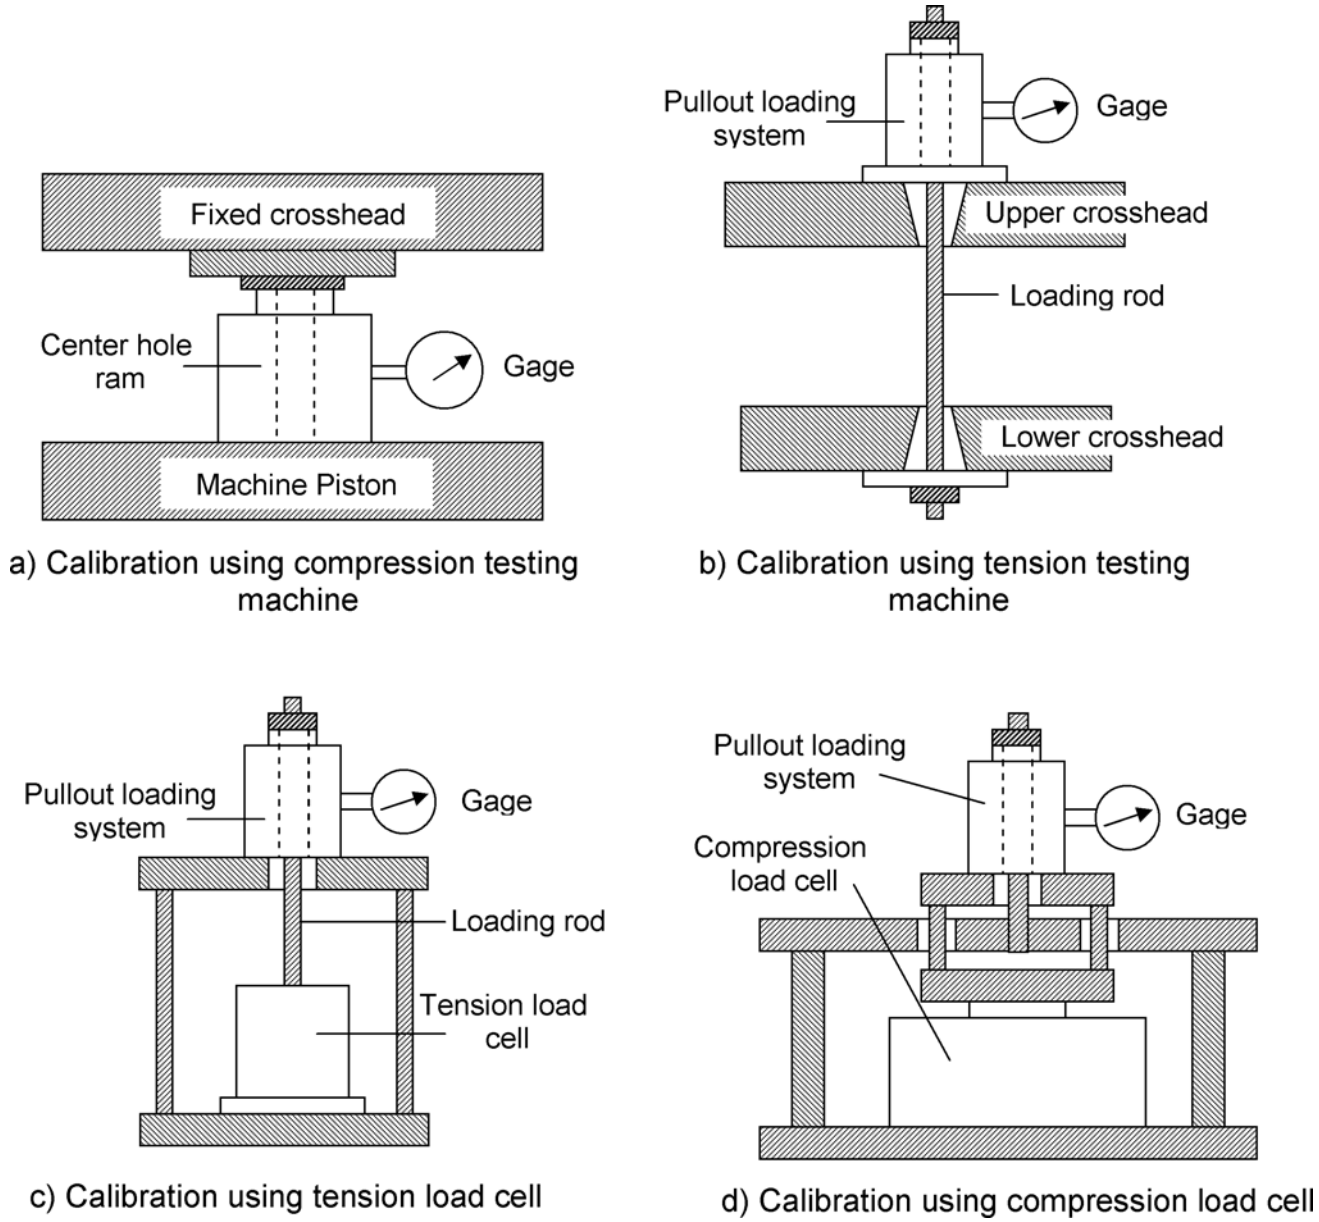

FIG. A1.1 Schematics of Acceptable Methods to Calibrate Pullout Load Measuring System

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Cold-rolled steel plate at least 13 mm thick is recommended.

A1.3 Using the pullout loading system, apply increasing loads over the operating range, and record the gauge reading and the corresponding force measured by the testing machine or load cell. Take readings at approximately 10 load levels distributed over the operating range of the pullout loading system.

NOTE A1.2—Low values of force should be avoided in the calibration process because the effects of friction may introduce significant errors. The manufacturer should provide the operating range of the pullout loading system.

A1.4 Use the readings obtained during calibration loading to calculate an appropriate regression equation using the least-squares curve-fitting method.

NOTE A1.3—Appendix X2 provides an example to illustrate the development of a calibration equation. Additional information is provided in Practice E 74.

A1.5 The difference between the force based on the regression equation and the force measured by the testing machine or the load cell shall not be greater than ±2 % of the measured force over the operating range. If this tolerance is not met, the pullout loading system shall not be used until this requirement is satisfied.

APPENDIXES

(Nonmandatory Information)

X1. STRESS CALCULATION

X1.1 When a stress calculation is desired, compute a nominal normal stress on the assumed conical fracture surface by dividing the pullout force by the area of the frustum and multiplying by the sine of one-half the apex angle (see Fig. 1). Use the following equations:

$$f_n = \frac{P}{A}\sin\alpha \tag{X1.1}$$

$$\sin\alpha = \frac{d_3 - d_2}{2S} \tag{X1.2}$$

$$A = \pi S\frac{d_3 + d_2}{2} \tag{X1.3}$$

$$S = \sqrt{h^2 + \left(\frac{d_3 - d_2}{2}\right)^2} \tag{X1.4}$$

where:

f_n = nominal normal stress, MPa,
P = pullout force, N,
α = ½ the frustum apex angle, or $\tan^{-1}(d_3 - d_2)/2h$,
A = fracture surface area, mm^2 ,
d_2 = diameter of pullout insert head, mm,
d_3 = inside diameter of bearing ring or large base diameter of assumed conic frustum, mm,
h = height of conic frustum, from insert head to large-base surface, mm , and
S = slant length of the frustum, mm.

X1.2 The above calculation gives the value of the average normal stress on the assumed failure surface shown in Fig. 1. Because the state of stress on the conic frustum is not uniform, the calculated normal stress is a fictitious value. The calculated normal stress is useful when comparing pullout strengths obtained with different test geometries that fall within the limits of this test method.

X2. EXAMPLE TO ILLUSTRATE CALIBRATION PROCESS

X2.1 This appendix provides an example to illustrate the development of the calibration equation to convert the gauge reading on the pullout loading system to the force acting on the insert. Table X2.1 shows data that were obtained using the procedure in the annex. The first column shows the gauge reading and the second column shows the measured force.

X2.2 Fig. X2.1 shows a plot of the data in Table X2.1 along with the best-fit straight line to the data. A straight line was fitted using a commercial computer program for graphing and statistical analysis. The equation of the line is shown in the table of results on the graph and is as follows:

$$P\ (\text{kN}) = -0.55 + 1.089\ G\ (\text{kN}) \tag{X2.1}$$

TABLE X2.1 Example of Calibration Data and Residuals After Regression

Gauge Reading, kN	Measured Force, kN	Residuals, kN
2.0	1.6	0.03
5.0	4.8	0.09
10.0	10.5	–0.16
15.0	15.8	–0.02
20.0	21.2	0.03
25.0	26.7	–0.03
30.0	32.0	0.12
35.0	37.4	0.16
40.0	42.8	0.21
45.0	48.6	–0.14
50.0	54.2	–0.30
55.0	59.4	–0.06
60.0	64.5	0.29

www.technobetar.ir

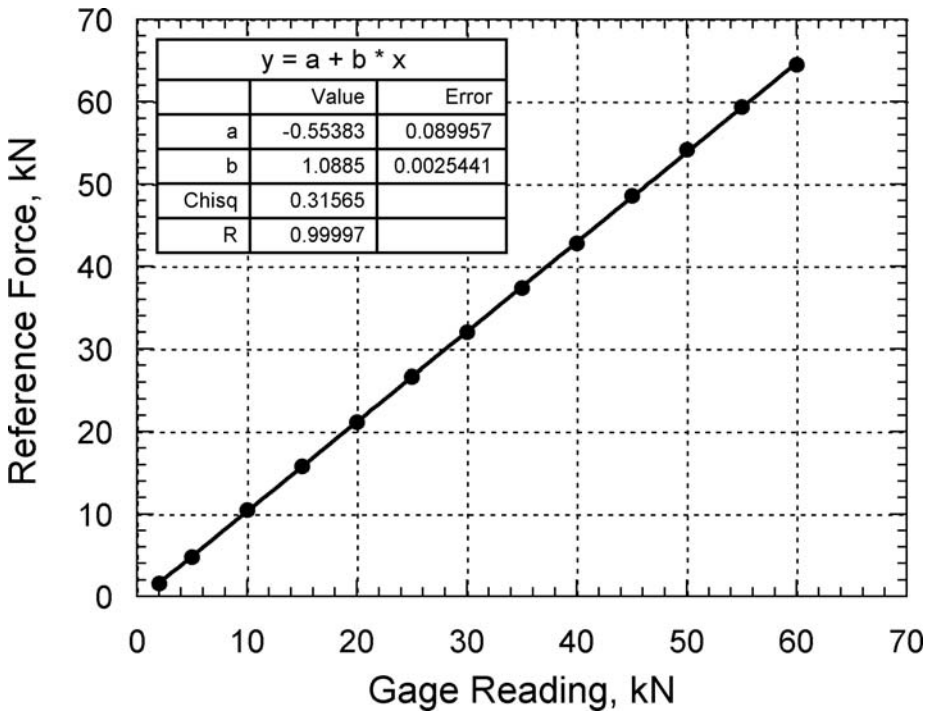

FIG. X2.1 Plot of Calibration Data from Table X2.1 and Best-Fit Straight Line

where:

P = estimated pullout force, kN, and

G = pullout force indicated by gauge of pullout loading system, kN.

The column labeled "error" in the table shown within Fig. X2.1 represents the standard deviations of the estimated intercept and slope. The low values of these standard deviations relative to the slope and intercept indicate that the intercept is not zero and that the slope is not equal to 1.00.

X2.3 Fig. X2.2 is a plot of the residuals of the best-fit line as a function of the measured force. These residuals are shown in the third column of Table X2.1, and they are the differences between the estimated force based on the best-fit equation and the measured force (Column 2 in Table X2.1). Also shown in Fig. X2.2 are the ±2 % limits required in accordance with 5.2.9. It is seen that, with the exception of the first three points, the residuals are well within the permitted tolerance. Thus, the calibration relationship for this particular apparatus satisfies the requirements of 5.2.9 provided that the pullout force is greater than about 10 kN.

X2.4 Fig. X2.2 shows that the residuals are not randomly distributed but appear to have a periodic variation with the level of force. This indicates that the true calibration equation is not a straight line. However, because the residuals are well below the ±2 % limits, it is not necessary to try to fit a higher order (polynomial) equation, and the straight line is adequate. Additional discussion on fitting higher order equations is provided in Practice E 74.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 900 – 01, that may impact the use of this test method. (Approved December 15, 2006)

(*1*) Revised 1.1 to clarify that the method does not address statistical analysis needed to estimate other types of strength.
(*2*) Revised 1.2 by deleting inch-pound values for information only.
(*3*) Revised 1.4 by adding a warning on chemical burns.
(*4*) Revised 3.1 by adding statement that test may not have to be carried out to ultimate load.
(*5*) Added 5.2.8 to make a peak load indicator mandatory.
(*6*) Revised 6.1 to permit the use of smaller specimens for correlation testing.
(*7*) Added Note 10 to recommend more than the minimum number of inserts as a precaution.
(*8*) Revised 7.1.2 by permitting the use of manually placed inserts as an alternative when specified.
(*9*) Revised 7.4 by including a minimum hold time for tests carried out to a specified load.
(*10*) Added 7.4.1 to prohibit testing frozen concrete.
(*11*) Added 10.2 to indicate that data are not available for a multi-laboratory precision statement.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 911 – 06

Standard Specification for Quicklime, Hydrated Lime, and Limestone for Selected Chemical and Industrial Uses[1]

This standard is issued under the fixed designation C 911; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers lime and limestone products suitable for the following chemical and industrial uses:

Cooking rags
Sulfite pulp
Silica brick
Other water treatment uses
Calcium carbide
Grease
Calcium silicate products
Hypochlorite (bleach)

The following uses are addressed in other ASTM standards:

Use	Standard(s)
Neutralization of Waste Acid (Test Methods)	C 400
Agricultural Liming Materials	C 602
Soil Stabilization	C 977
Asphalt	C 1097
Flue Gas Desulfurization (Test Methods)	C 1318
Drinking Water Softening	C 1529
Waste and Wastewater Neutralization	C 1529
Wastewater Treatment Plant Residuals (Biosolids) Stabilization	C 1529 and D 6249

1.2 The type designations in Table 1 signify the following:

Limestone, high-calcium—CL
Limestone, dolomitic—DL
Limestone, magnesian—ML
Quicklime, high-calcium—CQ
Quicklime, dolomitic—DQ
Quicklime, magnesian—MQ
Hydrated lime, high-calcium—CH
Hydrated lime, dolomitic—DH
Hydrated lime, magnesian—MH

1.3 The buyer shall designate the use, as listed in Table 1, and may specify one or more of the type designations in 1.1.

1.4 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

C 977 Specification for Quicklime and Hydrated Lime for Soil Stabilization
C 1097 Specification for Hydrated Lime for Use in Asphalt Cement or Bituminous Pavements
C 1318 Test Method for Determination of Total Neutralizing Capability and Dissolved Calcium and Magnesium Oxide in Lime for Flue Gas Desulfurization (FGD)
C 1529 Specification for Quicklime, Hydrated Lime, and Limestone for Environmental Uses
D 6249 Guide for Alkaline Stabilization of Wastewater Treatment Plant Residuals

3. Chemical Composition

3.1 The requirements for quicklime, hydrated lime, and limestone for the selected end uses are as shown in Table 1, and are on the basis of the weight of sample taken at the place of manufacture, except as noted in footnote *B* after the requirement. In this case, the requirement is on a moisture and carbon dioxide-free basis.

NOTE 1—Rags are cooked for the manufacture of paper in a digester under steam pressure with lime or with lime and soda ash. They are then washed to eliminate as much of the noncellulose material as possible. A standard composition without rejection limits is specified for the reason that lime of either higher or lower total oxides, available lime, calcium oxide, or calcium hydroxide than the standard, may safely be used under suitable conditions for the purpose herein specified, depending primarily upon economic considerations. In the present state of the art, it is believed that the more serviceable type of specification for the product herein

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved Nov. 15, 2006. Published November 2006. Originally approved in 1979. Last previous edition approved in 2005 as C 911 – 05.

[B] Standard composition.
[C] On a nonvolatile basis.

specified is that which defines a reasonable standard rather than one that fixes actual rejection limits. It is generally recognized that, other things being equal, lime meeting this standard is preferable to lime that does not, and lime surpassing the standard should be considered of premium quality.

NOTE 2—Lime is used in the "milk of lime" or "tank" system of sulfite pulp manufacture for making the cooking liquor. The milk of lime is held in solution or suspension in a series of tanks equipped with suitable agitators. The sulfur dioxide (SO_2) is forced or drawn through these tanks successively. In some cases, the tanks are built on top of each other in the form of a tower. The contents of the first tank are drawn off when the liquor has reached a certain strength (3.5 to 6 % total SO_2) and the contents of the second and third tanks progress to the first and second tanks respectively. The third tank is again charged with fresh milk of lime. There are other systems of absorption that provide for continuous instead of intermittent operation. The function of the lime is to furnish the base for the formation of the bisulfites of calcium and magnesium.

NOTE 3—In the manufacture of silica brick, silica in the form of massive quartzite or quartz conglomerate is ground until the particles are less than ¼ in. (6 mm) in size. Lime in the form of either slaked or hydrated lime is then added in quantities varying from 1.5 to 3.0 % calcium oxide (CaO), with sufficient water to produce about 5 to 7 % moisture content, and the shapes are molded and dried. They are then burned in downdraft or tunnel kilns until most of the quartzite has been converted into tridymite or cristobalite.

NOTE 4—For most water treatment applications, such as color removal and clarification of water for municipal and industrial supplies, high-calcium lime is preferred. However, for applications involving silica removal from boiler feedwater, dolomitic lime is usually preferred. Drinking water softening and wastewater neutralization are addressed in Specification C 1529.

NOTE 5—In manufacture of calcium hypochlorite bleach, lime hydrate in water suspension is reacted with chlorine. Lime hydrate suitable for this application should be rapidly reactive, low in sludge-forming impurities, and particularly low in iron oxide, that may catalyze bleach decomposition.

4. General Requirements

4.1 Quicklime shall be reasonably free of unslakable residues and shall be capable of disintegrating in water to form a suspension of finely divided material.

5. Sampling and Inspection

5.1 Conduct the sampling, inspection, rejection, retesting, packaging, and marking in accordance with Methods C 50.

6. Test Methods

6.1 The chemical analyses shall be made in accordance with Test Methods C 25.

6.2 The physical tests shall be made in accordance with Test Methods C 110.

7. Keywords

7.1 by-product lime; calcium oxide; calcium silicate; chemical uses; color removal; dolomitic hydrated lime; dolomitic lime; dolomitic limestone; dolomitic quicklime; high calcium hydrated lime; high calcium limestone; high calcium quicklime; hydrated lime; hypochlorite bleach; industrial uses; lime; limestone; magnesian hydrated lime; magnesian limestone; magnesian quicklime; quicklime; silica brick; silica removal; sulfite pulp

APPENDIX

(Nonmandatory Information)

X1. TEST METHOD FOR FREE CALCIUM OXIDE IN HIGH-CALCIUM HYDRATED LIME

X1.1 Scope

X1.1.1 This test method covers the determination of the amount of free calcium oxide (CaO) in high-calcium hydrated lime capable of being hydrated by steam at atmospheric pressure.

X1.2 Summary of Test Method

X1.2.1 This test method is based on the principle of gain in weight of CaO when it is hydrated to form calcium hydroxide ($Ca(OH)_2$).

X1.2.2 The sample is dried, subjected to steam at atmospheric pressure, again dried, and the gain in weight calculated to CaO.

X1.3 Apparatus

X1.3.1 *Drying Oven*, thermostatically controlled, CO_2-free atmosphere.

X1.3.2 *Analytical Balance*.

X1.3.3 *Steam Bath*, as shown in Fig. X1.1.

X1.4 Procedure

X1.4.1 Weigh a clean, dry, 10-mL Erlenmeyer flask on an analytical balance.

NOTE X1.1—Once started, complete the test without interruption.

X1.4.2 Add to the flask, by means of a widestem funnel, 3 to 5 g of the lime to be tested. Reweigh to get the exact sample weight.

NOTE X1.2—The flask should be kept stoppered at all times, except when weighing, drying, or steaming.

X1.4.3 Place the flask in the drying oven that has been previously heated to 120 °C, and maintain at this temperature for 30 min. Remove, stopper, cool in a desiccator, and weigh.

NOTE X1.3—Oven atmosphere can be kept CO_2 free by placing therein a container of soda lime, quicklime, or other suitable CO_2-absorbing medium.

X1.4.4 Place the flask and the sample in a vigorously boiling steam bath and steam for 30 min. Protect the flask in

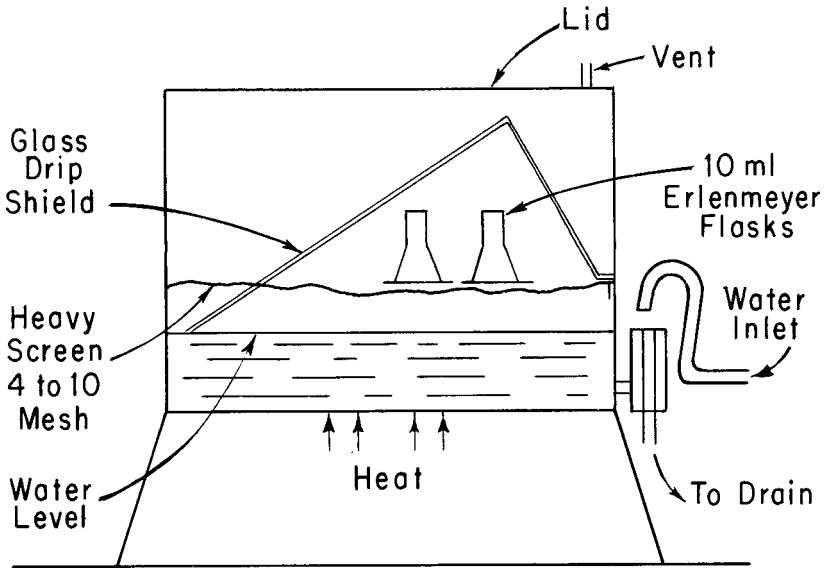

FIG. X1.1 Steam Chamber

www.technobetar.ir

the steam bath by a drip shield during the steaming period. Remove the flask to the oven, dry for 30 min at 120 °C, stopper, cool in a desiccator, and weigh.

X1.4.5 Record all weighings to the fourth decimal place.

X1.5 Calculation

X1.5.1 Calculate the percentage of water and CaO as follows:

$$\text{Free water, } \% = [(W_1 - W_2)/S] \times 100 \quad \text{(X1.1)}$$

$$\text{Free CaO, } \% = \frac{(W_3 - W_2) \times 3.114}{S} \times 100$$

where:

W_1 = weight of sample and flask before drying,
W_2 = weight of sample and flask after drying,
W_3 = weight of sample and flask after steaming and drying, and
S = weight of sample.

SUMMARY OF CHANGES

Committee C07 has identified the location of selected changes to this specification since the last issue, C 911 – 05, that may impact the use of this specification. (Approved November 15, 2006)

(*1*) Revised 1.1, moving part of it to new 1.2, and renumbered subsequent paragraphs.

(*2*) Revised Note 4.

(*3*) Revised the Use column in Table 1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 917 – 05

Standard Test Method for Evaluation of Cement Strength Uniformity From a Single Source[1]

This standard is issued under the fixed designation C 917; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method is intended for use in instances in which the purchaser desires information on the strength uniformity of a hydraulic cement produced at a single source. It is intended that this test method normally be used for the predominant cement manufactured at a cement plant. Guidelines for sampling, testing, presentation of results, and evaluation are given.

1.2 The values stated in inch-pound units are to be regarded as the standard. The values in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)
C 150 Specification for Portland Cement
C 219 Terminology Relating to Hydraulic Cement
C 595 Specification for Blended Hydraulic Cements
C 1157 Performance Specification for Hydraulic Cement
E 456 Terminology Relating to Quality and Statistics

3. Terminology

3.1 *Definitions*—For definitions of terms relating to this test method, refer to Terminologies C 219 and E 456.

4. Significance and Use

4.1 This test method is designed to present in a standardized format information on the variability of strength of cement from a single source over a period of time. It can be applied to all hydraulic cements covered in Specifications C 150, C 595, and C 1157.

NOTE 1—It should be recognized that concrete strength variability is influenced by other factors in addition to cement strength variability.

5. Sampling

5.1 All sampling shall be performed by quality control or testing personnel or someone specifically trained for this purpose.

5.2 Take random grab samples from delivery units or during the loading or unloading process. Delivery units larger than 125 tons (115 Mg) shall be sampled during loading or unloading. If samples are taken during loading or unloading, the two or more portions that are to be composited to make a sample shall be taken during the transfer to no more than 125 tons (115 Mg) of cement. Identify samples by the date on which the cement they represent was shipped or received.

NOTE 2—Standard statistical procedures are recommended for ensuring that samples are selected by a random procedure. These procedures can be used to select the days within a month or within a week that samples will be taken. Then the delivery unit or the time of day can be chosen randomly.

5.3 If taken from a truck or rail car, take at least two separate 5-lb (approximately 2.3-kg) grab samples and thoroughly mix together to obtain a minimum 10-lb (4.5-kg) test sample. Sample only through hatches in the top of the unit. Remove approximately a 12-in. (300-mm) layer of cement. Make a hole before obtaining a sample to avoid collecting dust collector material that may be discharged into the delivery unit after the cement flow ceases.

5.4 If taken from another point in the loading or unloading process, the sample shall consist of a minimum of two separate 5-lb (approximately 2.3-kg) grab samples thoroughly mixed together or at least 10 lb (4.5 kg) as accumulated by a continuous sampler. Take care to avoid segregation and contamination of samples taken from screws, pneumatic systems, or air slides.

5.5 When samples are taken at the cement plant and shipments or rate of production of the cement exceeds 25 000 tons (23 000 Mg) per month, take samples at a rate of at least ten per month and at least two per week. When shipment or rate

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.27 on Strength.

Current edition approved Feb. 1, 2005. Published February 2005. Originally approved in 1979. Last previous edition approved in 1998 as C 917–98.

www.technobetar.ir

of production of the cement is less than 25 000 tons (23 000 Mg) per month, take samples at a rate of at least one per 2500 tons (2300 Mg). When samples are taken at the cement plant, in no instance shall samples be taken more frequently than one per 200 tons (180 Mg) of cement shipped or received, except that sampling of consecutive shipments is permitted when they result from randomization.

6. Procedure

6.1 Test all samples for 7- and 28-day compressive strength in accordance with Test Method C 109/C 109M using three specimens for each test age. To be comparable, all tests used in a single evaluation must be made in a single laboratory and preferably by the same laboratory operator.

NOTE 3—When separate evaluations of a single source are made by two or more laboratories, additional tests of a standard cement or exchange of portions of the same sample of cement may be necessary to determine differences in testing that are likely to be obtained in the different laboratories. Five or more batches may be necessary to obtain a valid comparison between laboratories. Statistical techniques must be used to assess the validity of differences that might be obtained. Participation in the Cement Proficiency Sample Program of the CCRL by both laboratories will be helpful in resolving differences that are found.

6.1.1 When two laboratories exchange portions of the same sample and prepare single batches, results from the two laboratories shall not differ by more than 18.7 % of the average of the two laboratories (see Test Method C 109/C 109M multilaboratory d2s). If a larger number of samples are exchanged the difference in average strength shall not exceed $18.7/\sqrt{n}$ % of the overall average strength, where n is the number of samples exchanged and tested by each laboratory. A more precise calculation is outlined in Appendix X1.

6.2 Mix duplicate batches of mortar to determine the effect of testing variations on the uniformity of results made in a single laboratory. Make duplicate batches on a day different from the original batch of mortar.

6.2.1 When a uniformity testing program is started on shipments from a single source, make duplicate batches of mortar from every third cement sample. When duplicate tests have been made from a minimum of five cement samples, calculate the average range, $\bar{R}$, for the available duplicates, then calculate standard deviation and coefficient of variation for testing according to 7.1.3 and 7.1.4, respectively. Increase the number of duplicate batches used in the calculation until the results of ten cement samples are used in the calculation. After that time, use only the ten most recent results of duplicate testing in the calculation of the standard deviation and coefficient of variation for testing. See Table 1.

6.2.2 When at least ten sets of duplicate batches have been made and the coefficient of variation for testing is less than 4.0 %, the frequency of testing duplicate batches can be reduced to one out of ten consecutive cement samples. Resume testing one sample out of three if the coefficient of variation later exceeds 4.0 %. If the coefficient of variation for testing exceeds 5.5 %, the data are of questionable precision, and laboratory procedures and equipment should be thoroughly examined.

6.2.3 Use the results of duplicate tests indicating acceptable precision to estimate the single-laboratory testing variation for all other types of cement tested in that laboratory during the same period of time, provided that duplicate tests have been made on at least one sample per month.

7. Calculation

7.1 The calculations shall include the following:

7.1.1 *Average Strength*:

$$\bar{X} = \frac{X_1 + X_2 + \ldots + X_n}{n} \quad (1)$$

where:

$\bar{X}$ = average strength,

$X_1, X_2, \ldots, X_n$ = strength of individual tests, each of which is composed of the average of cubes in accordance with Test Method C 109/C 109M, and

n = number of individual samples.

7.1.2 *Total Standard Deviation*:

$$S_t = \sqrt{\frac{(X_1 - \bar{X})^2 + (X_2 - \bar{X})^2 + \ldots + (X_n - \bar{X})^2}{(n - 1)}} \quad (2)$$

where:

S_t = standard deviation, psi.

7.1.3 *Standard Deviation For Testing*:

$$S_e = 0.862\bar{R}$$

S_e = standard deviation estimated from tests of duplicate batches mixed in a single laboratory,

R = range, the difference between the strengths of the duplicate batches from a single sample (all numbers are positive),

$\bar{R}$ = average of the individual ranges, R, for the preceding ten tests of duplicate batches. See 6.2.1 if fewer than ten ranges are available, and

0.862 = range coefficient for duplicate tests of the same sample of cement.

7.1.4 *Coefficient of Variation for Testing*:

$$V_e = 100\, S_e / \bar{X}$$

where:

V_e = coefficients of variation estimated from tests of duplicate batches mixed in a single laboratory, and

$\bar{X}$ = average of the strengths of the duplicate batches from which $\bar{R}$ is calculated.

7.1.5 *Standard Deviation Corrected For Testing Variations*:

$$S_c = \sqrt{S_t^2 - S_e^2} \quad (3)$$

where:

S_c = net standard deviation of cement corrected for testing error,

S_t = total standard deviations for all tests included in the calculation, and

S_e = standard deviation of duplicate tests run on split sample to evaluate testing error.

The addition of the subscript 28 or 7 indicates the type of strength data used in the calculation.

12 /21	120	. . .	. . .	. . .	. . .	. . .	. . .	. . .	. . .	. . .	. . .	. . .	. . .	. . .	. . .

Notes: Initially one out of three samples are tested in duplicate until at least ten duplicate test results are available.

[A] Average of the test results A and B.

[B] Absolute difference between tests A and B.

[C] Average range is calculated for a minimum of five duplicate tests. Subsequently, ranges of the ten most recent duplicate tests are averaged.

[D] Standard deviation for testing is calculated as in 7.1.3: $S_e = 0.862 \times \bar{R}$.

[E] Coefficient of variation for testing is calculated as in 7.1.4: $V_e = 100\ S_e / \bar{X}$. Note that $\bar{X}$ is the average strength of the duplicate batches from which $\bar{R}$ is determined.

8. Report

8.1 Sufficient information shall be provided to identify the cement sampled including:

8.1.1 Name of manufacturer and location,

8.1.2 Type of cement or other identification,

8.1.3 Location of sampling,

8.1.4 Laboratory designation, and

8.1.5 Period of time represented by the report.

8.2 For ongoing programs, the minimum period covered by the report shall include all strength tests made in the preceding three months, but in no instance less than that period of time necessary to include 28-day strength tests of 20 consecutive samples.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:40:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.2.1 The report shall not cover a period of time greater than 12 months or tests of more than 120 samples.

8.3 The report of strength results shall be either in tabular form as shown in Table 2 or in graphical form as shown in Fig. 1, at the option of the reporting organization.

NOTE 5—For purposes of analyzing trends, the graphical presentation is to be preferred. Additionally, the average and standard deviation as calculated in Section 7 shall be shown.

8.4 Report the available 7 and 28-day compressive strength results on each sample including the date on which the sample was taken. Each value reported will be the average of tests of three cubes made from the same batch, except when one or more cubes are faulty. See Test Method C 109/C 109M.

8.4.1 Report the results of tests of duplicate batches tested within the period covered by the report. When duplicate batches are made from a cement other than that being tested during the same period of time, by the same laboratory, these test results will not normally be reported on a regular basis, but results of such tests will be made available on request. However, report the standard deviation, S_e, and the coefficient of variation, V_e, of duplicate batches.

8.5 The report shall include the following values calculated from the reported data. Each cement sample shall be represented only by a single result at each age in these calculations. The second of a pair of duplicate batch test results shall not be included in overall calculations, but shall be used only to establish testing error.

8.5.1 Calculated from the reported seven-day strength data:

(1) $\bar{X}_7$, the average,

(2) S_{t7}, the total standard deviation,

(3) n_7, the number of samples tested,

(4) S_{c7}, the standard deviation corrected for testing, and

(5) $\bar{X}_{5-7}$, the moving averages of the five most recent seven-day results.

8.5.2 Calculated from the reported 28-day strength data:

(1) $\bar{X}_{28}$, the average,

www.technobetar.ir

(2) S_{t28}, the total standard deviation,

(3) n_{28}, the number of samples tested,

(4) S_{c28}, the standard deviation corrected for testing, and

(5) $\bar{X}_{5-28}$, the moving averages of the five most recent 28-day results.

8.5.3 The calculations in 8.5.1 and 8.5.2 shall not be made and reported until five results are available. The moving average of the five most recent results should be updated with each successive result by adding the new value in the calculation and deleting the oldest previous value (see Table 1).

8.5.4 Whenever the reporting agency concludes that a consistent change in strength-producing properties has occurred, at its option, it may discontinue calculation until results from five additional samples of the cement have been obtained. In this instance, the values (8.5.1 and 8.5.2) calculated from the samples before the change shall also be reported (see 8.2.1).

8.5.5 When there is a break in the calculation, the sampling dates included in each set of calculated values (8.5.1 and 8.5.2) shall be clearly identified.

[A] "a" is the first batch of two made from this sample. See Table 1.

APPENDIXES

(Nonmandatory Information)

X1. COMPARISON OF RESULTS FROM TWO LABORATORIES USING TEST METHOD C 109

X1.1 Suppose n samples are split and tested by each Laboratory A and B with a single batch of mortar prepared on each sample in each laboratory.

X1.2 Compute the difference in results on each sample as $X_a - X_b$:

$$d_i = X_a - X_b \quad \text{(X1.1)}$$

d_i values may be positive or negative.

X1.3 Compute the average of these differences:

$$\bar{D} = \frac{d_1 + d_2 + \ldots + d_n}{n} \quad \text{(X1.2)}$$

where:

$\bar{D}$ = average difference in psi and d_i values may be positive or negative.

X1.4 Compute the standard deviation of these differences (7.1.2),

where:

S_d= standard deviation of the difference, psi.

X1.5 Compute the value $\bar{D}\sqrt{n} / S_d$ and compare to Student's t[4] for $n - 1$ at $\alpha = 0.05$, where t is from Student's t distribution.

X1.6 If $\left|\bar{D}\sqrt{n} / S_d\right| \geq t$, decide that averages in the two laboratories differ significantly; otherwise, decide that there is no reason to believe they differ.

Designation: C 918/C 918M – 07

Standard Test Method for Measuring Early-Age Compressive Strength and Projecting Later-Age Strength[1]

This standard is issued under the fixed designation C 918/C 918M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers a procedure for making and curing concrete specimens and for testing them at an early age. The specimens are stored under standard-curing conditions and the measured temperature history is used to compute a maturity index that is related to strength gain.

1.2 This test method also covers a procedure for using the results of early-age compressive-strength tests to project the potential strength of concrete at later ages.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 470/C 470M Specification for Molds for Forming Concrete Test Cylinders Vertically

C 617 Practice for Capping Cylindrical Concrete Specimens

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 1074 Practice for Estimating Concrete Strength by the Maturity Method

C 1231/C 1231M Practice for Use of Unbonded Caps in Determination of Compressive Strength of Hardened Concrete Cylinders

3. Terminology

3.1 *Definitions:*

3.1.1 Refer to Practice C 1074 for the definitions of the following terms: *datum temperature*, *equivalent age*, *maturity*, *maturity function*, *maturity index*, and *temperature–time factor*.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *potential strength*, *n*—the strength of a test specimen that would be obtained at a specified age under standard curing conditions.

3.2.2 *prediction equation*, *n*—the equation representing the straight-line relationship between compressive strength and the logarithm of the maturity index.

3.2.2.1 *Discussion*—The prediction equation is used to project the strength of a test specimen based upon its measured early-age strength. The general form of the prediction equation used in this test method is:

$$S_M = S_m + b(\log M - \log m) \quad (1)$$

where:

S_M = projected strength at maturity index M,
S_m = measured compressive strength at maturity index m,
b = slope of the line,

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved July 15, 2007. Published August 2007. Originally approved in 1980. Last previous edition approved in 2002 as C 918 – 02.

www.technobetar.ir

M = maturity index under standard curing conditions, and
m = maturity index of the specimen tested at early age.

The prediction equation is developed by performing compressive strength tests at various ages, computing the corresponding maturity indices at the test ages, and plotting the compressive strength as a function of the logarithm of the maturity index. A best-fit line is drawn through the data and the slope of this line is used in the prediction equation.

3.2.3 *projected strength*, *n*—the potential strength estimated by using the measured early-age strength and the previously established prediction equation.

4. Summary of Test Method

4.1 Cylindrical test specimens are prepared and cured in accordance with the appropriate sections of Practice C 31/C 31M or in accordance with Practice C 192/C 192M. The temperature of a representative specimen is monitored during the curing period. Specimens are tested for compressive strength at an early age beyond 24 h, and the concrete temperature history is used to compute the maturity index at the time of test.

4.2 A procedure is presented for acquiring a series of compressive strength values and the corresponding maturity indices at different ages. These data are used to develop a prediction equation, that is, used subsequently to project the strengths at later ages based upon measured early-age strengths.

5. Significance and Use

5.1 This test method provides a procedure to estimate the potential strength of a particular test specimen based upon its measured strength at an age as early as 24 h.[3] The early-age test results provide information on the variability of the concrete production process for use in process control.

5.2 The relationship between early-age strength of test specimens and strength achieved at some later age under standard curing depends upon the materials comprising the concrete. In this test method, it is assumed that there is a linear relationship between strength and the logarithm of the maturity index. Experience has shown that this is an acceptable approximation for test ages between 24 h and 28 days under standard curing conditions. The user of this test method shall verify that the test data used to develop the prediction equation are represented correctly by the linear relationship. If the underlying relationship between strength and the logarithm of the maturity index cannot be approximated by a straight line, the principle of this test method is applicable provided an appropriate equation is used to represent the non-linear relationship.

5.3 Strength projections are limited to concretes using the same materials and proportions as the concrete used to establish the prediction equation.

NOTE 1—Confidence intervals developed in accordance with 10.2 are helpful in evaluating projected strengths.

5.4 This test method is not intended for estimating the in-place strength of concrete. Practice C 1074 provides procedures for using the measured in-place maturity index to estimate in-place strength.

6. Apparatus

6.1 *Equipment and Small Tools*, for fabricating specimens and measuring the characteristics of fresh concrete, shall conform to the applicable requirements of Practices C 31/C 31M or C 192/C 192M.

6.2 *Molds* shall conform to the requirements for cylinder molds in Specification C 470/C 470M.

6.3 *Temperature Recorder*:

6.3.1 A device is required to monitor and record the temperature of a test specimen as a function of time. Acceptable devices include thermocouples or thermistors connected to continuous chart recorders or digital data-loggers. For digital instruments, the recording time interval shall be ½ h or less for the first 48 h and 1 h or less thereafter. The temperature recording device shall be accurate to within 1 °C [±2 °F]

6.3.2 Alternative devices include commercial maturity instruments that automatically compute and display the temperature-time factor or the equivalent age as described in Practice C 1074.

NOTE 2—Commercial maturity instruments use specific values of the datum temperature to evaluate the temperature-time factor or of the Q-value to evaluate equivalent age. Refer to the Appendix of Practice C 1074 for additional explanation and recommendations.

7. Sampling

7.1 Sample and measure the properties of the fresh concrete in accordance with Practices C 31/C 31M or C 192/C 192M.

8. Procedure for Early-Age and Projected Strengths

8.1 Mold and cure the specimens in accordance with the standard curing procedure in Practice C 31/C 31M or in accordance with Practice C 192/C 192M whichever is applicable. Record the time when molding of the specimens is completed.

8.2 Embed a temperature sensor into the center of one of the specimens of the sampled concrete. Activate the temperature recording device. Continue curing for at least 24 h. Maintain a record of the concrete temperature during the entire curing period.

8.3 *Capping and Testing*—Remove the specimens from the molds as soon as practical after 24 h. Cap the specimens in accordance with Practice C 617 or Practice C 1231/C 1231M.

8.3.1 The capping materials, if used, shall develop, at the age of 30 min, a strength equal to or greater than the strength of the cylinders to be tested.

8.3.2 Do not test specimens sooner than 30 min after capping.

8.4 Determine the cylinder compressive strength in accordance with Test Method C 39/C 39M at an age of 24 h or later. Record the strength and the age at the time of the test. The age of the cylinder is measured to the nearest 15 min from the time of molding. Strength at each test age shall be the average strength of at least two cylinders.

[3] For additional information, see *Significance of Tests and Properties of Concrete and Concrete-Making Materials*, *ASTM STP 169C*, Chapter 15, "Prediction of Potential Concrete Strength at Later Ages," 1994.

www.technobetar.ir

8.5 Determine the maturity index at the time of test by using the manual procedure described in the section titled Maturity Functions in Practice C 1074 or by using a maturity instrument. Record the maturity index, *m*, of the early-age test specimens.

8.6 When the data representing the compressive strength and the maturity index, *m*, are to be used to project the strength of the concrete at some later age, determine the projected strength by using the prediction equation determined in Section 9.

9. Procedure for Developing Prediction Equation

9.1 Develop a prediction equation for each concrete to be used on the job. Prepare specimens in accordance with Practice C 192/C 192M. Use the procedure in Section 8 to obtain compressive strength values and the corresponding maturity indices at the times of testing. These data shall include tests at ages of 24 h, 3, 7, 14, and 28 days. If the age for which the projected strength is to be determined exceeds 28 days, the data shall include tests at the desired later age (see 5.2). Strength at each age shall be the average strength of at least two cylinders.

9.1.1 Field data are acceptable, provided they furnish all of the information in 9.1, and provided the specimens are cured in accordance with the section on standard curing of Practice C 31/C 31M.

9.2 The constant *b* for use in the prediction equation (see Eq 1) is established using one of two alternative methods: (*1*) by regression analysis, or (*2*) by manual plotting.

9.2.1 *Regression Analysis*—Convert the values of the maturity indices by taking their logarithms. Plot the average cylinder strength versus the logarithm of the maturity index. Compute the best-fit straight line to the points using an appropriate calculator or computer program. The straight line has the following equation:

$$S_m = a + b \log m \tag{2}$$

where:
S_m = compressive strength at m,
a = intercept of line,
b = slope of line, and
m = maturity index.

Plot the best-fit straight line on the same graph as the data to verify that the correct equation has been determined.

9.2.2 *Manual Plotting*—Prepare a sheet of semi-log graph paper with the *y*-axis representing compressive strength and the logarithmic scale (*x*-axis) representing the maturity index (see Note 3). Plot the strength values from 9.1 versus the corresponding maturity index. Determine the best-fitting straight line by drawing a line that visually minimizes the distances between the points and the line. The slope of the line is the vertical distance, in units of stress, between the intersection of the line with the beginning and the end of one cycle on the *x*-axis (see Fig. X1.1). This slope is the value of *b* for use in the prediction equation (see Eq 1).

NOTE 3—The scale for the *y*-axis and the number of cycles in the semi-log graph paper should be chosen so that the data fill up as much of the paper as possible. When the maturity index is expressed as the temperature-time factor in degree-hours, three cycles are generally appropriate. If the maturity index is expressed as the equivalent age in hours, two cycles are appropriate.

9.3 Use the constant, *b*, and Eq 1 to determine the projected strength based on early-age test results.

NOTE 4—If it is desired to check the accuracy of the first estimate of the value of *b*, fabricate companion specimens to those for testing at an early age, cure them in accordance with the standard curing procedure in Practice C 31/C 31M, record their temperature histories and test them at 28 days. The value of *b* is re-estimated by use of the following equation:

$$b = \frac{\Sigma(S - S_m)}{\Sigma(\log M - \log\ m)} \tag{3}$$

where:
S = measured compressive strength at M,
M = maturity index corresponding to test at 28 days,
S_m = measured compressive strength at m, and
m = maturity index corresponding to early-age test.

10. Interpretation of Results

10.1 As stated in Section 12, the variability of early-age compressive strength obtained by this test method is the same or less than that obtained from traditional test methods. Thus results are applicable for rapid assessment of variability for process control and signaling the need for adjustments. Use of the results from this test method to predict specification compliance of strengths at later ages must be applied with caution because strength requirements in existing specifications and codes are not based upon early-age testing.

10.2 Develop a one-sided confidence interval for the projected strength for use in the acceptance decision. The confidence interval is based on the measured differences between projected and measured strengths at a designated age. Usually such an interval is developed at a 95 % confidence level, and the decision is to accept the concrete as conforming to specification requirements if the following condition is satisfied:

$$S_M > (S_L + K) \tag{4}$$

where:
S_M = projected strength at designated age,
S_L = specified lower limit, specifically, the specified strength at the designated age,

$$K = \bar{d} + t_{0.95,\,n-1}\,\frac{s_d}{\sqrt{n}} \tag{5}$$

$\bar{d}$ = average difference between the measured and projected strength.

$$\bar{d} = \frac{\sum_{i=1}^{n}(S_M - S)_i}{n} = \frac{\sum_{i=1}^{n} d_i}{n} \tag{6}$$

S = measured strength after standard curing up to designated age,
d_i = the difference between the ith pair of strength values,
n = number of paired (S_M and S) values used in the analysis,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:40:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$t_{0.95,n-1}$ = value from the t-distribution at the 95 % level for $n - 1$ degrees of freedom, and

s_d = standard deviation for the difference between the measured and projected strengths.

$$s_d = \sqrt{\frac{\sum_{i=1}^{n}(d_i - \bar{d})^2}{(n-1)}} \quad (7)$$

11. Report

11.1 The report of the early-age test results shall include the following:

11.1.1 Identification number of test cylinder,

11.1.2 Diameter of test cylinder, mm [in.],

11.1.3 Cross-sectional area of test cylinder, mm^2 [$in.^2$],

11.1.4 Maximum test load on cylinder, N [lb],

11.1.5 Compressive strength of cylinder calculated to the nearest 0.1 MPa [10 psi],

11.1.6 Type of fracture of cylinder, if other than the usual cone,

11.1.7 Age of cylinder at the time of test,

11.1.8 Initial mix temperature to the nearest 1 °C [2 °F],

11.1.9 Temperature records, and

11.1.10 Method of transportation used for shipping the specimens to the laboratory.

11.2 If the early-age strength data are used to project later-age strength, the report shall include the following:

11.2.1 The maturity index, *m*, of the early-age specimens at the time of test,

11.2.2 The age of the projected strength, and

11.2.3 The projected strength calculated to the nearest 0.1 MPa [10 psi].

12. Precision and Bias

12.1 *Precision*:

12.1.1 The data used to prepare the following precision statements were obtained using measurements in the inch-pound system.

12.1.2 The single laboratory coefficient of variation has been determined as 3.6 % for a pair of cylinders (150 by 300 mm [6 by 12 in.]) cast from the same batch. Therefore, results of two properly conducted strength tests by the same laboratory on two individual cylinders made with the same materials should not differ more than 10 % of their average (see Note 5).

12.1.3 The single-laboratory, multi-day coefficient of variation has been determined as 8.7 % for the average of pairs of cylinders (150 by 300 mm [6 by 12 in.]) cast from single batches mixed on two days. Therefore, results of two properly conducted strength tests each consisting of the average of two cylinders from the same batch made in the same laboratory on different days with the same materials and proportions should not differ by more than 25 % of their average (see Note 5).

NOTE 5—These numbers represent, respectively, the (1s %) and d2s %) limits as described in Practice C 670.

12.2 *Bias*—This test method has no determinable bias as the values obtained can only be defined in terms of this test method.

13. Keywords

13.1 compressive strength; early-age strength; maturity; potential strength; projected strength

APPENDIX

(Nonmandatory Information)

X1. EXAMPLE OF USE

X1.1 *Development of Prediction Equation:*

X1.1.1 To establish a reliable relationship between strength and the maturity index, concrete must be made from the actual materials, including admixtures, to be used in the work. While field data are acceptable, the initial data will normally originate in the laboratory before field production begins. Compressive strength specimens will, therefore, normally be made and cured in the laboratory and tested at ages of 24 h, 3, 7, 14, and 28 days. It is suggested that a minimum of 14 cylinders be made and cured in accordance with Practice C 192/C 192M.

X1.1.1.1 *Example Data*—An example of age-strength data obtained from test cylinders (two at each age) is as follows:

Age	Average Strength, MPa [psi]
24 h	9.4 [1370]
3 days	17.1 [2480]
7 days	21.8 [3160]
14 days	25.6 [3710]
28 days	29.3 [4250]

X1.1.1.2 In this example, the temperature-time factor, with a datum temperature of 0 °C [32 °F], is used as the maturity index. Refer to Practice C 1074 for additional information. The temperature-time factor is calculated from the measured temperature history of the concrete by dividing the age into suitable time intervals and summing the products of the time

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:40:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

intervals and the corresponding average temperatures for each interval. For this example, it is assumed that the concrete temperature is 21 °C [70 °F] prior to stripping the molds and is 23 °C [73 °F] thereafter. The cumulative temperature-time factor at the various test ages is calculated as shown in Table X1.1.

X1.1.2 The strength data shown in X1.1.1.1 and the temperature-time factor values in Table X1.1 can be plotted using semi-log axes as shown in Fig. X1.1, which is a computer generated plot.

X1.1.3 Determine the best-fit straight line through the plotted points. In this example, the straight line was obtained by regression analysis using a computer program. This line represents the prediction equation which is the assumed relationship between strength and the temperature-time factor for this particular concrete. The equation for this straight line is expressed in the following form:

$$S_M = S_m + b\,(\log M - \log m) \quad \text{(X1.1)}$$

where S_M and S_m are the strengths at values of the temperature-time factor equal to M and m, respectively.

X1.1.4 The value b is the slope of the prediction equation and is the vertical distance, in units of stress, between the intersections of the line with the beginning and the end of one cycle on the x-axis (see Fig. X1.1). For this particular example, $b = 13.3$ MPa [1930 psi], which represents the strength increase for a tenfold increase in the temperature-time factor.

X1.1.5 Any concrete produced from the same materials and proportions that were used to develop the prediction equation would have the same strength versus temperature-time factor relationship.

X1.2 *Projected Strength:*

X1.2.1 To use the prediction equation to project the strength of field concrete based upon early-age strengths, sample and test the fresh concrete in accordance with Practice C 31/C 31M. Mold and cure at least three specimens in accordance with the standard curing procedure in Practice C 31/C 31M. Install a temperature recording device into a cylinder to monitor the concrete temperature. Continue curing for at least 24 h.

TABLE X1.1 Temperature-Time Factor at Test Ages

Age, days	Age Increment, (Δ*t*), h	Temperature, T, °C	Temperature-Time Factor Increment, (T-0) × Δ*t*,° C·h	Cumulative Temperature-Time Factor, °C·h (°F·h)
1	24	21	504	504 [907]
3	48	23	1104	1808 [2894]
7	96	23	2208	3816 [6869]
14	168	23	2864	7680 [13 824]
28	336	23	7728	15 408 [27 734]

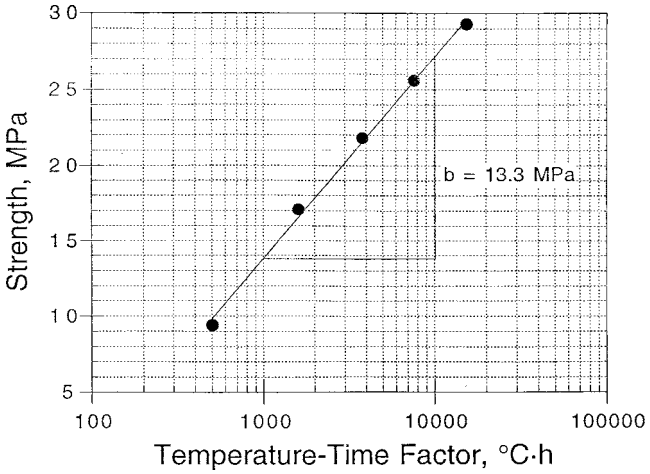

FIG. X1.1 Example Data of Strength as a Function of the Logarithm of the Temperature-Time Factor and the Best-Fit Straight Line that Represents the Prediction Equation

X1.2.2 As soon as practical after the minimum 24-h curing period, remove the specimens from the molds and prepare for testing in accordance with Test Method C 39/C 39M. Record the age at the time of test. Use this age, together with the recorded temperature history, to determine the maturity index, m, at time of test. Report the early-age compressive strength, S_m, as the average of the cylinders tested. The prediction equation is then used to project the strength of the concrete represented by the test specimens.

X1.2.3 As an example:

X1.2.3.1 Compressive strength specimens fabricated in the field were cured for 24 h under standard conditions at the job site. At an age of 24 h, the specimens were removed from their molds, capped, and the caps were allowed to harden. The cylinders were tested at an age of 26 h. The average strength at this age was 9.8 MPa [1420 psi].

X1.2.3.2 Columns 1 and 2 in Table X1.2 show the recorded temperature history obtained from the instrumented specimen. The sixth column shows the increment of temperature-time factor during each age interval. The last column shows the cumulative temperature-time factor. At an age of 26 h, the cumulative temperature-time factor m is 616 °C·h [1109 °F·h].

X1.2.3.3 The temperature-time factor after 28 days of curing at the standard temperature of 23 °C [73 °F] is:

$$M = (23 - 0)\ °C \times 28\ \text{days} \times 24\ \text{h} = 15\,456\ °C \cdot \text{h}\ [27\,829\ °F \cdot \text{h}] \quad \text{(X1.2)}$$

X1.2.3.4 The projected 28-day strength is calculated as:

$$S_M = S_m + b(\log M - \log m)$$
$$S_M = 9.8 + 13.3\ (\log 15\,546 - \log 616)$$
$$S_M = 9.8 + (4.189 - 2.790)$$
$$S_M = 9.8 + 18.6$$
$$S_M = 28.4\ \text{MPa}\ [4120\ \text{psi}]$$

Therefore, had the specimens been cured at 23 °C [73 °F] for the full 28 days, their expected average compressive strength would be 28.4 MPa [4120 psi] if tested at 28 days.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 918 – 02, that may impact the use of this test method. (Approved July 15, 2007)

(*1*) Revised the standard to make it a dual-units standard.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 926 – 06

Standard Specification for Application of Portland Cement-Based Plaster[1]

This standard is issued under the fixed designation C 926; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the requirements for the application of full thickness portland cement-based plaster for exterior (stucco) and interior work.

1.2 This specification sets forth tables for proportioning of various plaster mixes and plaster thickness.

NOTE 1—General information will be found in Annex A1. Design considerations will be found in Annex A2.

1.3 The values stated in inch-pound units are to be regarded as the standard. The SI (metric) values given in parentheses are approximate and are provided for information purposes only.

1.4 The text of this specification references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.5 Details of construction for a specific assembly to achieve the required fire resistance shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing laboratories.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 207 Specification for Hydrated Lime for Masonry Purposes

C 219 Terminology Relating to Hydraulic Cement

C 260 Specification for Air-Entraining Admixtures for Concrete

C 595 Specification for Blended Hydraulic Cements

C 631 Specification for Bonding Compounds for Interior Plastering

C 897 Specification for Aggregate for Job-Mixed Portland Cement-Based Plasters

C 932 Specification for Surface-Applied Bonding Agent for Exterior Plastering

C 1063 Specification for Installation of Lathing and Furring to Receive Interior and Exterior Portland Cement-Based Plaster

C 1116 Specification for Fiber-Reinforced Concrete and Shotcrete

C 1328 Specification for Plastic (Stucco) Cement

E 90 Test Method for Laboratory Measurement of Airborne-Sound Transmission Loss of Building Partitions and Elements

E 119 Test Methods for Fire Tests of Building Construction and Materials

E 492 Test Method for Laboratory Measurement of Impact Sound Transmission Through Floor-Ceiling Assemblies Using the Tapping Machine

2.2 *ANSI Standard:*

A108.1 Specification for Installation of Ceramic Tile[3]

3. Terminology

3.1 Terms shall be defined as in Terminologies C 11 and C 219, except as modified herein.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *accelerator*—an admixture that will shorten the setting time of plaster.

3.2.2 *admixture*—a material other than water, aggregate, or basic cementitious material added to the batch before or during job mixing.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for Application of Gypsum and Other Products on Assemblies.

Current edition approved June 1, 2006. Published June 2006. Originally approved in 1981. Last previous edition approved in 2005 as C 926–98a(2005).

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

3.2.3 *acid etching*—the cleansing and controlled erosion of a solid surface, using an acid wash.

3.2.4 *air entrainment*—the use of an air-entraining admixture or air-entraining cementitious material in a plaster mix to yield a controlled quantity of minute (typically between 10 and 1000 μm in diameter) disconnected air bubbles in the plaster (see *entrapped air*).

3.2.5 *backplaster*—plaster applied to the face of metal lath opposite a previously applied plaster.

3.2.6 *bond*—the state of adhesion between plaster coats or between plaster and plaster base.

3.2.7 *bonding compound or agent*—compounds surface applied or integrally mixed with plaster to improve the quality of bond between plaster and plaster base or between plaster coats.

3.2.8 *cementitious material*—a material that, when mixed with water and with or without aggregate, provides the plasticity and the cohesive and adhesive properties necessary for placement and the formation of a rigid mass.

3.2.9 *coat*—a thickness of plaster applied in a single operation.

3.2.9.1 *basecoat*—all plaster applied before the application of the finish coat.

3.2.9.2 *bedding coat*—a plaster coat that receives aggregate or other decorative material impinged into its surface before it sets.

3.2.9.3 *brown coat*—in three-coat work, the second coat, applied over the scratch coat. In two-coat work, brown coat refers to the double-up basecoat. In either use, the brown coat is the coat directly beneath the finish coat.

3.2.9.4 *dash-bond coat*—a thick wet mixture of portland cement and water, with or without aggregate, dashed onto the surface of a plaster base such as smooth monolithic concrete or concrete block surfaces to improve the mechanical key for subsequent plaster coats.

3.2.9.5 *double-up coat*—the brown-coat plaster applied to the scratch coat plaster before the scratch-coat plaster has set.

3.2.9.6 *finish coat*—the final layer of plaster applied over basecoat plaster.

3.2.9.7 *fog coat*—a light coat of cement and water, with or without aggregate or color pigment, applied by machine spray to improve color consistency.

3.2.9.8 *scratch coat*—the first coat of plaster applied to a plaster base.

3.2.9.9 *skim coat*—a thin finish coat applied to an existing plaster surface or other substrate to improve appearance.

3.2.9.10 *three-coat work*—application of plaster in three successive coats with time between coats for setting or drying, or both.

3.2.10 *cold joint ("joining" or "jointing")*—the juncture of fresh plaster application adjacent to set plaster, in the same plane.

3.2.11 *curing*—the act or processes of producing a moisture environment favorable to cement hydration, resulting in the setting or hardening of the plaster.

3.2.12 *entrapped air*—unintentional air voids in the plaster generally larger than 1 mm.

3.2.13 *factory prepared ("mill-mixed" or "ready mixed")*—pertaining to material combinations that have been formulated and dry-blended by the manufacturer, requiring only the addition of and mixing with water to produce plaster.

3.2.14 *fiber, natural or synthetic*—an elongated fiber or strand admixture added to plaster mix to improve cohesiveness or pumpability, or both.

3.2.15 *floating*—act of compacting and leveling brown-coat plaster to a reasonably true surface plane using a float tool or the act of bringing the aggregate to the surface of finish-coat plaster.

3.2.16 *key (also mechanical key)*—plaster that physically surrounds, penetrates, or deforms to lock onto the perforations or irregularities of the plaster base or previous coat of plaster.

3.2.17 *metal plaster base*—expanded metal lath, or welded or woven wire lath.

3.2.18 *plaster*—portland cement-based cementitious mixture (see *stucco*).

3.2.19 *required*—pertaining to a mandatory obligation imposed by a force outside of this specification, such as a building code, project specification, contract, or purchase order.

3.2.20 *rustication (also "break")*—an interruption or change in plane of a plastered surface.

3.2.21 *scoring (also known as "scratching")*—the grooving of the surface of an unset plaster coat to provide a key for a subsequent coat.

3.2.22 *set*—the chemical and physical change in plaster as it goes from a plastic, workable state to a rigid state.

3.2.23 *stucco*—portland cement-based plaster used on exterior locations.

3.2.24 *stucco finish*—a factory-prepared, dry blend of materials for finish coat applications.

3.2.25 *temper, v*—to mix or restore unset plaster with water to a workable consistency.

3.2.26 *texture*—any surface appearance as contrasted to a smooth surface.

4. Materials

4.1 Materials shall conform to the requirements of the referenced specifications and standards and to the requirements specified herein.

4.2 *Cement*:

4.2.1 *Portland Cement*—Specification C 150, Type I, II, and III, as specified. White where specified.

4.2.2 *Air-Entraining Portland Cement*—Specification C 150, type as specified. White where specified.

4.2.3 *Masonry Cement*—Specification C 91, Types N, S, and M. White where specified.

4.2.4 *Blended Hydraulic Cement*—Specification C 595, Type IP, I(PM), IS, and I(SM) as specified.

4.2.5 *Air-Entraining Blended Hydraulic Cement*—Specification C 595, Type IP-A, I(PM)-A, IS-A, and I(SM)-A as specified.

4.2.6 *Plastic Cement*—Plastic Cement shall meet the requirements of Specification C 1328, Standard Specification for Plastic (Stucco) Cement.

NOTE 2—Plastic cements are not available nationally.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

4.3 *Type "S" Hydrated Lime*—A hydrated lime that contains not more than 8 % unhydrated oxides when tested in accordance with Test Methods C 25. See Specifications C 206 and C 207 for a complete description of a Type "S" hydrated lime.

4.4 *Aggregates*:

4.4.1 *Sand for Base Coats*—Specification C 897. Aggregate failing to meet gradation limits in Specification C 897 shall be permitted to be used, provided the plaster made with this sand has an acceptable demonstrated performance record in similar construction and climate conditions.

4.4.2 *Perlite*—Specification C 35.

4.4.3 *Sand for Job-Mixed Finish Coats*—Specification C 897.

4.5 *Water*—Water used in mixing, application, and finishing of plaster shall be clean, fresh, suitable for domestic water consumption, and free of such amounts of mineral or organic substances as would affect the set, the plaster, or any metal in the system.

4.6 *Admixtures*—See 3.2.2 and .

4.7 *Fibers*—Specification C 1116 on alkali-resistant fibers, glass fibers, nylon, polypropylene or carbon fibers.

5. Requirements for Bases to Receive Portland Cement-Based Plaster

5.1 Metal bases and accessories used to receive plaster shall be installed in conformance with Specification C 1063, except as otherwise specified.

NOTE 3—All metal, or PVC, or CPVC plastic members should be free of deleterious amounts of rust, oil, or other foreign matter, which could cause bond failure or unsightly discoloration.

5.2 Surfaces of solid bases to receive plaster, such as masonry, stone, cast-in-place or precast concrete shall be straight and true within ¼ in. in 10 ft (2.1 mm/m) and shall be free of form oil or other elements, which would interfere with bonding. Form ties or other obstructions shall be removed or trimmed back even with the surface of the solid base.

5.2.1 Solid surfaces shall have the suction (ability to absorb water) or surface roughness, or both, to provide the bond required for the plaster.

5.2.2 Smooth or nonabsorbent solid surfaces, such as cast-in-place or precast concrete, shall be prepared to receive portland cement plaster by one of the following methods:

5.2.2.1 Sandblasting, wire brushing, acid etching, or chipping or a combination thereof,

5.2.2.2 Application of a dash-bond coat applied forcefully against the surface, left untroweled, undisturbed, and moist cured for at least 24 h, or

5.2.2.3 Application of a bonding compound suitable for exterior or interior exposure solid surfaces in accordance with the manufacturer's written directions.

5.2.3 Where bond cannot be obtained over the entire surface to receive plaster by one or more of the methods in 5.2.2, or where total plaster thickness will exceed the total thickness specified in Table 1 for types of solid bases, furred or self-furring metal plaster base shall be installed in accordance with Specification C 1063.

6. Plaster Proportions and Mixing

6.1 *Proportions*:

6.1.1 All portland cement plasters shall be mixed and proportioned in accordance with the following tables and accompanying requirements, using measuring devices of known volume with successive batches proportioned alike.

6.1.2 Plaster mix used shall be as designated and referenced to Table 2.

6.1.3 Base-coat proportions shall be as shown in Table 3 for the mix specified from Table 2.

6.1.3.1 *Measurement of Materials*—The method of measuring materials for the plaster shall be such that the specified proportions are controlled and accurately maintained. The weights per cubic foot of the materials are considered to be as follows:

Material	Weight, lb/ft^3(kg/m^3)
Portland cement	94 (1505)
Blended cement	Weight printed on bag
Masonry or plastic cement	Weight printed on bag
Hydrated Lime	40 (640)
Lime Putty	80 (1280)
Sand, Damp and Loose (6.1.3.2)	80 (1280) of dry sand

TABLE 1 Nominal Plaster Thickness[A] for Three- and Two-Coat Work, in. (mm)

BASE	Vertical				Horizontal			
	1st Coat	2nd Coat	3rd Coat[B]	Total	1st Coat	2nd Coat	3rd Coat[B]	Total
	Interior/Exterior							
Three-coat work:[C]								
Metal plaster base	⅜ (9.5)	⅜ (9.5)	⅛ (3)	⅞ (22)	¼ (6)	¼ (6)	⅛ (3)	⅝ (16)
Solid plaster base:								
Unit masonry	¼ (6)	¼ (6)	⅛ (3)	⅝ (16)	Use two-coat work			
Cast-in-place or precast concrete	¼ (6)	¼ (6)	⅛ (3)	⅝ (16)				⅜ (9.5), max
Metal plaster base over solid base	½ (12.5)	¼ (6)	⅛ (3)	⅞ (22)	½ (12.5)	¼ (6)	⅛ (3)	⅞ (22)
Two-coat work:								
Solid plaster base:								
Unit masonry	⅜ (9.5)	⅛ (3)		½ (12.5)				⅜ (9.5)
Cast-in-place or pre-cast concrete	¼ (6)	⅛ (3)		⅜ (9.5)				⅜ (9.5)

[A] Exclusive of texture.
[B] For solid plaster partitions, additional coats shall be applied to meet the finished thickness specified.
[C] For exposed aggregate finishes, the second (brown) coat shall become the "bedding" coat and shall be of sufficient thickness to receive and hold the aggregate.

TABLE 2 Plaster Bases—Permissible Mixes

NOTE—See Table 3 for plaster mix symbols.

Property of Base	Mixes for Plaster Coats	
	First (Scratch)	Second (Brown)
Low absorption, such as dense, smooth clay tile, brick, or concrete	C	C, CL, M, or CM
	CM or MS	CM, MS, or M
	P	P
High Absorption, such as concrete masonry, absorptive brick, or tile	CL	CL
	M	M
	CM or MS	CM, MS, or M
	P	P
Metal plaster base	C	C, CL, M, CM, or MS
	CL	CL
	CM or MS	CM, MS, or M
	M	M
	CP	CP or P
	P	P

6.1.3.2 For purposes of this specification, a weight of 80 lb (1280 kg) of oven-dried sand shall be used. This is, in most cases, equivalent to one cubic foot of loose, damp sand.

6.1.4 Finish-coat proportions for job-mixed finish coats shall be as specified in Table 4.

6.1.5 *Factory-Prepared Finish Coats*—See 3.2.14.

6.1.6 Dash-bond coat proportions shall be 1 volume part portland cement and not more than 2 volume parts of aggregate mixed to a consistency that will permit application as specified in 7.1.5.

6.1.7 Admixtures shall be proportioned, mixed, and applied in accordance with the printed directions of the manufacturer. (See A2.5.)

6.2 *Mixing*:

6.2.1 All plaster shall be prepared in a mechanical mixer, using sufficient water to produce a workable consistency and uniform color. (See X1.1.)

6.2.2 Base-coat plasters that have stiffened because of evaporation of water shall be permitted to be tempered one time only to restore the required consistency. Plaster not used within 1½ h from start of initial mixing shall be discarded.

NOTE 4—Severe hot, dry climate conditions accelerate the stiffening of plaster and require reduction of this limit. The use of cold waters will slow the stiffening process.

6.2.3 Finish-coat plaster shall not be tempered.

7. Application

7.1 *General*:

7.1.1 Portland cement plaster shall be applied by hand or machine to the nominal thickness specified in Table 1.

7.1.2 Plaster nominal thickness shall be measured from the back plane of the metal plaster base, exclusive of ribs or dimples, or from the face of the solid backing with or without metal plaster base, to the outer surface exclusive of texture variations.

7.1.3 Portland cement-based plaster shall be applied on furred metal plaster base when the surface of solid backing consists of gypsum board, gypsum plaster, wood, or rigid foam board-type products.

NOTE 5—On horizontal ceiling supports or roof soffits protected by a drip edge, gypsum board products shall be permitted to be used as backing for metal base to receive portland cement plaster.

7.1.4 Separation shall be provided where plaster abuts dissimilar construction materials or openings. (See A2.1.4.)

7.1.5 Each plaster coat shall be applied to an entire wall or ceiling panel without interruption to avoid cold joints and abrupt changes in the uniform appearance of succeeding coats. Wet plaster shall abut set plaster at naturally occurring interruptions in the plane of the plaster, such as corner angles, rustications, openings, and control joints where this is possible. Joinings, where necessary, shall be cut square and straight and not less than 6 in. (152 mm) away from a joining in the preceding coat.

7.1.6 Metal plaster base shall be covered with three-coat work with or without solid backing. The combined total nominal thickness shall be as shown in Table 1. A dash-bond coat shall not replace one of the specified number of coats.

7.1.7 Two-coat work shall be used only over solid bases meeting the requirements of 5.2. The combined total nominal thickness shall be as shown in Table 1. A dash-bond coat shall not replace one of the specified number of coats.

7.1.8 Backplaster where required, shall be applied only after the coat on the opposite side has set sufficiently to resist breaking or cracking the plaster keys.

7.1.9 Each coat shall be permitted to set before the next coat is applied. (See X1.4.2.)

7.1.10 Plaster coats that have become dry shall be evenly dampened with water prior to applying subsequent coats to obtain uniform suction. There shall be no visible water on the surface when plaster is applied.

7.2 *Plaster Application on Metal Plaster Bases*:

7.2.1 The first (scratch) coat shall be applied with sufficient material and pressure to form full keys through, and to embed the metal base, and with sufficient thickness of material over the metal to allow for scoring the surface.

7.2.1.1 As soon as the first (scratch) coat becomes firm, the entire surface shall be scored in one direction only. The vertical surfaces shall be scored horizontally.

7.2.1.2 The first (scratch) coat shall become sufficiently rigid to support the application of the second (brown) coat without damage to the monolithic continuity of the first (scratch) coat or its key.

7.2.2 The second (brown) coat shall be applied with sufficient material and pressure to ensure tight contact with the first (scratch) coat and to bring the combined thickness of the base coat to the nominal thickness shown in Table 1.

7.2.2.1 The surface of the second (brown) coat shall be brought to a true, even plane with a rod or straightedge, filling surface defects in plane with plaster. Dry rodding the surface of the brown coat shall be permitted.

7.2.2.2 The surface shall be floated uniformly to promote densification of the coat and to provide a surface receptive to bonding of the finish coat.

7.2.3 The third (finish) coat shall be applied with sufficient material and pressure to ensure tight contact with, and complete coverage of the base coat and to the nominal thickness shown in Table 1 and 7.3.1.1.

www.technobetar.ir

TABLE 3 Base-Coat Proportions,[A] Parts by Volume[B]

Plaster Mix Symbols	Cementitious Materials					Volume of Aggregate per Sum of Separate Volumes of Cementitious Materials	
	Portland Cement or Blended Cement	Plastic Cement	Masonry Cement		Lime	1st Coat	2nd[C] Coat
			N	M or S			
C	1	. . .	. . .	. . .	0–¾	2½ –4	3–5
CL	1	. . .	. . .	. . .	¾ –1½	2½ –4	3–5
M	. . .	. . .	1	. . .	. . .	2½ –4	3–5
CM	1	. . .	1	. . .	. . .	2½ –4	3–5
MS	. . .	. . .	. . .	1	. . .	2½ –4	3–5
P	. . .	1	. . .	. . .	. . .	2½ –4	3–5
CP	1	1	. . .	. . .	. . .	2½ –4	3–5

[A] The mix proportions for plaster scratch and brown coats to receive ceramic tile shall be in accordance with the applicable requirements of ANSI A108.1 series applicable to specified method of setting time.
[B] Variations in lime, sand, and perlite contents are allowed due to variation in local sands and insulation and weight requirements. A higher lime content will generally support a higher aggregate content without loss of workability. The workability of the plaster mix will govern the amounts of lime, sand, or perlite.
[C] The same or greater sand proportion shall be used in the second coat than is used in the first coat.

TABLE 4 Job-Mixed Finish Coat Proportion Parts by Volume

Plaster Mix Symbols[A]	Cementitious Materials					Volume of Aggregate per Sum of Separate Volumes of Cementitious Materials[B]
	Portland Cement or Blended Cement	Plastic Cement	Masonry Cement[A]		Lime	
			N	M or S		
F	1	. . .	. . .	. . .	¾ –1½	1½ –3
FL	1	. . .	. . .	. . .	1½ –2	1½ –3
FM	. . .	. . .	1	. . .	. . .	1½ –3
FCM	1	. . .	1	. . .	. . .	1½ –3
FMS	. . .	. . .	. . .	1	. . .	1½ –3
FP	. . .	1	. . .	. . .	. . .	1½ –3

[A] Additional portland cement is not required when Type S or M masonry cement is used.
[B] In areas not subject to impact, perlite aggregate shall be permitted to be used over base-coat plaster containing perlite aggregate.

7.3 *Plaster Application on Solid Plaster Bases*:

7.3.1 High-suction bases shall be evenly dampened with clean water prior to the application of plaster. Do not dampen low-suction solid bases, such as dense concrete or smooth brick.

7.3.1.1 Where masonry or concrete surfaces vary in plane, plaster thickness required to produce level surfaces shall not be required to be uniform.

7.3.2 *Three-Coat Application on Solid Bases*:

7.3.2.1 The first (scratch) coat shall be applied with sufficient material and pressure to ensure tight contact and complete coverage of the solid base, to the nominal thickness shown in Table 1. As soon as the first (scratch) coat becomes firm, the entire surface shall be scored in one direction only. The vertical surfaces shall be scored horizontally.

7.3.2.2 The second (brown) coat shall be applied using the same procedures specified in 7.2.2 and 7.2.2.1, bringing the surface to a true, even plane with a rod or straightedge, filling any defects in plane with plaster and darbying. The surface shall be floated uniformly to provide a surface receptive to the application of the third (finish) coat.

7.3.2.3 The third (finish) coat shall be applied as specified in 7.2.3.

7.3.3 *Two-Coat Application on Solid Plaster Bases*:

7.3.3.1 The first (scratch) coat shall be applied as specified in 7.3.2.1.

7.3.3.2 The second (finish) coat shall be applied as specified in 7.2.3.

7.4 *Finish-Coat Application*:

7.4.1 Job-mixed or factory-prepared finish coats shall be applied, by machine or by hand, as specified in 7.2.3.

7.4.2 The use of excessive water during the application and finishing of finish-coat plaster shall be avoided.

7.5 *Fog-Coat Application*—Job-mixed or factory-prepared fog coats shall be applied in accordance with the directions of the manufacturer.

8. Curing and Time Between Coats

8.1 Provide sufficient moisture in the plaster mix or by moist or fog curing to permit continuous hydration of the cementitious materials. The most effective procedure for curing and time between coats will depend on climatic and job conditions. (See X1.4.2.)

8.2 Sufficient time between coats shall be allowed to permit each coat to cure or develop enough rigidity to resist cracking or other physical damage when the next coat is applied. (See X1.4.2.)

9. Product Marking

9.1 Packaged materials shall be clearly marked or labeled to indicate product, brand name, the manufacturer, and the weight of the material contained therein. Similar information shall be provided in the shipping advices accompanying the shipment of bulk materials.

10. Delivery of Materials

10.1 Packaged materials shall be delivered in factory-sealed, unopened, and unbroken packages, containers, or bundles.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:40:50 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.2 Bulk materials shall be delivered in clean transport vessels, free of contaminates.

11. Protection of Materials

11.1 Weather-sensitive materials shall be kept in a dry condition until ready for use. (See A2.4.)

11.2 Bulk materials shall be stored to prevent subsequent contamination and segregation.

12. Environmental Conditions

12.1 Portland cement-based plaster shall not be applied to frozen base or to a base containing frost. Plaster mixes shall not contain frozen ingredients. Plaster coats shall be protected from freezing for a period of not less than 24 h after set has occurred.

12.2 Portland cement plaster shall be protected from uneven and excessive evaporation during dry weather and from strong blasts of dry air.

12.3 *Plaster Application*—When artificial heat is required, heaters shall be located to prevent a concentration of heat on uncured plaster. Heaters shall be vented to the outside to prevent toxic fumes and other products of combustion from adhering to or penetrating plaster bases and plaster. Adequate ventilation shall be maintained in all areas, particularly in interior areas with little or no natural air movement.

12.3.1 Interior environment shall be maintained at a temperature above 40 °F not less than 48 h prior to and during application of portland cement-based plaster. Interior temperature shall be maintained above 40 °F until normal occupancy.

12.3.2 For exteriors, plaster shall be applied when the ambient temperature is higher than 40 °F (4.4 °C), unless the work area is enclosed and heat is provided as described in 12.3.

13. Keywords

13.1 brown coat; cementitious; exterior plaster; fog coat—bond; portland cement; scratch coat; stucco

ANNEXES

(Mandatory Information)

A1. GENERAL INFORMATION

A1.1 The work shall include all labor, materials, services, equipment, and scaffolding required to complete the plastering of the project in accordance with the drawings and specifications, except heat, electric power, and potable water.

A1.2 Where a specific degree of fire resistance is required for plastered assemblies and constructions, details of construction shall be in accordance with official reports of fire tests conducted by recognized testing laboratories, in accordance with Test Methods E 119.

A1.3 Where a specific degree of sound control is required for plastered assemblies and constructions, details of construction shall be in accordance with official reports of tests conducted by recognized testing laboratories, in accordance with applicable sound tests of Test Methods E 90 or E 492.

A1.4 Scaffolding shall be constructed and maintained in strict conformity with applicable laws and ordinances.

A1.5 Work schedules shall provide for completion of work affecting supports, framework or lath of a suspended ceiling (such as loading) before plastering work is accomplished.

A1.6 Surfaces and accessories to receive plaster shall be examined before plastering is applied thereto. The proper authorities shall be notified and unsatisfactory conditions shall be corrected prior to the application of plaster. Unsatisfactory conditions shall be corrected by the party responsible for such conditions.

A1.6.1 Metal plaster bases, backing, attachment, and accessories to receive plaster shall be examined to determine if the applicable requirements of Specification C 1063 have been met unless otherwise required by the contract specifications.

A1.6.2 The construction specifier shall describe, in the proper section of the contract specifications, the physical characteristics of solid surface bases to receive plaster. The plane tolerance shall be not more than ¼ in. in 10 ft (3.1 mm/m). The mortar joints shall be flush and not struck. Dissimilar materials such as ties, reinforcing steel, and so forth, shall be cut back ⅛ in. (3 mm) below the surface and treated with a corrosion-resistant coating. Masonry shall be solid at corners and where masonry changes thickness in a continuous construction. Form release compounds shall be compatible with plaster or be completely removed from surfaces to receive plaster. The plastering contractor shall use this portion of the construction specifications for acceptance or rejection of such surfaces.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

A2. DESIGN CONSIDERATIONS

A2.1 Exterior plaster (stucco) is applied to outside surfaces of all types of structures to provide a durable, fire-resistant covering. Interior plaster is applied to inside surfaces that will be subjected to various exposures, such as abrasion, vibration, or to continuous or frequent moisture and wetting, or to freezing or thawing.

A2.1.1 Sufficient slope on faces of plastered surfaces shall be provided to prevent water, snow, or ice from accumulating or standing. Air-entrained portland cement plaster provides improved resistance to freeze/thaw deterioration. Resistance to rain penetration is improved where plaster has been adequately densified during application and properly cured. Plaster shall not, however, be considered to be "waterproof."

A2.1.2 The construction specifier shall describe, in the appropriate section of the contract specifications, the requirements for furnishing and application of flashing. Flashing shall be specified at openings, perimeters, and terminations to prevent water from getting behind plaster. Flashing shall be corrosion-resistant material. Aluminum flashing shall not be used. Flashing supplemented with sealant shall be permitted.

A2.1.3 Sealing or caulking of V-grooves, exposed ends, and edges of plaster panels or exterior work to prevent entry of water shall be provided.

A2.1.4 To reduce spalling where interior plaster abuts openings, such as wood or metal door or window frames, or fascia boards, the edge of three-coat plaster shall be tooled through the second and finish coats to produce a continuous small V-joint of uniform depth and width. On two-coat work, the V-joint shall be tooled through the finish coat only.

A2.1.5 Provide in the appropriate project specification section that solid bases to receive plaster shall not be treated with bond breakers, parting compounds, form oil, or other material that will prevent or inhibit the bond of the plaster to the base.

A2.1.6 Maximum allowable deflection for vertical or horizontal framing for plaster, not including cladding, shall be L/360.

A2.2 *Provisions for Drainage Behind Exterior Plaster:*

A2.2.1 In multistory construction where lath and portland cement plaster exterior walls are continuous past a floor slab, tracks or plates and studs shall be offset to provide a space not less than ⅜ in. (9.5 mm) between the inner face of the exterior plaster and the edge of the floor slab.

A2.2.2 At the bottom of exterior walls where the wall is supported by a floor or foundation, a drip screed and through-wall flashing or weep holes or other effective means to drain away any water that may get behind the plaster shall be provided.

A2.2.3 Where vertical and horizontal exterior plaster surfaces meet, both surfaces shall be terminated with casing beads with the vertical surface extending at least ¼ in. (6 mm) below the intersecting horizontal plastered surface, thus providing a drip edge. The casing bead for the horizontal surface shall be terminated not less than ¼ in. from the back of the vertical surface to provide drainage.

A2.3 *Relief from Stresses:*

A2.3.1 For information on control joints and perimeter relief see the Installation Section of Specification C 1063.

A2.3.1.1 Control joints shall be cleaned and clear of plaster within the control area after plaster application and before final plaster set.

A2.3.1.2 Prefabricated control joint members shall be installed prior to the application of plaster; therefore, the decision to use them, the type selected, their location, and method of installation shall be determined and specified in project specification sections other than the section on plastering.

A2.3.1.3 A groove or cut in plaster only shall not be considered a control or expansion joint.

A2.3.2 Where plaster and metal plaster base continues across the face of a concrete column, or other structural member, water-resistive building paper or felt shall be placed between the metal plaster base and the structural member (paper or plastic-backed metal plaster base shall be permitted). Where the width of the structural member exceeds the approved span capability of the metal plaster base, self-furring metal plaster base shall be used and sparingly scatter nailed to bring paper and metal base to general plane.

A2.3.3 Where dissimilar base materials abut and are to receive a continuous coat of plaster: (*1*) a two-piece expansion joint, casing beads back-to-back, or premanufactured control-expansion joint member shall be installed; or (*2*) the juncture shall be covered with a 6-in. (152-mm) wide strip of galvanized, self-furring metal plaster base extending 3 in. (76 mm) on either side of the juncture; or (*3*) where one of the bases is metal plaster base, self-furring metal plaster base shall be extended 4 in. (102 mm) onto the abutting base.

A2.4 *Weather-Sensitive Materials*—Water-sensitive materials shall be stored off the ground or floor and under cover, avoiding contact with damp floor or wall surfaces. Temperature-sensitive materials shall be protected from freezing. Bulk materials shall be stored in the area of intended use and caution shall be exercised to prevent contamination and segregation of bulk materials prior to use.

A2.5 *Admixtures*—Admixtures shall be proportioned and mixed in accordance with the published directions of the admixture manufacturer.

A2.5.1 The quantity of admixtures required to impart the desired performance is generally very small in relation to the quantities of the other mix ingredients. Batch-to-batch quantities shall be measured accurately.

A2.5.2 Air-entraining agents cause air to be incorporated in the plaster in the form of minute bubbles, usually to improve frost or freeze-thaw resistance, or workability of the plaster during application. Air-entraining agents for portland cement-based plaster shall meet the requirements of Specification C 260.

APPENDIX

(Nonmandatory Information)

X1. GENERAL INFORMATION

X1.1 *Additions*—Bonding compounds or agents may be pre-applied to a surface to receive plaster. In this usage it is not considered an admixture. Bonding compounds that are integrally mixed with plaster prior to its application are considered admixtures. Where exterior exposure and cyclic wetting are anticipated, the re-emulsification capability of the bonding material must be considered. Bonding agents are only as good as the material surface to which they are applied; therefore, form release materials must be removed from concrete or be compatible with the bonding material used. Bonding agents in plaster mixes may increase the cohesive properties of the plaster. Bonding agents should meet the requirements of Specifications C 631 or C 932.

X1.1.1 By the use of a suitable admixture or additive, it is possible to improve plaster's resistance to moisture movement. However, the use of the terms damproofing or water proofing is misleading, and their use shall be discouraged.

X1.1.2 Natural or synthetic fibers, ½ to 2 in. (13 to 51 mm) in length and free of contaminates may be specified to improve resistance to cracking or to impart improved pumpability characteristics. The quantities per batch shall be in accordance with the published directions of the fiber manufacturer. No more than 2 lb (0.90 kg) of fiber should be used per cubic foot of cementitious material. Asbestos fibers should not be used. Alkaline-resistant glass fibers are recommended where glass fiber is used.

X1.1.3 Plasticizers containing hydrated lime putty, air-entraining agents, or approved fatteners to increase the workability of a portland cement plaster may be used. Plaster consistency and workability are affected by plasticizers that are beneficial in proper quantities from an economic standpoint, but in excess can be detrimental to the long-term performance of the plaster in place.

X1.1.4 Color material for integral mixing with plaster should not significantly alter the setting, strength development, or durability characteristics of the plaster. Natural or mineral pigments that are produced by physical processing of materials mined directly from the earth appear to offer the best long-term performance with respect to resistance to fading. Plaster color is determined by the natural color of the cementitious materials, aggregate, and any color pigment, and their proportions to each other. The use of white cement with the desired mineral oxide pigment color material may result in truer color.

X1.1.4.1 The uniformity of color cannot be guaranteed by the materials manufacturer of the component materials or by the applicating contractor. Color uniformity is affected by the uniformity of proportioning, thoroughness of mixing, cleanliness of equipment, application technique, and curing conditions and procedure, which are generally under the control of the applicator. Color uniformity is affected to an even greater degree by variations in thickness and differences in the suction of the base coat from one area or location to another, the type of finish selected, the migration of color pigments with moisture, and with job site climatic and environmental conditions. These factors are rarely under the control of the applicator.

X1.2 *Finish Coat Categories* (applicable to both natural and colored finishes):

X1.2.1 Texture, as a description of surface appearance, is identified generally with the method and tools used to achieve the finish. Texture can be varied by the size and shape of the aggregate used, the equipment or tools employed, the consistency of the finish coat mix, the condition of the base to which it is applied, and by subsequent decorative or protective treatment.

X1.2.2 There are many factors that affect the ultimate appearance of textured and integrally colored plaster. A suitably sized sample panel should be submitted for approval by the architect and the owner. Once approved, the sample should be maintained on site for reference and comparison.

X1.2.3 With the almost limitless variations possible for finish appearance or texture, the same term may not have the same meaning to the specifier, the contractor, and the actual applicator. The specifier is cautioned to use an approved range of sample panels. To provide some guidance, the following categories are generally understood and recognized to imply a particular method of application technique or resulting finished appearance:

X1.2.4 *Smooth Trowel*—Hand- or machine-applied plaster floated as smooth as possible and then steel-troweled. Steel troweling should be delayed as long as possible and used only to eliminate uneven points and to force aggregate particles into the plaster surface. Excessive troweling should be avoided.

X1.2.5 *Float*—A plaster devoid of coarse aggregate applied in a thin coat completely covering the base coat, followed by a second coat that is floated to a true plane surface yielding a relatively smooth to fine-textured finish, depending on the size of aggregate and technique used. It is also known as sand finish.

X1.2.6 *Trowel-Textured (such as Spanish Fan, Trowel Sweep, English Cottage)*—A freshly applied plaster coat is given various textures, designs, or stippled effects by hand troweling. The effects achieved may be individualized and may be difficult to duplicate by different applicators.

X1.2.7 *Rough-Textured (such as Rough Cast, Wet Dash, Scottish Harl)*—Coarse aggregate is mixed intimately with the plaster and is then propelled against the base coat by trowel or by hand tool. The aggregate is largely unexposed and deep textured.

X1.2.8 *Exposed Aggregate (also known at Marblecrete)*—Varying sizes of natural or manufactured stone, gravel, shell, or

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:40:50 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

ceramic aggregates are embedded by hand or machine propulsion into a freshly applied finish "bedding" coat. The size of the aggregate determines the thickness of the "bedding" coat. It is generally thicker than a conventional finish coat.

X1.2.9 *Spray-Textured*—A machine-applied plaster coat directed over a previously applied thin smooth coat of the same mix. The texture achieved depends on the consistency of the sprayed mixture, moisture content of the base to which it is applied, the angle and distance of the nozzle to the surface, and the pressure of the machine.

X1.2.10 *Brush-Finish*—A method of surfacing or resurfacing new or existing plaster. The plaster is applied with a brush to a thickness of not less than 1/16 in. (1.6 mm). For an existing plaster surface the bond capability must be determined by test application or a bonding compound must be applied prior to the brush application.

X1.2.11 *Miscellaneous Types*—This finish coat category is somewhat similar to trowel-textured finishes, except that the freshly applied plaster is textured with a variety of instruments other than the trowel, such as swept with a broom or brush, corrugated by raking or combing, punched with pointed or blunt instrument, scored by aid of a straightedge into designs of simulated brick, block, stone, and so forth. A variation of texturing a finish coat involves waiting until it has partially set and then flattening by light troweling of the unevenly applied plaster or by simulating architectural terracotta.

X1.2.12 *Scraffitto*—A method of applying two or more successive coats of different colored plaster and then removing parts of the overlaid coats to reveal the underlaying coats, usually following a design or pattern. This is not generally considered a finish coat operation because of the number of thickness of coats.

X1.3 When specified as alternate for final coat, trowel- or plaster machine-applied textured acrylic finishes containing aggregate may be substituted for portland cement finish coats, provided brown coat is properly prepared and finish is applied according to the manufacturer's directions.

X1.3.1 *Staining of Plaster*—Staining and discoloration of plaster, caused by free water draining from one plane of plaster to another or from a dissimilar material onto a plaster surface, can be minimized by providing sufficient depth and angle for drip caps and the use of water-resistive surface coatings.

X1.3.2 Staining of plaster due to entrapment of moisture behind the plaster, can be avoided or minimized by providing an air space for ventilation between the back of the plaster and adjacent material. This type of staining may occur where insulation with or without vapor barrier, or other material containing asphaltic or coal tar derivatives, fireproofing salts, and so forth, can migrate with moisture movement to the finished plaster surface.

X1.3.3 Integrally colored plaster can be discolored or altered in shade if subjected to moisture, either from uncured base coats or external sources, such as rain, too soon after applications.

X1.4 *Installation Instructions:*

X1.4.1 Hand mixing should not be permitted, except as approved by the contract specifier.

X1.4.1.1 After all ingredients are in the mixer, mix the plaster for 3 to 5 min.

X1.4.1.2 The amount of water used in the plaster mix should be determined by the plasterer. Factors such as the suction of the base, or of the previous coat, water content of the aggregate, drying conditions, and finishing operations should be considered in determining water usage. Use of excessive water may result in dropouts, fall or slide off, excessive shrinkage, high porosity, and lower strength.

X1.4.2 *Time Between Coats and Curing for Portland Cement-Based Plaster:*

X1.4.2.1 The timing between coats will vary with climatic conditions and types of plaster base. Temperature and relative humidity extend or reduce the time between consecutive operations. Cold or wet weather lengthens and hot or dry weather shortens the time period. Moderate changes in temperature and relative humidity can be overcome by providing additional heating materials during cold weather and by reducing the absorption of the base by pre-wetting during hot or dry weather.

X1.4.2.2 In order to provide more intimate contact and bond between coats and to reduce rapid water loss, the second coat should be applied as soon as the first coat is sufficiently rigid to resist cracking, the pressures of the second coat application, and the leveling process.

X1.4.2.3 The amount of water and the timing for curing portland cement plaster will vary with the climatic conditions, the type of base, and use or nonuse of water-retentive admixtures.

X1.4.2.4 Some moisture must be retained in or added back to freshly applied portland cement-based plaster. If the relative humidity is relatively high (above 75 %), the frequency for rewetting a surface may be reduced. If it is hot, dry, and windy, the frequency of rewetting must be increased.

X1.4.2.5 Consider the physical characteristics of the structure as well as the previously mentioned conditions when selecting the method of curing. The method can be one or a combination of the following:

(*1*) Moist curing is accomplished by applying a fine fog spray of water as frequently as required, generally twice daily in the morning and evening. Care must be exercised to avoid erosion damage to portland cement-based plaster surfaces. Except for severe drying conditions, the wetting of finish coat should be avoided, that is, wet the base coat prior to application of the finish coat.

(*2*) Plastic film, when taped or weighted down around the perimeter of the plastered area, can provide a vapor barrier to retain the moisture between the membrane and plaster. Care must be exercised in placing the film: if too soon, the film may damage surface texture; if too late, the moisture may have already escaped.

(*3*) Canvas, cloth, or sheet material barriers can be erected to deflect sunlight and wind, both of which will reduce the rate of evaporation. If the humidity is very low, this option alone may not provide adequate protection.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 926 – 98a(2005), that may impact the use of this specification. (Approved June 1, 2006)

(*1*) Removed reference to "plastering section" in A2.3.1.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C928/C928M – 09

Standard Specification for Packaged, Dry, Rapid-Hardening Cementitious Materials for Concrete Repairs[1]

This standard is issued under the fixed designation C928/C928M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers packaged, dry, cementitious mortar or concrete materials for rapid repairs to hardened hydraulic-cement concrete pavements and structures. Materials that contain organic compounds, such as bitumens, epoxy resins, and polymers, as the principal binder are not included.

1.1.1 Packaged, dry, concrete material contains aggregate of which at least 5 % by mass of the total mixture is retained on a 9.5-mm [⅜-in.] sieve.

1.1.2 Packaged, dry, mortar material contains aggregate of which less than 5 % by mass of the total mixture is retained on a 9.5-mm [⅜-in.] sieve.

1.2 Aqueous solutions, aqueous emulsions or dispersions may be included as components of the packaged materials. The manufacturer may specify that these liquids are to replace some or all of the mixing water.

1.3 Aggregates must be included as a component of the packaged materials. The manufacturer may recommend job site addition of specific amounts and types of additional aggregates to his product for some uses. However, such reformulated products are not within the scope of this specification.

1.4 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.5 The following safety hazards caveat pertains to the test methods portion of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C1012 Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution
E96/E96M Test Methods for Water Vapor Transmission of Materials

3. Materials and Manufacture

3.1 Three types of packaged, dry, rapid-hardening concrete and three types of packaged, dry, rapid-hardening mortar are identified in Table 1.

TABLE 1 Performance Requirements[A]

	3 h	1 day	7 days	28 days
Compressive Strength, min, MPa [psi]				
R1 concrete or mortar	3.5 [500]	14 [2000]	28 [4000]	[B]
R2 concrete or mortar	7.0 [1000]	21 [3000]	28 [4000]	[B]
R3 concrete or mortar	21 [3000]	35 [5000]	35 [5000]	[B]
Bond strength, min, MPa [psi]				
R1, R2 and R3 concrete or mortar	—	7 [1000]	10 [1500]	—
Length change, based on length at 3 h, max, %				
R1, R2, and R3 concrete or mortar	allowable increase after 28 days in water			+0.15
	allowable decrease after 28 days in air			–0.15
Consistency of concrete or mortar[C]			concrete slump, min, mm [in.]	Flow of mortar, min, %
R1 consistency after 15 min after addition of mixing liquid			75 [3]	100
R2 and R3 consistency at 5 min after addition of mixing liquid			75 [3]	100
Scaling resistance to deicing chemicals after 25 cycles of freezing and thawing				
Concrete, max visual rating			2.5	
Mortar, max scaled material[D]			5 kg/m^2 [1 lb/ft^2]	

[A] It is recognized that other characteristics of rapid-hardening concrete repair materials might need consideration. Such characteristics might be necessary in some environments and applications; however, to impose specification limits on all products is considered beyond the scope of this specification. Optional considerations with suggested methods of test may include tests for the following:

Time of setting	Test Method C403/C403M
Flexural strength	Test Method C78
Freeze thaw	Test Method C666/C666M, Procedure A
Sulfate expansion	Test Method C1012

[B] The strength at 28 days shall be not less than the strength at 7 days.

[C] Slump or flow requirements are waived for materials intended for vertical or overhead applications.

[D] A 250-mm [10-in.] square spalled to an average depth of 3 mm [⅛ in.] for 100 % of its surface would have about 10 kg/m^2 [2.0 lb/ft^2] of scaled material.

4. Chemical Composition

4.1 If the material contains soluble chlorides or other ingredients in sufficient quantity to cause corrosion to steel reinforcement, the package markings shall contain the following statement in letter size no smaller than the directions for use:

> This material is not recommended for use in a moist environment in contact with steel reinforcement.

4.1.1 Consider a total chloride ion content (Berman, 1972)[3,4] in the packaged repair material greater than 600 g/m^3 [1 lb/yd^3] of the hardened repair material indicative that the packaged material contains sufficient chlorides to cause corrosion to steel reinforcement when the concrete is exposed to weather, is on the ground, or is in an otherwise moist environment. A much lower chloride ion content is suggested for use in prestressed concrete. Guidance for such users is outside the scope of this specification.

4.2 If the material contains metallic iron in excess of 1 % by weight, the package markings shall contain the following statement in letter size no smaller than the directions for use:

> If small or scattered spots of iron-staining are considered objectionable, do not use this material where it will be exposed.

5. Performance Requirements

5.1 The materials shall comply with the performance requirements in Table 1 for the applicable type.

6. Sampling

6.1 A lot is the quantity of packaged repair material normally placed on a pallet. In general, this quantity will weigh from 900 to 1800 kg [2000 to 4000 lb].

6.2 A unit sample is a single package of material randomly selected from the lot.

7. Specimen Preparation

7.1 *Concrete*—Mechanically mix the packaged dry concrete material with mixing liquid. Determine the properties of the unhardened mixture, and mold and cure the specimens in accordance with Practice C192/C192M or modifications as outlined herein.

7.1.1 The sample of packaged dry material shall be any combination of whole packages yielding not less than 20 L [⅔ ft^3] of hardened material.

7.1.2 Base the quantity of water, other liquid component, or both added to the sample on the quantity per bag stated in the directions for use.

7.1.3 Place the sample in the mixing machine and add the required amount of liquid. Start mixing immediately. Continue mixing for the length of time indicated in the directions for use.

7.1.4 When making the slump test in accordance with Test Method C143/C143M, schedule work so the test will be completed in 5 ± ½ min after the mixing liquid is added to the R2 or R3 materials or 15 ± ½ min after mixing the liquid with the R1 materials.

7.1.5 Mold the required number of specimens using additional samples as may be necessary, mixed in accordance with

[3] Berman, H. A., Determination of Chloride in Hardened Portland Cement Paste, Mortar, and Concrete, *ASTM Journal of Materials*, Vol. 7 , No. 3, pp. 330–335, 1972 .

[4] Clear, K. C., and Harrigan, E. T., "Sampling and Testing for Chloride Ion in Concrete," Report No. FHWA-RD77-85, Federal Highway Administration, Washington, DC, August 1977 (Available as PB 275–428/AS National Technical Information Services).

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.1.1-7.1.4. Do not use the mixtures for molding test specimens when the slump is less than that specified in Table 1.

NOTE 1—Where the nominal maximum particle size is not greater than 25 mm [1 in.], the use of cylindrical molds 100 mm [4 in.] in diameter by 200 mm [8 in.] in length is suggested.

7.2 *Mortar*—Mechanically mix packaged dry mortar material with mixing liquid. Determine the properties of the unhardened mixture, and mold and cure the specimens in accordance with Test Method C109/C109M or modifications as outlined herein.

7.2.1 The sample of packaged dry material shall weigh 3000 ± 3 g [6.6 ± 0.005 lb] and shall be representatively obtained from a whole package in accordance with Practice C702.

7.2.2 Base the quantity of water, or other liquid component, or both added during mixing on the quantity per unit of weight stated in the directions for use.

7.2.3 When making the flow test in accordance with the section on consistency in Test Method C109/C109M, schedule work so the test will be completed in 5 ± ½ min after the start of mixing liquid with the R2 or R3 materials or 15 ± ½ min after mixing the liquid with the R1 materials.

7.2.4 Mold the required number of specimens using additional samples as necessary mixed in accordance with 7.2.1-7.2.3. Do not use the mixtures for molding test specimens when the flow is less than that specified in Table 1.

7.3 In those cases where the manufacturer has indicated in the package markings, or elsewhere, that the packaged repair material can be mixed and applied at temperatures that lie beyond the range of 20 ± 8 °C [70 ± 15 °F], the product must meet the requirements of Table 1. Specimens must be made and cured in accordance with the procedures of this section. The mixing, molding and curing temperatures during the first 3 h after molding shall be within ±1 °C [±2 °F] of the extreme temperature(s) stated by the manufacturer in the package markings.

8. Test Methods

8.1 *Manifestly Faulty Specimens*—Treat manifestly faulty specimens in accordance with the corresponding section in Specification C494/C494M.

8.2 *Compressive Strength*—Prepare and test three test specimens for each age of test and each level of mixing temperature. Test in accordance with Test Method C39/C39M for concrete and Test Method C109/C109M for mortar.

8.3 *Length Change*—Prepare and test specimens in accordance with Test Method C157/C157M, except as modified by this section and 7.3. Use 25 mm [1-in.] prism for mortar material and 75 mm [3-in.] prism for concrete material.

8.3.1 Remove specimens from the molds at an age of 2½ to 2¾ h after the addition of mixing liquid to the dry cementitious mixture during the mixing operation.

8.3.2 Make the initial observation of length at 3 to 3¼ h after the addition of mixing liquid to the dry cementitious mixture during the mixing operation. When specimens are cured at temperatures other than 23 ± 2 °C [73.4 ± 3 °F], then both initial and final length observations must be made with the bars conditioned to ±2 °C [±3 °F] of initial temperatures.

8.3.3 Immediately store one set of specimens as for "Air Storage" and one set as for "Water Storage" except that the water-stored specimens shall be stored in untreated tap water with no more than one set of specimens per container.

8.3.4 Take observations of length at age 28 days ± 20 h. Determine the average percent change in length when stored in water, and the average change in length of specimens stored in air.

8.4 *Scaling Resistance*—Make and cure the test specimens in accordance with Test Method C672/C672M, except as provided herein. For specimens of mortar omit the visual rating procedure after every 5 cycles and after 25 cycles determine the amount of scaling as the oven dry 110 ± 5 °C [230 ± 9 °F] mass per unit area of exposed test area.

8.5 *Slant Shear Bond Strength*—Prepare six complete test specimens in accordance with Test Method C882 for Type II and V systems except as modified by this section.

8.5.1 Do not apply a bonding system to prepared surface unless a bonding system is required by the manufacturer of the rapid-hardening cementitious material. Fill the top half of the cylinder with the rapid-hardening cementitious material instead of the portland cement mortar specified.

8.5.2 Test three specimens in compression at 1 day and three at 7 days. Calculate the bond strength on the elliptical area and report the failure type.

9. Report

9.1 Report the following:

9.1.1 Source and identification, including type, of material tested,

9.1.2 Details of any variations and options practiced by the tester that are recommended or allowed by the manufacturer or others,

9.1.3 Compressive strength of material at 3 h, 1 day, 7 days and 28 days,

9.1.4 Bond strength at 1 day and 7 days,

9.1.5 Percent length change at 28 days in water and in air,

9.1.6 Percent flow in mortar at 5 or 15 min,

9.1.7 Slump in concrete at 5 or 15 min, and

9.1.8 Scaling resistance after 25 cycles.

10. Precision and Bias

10.1 *Length Change*:

10.1.1 *Precision*—The precision of the length change test method described in section 8.3 is based on an interlaboratory study that was conducted in 2007.[5] Seven laboratories tested one rapid-hardening material that consisted of commercially available rapid hardening cement blended with three parts standard graded sand complying with Specification C778. The precision values were calculated for both "water storage" and "air storage" of test specimens. A test result is defined in this specification as the average of three separate measurements (triplicate lengthchange specimens).

[5] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1035.

www.technobetar.ir

10.1.2 The single-operator standard deviation for water storage of test specimens has been found to be 0.0031 %.[6] Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 0.009 %.[6] The single-operator standard deviation for air storage of test specimens has been found to be 0.0067 %.[6] Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 0.019 %.[6]

10.1.3 The multi-laboratory standard deviation for water storage of test specimens has been found to be 0.0078 %.[6] Therefore, results of two properly conducted tests from two different laboratories on the same material are not expected to differ by more than 0.022 %.[6] The multilaboratory standard deviation for air storage of test specimens has been found to be 0.015 %.[6] Therefore, results of two properly conducted tests from two different laboratories on the same material are not expected to differ by more than 0.041 %.[6]

10.1.4 *Bias*—Since there is no accepted reference material suitable for determining any bias that might be associated with this test method, no statement on bias is being made.

11. Rejection

11.1 The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer or supplier promptly and in writing.

12. Certification

12.1 When specified in the purchase order or contract, a producer, supplier, or an independent testing laboratory shall furnish certification to the purchaser that the material has been tested in accordance with this specification and found to meet the requirements. When specified in the purchase order or contract, a report of test results on samples taken from material shipped shall be furnished.

13. Product Marking

13.1 Mark all packages to contain the following information:

13.1.1 Specification designation.

13.1.2 R1 or R2 or R3 type.

13.1.3 Directions for use that shall include but are not limited to:

13.1.3.1 When a bonding agent is used in the test of bond strength, the type and kind of adhesive recommended to bond fresh repair material to the concrete or mortar being repaired.

13.1.3.2 The recommended amount of water, other liquid component, or both, to be mixed with the package contents.

13.1.3.3 The recommended length of mixing time or sequence of mixing and resting times in minutes.

13.1.4 Date the material was packaged.

13.1.5 The yield in litres [cubic feet] or yield in square metres per centimetre [square feet per inch] thickness when mixed with the recommended amount of liquid.

13.1.6 The net weight in each container. The contents of any container shall not vary by more than 2 % from the weight stated in the markings. The average weight of filled containers in a lot shall be not less than the weight stated in the markings.

13.1.7 If the product is formulated for use in vertical or overhead applications, it shall be so stated on the package.

14. Packaging

14.1 The material from which the containers are made shall have water vapor transmission not greater than 100 g/m^2 [0.2 lb/ft^3] in 24 h as determined in accordance with Procedure B of Test Methods E96/E96M.

15. Keywords

15.1 cementitious mortar or concrete materials for repair; concrete; packaged; mortar; packaged; packaged dry materials for concrete repair; rapid hardening materials; repair materials

[6] These measurements represent, respectively, the (1s) and (d2s) limits in accordance with Practice C670.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C928/C928M – 08, that may impact the use of this specification. (Approved December 1, 2009)

(*1*) Added new Section 10 Precision and Bias and renumbered subsequent sections and footnotes.

Committee C09 has identified the location of selected changes to this specification since the last issue, C928 – 05, that may impact the use of this specification. (Approved October 1, 2008)

(*1*) Revised the standard as a combined units standard.

Designation: C 932 – 06

Standard Specification for Surface-Applied Bonding Compounds for Exterior Plastering[1]

This standard is issued under the fixed designation C 932; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers minimum requirements for exterior surface-applied bonding compounds for improving the adhesion of cementitious material to concrete or other masonry surfaces or any structurally sound surfaces.

1.2 This specification also covers test methods for determining performance requirements and physical properties.

1.3 The values stated in inch-pound units are to be regarded as the standard. The SI metric values given in parentheses are approximate and are provided for information purposes only.

1.4 The following safety hazards caveat pertains only to the test methods described in Sections 9, 10, 11, and 12 in this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars(Using 2-in. or [50-mm] Cube Specimens)

C 150 Specification for Portland Cement

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 778 Specification for Sand

3. Terminology

3.1 Definitions used in this specification shall be in accordance with Terminology C 11.

4. Physical Properties

4.1 *Surface Applied Bonding Compound*—A freeze-thaw stable composition, suitable for brush, roller, or spray application. It shall be tinted to show by visual inspection where it has been applied. The tint shall not bleed through the material being bonded.

4.2 *Consistency*—The bonding compound shall be free of foreign matter as determined by visual inspection and shall be of such uniform consistency that when applied in accordance with the producers directions by brush, roller, or spray to concrete, masonry, or other structurally sound surface, the bonding compound shall flow on evenly and dry uniformly.

4.3 *Film Characteristics*—The film-forming property shall be determined by visual inspection to determine the presence of a continuous film not broken by fisheyes, cracking, pull-back, or any other discontinuity in the film surface. It shall not be noticeably affected by alkaline surfaces or weak acids.

4.4 *Re-Emulsification*—Product conforming with this specification shall not re-emulsify.

5. Performance Requirements

5.1 *Bonding Capability*—The bonding compound shall be capable of bonding cementitious materials when applied in accordance with the producer's directions and tested as specified in Section 12.

5.2 *Degradation*—Bonding compound which separates shall be able to be re-mixed to a uniform consistency when tested as specified in Section 10.

5.3 *High Temperature Test*—The bond strength shall be not less than 150 psi (1034 kPa) when tested as specified in Section 9.

5.4 *Freeze-Thaw Stability*—The bond strength shall be not less than 150 psi (1034 kPa) and 100 psi (690 kPa) when tested under the dry and wet conditions, respectively, as specified in Section 11.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved March 1, 2006. Published March 2006. Originally approved in 1980. Last previous edition approved in 2005 as C 932 – 05.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

5.5 *Tensile Bond Strength*—Bond strength of a fresh sample or a 6-month-old sample of bonding compound shall have an average tensile strength of not less than 150 psi (1034 kPa) and 100 psi (690 kPa) when tested under the dry and wet conditions, respectively, as specified in Section 12.

6. Sampling

6.1 Take a sample of not less than 2.2 lb (1000 g) from each shipment or consignment for analysis and tests. Except in special cases, take the sample from not less than three separate containers, chosen at random. In addition, take samples from containers that appear to be nonrepresentative, and test separately. Place the samples immediately in airtight glass containers and transport to the testing laboratory in these containers. Take precautions to reduce evaporation or drying to a minimum. Thoroughly mix the bonding compound in the container if there is a tendency for liquid phase separation.

7. Apparatus

7.1 *Moist Cabinet*—Specification C 511.

7.2 *Oven*—A forced draft type oven, having a temperature controlled at 140 ± 5 °F (60 ± 3 °C) for high temperature tests.

7.3 *Freezer*—A freezer having a controlled temperature of −10 ± 2 °F (-23 ± 1 °C).

7.4 *Balance*—A balance capable of weighing not less than 5.5 lb (2500 g) at a precision of 0.0002 lb (0.1 g).

7.5 *Timing Device*—An instrument capable of reading to the nearest second.

7.6 *Tamper*—A tamper made up of a nonabsorptive, nonabrasive, non-brittle material and having a cross section of ½ in. by 1 in. (13 × 25 mm) and approximately 5 to 6 in. (130 to 150 mm) long. The tamping face shall be flat and at right angles to the length of the tamper.

7.7 *Straight Edge*—A steel straight edge not less than 4 in. (100 mm) long and not less than 1⁄16 in. (1.6 mm) nor more than ⅛ in. (3.2 mm) in thickness.

7.8 *Spatula*—A spatula with a metal blade 6 in. (150 mm) in length and ½ in. (13 mm) in width, with straight edges.

7.9 *Paint Brush*—A standard 1 in. (25 mm) wide brush, with synthetic bristles.

7.10 *Testing Machine*—Any type that is of sufficient capacity and that is capable of applying the load continuously and without shock at the rate of 0.05 in. (1.27 mm) per minute, with provision for adjustment of the rate of loading.

7.11 *Briquet Molds*—The molds for making test specimens shall be made of metal not attacked by the mortar and shall have sufficient material in the sides to prevent spreading during molding. Gang molds, when used, shall be of the type shown in Fig. 1. The dimensions of the briquet molds shall conform to the following requirements: width of mold, between inside faces, at waist line of the briquet, 1 in. (25.4 mm) with permissible variations of ±0.01 in. (0.25 mm) for molds in use and ±0.005 in. (0.13 mm) for new molds; thickness of molds measured at the point of greatest thickness on either side of the mold at the waist line, 1 in. (25.4 mm) with permissible variations of +0.004 in. (0.10 mm) and – 0.002 in. (0.05 mm) for new molds and −0.02 in. (0.5 mm) for molds in use. The briquet specimens shall conform to the dimensional requirements shown in Fig. 2.

7.12 *Saw*—A table saw equipped with an abrasive cutting blade or other blade suitable for cutting cementitious materials.

7.13 *Clips for Briquet Testing Machine*—The clips for holding the tension test specimen shall be in accordance with Fig. 3.

8. Conditioning

8.1 *Room Temperature and Humidity*—Maintain the air temperature in the vicinity of the mixing and testing area at 70 ± 5 °F (21 ± 3 °C). Maintain the relative humidity at 50 ± 2 %.

8.2 *Temperature of the Mixing Water*—72 ± 2 °F (22 ± 1 °C).

9. High Temperature Test

9.1 *Significance and Use*—This test method provides procedures for evaluating the adhesive strength of bonding compounds after being exposed to accelerated aging at high temperature.

9.2 *Specimen Preparation*—For each test specimen, transfer the bonding compound, taken from the sample obtained, into a standard 1 pt. (500 mL) glass container.

9.3 *Procedure*—Place the specimen in the oven for 30 days. Remove the container, allow the compound to cool to room temperature, mix the compound to a uniform consistency, and test as specified in Section 12.

9.4 *Tests and Retests*—Test six briquets and report the average of the test results. If the result of any one of the six tests varies more than 15 % from the average, reject it and report the average of the other five tests. If the results from more than two tests vary more than 15 % from the average, reject the series and retest.

9.5 *Precision and Bias*—The precision and bias of the high temperature test for determining bond strength after exposure to high temperature are essentially the same as specified in the test method for bond strength, paragraph 12.7.

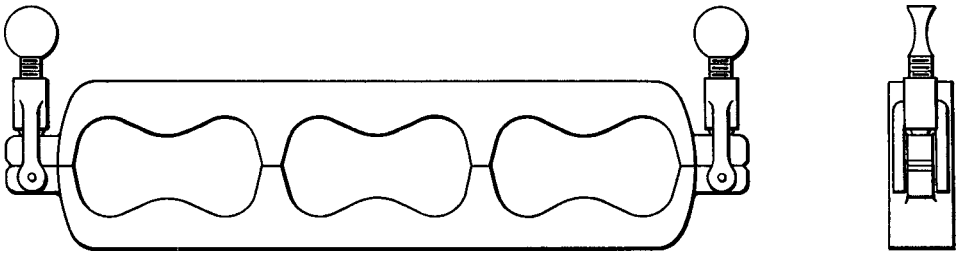

FIG. 1 Briquet Gang Mold

NOTE 1—1 in. = 25.4 mm.

FIG. 2 Briquet Specimen for Tensile Strength Test

10. Degradation Test

10.1 *Significance and Use*—This test method simulates the effects of high temperature storage on the physical properties of bonding compound.

10.2 *Specimen Preparation*—For each test, transfer the bonding compound, from the sample obtained, into a standard 1 pt. (500 mL) glass container.

10.3 *Procedure*—Place the specimen in the oven for 15 days. Remove the container from the oven and examine the contents for settling and separation. Place the container back in the oven for an additional 15 days. Remove the container and examine the contents again for settling and separation. Allow the compound to come to room temperature, and mix to a uniform consistency. Mix by hand stirring with a wood, metal, or plastic paddle for not more than five minutes.

10.4 *Tests and Retests*—Bonding compound that fails to be remixed to a uniform consistency shall be considered to have failed the test.

10.5 *Report*—Determine the extent of settling and separation by measuring and report as a percentage of the height of the specimen in the clear glass container, represented by the location of the liquid/solid interface.

10.6 *Precision and Bias*—No information is presented about either the precision or bias of the Degradation test for measuring settling, separation, or the ability to be mixed to a uniform consistency since the test result is non-quantitative.

11. Freeze-Thaw Cycle Test

11.1 *Significance and Use*—This test method provides procedures for determining the bond strength of bonding compounds after being exposed to accelerated storage conditions of alternate freezing and thawing.

11.2 *Specimen Preparation*—For each test specimen, transfer the bonding compound, taken from the sample obtained, into a standard 1 pt. (500 mL) glass container having a screw on or friction fit cover.

11.3 *Procedure*—Place a covered specimen in the freezer for 16 h. Remove the specimen and allow to thaw at room temperature for 8 h. Repeat this procedure for 5 cycles. After the fifth cycle, allow the compound to come to room temperature, then test as specified in Section 12.

11.4 *Tests and Retests*—Test six briquets and report the average of the test results. If the result of any one of the six tests varies more than 15 % from the average, reject it and report the average of the other five tests. If the results from more than two tests vary more than 15 % from the average, reject the series and retest.

11.5 *Precision and Bias*—The precision and bias of the freeze-thaw cycle test for determining bond strength after exposure to alternate freezing and thawing are essentially the same as specified in the test method for bond strength, paragraph 12.7.

12. Bond Strength Test

12.1 *Significance and Use*—This test method provides a method for determining the ability of bonding compound, after being subject to various simulated conditions of aging and exposure to temperature extremes, to adhere cementitious materials to a properly prepared substrate.

12.2 *Materials*:

12.2.1 *Cement*—Specification C 150.

12.2.2 *Graded Standard Sand*—Specification C 778.

12.3 *Preparation of Briquets*:

12.3.1 Prepare not less than six briquets for each series of tests.

12.3.2 Prepare the proportions of the standard mortar in accordance with the procedure given in Test Method C 109/C 109M.

12.3.3 Mechanically mix the mortar in accordance with the procedure given in Practice C 305.

12.3.4 Prepare molds by coating the molds with a thin film of mineral oil. Support the molds on a lightly oiled glass or metal plate.

12.3.5 Cast the briquets immediately after completely mixing the mortar, half fill the molds and puddle the mortar uniformly with the tamper, taking care not to displace the divider. Slightly over fill the molds with additional mortar and repeat the puddling. After the mortar has set, cut off the excess to a plane surface flush with the top of the mold, using a broad knife or similar implement.

12.3.6 Immediately after molding, place the molds, on the base plate, into the moist cabinet for 48 h.

12.3.7 Remove the briquets from the mold and store them at room temperature and humidity for not less than 48 h.

12.3.8 Examine the specimens, discard any that have air holes or excessively rough surfaces.

12.3.9 Saw the specimens in half at the mid-point of the waist line, aligning the saw blade so that the entire saw kerf is taken out of one side of the briquet, and the remaining side maintains a 1 in. cross section. Discard the smaller portion of the briquet.

12.4 *Procedure*:

12.4.1 Thoroughly clean dust and loose particles from the flat waist surface of the specimen. Apply the bonding compound, in accordance with the producer's directions, to the flat waist surface of the briquet by means of a paint brush.

12.4.2 Place the half briquet, coated with bonding compound, into the mold. Fill the remaining space in the mold with mortar, mixed and molded as specified in 12.3.

12.4.3 The time between coating the briquet with compound and casting the mortar against it shall be immediately after the compound has dried, or as recommended by the manufacturer, except when otherwise specified for a ten day waiting period.

12.4.4 Place the filled briquet mold in the moist cabinet for 24 h, then remove the briquets from the molds.

12.5 *Test Method*:

12.5.1 Test the briquets at the following intervals:

12.5.1.1 *Dry Condition*—Air cure three briquets for 14 days and test.

12.5.1.2 *Wet Condition*—Air cure three briquets for 7 days, soak in water for 7 days, and test.

12.5.2 Remove any loose particles or flash from the surfaces that will be in contact with the clips of the testing machine. Make sure the bearing surfaces of the clips are clean and free of sand, and the roller bearings are lubricated and maintained to ensure freedom of turning. Keep the stirrups supporting the clips free of accumulations. Keep the pivots in proper adjustment so that the clips swing freely on the pivots without binding the stirrups. Carefully center the briquets in the clips and apply the load continuously at the rate of 0.05 in. (1.27 mm)/min.

12.6 *Tests and Retests*—Test each group of three briquets for bond strength and report the average of the three briquets. If the result of any one of the three tests varies more than 15 % from the average, reject it and report the average of the other two tests. If the results from more than one test vary more than 15 % from the average, reject the series and retest.

12.7 *Precision and Bias*—Precision and bias have not been determined for the test method specified.

13. Inspection

13.1 Inspection of the bonding compound shall be agreed upon between the producer or purchaser and the supplier as part of the purchase agreement.

14. Rejection

14.1 Rejection of bonding compound that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the product has failed to conform to the requirements of this specification.

www.technobetar.ir

15. Certification

15.1 When specified in the purchase agreement, the producer or supplier shall furnish a report certifying that, at the time of shipment, the bonding compound is in compliance with the requirements of this specification.

16. Package and Package Marking

16.1 *Packaging*—The bonding compound shall be packed in standard commercial containers. The containers shall be so constructed as to ensure acceptance by common or other carriers for safe transportation at the lowest rate to the point of delivery, unless otherwise specified in the purchase order.

16.2 *Marking*—Shipping containers shall be marked with the name of the bonding compound, the quantity contained therein, the name, brand, or trade mark of the producer or supplier, the shelf life, the batch number, and the ASTM designation.

17. Keywords

17.1 bond; bonding compound; mortar; surface-applied bonding compound

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 932 – 05, that may impact the use of this specification. (Approved March 1, 2006)

(*1*) Added new paragraph 4.4.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 932 – 03, that may impact the use of this standard. (Approved May 1, 2005)

(*1*) Revised 12.6.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 933 – 09

Standard Specification for Welded Wire Lath[1]

This standard is issued under the fixed designation C 933; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers welded wire lath, flat or self-furring, with or without backing, designed for use as a base to receive portland cement-based interior plaster and exterior stucco.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

A 641/A 641M Specification for Zinc–Coated (Galvanized) Carbon Steel Wire

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

2.2 *Federal Specifications:*

UU-B-790 Building Paper, Vegetable Fiber: (Kraft, Waterproofed, Water Repellent and Fire Resistant)[3]

3. Terminology

3.1 Definitions of terms used in this standard shall be in accordance with Terminology C 11.

4. Materials and Manufacture

4.1 Welded wire lath shall be fabricated from not less than 0.0625 in. (1.588 mm), cold-drawn, galvanized steel wire, conforming to Specification A 641/A 641M.

4.1.1 The wire shall be zinc-coated (galvanized) in accordance with Specification A 641/A 641M.

4.1.2 The backing shall conform to Federal Specification UU-B-790. The backing shall be either absorptive or water resistant. The backing shall have a bursting strength of not less than that required to maintain integrity under normal hand- or machine-application pressures.

4.1.3 The backing shall be attached to the lath to prevent accidental removal during shipping, handling or installation. Attachment of the backing shall allow lapping of wire-to-wire and backing-to-backing of not less than one mesh at ends and edges and shall permit full embedment, in not less than ¼ in. (6 mm) of plaster, of not less than one-half of the total length and width of the wire.

4.1.4 The thickness of the embedment of the lath and plaster shall be measured from the back plane of the back wire, exclusive of furring, to the backing or surface of the substrate.

5. Dimensions and Permissible Variations

5.1 *Openings and Stiffening*:

5.1.1 Lath shall be welded at all intersections of wire to form openings not more than 2 in. (51 mm) by 2 in. (51 mm).

5.1.2 Heavy-duty lath shall be stiffened continuously and parallel to the long dimension of the lath at intervals of not more than 6 in. (152 mm). Wire stiffeners used for this purpose shall range from 15-gauge (0.072 in.) to 11-gauge (0.1205 in.). The weight per square yard shall range from 1.14 to 1.95 lb/yd^2 (0.618 to 1.058 kg/m^2) for the heavy-duty lath.

5.1.3 Self-furring crimps on self-furring lath shall project not less than ¼ in. (6.4 mm) from the plane of the back of the lath.

5.2 *Thickness*—The nominal thickness shall be ⅛ in. (3.2 mm), exclusive of self-furring crimps, with a permissible variation of ±1/32 in. (0.8 mm).

5.3 *Width*—The nominal width shall be 28 in. (710 mm) to 54 in. (1370 mm), with a permissible variation of ±¾ in. (19 mm).

5.4 *Length*—The minimum length shall be 48 in. (1220 mm) for sheets or a maximum of 150 ft (45.720 m) for rolls with a permissible variation of ± ¾ in. (19 mm) for sheets or rolls.

5.5 *Weight*—The nominal weight, exclusive of backing, shall be from 1.14 to 1.95 lb/yd^2 (0.618 to 1.058 kg/m^2). Permissible variation in percentage over and under the nominal weights shall be in accordance with mill tolerances.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved July 15, 2009. Published August 2009. Originally approved in 1980. Last previous edition approved in 2007 as C 933 – 07b.

6. Sampling

6.1 When specified by the purchase agreement, samples of welded wire lath shall be taken at the place of manufacture or at the place of destination. If samples are taken at the destination, such samples shall be taken within 24 h of the receipt of the material.

6.2 At least 0.25 % of the number of sheets of welded wire lath in a shipment, but not less than three sheets, shall be so selected as to be representative of the shipment and shall constitute a sample for the purpose of tests by the purchaser or user.

7. Inspection

7.1 Inspection of the welded wire lath shall be agreed upon between the purchaser and the producer or supplier as part of the purchase agreement.

8. Rejection

8.1 Rejection of welded wire lath that fails to conform to the requirements of the specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the welded wire lath has failed to conform to the requirements of the specification.

9. Packaging and Package Marking

9.1 Welded wire lath shall be packaged in bundles or rolls.

9.2 Unless otherwise required by the purchase agreement, lath shall have legibly marked thereon the following: the product description; the name of the producer or seller; the brand name (if any); and the ASTM designation for the product.

9.2.1 Each bundle or roll of lath with no backing shall be marked with metal or paper tags securely attached to the bundles or rolls.

9.2.2 Each sheet of lath with backing shall be marked on the backing material.

10. Keywords

10.1 lath; metal plaster base; plaster; self-furring lath; stucco; wire lath

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 933 – 07b, that may impact the use of this specification. (Approved July 15, 2009)

(*1*) Revised 4.1.3 to change the embedment depth from ⅛ in. to ¼ in.

Designation: C 937 – 02

Standard Specification for Grout Fluidifier for Preplaced-Aggregate Concrete[1]

This standard is issued under the fixed designation C 937; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers fluidifier for grout used for preplaced-aggregate (PA) concrete.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information purposes only.

1.3 The following precautionary caveat pertains only to the test method portion, Section 8, of this standard: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 33 Specification for Concrete Aggregates[2]

C 150 Specification for Portland Cement[3]

C 618 Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete[2]

C 637 Specification for Aggregates for Radiation-Shielding Concrete[2]

C 938 Practice for Proportioning Grout Mixtures for Preplaced-Aggregate Concrete[2]

C 939 Test Method for Flow of Grout for Preplaced-Aggregate Concrete (Flow Cone Method)[2]

C 940 Test Method for Expansion and Bleeding of Freshly Mixed Grouts for Preplaced-Aggregate Concrete in the Laboratory[2]

C 941 Test Method for Water Retentivity of Grout Mixtures for Preplaced-Aggregate Concrete in the Laboratory[2]

C 942 Test Method for Compressive Strength of Grouts for Preplaced-Aggregate Concrete in the Laboratory[2]

C 943 Practice for Making Test Cylinders and Prisms for Determining Strength and Density of Preplaced-Aggregate Concrete in the Laboratory[2]

C 953 Test Method for Time of Setting of Grouts for Preplaced-Aggregate Concrete in the Laboratory[2]

TABLE 1 Expansion Limits

Alkali Content of Cement, % Expressed as Na_2O	Expansion Limits, %
0.80 or more	7 to 14
0.40 to 0.79	5 to 12
0.39 or less	3 to 9

3. Ordering Information

3.1 The purchaser shall specify the material desired as "grout fluidifier for preplaced-aggregate concrete." The material shall meet the requirements of this specification.

4. Materials

4.1 Grout ingredients shall conform to the following requirements:

4.1.1 Portland cement shall meet the requirements of Specification C 150 for the type to be used.

4.1.2 Pozzolan shall meet the requirements of Specification C 618.

4.1.3 Fine aggregate shall meet the requirements of Specification C 33 except that grading shall conform to Specification C 637, Table number 2, Grading 1 for Fine Aggregate.

5. Physical Requirements

5.1 The fluidifier, when tested in grout as specified herein, shall conform to the following requirements:

Reduction in mixing water, min, % of control (Test Method C 941)	3
Expansion, 3 h after mixing, (Test Method C 940)	See Table 1
Bleeding, 3 h after mixing, (Test Method C 940), max, %	2
Increase in water retentivity (Test Method C 941), min, % of control	60
Initial setting time, min, h (Test Method C 953)	4
Final setting time, max, h (Test Method C 953)	24

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C9.41 on Concrete for Radiation Shielding.

Current edition approved Dec. 10, 2002. Published February 2003. Originally approved in 1980. Last previous edition approved in 1997 as C 937–97.

www.technobetar.ir

Compressive strength at 7 days and 28 days, (Test Method C 942), min, % of control	90

6. Composition

6.1 The fluidifier shall be composed of materials that will yield a product having the properties stipulated under Physical Requirements when tested in accordance with this specification.

7. Sampling

7.1 The test sample of fluidifier shall have a mass of at least 225 g (½ lb) and shall be representative of the material supplied. When feasible, the test sample shall be composited from grab samples taken from not fewer than four packages selected at random.

8. Test Method

8.1 *Summary of Method*—Physical properties of grout containing fluidifier are determined and compared with corresponding properties of grout made without fluidifier.

8.2 *Significance and Use*—The effects of adding fluidifier to a standard grout mixture are determined in order to evaluate its ability to reduce mixing water, prevent early stiffening, hold solid constituents in suspension, produce controlled expansion prior to initial setting, and maintain or increase compressive strength.

8.3 *Procedure*:

8.3.1 Have all grout materials including mixing water at 23.0 ± 2.0°C (73.5 ± 3.5°F) at the start of the test.

8.3.2 Maintain the laboratory and curing room at 23.0 ± 2.0°C (73.5 ± 3.5°F) at all times during testing.

8.3.3 *Grout Preparation*:

8.3.3.1 Proportion two grout mixtures, one a control mixture without and one a test mixture with the grout fluidifier under consideration, each containing equal parts, by weight, of cementitious material and fine aggregate, with sufficient water to produce a grout efflux time by Test Method C 939 of 21 ± 2 s. The cementitious material shall consist of two parts portland cement to one part of pozzolan, by weight.

8.3.3.2 The test mixture shall contain grout fluidifier equal to 1% of the combined weight of portland cement plus pozzolan; unless otherwise recommended by the manufacturer. The control mixture shall contain no fluidifier.

8.3.3.3 The volume of each batch shall be approximately 0.03 m^3(1 ft^3).

8.3.3.4 Mix grout in a mixer of the type shown in Fig. 1 of Practice C 938. Dampen the inside of the drum, start the mixer and charge ingredients within a period of 2 min in the following order: water, fluidifier (if used), pozzolan, cement, and fine aggregate. Mix for 3 to 3¼ min.

8.3.3.5 Determine time of efflux by Test Method C 939. If within acceptable range, proceed with tests to provide data required for the calculations.

8.4 *Calculations*—Calculate the following items:

8.4.1 Reduction in water requirement (R_w):

$$R_w = \frac{(W_c - W_t) \times 100}{W_c} \quad (1)$$

where:

R_w = reduction in water requirement, %,
W_c = mass of water required in grout mixture without fluidifier, and
W_t = mass of water required in grout mixture with fluidifier.

8.4.2 Increase in water retentivity (I_r):

$$I_r = \frac{(R_t - R_c) \times 100}{R_c} \quad (2)$$

where:

I_r = increase in water retentivity, %,
R_c = time required to extract 60 mL of water from the control sample without fluidifier, s, and
R_t = time required to extract 60 mL of water from the test sample with fluidifier.

8.5 *Report*—For each grout mixture, the following test data shall be reported:

8.5.1 Description and source of materials used,
8.5.2 Material proportions by mass,
8.5.3 Average time of grout efflux, s,
8.5.4 Expansion and bleeding, %,
8.5.5 Water retentivity, s,
8.5.6 Initial setting time, h,
8.5.7 Final setting time, h,
8.5.8 Compressive strength at 7 days, psi or MPa, and
8.5.9 Compressive strength at 28 days, psi or MPa.
8.5.10 The following computed values shall also be reported:
8.5.11 Reduction in water requirement, R_w %,
8.5.12 Increase in water retentivity, I_r %, and
8.5.13 Compressive strength at 7 days, expressed as percentage of control specimens, %.

9. Rejection

9.1 The fluidifier shall be rejected if it fails to meet any of the requirements of this specification.

10. Packaging and Marking

10.1 Grout fluidifier shall be packaged in moisture-resistant containers and stored in a dry covered area to prevent deterioration.

10.2 Containers shall be marked to provide at least the following information:

10.2.1 A statement to the effect that the contained material meets the requirements of this specification.
10.2.2 Weight of the contained material.
10.2.3 Basic instructions for use of the material.
10.2.4 Manufacturer's lot number and date of manufacture.

11. Keywords

11.1 efflux time; fluidifier; grout; pre-placed aggregate; water demand; water retentivity

Designation: C 938 – 02

Standard Practice for Proportioning Grout Mixtures for Preplaced-Aggregate Concrete[1]

This standard is issued under the fixed designation C 938; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This practice describes the laboratory procedure for selecting proportions for grout mixtures required in the production of preplaced-aggregate (PA) concrete.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens[2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)[3]

C 150 Specification for Portland Cement[3]

C 185 Test Method for Air Content of Hydraulic Cement Mortar[3]

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory[2]

C 618 Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete[2]

C 637 Specification for Aggregates for Radiation-Shielding Concrete[2]

C 937 Specification for Grout Fluidifier for Preplaced-Aggregate Concrete[2]

C 939 Test Method for Flow of Grout for Preplaced-Aggregate Concrete (Flow-Cone Method)[2]

C 940 Test Method for Expansion and Bleeding of Freshly Mixed Grouts for Preplaced-Aggregate Concrete in the Laboratory[2]

C 941 Test Method for Water Retentivity of Grout Mixtures for Preplaced-Aggregate Concrete in the Laboratory[2]

C 942 Test Method for Compressive Strength of Grouts for Preplaced-Aggregate Concrete in the Laboratory[2]

C 943 Practice for Making Test Cylinders and Prisms for Determining Strength and Density of Preplaced-Aggregate Concrete in the Laboratory[2]

3. Summary of Practice

3.1 Grouts at fluid consistency are prepared from one or more mixtures of cement, pozzolan, fine aggregate, grout fluidifier, with or without other chemical admixtures, and water, and tested to determine:

3.1.1 The properties of the grout, and

3.1.2 The properties of PA concrete made with the grout when the grout is intended for such use.

3.2 The procedure and equipment required for mixing this grout are prescribed in this practice.

4. Significance and Use

4.1 This practice provides a standard procedure for selecting proportions for mixtures of grout to be used at fluid consistency in the production of PA concrete meeting applicable criteria for strength, density, and other properties.

4.2 This practice is also useful for determining the composition of grout mixed at fluid consistency and meeting specified requirements for filling voids, cavities, and spaces in rock, foundations, and concrete structures.

5. Apparatus

5.1 *Mixer*, constructed as shown in Fig. 1. The three mixer blades shall be made of steel plate, 3-mm (⅛-in.) thick, with a 100 by 125-mm (4 by 5-in.) elliptical shape. Each blade shall have two 25 by 75-mm (1 by 3-in.) slots centered on the major axis, and shall be welded to the shaft at an angle of approximately 23° with the horizontal in such a way as to force grout

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.41 on Concrete for Radiation Shielding.

Current edition approved Dec. 10, 2002. Published February 2003. Originally approved in 1982. Last previous edition approved in 1997 as C 938–97.

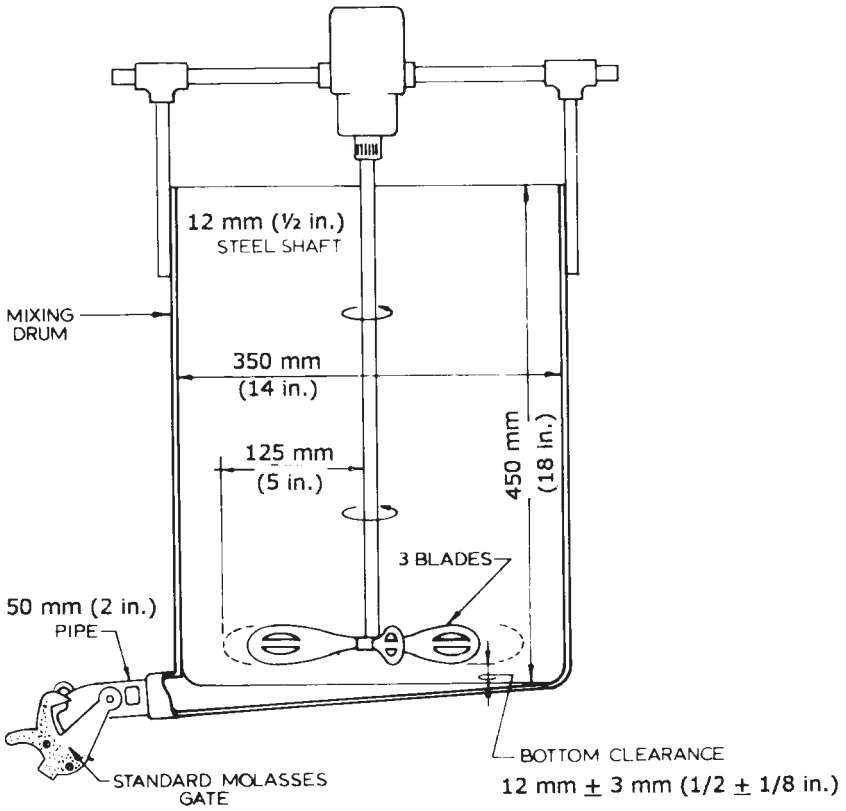

FIG. 1 Grout Mixer

to the bottom of the mixer during rotation. The mixer blades shall be powered to rotate at approximately 275 r/min under load.

5.2 *Scales or Balance*, accurate to within 0.3 % of the test mass at any point within range of use.

6. Materials

6.1 Materials for test purposes, except mixing water, shall meet the following requirements unless otherwise specified in project documents:

6.1.1 Portland cement, Specification C 150, nonair-entraining,

6.1.2 Pozzolan, if used, Specification C 618,

6.1.3 Fluidifier, Specification C 937, and

6.1.4 Fine aggregate, Specification C 637, Table number 2, Grading 1 for specific gravity under 3.0 and Grading 2 for specific activity 3.0 or heavier.

6.2 Where grout is being proportioned for use on a specific project, materials for test purposes shall be from and representative of the same source or type and description as will be used or is being considered for use on the project.

6.3 *Mixing water*, if clean and potable, is acceptable for normal test purposes.

7. Sampling

7.1 Samples of mixed grout for testing shall be representative of the batch from which they are drawn.

7.2 Agitation of the batch shall be continuous until all samples required from that batch have been drawn.

7.3 Grout in the mixer shall not be retempered by the addition of water. If mixing water is added in increments to adjust fluidity, a new batch shall be prepared for testing.

7.4 Samples shall be drawn for testing in the following order: (*1*) consistency, (*2*) expansion and bleeding, and (*3*), other requirements.

8. Conditioning

8.1 Maintain laboratory at and bring all grout materials to 23.0 ± 2.0°C (73.5 ± 3.5°F) unless otherwise specified.

9. Procedure

9.1 Prebatch grout ingredients by mass to provide a batch volume after mixing of approximately 0.03 m^3 (1 ft^3).

9.2 The first trial mixture, unless otherwise specified, shall contain equal parts, by mass, of cementitious material and fine aggregate, fluidifier in amount 1 % mass of cementitious material, unless otherwise recommended by manufacturer, and sufficient water to produce a flow of 21 ± 2 s. The cementitious material shall consist of two parts of portland cement to one part of pozzolan by mass.

9.3 In subsequent trial mixtures, the proportions of materials shall be varied as needed to satisfy design criteria. Adjusted mixtures may contain a cementitious ratio of portland cement to pozzolan other than as stipulated for the first trial mixture.

9.4 Dampen the inside of the mixer drum, turn the mixer on and charge the ingredients within 2 min in the following order: (*1*) water, (*2*) fluidifier, (*3*) pozzolan (if used), (*4*) portland

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:41:01 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

cement, and (5) fine aggregate. After all materials have been added, mix for 3 to 3¼ min.

9.5 Determine the following fluid grout properties in the order shown of each trial mixture:

Property	Test Method
Flow (time of efflux)	C 939
Expansion and bleeding	C 940
Water retentivity	C 941, if required
Unit mass	see 9.5.1
Other	as required

9.5.1 Determine the unit mass of the fluid grout using the measure described in the Apparatus section under "Measure" in Test Method C 185. Pour the grout into a container, tap the side lightly five times with a tapping stick as described in Test Method C 185, strike off, then measure mass.

9.6 Determine the following hardened grout and PA concrete properties:

Property	Test Method
Compressive strength of grout	C 942
Compressive strength of PA concrete	C 943, if required
Unit mass of grout	see 9.6.1
Unit mass of PA concrete	see 9.6.1, if required

9.6.1 To determine the unit mass of grout or PA concrete, measure mass of the specimen to an accuracy of at least one part in 250. Divide the masses by volumes determined as follows:

9.6.1.1 *Cubes*—Take two measurements of each dimension to nearest 0.25 mm (0.01 in.). Compute the volume from average measurements.

9.6.1.2 *PA Cylinders*—Take measurements of two diameters at right angles at approximate mid-height. Measure the length of the cylinder at opposite ends of a diameter. Make all measurements to nearest 0.25 mm (0.01 in.). Compute the volume from average measurements.

10. Report

10.1 For each mixture, including the final mixture, the following shall be reported:

10.1.1 A description of all materials used including type and alkali content of portland cement, type of pozzolan, source and name of fluidifier, and sieve analysis and specific gravity of fine and coarse aggregate.

10.2 For each trial mixture the following fluid grout properties shall be reported: (*1*) time of efflux, (*2*) expansion and free water, (*3*) water retentivity (if required), (*4*) and other specified data.

10.3 For final mixture(s) selected, the report shall include compressive strength of grout at ages of 7, 28, and 90 days, and unit mass unless otherwise required.

10.4 For PA concrete cylinders, the report shall include compressive strengths at ages of 7, 28, and 90 days, and unit mass unless otherwise required.

11. Keywords

11.1 concrete; grouts; pre-placed aggregate

Designation: C 939 – 02

Standard Test Method for Flow of Grout for Preplaced-Aggregate Concrete (Flow Cone Method)[1]

This standard is issued under the fixed designation C 939; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers a procedure, used both in the laboratory and in the field, for determining the time of efflux of a specified volume of fluid hydraulic cement grout through a standardized flow cone and used for preplaced-aggregate (PA) concrete; however, the test method may also be used for other fluid grouts.

1.2 It is for use with neat grout and with grouts containing fine aggregate all passing a 2.36-mm (No. 8) sieve.

1.3 This test method is intended for use with grout having an efflux time of 35 s or less.

1.4 When efflux time exceeds 35 s, flowability is better determined by flow table, found in Test Method C 109/C 109M, using 5 drops in 3 s.

1.5 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)[2]

C 938 Practice for Proportioning Grout Mixtures for Preplaced-Aggregate Concrete[3]

3. Summary of Test Method

3.1 The time of efflux of a specified volume of grout from a standardized flow cone is measured.

4. Significance and Use

4.1 This test method is applicable to the determination of the fluidity of various fluid grout mixtures.

5. Interferences

5.1 The presence of solid particles retained on the 2.36-mm (No. 8) sieve or lumps of unmixed material in the grout may cause the grout to flow unevenly through the discharge tube of the flow cone or stop the flow completely. Uneven flow will result in slower transit of the grout, thereby indicating a false consistency.

6. Apparatus

6.1 *Flow Cone*, with dimensions as shown in Fig. 1. The discharge tube shall be stainless steel. The body can be stainless steel, cast aluminum, or other essentially noncorroding metal.

NOTE 1—Cones with high-density polyethylene bodies are acceptable for field use in situations where precision as described in this test method is not required.

6.2 *Receiving Container*, capacity 2000 mL, minimum.

6.3 *Ring Stand* or other device, capable of supporting the flow cone in a vertical, steady position over the receiving container.

6.4 *Level*, carpenter's or similar.

6.5 *Stop Watch*, least reading of not more than 0.2 s.

6.6 *Grout Mixer*, conforming to Practice C 938.

7. Test Sample

7.1 The grout test sample shall be in excess of 1725 mL and shall be representative of the grout in the mixer.

7.2 When sampling and testing is being done for the purpose of proportioning or comparing mixes or for qualifying materials, the temperature of the dry materials and mixing

[1] This test method is under the jurisdiction of ASTM Committe C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.41 on Concrete for Radiation Shielding.

Current edition approved Dec. 10, 2002. Published February 2003.Originally approved in 1981. Last previous edition approved in 1997 as C 939–97.

NOTE 1—Other means of indicating grout level may be used as long as accurate indication of grout level on volume is obtained.

FIG. 1 Cross Section of Flow Cone

water shall be such that the temperature of the freshly mixed grout is 23.0 ± 2.0°C (73.5 ± 3.5°F), unless otherwise specified.

8. Calibration of Apparatus

8.1 Mount the flow cone firmly in such a manner that it is free of vibration. Level the top to assure verticality. Close the outlet of the discharge tube with a finger or a stopper. Introduce 1725 ± 5 mL of water into the cone. Adjust the point gage to indicate the level of the water surface. Then allow the water to drain.

8.2 Before first use of the flow cone with grout and periodically thereafter, check the accuracy of the cone by filling it with water as described in 8.1. After checking or adjusting the point gage, start the stop watch and simultaneously remove the finger. Stop the watch at the first break in the continuous flow of water. The time indicated by the stop watch is the time of efflux of water. If this time is 8.0 ± 0.2 s, the cone may be used for determining the time of efflux of grout.

9. Procedure

9.1 Moisten the inside of the flow cone by filling the cone with water and, 1 min before introducing the grout sample, allow the water to drain from the cone. Close the outlet of the discharge tube with a finger or a stopper. Introduce the grout into the cone until the grout surface rises to contact the point gage, start the stop watch, and simultaneously remove the finger or stopper. Stop the watch at the first break in the continuous flow of grout from the discharge tube, then look into the top of the cone; if the grout has passed sufficiently, such that light is visible through the discharge tube, the time indicated by the stop watch is the time of efflux of the grout. If light is not visible through the discharge tube, then the use of the flow cone is not applicable for grout of this consistency. At least two tests having times of efflux within 1.8 s of their average shall be made for each grout mixture.

9.2 The test for time of efflux shall be made within 1 min of drawing of the grout from the mixer or transmission line. When grout is being placed over a significant period of time, the time of efflux may be determined at selected intervals to demonstrate that the consistency is suitable for the work.

10. Report

10.1 Report the following information:

10.1.1 Identification of sample,

10.1.2 Identification of materials in the sample, the proportions, and whether laboratory-prepared or taken from the field production mix,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:41:03 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.1.3 Average time of efflux to nearest 0.2 s and time interval from completion of mixing at which the test was made, and

10.1.4 Temperature, ambient and of the sample at the time of test.

11. Precision and Bias

11.1 *Precision*—The following within-laboratory, multiple-operator precision applies. The single laboratory standard deviation has been found to be 0.88 s. Therefore, results from two properly conducted tests on the same material should not differ by more than 2.49 s.

11.2 *Bias*—No statement on bias can be prepared because there are no standard reference materials.

12. Keywords

12.1 flow cone; grout; preplaced—aggregate concrete; time of efflux

Designation: C 940 – 98a (Reapproved 2003)

Standard Test Method for Expansion and Bleeding of Freshly Mixed Grouts for Preplaced-Aggregate Concrete in the Laboratory[1]

This standard is issued under the fixed designation C 940; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method determines the amount of expansion and accumulation of bleed water at the surface of freshly mixed hydraulic-cement grout used in the production of preplaced-aggregate (PA) concrete.

1.2 It is for use with cement grout whether or not it includes fine aggregate or mineral admixtures or both.

1.3 The values stated in SI units are to be regarded as standard.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 937 Specification for Grout Fluidifier for Preplaced-Aggregate Concrete

3. Terminology

3.1 *Definition of Terms*—Terms used in this test method are defined in Terminology C 125 or in this section.

3.1.1 *bleeding*—This term is defined as stated in Terminology C 125, with the exception that it pertains to grout in this test method.

3.1.2 *expansion*—increase in the volume of a grout, expressed as a percentage of the original volume of the grout.

4. Summary of Test Method

4.1 Grout is placed in a graduated cylinder. Changes in total volume and accumulation of bleed water, if any, on the surface of the grout are observed over a period of time.

5. Significance and Use

5.1 This method is useful for determining the expansion and bleeding characteristics of freshly mixed fluid grout used in PA concrete.

6. Interferences

6.1 Failure to obtain a uniformly smooth mixture, free of lumps, will cause excessive bleeding and may result in reduced expansion.

6.2 The capability of most admixtures to produce expansion and the tendency to bleed is related to the temperature of the grout during the period of test.

7. Apparatus

7.1 *Glass Graduate*, 1000 mL, reading to 10 mL.

7.2 *Glass Graduate*, 25 mL, reading to 1 mL.

7.3 *Thermometer*, accurate to 0.5°C (1°F) for measuring grout and air temperature.

8. Test Sample

8.1 The grout test sample shall consist of approximately 1500 mL and shall be representative of the grout in the mixer.

9. Procedure

9.1 When sampling and testing are being performed in the laboratory for the purpose of designing or comparing mixtures or for qualifying admixtures including grout fluidifiers proceed in the following manner:

9.1.1 Maintain the ambient temperature of the room in which the test is performed at 23.0 ± 2°C (73.4 ± 3°F), unless otherwise specified.

9.1.2 Bring the temperature of all dry materials and mixing water to a constant temperature of 23.0 ± 2°C (73.4 ± 3°F) before mixing, unless otherwise specified.

---

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.41 on Concrete for Radiation Shielding.

Current edition approved May 10, 1998. Published December 1998. Originally approved in 1981. Last previous edition approved in 1998 as C 940 – 98a.

www.technobetar.ir

9.1.3 Start volume measurements within 3 min of completion of mixing.

9.2 When sampling and testing are being performed in the field, record the temperature of the grout sample and the ambient temperature of the area in which the test readings are made. Record the time interval between completion of mixing and start of test.

9.3 Immediately after the completion of mixing, measure the temperature of the grout. Then introduce the grout into a 1000-mL graduated cylinder until the volume of the sample is 800 ± 10 mL. Record the volume of the sample and the time at which the reading was made. Place the graduated cylinder on a level surface free of vibration. Cover to prevent evaporation of the bleed water.

9.4 Take and record the readings, estimated to the nearest 1 mL, of the upper surfaces of the grout and bleed water, if any, of the sample in the graduate at 15-min intervals for the first 60 min and thereafter at hourly intervals until two successive readings show no further expansion or bleeding. When the test for expansion and bleeding is used in connection with Specification C 937, it shall be discontinued 3 h after the initial reading.

9.5 At the conclusion of the test, decant the bleed water into a 25-mL graduate by tilting the specimen and drawing the water off with a pipet or large medicine dropper. Record the final volume of bleed water to the nearest 0.5 mL.

10. Calculation

10.1 Calculate the expansion of the grout, and its bleeding and the combined expansion of grout plus bleed water as percentages of the initial volume of the grout, as follows:

$$\text{Expansion, \%} = \frac{V_g - V_1}{V_1} \times 100$$

$$\text{Bleeding, \%} = \frac{V_2 - V_g}{V_1} \times 100 \text{ at prescribed intervals}$$

$$\text{Combined Expansion, \%} = \frac{V_2 - V_1}{V_1} \times 100$$

$$\text{Final bleeding, \%} = \frac{V_w}{V_1} \times 100$$

where:

V_1 = volume of sample at beginning of test, mL,
V_2 = volume of sample at prescribed intervals, measured at upper surface of water layer, mL,
V_g = volume of grout portion of sample at prescribed intervals, at upper surface of grout, mL, and
V_w = volume of decanted bleed water, mL.

11. Report

11.1 The report shall include the following:

11.1.1 Identification of the grout sample.

11.1.2 Expansion of grout to the nearest 0.2 % for each prescribed interval.

11.1.3 Bleeding of grout to the nearest 0.2 % for each prescribed interval.

11.1.4 Combined expansion of grout plus bleed water to the nearest 0.2 % for each prescribed interval.

11.1.5 Final bleeding to nearest 0.2 %.

11.1.6 Temperature of grout sample at start of test.

11.1.7 Ambient temperature of laboratory or testing area at the beginning and end of test.

12. Precision and Bias

12.1 *Precision*:

12.1.1 *Bleeding*—The single laboratory, three operators, standard deviation has been found to be 0.06 %. Therefore, results from two properly conducted tests (by the same operator) on the same material should not differ by more than 0.17 %.

12.1.2 *Combined Expansion*—The single laboratory, three operators, standard deviation has been found to be 0.37 %. Therefore, results from two properly conducted tests (by the same operator) on the same material should not differ by more than 1.04 %.

12.2 *Bias*—No statements on bias can be prepared because there are no standard reference materials.

13. Keywords

13.1 bleeding; concrete; expansion; grouts; preplaced-aggregate; preplaced-aggregate concrete

Designation: C 941 – 02

Standard Test Method for Water Retentivity of Grout Mixtures for Preplaced-Aggregate Concrete in the Laboratory[1]

This standard is issued under the fixed designation C 941; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the procedure for determining the water retentivity of freshly mixed hydraulic cement grout mixtures for preplaced-aggregate (PA) concrete.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

E 832 Specification for Laboratory Filter Papers[2]

3. Summary of Test Method

3.1 The time required for the extraction of a standard amount of water by vacuum from a grout sample is measured.

4. Significance and Use

4.1 This test method measures the ability of a grout mixture to retain its mixing water.

4.2 It is used for qualifying grout fluidifiers to be used in the production of PA concrete.

4.3 It may be used to compare the effects of various admixtures or materials combinations on the water retentivity properties of any cement-water grout.

5. Apparatus

5.1 *Extraction Apparatus*, assembled as in Fig. 1, including the following:

5.1.1 *Funnel*, porcelain Büchner filtering, 111 mm inside diameter at the perforated plate and 500 mL in volume.

5.1.2 *Filter Paper*, Specification E 832, Type 2, Class G, disk, 11-cm diameter filter paper.

5.1.3 *Graduated Cylinder*, 250 mL cut down to about 130 mL.

5.1.4 *Vacuum Gage* or manometer graduated in increments of 1 kPa to 100 kPa (30-in. Hg) vacuum.

5.1.5 *Vacuum Pump* or other source of reduced pressure, capable of maintaining a minimum vacuum of 95 kPa (28 in. Hg) on a system having a volume of not less than 1 L.

5.2 *Stop Watch*, having a least reading of not more than 0.2 s.

5.3 *Thermometer*, accurate to 0.5°C (1.0°F), for measuring ambient and grout temperatures.

6. Sampling

6.1 The test sample shall consist of at least 500 mL of freshly mixed grout representative of grout in the mixer. The temperature of the laboratory sample of grout shall be 23.0 ± 2.0°C (73.5 ± 3.5°F).

7. Procedure

7.1 Dampen a single filter paper disk and place it on the perforated plate of the filtering funnel (see Fig. 1). Keep the top of the filtering funnel level. Apply to and maintain a minimum vacuum in the system below the stopcock of 95 kPa (28 in. Hg) for the duration of the test. Introduce grout into the funnel until it is filled flush with the top. Open the stopcock between the filtering funnel and the graduated cylinder and at the same time start the stop watch. Perform these operations not more than 1 min after taking the grout sample from the mixer.

7.2 When 60 mL of water have been removed from the sample, stop the stop watch.

7.3 When using this method for acceptance testing of a grout fluidifier, take the test sample within 1 min after completion of 3 to 3¼ min mixing.

8. Report

8.1 Report the following information:

8.1.1 Identification of the grout sample,

8.1.2 Required time to extract 60 mL of water from the sample, to the nearest 1 s,

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.41on Concrete for Radiation Shielding.

Current edition approved Dec. 10, 2002. Published February 2003. Originally approved in 1981. Last previous edition approved in 1996 as C 941–96.

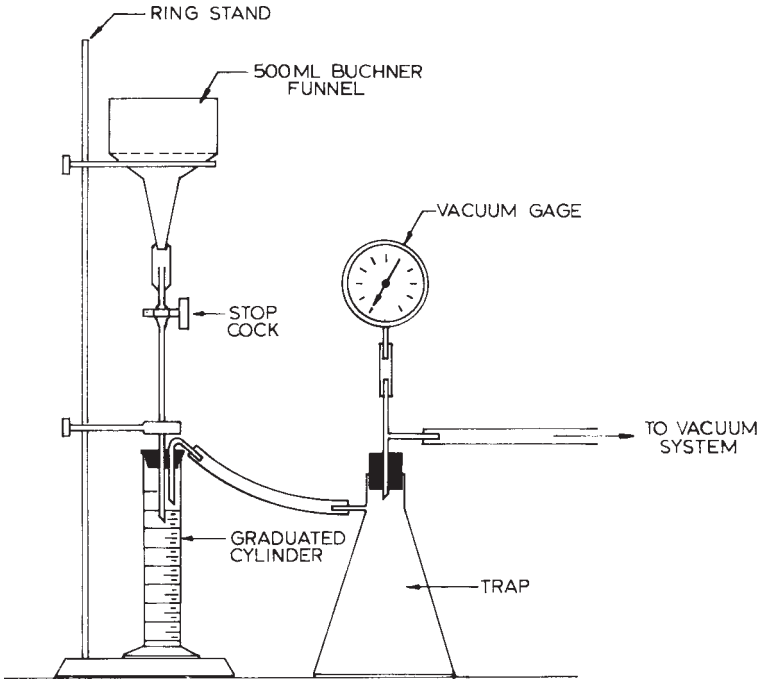

FIG. 1 Extraction Apparatus

8.1.3 Temperature of the grout sample at the beginning of the test, and

8.1.4 Ambient temperature during the test.

9. Precision and Bias

9.1 *Precision*—The single laboratory, three operators standard deviation has been found to be 11 s. Therefore, results from two properly conducted tets (by the same operator) on the same material should not differ by more than 31 s.

9.2 *Bias*—No statement on bias can be prepared because there are no standard reference materials.

10. Keywords

10.1 grout fluidifier; preplaced-aggregate concrete; water retentivity

Designation: C 942 – 99 (Reapproved 2004)

Standard Test Method for Compressive Strength of Grouts for Preplaced-Aggregate Concrete in the Laboratory[1]

This standard is issued under the fixed designation C 942; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the determination of the compressive strength of hydraulic cement grout for preplaced-aggregate (PA) concrete.

1.2 The values stated in SI units are to be regarded as standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 937 Specification for Grout Fluidifier for Preplaced-Aggregate Concrete

C 938 Practice for Proportioning Grout Mixtures for Preplaced-Aggregate Concrete

C 939 Test Method for Flow of Grout for Preplaced-Aggregate Concrete (Flow Cone Method)

3. Summary of Test Method

3.1 Compressive strength of hardened grout is determined using top-restrained cubes as defined in Test Method C 109/C 109M.

4. Significance and Use

4.1 This test method affords a means for determining the compressive strength of grouts that expand and, in use, harden under conditions of partial to total restraint.

4.2 It is particularly applicable for determining the effect on compressive strength of grout fluidifier to be used with grout for PA concrete (See Specification C 937).

5. Apparatus

5.1 *Scales, masses, sieves, glass graduates, and three-gang molds*, for 2-in. (or 50-mm) cube specimens, baseplates, trowel, and testing machine as specified in Test Method C 109/C 109M.

5.2 *Plates*, to cover specimen molds, capable of supporting the weight or being held down by C-clamps, as described in 9.3.

5.3 *Mass of 7 kg (or 15 lb) or C-clamps*, for holding down the cover plates.

6. Temperature and Humidity

6.1 Temperature and humidity conditions for tests performed in the laboratory shall be in accordance with Test Method C 109/C 109M unless otherwise specified.

6.2 Temperature and humidity conditions for tests performed in the field shall be as prescribed for curing cylinders in Practice C 31/C 31M.

7. Sampling

7.1 The test sample shall consist of approximately 1500 mL of grout and shall be representative of the material in the mixer.

7.2 Grout proportioned at the mixer from hydraulic cement(s) with or without other materials shall be mixed in accordance with Specification C 937.

7.3 Packaged grouts requiring only the addition of water or other fluid shall be mixed in accordance with the manufacturer's printed recommendations.

www.technobetar.ir

8. Preparation of Specimen Molds

8.1 Prepare the molds as specified in Test Method C 109/C 109M.

9. Procedure

9.1 Determine the consistency of grout as follows:

9.1.1 Use the flow cone, Test Method C 939, for grout to be used for PA concrete or whenever the consistency is less than 35 s.

9.1.2 For grouts at consistencies thicker than above, determine the consistency on the flow table, Test Method C 109/C 109M, using 5 drops of the table in 3 s. When placing grout in the mold, puddle each layer five times with the gloved finger.

9.2 Measure the temperature of the grout.

9.3 Mold sets of cube specimens for testing in compression.

9.3.1 A three-gang cube mold shall constitute one test set. Provide at least one test set for each age at which the strength is to be determined, but not less than two sets.

9.3.2 Fill each mold in the set halfway. Puddle each with a gloved finger five times to release entrapped air. Fill the mold and puddle again. Bring the excess grout to the center and finish the surface by cutting off the excess with the straight edge of a trowel held vertically and drawn across the top of the mold with a sawing motion.

9.3.3 Place the cover plate over the mold (three-gang), taking care that the grout or loose grains of sand do not prevent seating of the plate.

9.3.4 Place a mass of 7 kg (or 15 lb) on each cover plate or fix the cover plates to the molds with C-clamps, finger tightened.

10. Storage and Curing

10.1 Immediately upon completion of molding:

10.1.1 Place laboratory specimens in the moist room and cure in accordance with the applicable portions of Test Method C 109/C 109M.

10.1.2 Store field specimens and cure in accordance with Curing Cylinders of Practice C 31/ 31M.

10.2 *Stripping*—With grouts that expand prior to hardening, do not strip molds before age 24 h or final set, whichever occurs later.

10.2.1 Do not strip molds from grouts containing expansive-cement systems before age 3 days.

11. Determination of Compressive Strength

11.1 Determine the compressive strength at ages 7 and 28 days, unless otherwise specified, in accordance with Test Method C 109/C 109M.

12. Report

12.1 The report shall include the following:

12.1.1 Identification, date of mixing, and whether laboratory or field tested.

12.1.1.1 If field tested, include description of curing procedure and temperature.

12.1.2 Average compressive strength for each set of grout specimens to nearest 0.1 MPa (or 10 psi) at 7 and 28 days of age, unless otherwise specified.

13. Precision and Bias

13.1 *Precision*—The single-operator coefficient of variation has been found to be 1.6 %. Therefore, results of two properly conducted tests by the same operator on the same sample using proper equipment should not differ from each other by more than 4.5 % of their average.[3]

13.2 *Bias*—No statement on bias has been made since there are no standard reference materials.

[3] The precision data are based on testing results available from ASTM. Request RR: C08-1014.

Designation: C 943 – 02

Standard Practice for Making Test Cylinders and Prisms for Determining Strength and Density of Preplaced-Aggregate Concrete in the Laboratory[1]

This standard is issued under the fixed designation C 943; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers procedures for making standard test cylinders used to determine the compressive strength and density of preplaced-aggregate (PA) concrete.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory[2]

C 637 Specification for Aggregates for Radiation-Shielding Concrete[2]

C 937 Specification for Grout Fluidifier for Preplaced-Aggregate Concrete[2]

C 938 Practice for Proportioning Grout Mixtures for Preplaced-Aggregate Concrete[2]

C 939 Test Method for Flow of Grout for Preplaced-Aggregate Concrete (Flow Cone Method)[2]

C 940 Test Method for Expansion and Bleeding of Freshly Mixed Grouts for Preplaced-Aggregate Concrete in the Laboratory[2]

3. Summary of Practice

3.1 Coarse aggregate is placed in a standard cylinder mold having end plates to which pipe fittings have been attached. Grout is pumped into the mold until full. The test cylinder, demolded after hardening, may be cured and used for determination of strength or cut into prisms for the determination of unit weight.

4. Significance and Use

4.1 This practice is used for making test cylinders or prisms of PA concrete. Cylinders are used for determining compressive strength and approximate density. Prisms, cut from cylinders, eliminate the surface effect and thus more accurately represent the actual density of PA concrete in place.

5. Apparatus

5.1 *Cylinder Molds* (Fig. 1), cast iron or steel, for making 150 by 300-mm (6 by 12-in.) cylinders. Base and top plates shall be arranged for tight assembly to the cylinder. All mating and inside surfaces shall be machined smooth such that the assembled mold will be essentially watertight. End plates shall be drilled and tapped at their centers for standard 19 mm (¾-in.) pipe nipples. The top end plate shall also be perforated, as shown in Fig. 2.

5.2 *Venting Fabric*, white cotton cloth, free of oil and grease.

5.3 *Grouting Apparatus* (Fig. 3), capable of delivering grout at a uniform rate of 1.4 to 2.8 L (0.05 to 0.10 ft^3)/min at pressures up to 345 kPa (50 psi).

5.4 *Mallet*, with rubber or rawhide head weighing approximately ¼ kg (½ lb).

5.5 *Platform Scales*, accurate to within 0.3 % of the test load at any point within the range of use.

5.6 *Stop Watch*, least reading not more than 0.2 s.

5.7 *Flow Cone*—See Test Method C 939.

5.8 *Thermometer*, accurate to 0.5°C (1°F), for measuring ambient and grout temperatures.

6. Materials

6.1 *Coarse Aggregate*—Except when tests are made for specific projects, coarse aggregate shall conform to the requirements of Specification C 637, Table number 2, Coarse Aggregate, Grading 1, unless Grading 2 is specified.

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.41 on Concrete for Radiation Shielding.

Current edition approved Dec. 10, 2002. Published February 2003. Originally approved in 1980. Last previous edition approved in 1996 as C 943–96.

www.technobetar.ir

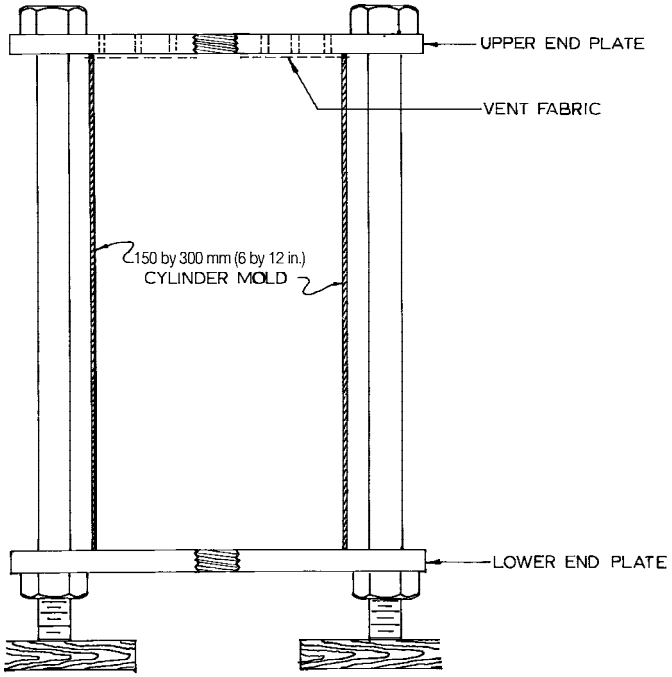

FIG. 1 Cylinder Mold Assembly Cross Section

6.2 *Grout*—Except when tests are made for specific projects, grout ingredients, proportioning, and mixing shall be in accordance with Practice C 938.

6.3 *Tests for Specific Projects*—When tests are to be made for specific projects, materials shall be representative of those in use or proposed for use in the work.

6.3.1 If not taken from project-mixed grout being used in the work, grout materials shall be mixed in the laboratory using the procedure described in Specification C 937.

7. Sampling

7.1 Coarse aggregate shall be representative of material used or to be used in the work or of that tested and stockpiled for test work.

7.2 Grout to be used in making PA concrete cylinders shall be typical of the batch from which it is drawn.

8. Preparation and Measurement of Prisms

8.1 When the determination of unit weight is required, prisms shall be cut from the central portions of the cylinders to dimensions as close as feasible to 101 by 101 by 254 mm (4 by 4 by 10 in.). Weigh the specimen to an accuracy of at least 1 part in 250. Compute the volume from the averages of two measurements of each dimension, taken to the nearest 0.25 mm (0.01 in.).

9. Procedure

9.1 *Temperature*:

9.1.1 When test cylinders are prepared in the laboratory, bring all materials to and maintain the laboratory in a temperature range of 23.0 ± 2.0°C (73.5 ± 3.5°F).

9.1.2 When test cylinders are prepared in the field, record ambient temperature in the vicinity of test operation.

9.2 Place each cylinder mold upright on its bottom plate on a firm, level surface.

9.3 Place the coarse aggregate in the mold in three approximately equal layers. Consolidate each layer by striking the mold ten times around its periphery with the mallet. When the mold has been filled, strike off the contents so that no aggregate particle projects above the plane of the top of the mold.

9.4 Place a single layer of venting fabric, in which a hole has been cut to match the 19-mm (¾-in.) hole in the top end plate, over the aggregate. Place the top plate on the mold, install bolts, and tighten. Attach the top and bottom valve assemblies and prepare to connect to hose from grout pump, as shown in Fig. 3.

9.5 Measure flow (Test Method C 939) and temperature of the representative sample of grout. Pour 800 ± 10 mL into a 1000-mL graduate for observation of expansion and bleeding, Test Method C 940.

9.6 If grout consistency is satisfactory, charge grout hopper and pump to waste until all water and diluted grout in the pump system has been expelled. Divert the grout flow to recirculation (to hopper) and make the connection to the bottom of the cylinder mold at valve *3*, shown in Fig. 3.

9.7 With valves *2*, *3*, and *4* open, fill the cylinder slowly by partially closing bypass valve *1*. When grout flows freely through upper plug valve *4*, open bypass and close valves *2* and *4*. Apply 70 to 100 kPa (10 to 15 psi) air pressure on the sample for 30 ± 5 s through air valve *5*; then close valve *3*. Move the grout supply line to succeeding cylinders in turn and repeat the above procedure for each.

9.7.1 The total elapsed time for intruding and pressurizing a cylinder mold shall be between 1½ and 3 min.

9.7.2 Grout, if continually agitated, may be used for intruding PA cylinders for as long as 30 min after original mixing provided no additional water is added and fluidity remains under 35 s, flow cone, Test Method C 939.

9.8 After grout expansion is complete, as determined by observation of the specimen set aside for the purpose, 9.5, remove the upper valve assembly and install a pipe plug in the center hole of the upper plate. Using care to avoid jarring the specimen, invert the cylinder, remove valve *3* assembly, and install a pipe plug in the center hole of the lower plate. Carefully turn the assembly back to its original position. Clean valves and fittings immediately upon removal from end plates.

10. Handling and Curing

10.1 Do not disturb the specimen after removal of valve assemblies for at least 24 h. Then strip molds and cure cylinders in accordance with the section on Curing of Practice C 192/C 192M.

10.2 Protect field-made specimens during initial storage period in the molds from direct sunlight or freezing temperatures. When large amounts of pozzolan are used in the grout mixture or in cool curing conditions, delay stripping of cylinders to avoid damaging the specimens.

11. Report

11.1 Report the following information:

11.1.1 Identification of specimens, date cast, and whether done in laboratory or field.

Designation: C 944 – 99 (Reapproved 2005)

Standard Test Method for Abrasion Resistance of Concrete or Mortar Surfaces by the Rotating-Cutter Method[1]

This standard is issued under the fixed designation C 944; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers a procedure for determining the resistance of either concrete or mortar to abrasion. This test method is similar to Procedure B of Test Method C 779/C 779M.

1.2 The values stated in SI units or inch–pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non–conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 42 Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 418 Test Method for Abrasion Resistance of Concrete by Sandblasting

C 779/C 779M Test Method for Abrasion Resistance of Horizontal Concrete Surfaces

3. Significance and Use

3.1 This test method gives an indication of the relative wear resistance of mortar and concrete based on testing of cored or fabricated specimens. This test method has been successfully used in the quality control of highway and bridge concrete subject to traffic. Primarily intended for use on the top ends of 152-mm [6-in.] diameter concrete cores, mortar specimens, or other samples of concrete of insufficient test area to permit the conduct of tests by Test Method C 418 or C 779/C 779M, this test method is also applicable on concrete surfaces in place by measuring the abrasion loss as described in Section 9, Procedure B, of Test Method C 779/C 779M.

4. Apparatus

4.1 *Abrasion Device*—A drill press or similar device with a chuck capable of holding and rotating the abrading cutter at a speed of 200 r/min and exerting a force of either a normal load of 98 ± 1 N [22 ± 0.2 lbf] or a double load of 197 ± 2 N [44 ± 0.4 lbf] on the test specimen surface. Fig. 1 shows a commercial drill press and Fig. 2 illustrates details of the rotating cutter. The difficulty in maintaining a constant load on the abrading cutter when using the lever, gear, and spring system of a drill press has been eliminated by placing the desired load directly upon the spindle that turns the cutter. The machine consists essentially of a frame that supports the drive motor, stepped pulley, and spindle. A clamping device to hold the specimen is built into the base.

4.2 *Rotating Cutter*—A rotating cutter similar to that shown in Fig. 2 and Fig. 3 shall be used in which 22 37.5 mm [1.5 in.] diameter dressing wheels and 24 25.4 to 31.75 mm [1 to 1.25 in.] diameter washers are mounted. The washers as received shall be stacked and locked on a bolt for the purpose of reducing their diameter to the specified range to avoid restricting abrasion of the concrete by the washers. Cutter assembly, including washers, shall be locked onto horizontal rods such that individual dressing wheels are free to turn independently. The overall diameter of the cutter or the diameter of the circular area abraded is 82.5 mm [3¼ in.]. Care shall be taken to achieve constant contact between the rotating cutter and the entire test surface of the sample. This can be better accomplished if the cutters have a swivel connection allowing some vertical movement. If the dressing wheels have one rounded edge, they shall be mounted with the rounded edge toward the vertical shaft. The individual grinding wheel dressers on the horizontal shaft of the cutter shall be repositioned whenever a

www.technobetar.ir

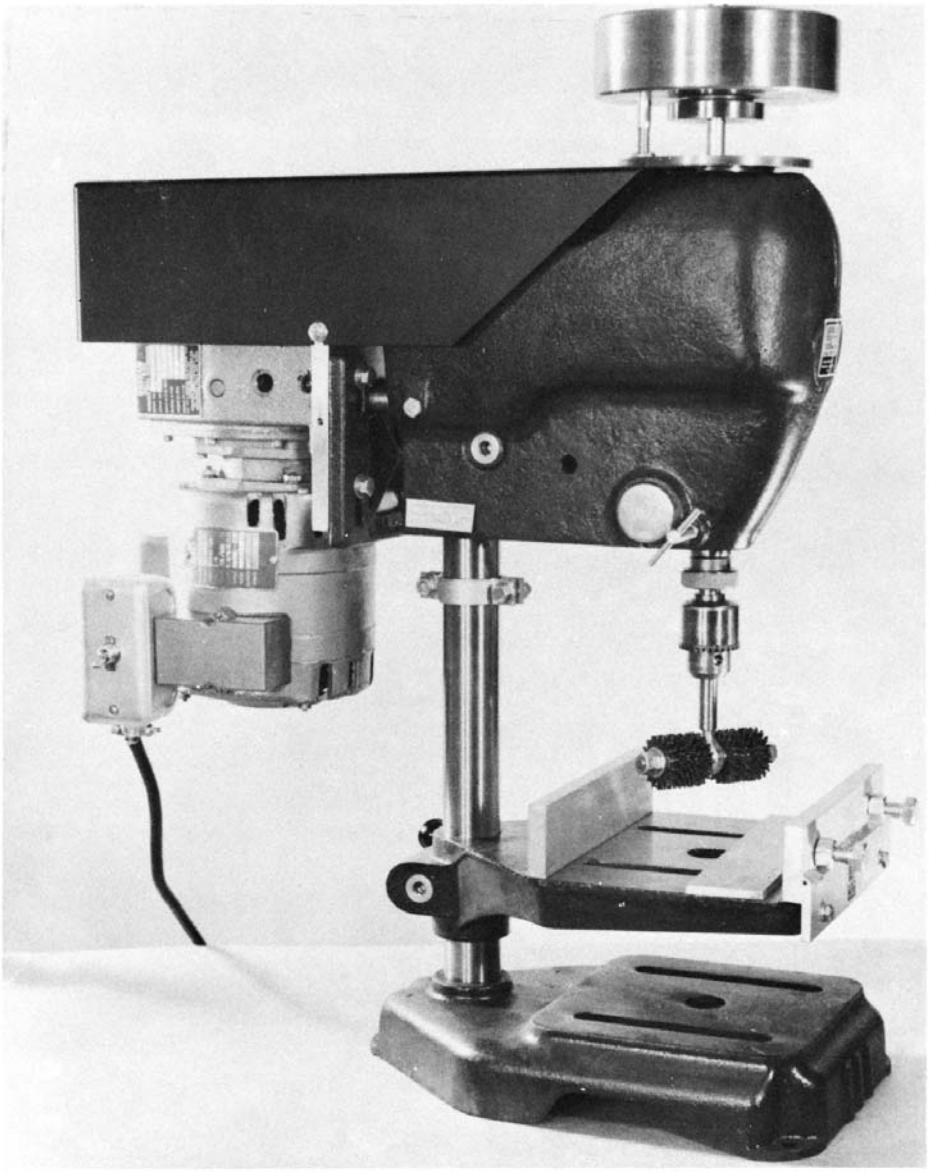

FIG. 1 Rotating-Cutter Drill Press

change in the diameter of the outer cutters becomes apparent. This is accomplished by reversing each set of dressing wheels to bring the smaller diameter cutters toward the vertical shaft.

4.2.1 In making a test, the rotating cutter is held in a raised position by means of the rod provided, the specimen clamped securely in position, and motor started. The rotating cutter is then lowered into contact with the specimen for a specified time, after which the cutter is raised.

4.2.2 A set of dressing wheels shall be replaced periodically, preferably after each 90 min of use. The washers may be ground or replaced to maintain the proper diameter.

4.3 *Balance*—A balance having a capacity of at least 4 kg, and accurate to at least 0.1 g.

4.4 *Leveling Plate*—The base plate upon which the specimen rests shall be capable of rotating in the horizontal plane so that the specimens when placed thereon can be positioned to secure maximum contact with the rotating cutter throughout the full test area.

5. Sampling

5.1 Cores shall be taken in accordance with Test Method C 42.

6. Specimens

6.1 The specimens used in this test shall be of any size and shape that can be accommodated by the abrasion device and the balance provided. The surface to be tested shall be either formed or finished and shall be positioned in the plane of contact of the cutter.

7. Procedure

7.1 Determine the mass of the specimen to the nearest 0.1 g.

7.2 Fasten the specimens securely in the abrasion device so that the surface to be tested is normal to the shaft.

7.3 Mount the rotating cutter device in the abrasion device.

7.4 Start the motor and lower the cutter slowly until just in contact with the surface of the specimen.

www.technobetar.ir

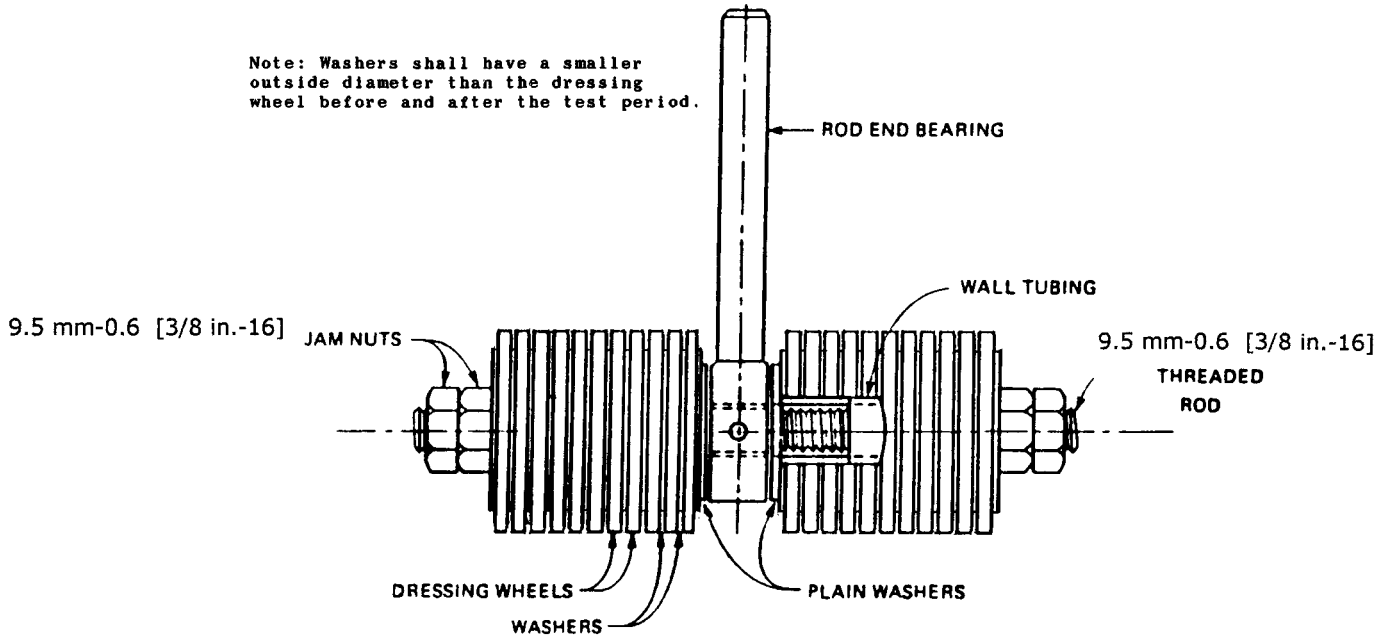

FIG. 2 Typical Rotating Cutters

7.5 Continue abrasion with a normal or a double load on the specimen for 2 min after contact between the cutter and the surface. At the end of each 2-min abrasion period, remove the test specimen from the device and clean surfaces to remove debris using a soft brush or blow the surface with air. Determine the specimen mass to the nearest 0.1 g. The minimum test schedule shall involve three 2-min periods conducted on three separate areas of representative surfaces of the concrete or mortar.

7.6 For concrete that is highly resistant to abrasion additional testing may be required. Doubling the applied load, or the time, or both, as shown in the following chart, should provide more comprehensive information on such concrete.

Abrasion Cycle		Load, N (lbf)	Test Frequency/Period
A	Normal	98 (22)	3 × 2 min
B	Double load	197 (44)	3 × 2 min

7.7 When testing surfaces in place, or when the depth of wear is to be determined due to significant differences in surface density, refer to Test Method C 779/C 779M Procedure B, to determine abraded depth using the apparatus in this test method.

8. Report

8.1 Report the following information on:

8.1.1 Description of surface,

8.1.2 Size of specimen,

8.1.3 Type of finish,

8.1.4 Concrete compaction, age, and strength,

8.1.5 Applied surface treatment,

8.1.6 Time of abrasion and load used (normal or double),

8.1.7 Average loss in grams or depth of wear in millimetres and,

8.1.8 Loss in mass and time abraded.

9. Precision and Bias

9.1 *Precision*—Criteria for judging the acceptability of abrasion resistance test results obtained by this test method are as follows:

9.1.1 *Normal Load Condition*—The single-operator coefficient of variation has been found to be 21 %. Therefore, the results of two properly conducted tests by the same operator on similar samples should not differ from each other by more than 59 % of the average.

9.1.2 *Double Load Condition*—The single-operator coefficient of variation has been found to be 12.6 %. Therefore, the results of two properly conducted tests by the same operator on similar samples should not differ from each other by more than 36 % of their average.

9.2 *Bias*—The procedure in this test method has no bias because the value of abrasion resistance of concrete surfaces can be only defined in terms of a test method.

10. Keywords

10.1 abrasion; concrete; impact; mortar; wear

Designation: C 953 – 06

Standard Test Method for Time of Setting of Grouts for Preplaced-Aggregate Concrete in the Laboratory[1]

This standard is issued under the fixed designation C 953; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This method covers the determination test of time of setting of hydraulic cement grout mixtures used in preplaced-aggregate (PA) concrete using the vicat apparatus.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 191 Test Methods for Time of Setting of Hydraulic Cement by Vicat Needle

C 938 Practice for Proportioning Grout Mixtures for Preplaced-Aggregate Concrete

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

3. Summary of Method

3.1 The time of setting, initial and final, of a sample of fluid grout is determined using the Vicat apparatus.

4. Significance and Use

4.1 This test method determines the setting time of grout mixed to the fluid consistency required for its use in PA concrete.

4.2 The time of setting is also useful in determining the acceptability of components of grout that must be mixed to the fluid consistency required for production of PA concrete.

5. Apparatus

5.1 *Vicat Apparatus*, in accordance with Test Method C 191.

5.2 *Moist Room*, maintained in accordance with Specification C 511.

6. Test Sample

6.1 The test sample shall consist of at least 300 mL of grout taken from a freshly-mixed batch prepared in accordance with Practice C 938 obtained from a mixer at the laboratory or construction site.

7. Procedure

7.1 Warm the Vicat conical ring and base plate to approximately 100 °C.

7.2 Apply a thin film of paraffin wax to the base of the conical ring and place the waxed conical ring on the base plate. Place a weight on the conical ring to ensure intimate contact with the base plate and allow the conical ring and plate to cool to room temperature.

7.3 Fill the conical ring apparatus with grout flush with its top within 2 min after completion of mixing. Strike off the grout flush with the top of the conical ring by a single oblique stroke of a sharp-edged trowel held at a slight angle to the top of the ring. Smooth the top, if necessary, with a few light touches of the pointed end of the trowel. Take care not to compress the sample during these cutting and smoothing operations. The time of completion of molding shall be taken as the start of measurement of time of set.

7.4 Store the specimen in the moist room.

7.5 Determine the time of setting using the procedure described in Test Method C 191 except that the first reading shall be taken 3 h ± 15 min after pouring the specimen.

NOTE 1—Grouts used to evaluate grout fluidifier or for use in PA concrete will normally reach initial set in about 4 h.

8. Report

8.1 The report shall include the following:

8.1.1 Identification of the grout sample,

8.1.2 Time of initial setting and final setting in hours and minutes,

8.1.3 Temperature of group sample at the beginning of the test, and

Designation: C 954 – 07

Standard Specification for Steel Drill Screws for the Application of Gypsum Panel Products or Metal Plaster Bases to Steel Studs from 0.033 in. (0.84 mm) to 0.112 in. (2.84 mm) in Thickness[1]

This standard is issued under the fixed designation C 954; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers minimum requirements for steel drill screws for use in fastening gypsum panel products or metal plaster bases to steel members from 0.033 in. (0.84 mm) to 0.112 in. (2.84 mm) in thickness.

1.2 This specification also covers physical properties and test methods for determining performance requirements.

1.3 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 The following safety hazards caveat pertains only to the test methods described in this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

A 510 Specification for General Requirements for Wire Rods and Coarse Round Wire, Carbon Steel

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 1396/C 1396M Specification for Gypsum Board

C 1513 Specification for Steel Tapping Screws for Cold-Formed Steel Framing Connections

3. Terminology

3.1 *Definitions:*

3.1.1 For definitions relating to gypsum and related building materials and systems, see Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *steel drill screw*—self-drilling tapping screw with the ability to drill its own hole, form or cut mating threads without deforming its own threads or breaking during assembly.

4. Materials

4.1 Screws shall be manufactured from Grade 1018 to 1022 steel wire manufactured in accordance with Specification A 510.

5. Physical Properties

5.1 *Metallurgical Requirements*:

5.1.1 The surface of the screw shall be carbonitrided to a depth of 0.004 to 0.008 in. (0.10 to 0.20 mm).

5.1.2 The core hardness shall be 32 to 40 HRB after being drawn at a minimum temperature of 625 °F (330 °C).

5.1.3 The screw shall have no band of free ferrite between the case and core nor shall the case contain appreciable amounts of retained austenite or other soft constituents.

5.1.4 Surface hardness shall be determined by a micro hardness instrument at "the root of the thread profile," as exposed by removal of enough material to form a flat surface along the length of the screw.

5.1.5 *Ductility*—Screws shall have sufficient ductility to be able to withstand a 5° bend without visible signs of fracture when tested as specified in paragraph 8.2.1 of Specification C 1513.

5.2 *Dimensions and Permissible Variations*:

5.2.1 *General*:

5.2.1.1 *Head Diameter*— The head of the screw shall not be out of round more than 0.021 in. (0.51 mm) and have the following shape and dimensions:

5.2.1.2 *Screw Diameter*— Screws shall have a major diameter not less than 0.136 in. (3.45 mm).

5.2.1.3 *Points*, shall provide for self-drilling into steel studs from 0.333 in. (0.84 mm) to 0.112 in. (2.84 mm) in thickness and meet the performance tests in Section 6.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved Aug. 1, 2007. Published August 2007. Originally approved in 1981. Last previous edition approved in 2004 as C 954 – 04.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

5.2.1.4 *Driving Recess*, shall be a No. 2 "Phillips" design with a minimum depth of 0.104 in. (2.64 mm) as determined with a "Phillips" penetration depth gage or a recess of equal performance.

5.2.1.5 *Length*—Nominal lengths shall be minimum length.

5.2.2 *Screws for Fastening Gypsum Board*:

5.2.2.1 Screw-head minimum diameter shall be 0.3145 in. (8.00 mm).

5.2.2.2 The top of the head shall be flat. The outer flange thickness shall be 0.025 ± 0.005 in. (0.64 ± 0.13 mm). The contour beneath the flange head shall be such that the screw head shall be able to be driven so that the head of the screw rests immediately below the surface of the gypsum panel products.

5.2.2.3 The threads shall extend to the lower edge of the head contour.

5.2.3 *Screws for Fastening Metal Plaster Bases*:

5.2.3.1 Screw head minimum diameter shall be 0.437 in. (11.1 mm).

5.2.3.2 The top of the head shall be flat or contoured. The underside of the head shall be flat.

5.2.3.3 The threads shall extend to the underside of the head.

6. Performance Requirements

6.1 *Spin-Out*:

6.1.1 Screws shall self-drill and drive into a stud 0.0598 in. (1.5 mm) thick with an approximate hardness of 65 HRB without spin-out.

6.1.2 Screws shall self drill and drive into a stud 0.105 in. (2.7 mm) thick, with a hardness of 80 HRB without spin-out.

6.2 *Performance*:

6.2.1 When tested in accordance with Section 10, screws shall meet the requirements as follows:

6.2.1.1 *Gypsum Panel Products*—Screw threads shall be adequate to pull the head of the screw below the surface of the gypsum panel through four layers of kraft paper placed over the gypsum panel products and a steel stud 0.033 in. (0.84 mm) thick when tested in accordance with 10.5.1.

6.2.1.2 *Metal Plaster Bases*—Screw threads shall be adequate to pull metal lath tight against the flange of a steel stud 0.033 in. (0.84 mm) thick so that when subjected to a steady pull, the lath will tear and not slip out from under the screw head when tested in accordance with 10.5.1.

7. Finish and Appearance

7.1 Screws shall be corrosion-resistant treated with a material which will not inhibit adhesion to joint compounds or plaster and will not bleed through decorative finishes.

7.2 Screws shall be straight, clean, smooth, neatly formed, and free of defects such as burrs and deformations.

8. Sampling

8.1 Obtain not less than 90 screws from not less than five containers.

9. Number of Tests and Retests

9.1 Test a minimum of five screws for each test. If any of the first lot fails, test 25 more screws.

9.2 If two or more of the second lot fail the second test, then the represented lot fails to meet the specified requirements.

10. Test Method

10.1 *Summary of Test Method*:

10.1.1 This test method utilizes steel screws designed for use to hold gypsum panel products and metal plaster base materials applied with power-driven screw guns of 2500 r/min maximum to steel studs.

10.2 *Significance and Use*:

10.2.1 This test method evaluates the ability of steel drill screws used to secure gypsum panel products and metal plaster bases to certain steel framing members.

10.2.2 The test shall be conducted in a laboratory or on-site.

10.3 *Apparatus*:

10.3.1 *Power-Driven Drill Screw Gun*, having the capacity of turning 2500 r/min maximum (free spindle speed).

10.3.2 A *Vice,* or similar device to support the stud during the test.

10.4 *Materials*:

10.4.1 *Kraft Paper*, 0.010 in. (0.25 mm) thick.

10.4.2 *Steel Stud*—One section of 0.033-in. thick stud (0.84-mm), 1 section of 0.0598-in. (1.5-mm) thick stud and with a hardness of 65 HRB, and 1 section of 0.105-in. (2.7-mm) thick stud and with a hardness of 80 HRB.

10.4.3 *Gypsum Wallboard*— Specification C 1396/C 1396M, Type X, ⅝ in. (16 mm) thick.

10.4.4 *Screw Specimens*, to be tested.

10.4.5 *Diamond Mesh Metal Lath*, 2.5/lb/yd^2.

10.5 *Procedure for Performance Tests*:

10.5.1 Using the screw specimen, attach gypsum board or metal lath to center of a flange of a steel stud which has been securely and rigidly supported.

10.5.1.1 Grasp the metal lath with locking pliers and pull steadily in a plane parallel to the plane of the lath. Observe whether the lath tears before it slips out from under the screw head.

10.5.1.2 With the drill propelling the screw at 2500 r/min maximum (free spindle speed), exert a total pressure of 30 lbf (135.5 N) (dead weight plus applied force).

10.6 *Precision and Bias*—No statement is made regarding the precision and bias of this test method, since the result of the test method is reported in nonnumerical terms.

11. Inspection

11.1 Inspection of steel drill screws shall be agreed upon by the purchaser and the producer or supplier as part of the purchase agreement.

12. Rejection and Rehearing

12.1 Rejection of steel drill screws that fail to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing within 10 working days from receipt of shipment by the purchaser. Notice of rejection shall contain a specific statement as to the respects in which the screws have failed to conform to the requirements of this specification. In case of dissatisfaction with the results of the test, and at the request of the producer or

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

supplier, such notice of rehearing shall be supported by results of a test conducted by a mutually agreeable independent laboratory.

13. Certification

13.1 When specified in the purchase agreement, the producer or supplier shall furnish a report certifying that, at time of shipment, the screws were in compliance with the requirements of this specification.

14. Packaging and Marking

14.1 Screws shall be packaged in substantial commercial containers constructed so as to preserve the contents in good condition and to ensure acceptance and safe delivery by common or other carriers, at the lowest rate, to the point of delivery.

14.2 The containers shall be so constructed that the contents can be partially removed without destroying the container's ability to serve as a receptacle for the remainder of the contents.

14.3 Individual packages and shipping containers shall be marked with the type and length of screw and the name of the manufacturer or distributor.

15. Keywords

15.1 steel drill screw; steel self-drilling tapping screw

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 954 – 04, that may impact the use of this specification. (Approved August 1, 2007)

(*1*) Replaced reference to Specification C 36 with Specification C 1396/C 1396M in 10.4.3 and Referenced Documents.

Designation: C 955 – 09a

Standard Specification for Load-Bearing (Transverse and Axial) Steel Studs, Runners (Tracks), and Bracing or Bridging for Screw Application of Gypsum Panel Products and Metal Plaster Bases[1]

This standard is issued under the fixed designation C 955; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers steel studs, runners (tracks), and bracing or bridging (with a base metal thickness range of not less than 0.0329 in. (0.836 mm)) for screw application of gypsum panel products and metal plaster bases in load-bearing (transverse and axial) construction assemblies. Steel of lesser thickness shall be permitted in additional engineered products.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 The following precautionary caveat pertains only to the test method portion, Section 8, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

A 653/A 653M Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process

A 792/A 792M Specification for Steel Sheet, 55 % Aluminum-Zinc Alloy-Coated by the Hot-Dip Process

A 875/A 875M Specification for Steel Sheet, Zinc-5 % Aluminum Alloy-Coated by the Hot-Dip Process

A 1003/A 1003M Specification for Steel Sheet, Carbon, Metallic- and Nonmetallic-Coated for Cold-Formed Framing Members

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 954 Specification for Steel Drill Screws for the Application of Gypsum Panel Products or Metal Plaster Bases to Steel Studs from 0.033 in. (0.84 mm) to 0.112 in. (2.84 mm) in Thickness

2.2 *AISI Standard:* [3]

Specification for the Design of Cold-Formed Steel Structural Members

AISI Code of Standard Practice for Cold-Formed Steel Structural Framing Committee on Framing Standards—2006 Edition

3. Terminology

3.1 *Definitions:* Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *members*, *n*—studs, runners, tracks, bracing, bridging, accessories or other items manufactured in accordance with this standard.

3.2.2 *structural member*, *n*—a member in a steel framed system in which the loading exceeds any of the following conditions: a transverse load of 20 lbf/ft (290 N/m) of member length, or an axial load, exclusive of sheathing, of 200 lbf (890 N) per member.

4. Materials and Manufacture

4.1 Members shall be manufactured from steel meeting the requirements of Specification A 1003/A 1003M.

4.2 The minimum steel thickness (base steel) shall be not less than 0.0329 in. (0.84 mm).

4.3 Individual measurements before the application of protective coating shall be not less than 95 % of the specified design thickness.

4.4 Members shall have a protective coating in accordance with Table 1, CP 60 minimum.

4.5 Edges of members shall be manufactured to minimize burrs and sharp edges.

4.6 Factory punch-outs, when provided, shall be located along the centerline of the webs of members and shall have

TABLE 1 Coating Designations

Coating Classification	Coating Designator	Minimum Coating Requirements			
		Zinc-Coated[A] oz/ft² (g/m²)	Zinc Iron[B] oz/ft² (g/m²)	55 % Al-Zinc[C] oz/ft² (g/m²)	Zinc-5 %[D] oz/ft² (g/m²)
Metallic Coated	CP 60	G 60 (Z 180)	A 60 (ZF 180)	AZ 50 (AZM 150)	GF 30 (ZGF 90)
	CP 90	G 90 (Z 275)	Not Applicable	AZ 50 (AZM 150)	GF 45 (ZGF 135)
Painted Metallic	PM	The metallic coated substrate shall meet the requirements of metallic coated. In addition, the paint film shall have a minimum thickness of 0.5 mil (0.013 mm) per side (primer plus topcoat) with a minimum primer thickness of 0.1 mil (0.0002 mm) per side.[E]			

[A] Zinc-coated steel sheet as described in Specification A 653/A 653M.
[B] Zinc-iron alloy-coated steel sheet as described in Specification A 653/A 653M.
[C] 55 % Aluminum-zinc alloy-coated steel sheet as described in Specification A 792/A 792M.
[D] Zinc-5 % aluminum alloy-coated steel sheet as described in Specification A 875/A 875M.
[E] In accordance with the requirements of Specification A 1003/A 1003M.

center-to-center spacing of not less than 24 in. (610 mm). Web punch-outs maximum width shall be the lesser of 0.5 times the member depth, d, or 2½ in. (64 mm). Web punch-out length shall not exceed 4 ½ in. (114 mm). Minimum distance between the end of the member and the near edge of the web punch-out shall be 10 in. (254 mm). The size of the factory punch-outs shall not exceed the size used in design and the center-to-center spacing shall not be less than that used in design.

4.7 The properties and strength of members shall be computed in accordance with the AISI Specification for the Design of Cold-Formed Steel Structural Members.

5. Performance Requirements

5.1 When tested in accordance with Section 8, members shall be capable of pulling the head of the screw below the surface of the gypsum panel product without spin out (see Fig. 1).

6. Dimensions and Permissible Variations

6.1 Data for calculating design performance shall be supplied by the manufacturer.

6.2 The width of the surface to which the sheathing board is attached shall be not less than 1¼ in. (32 mm).

6.3 Runners (track) shall be formed in a U-shaped configuration, having a depth compatible with that of the studs of the same nominal size.

6.4 Minimum height of runner (track) flanges shall be ¾ in. (19 mm).

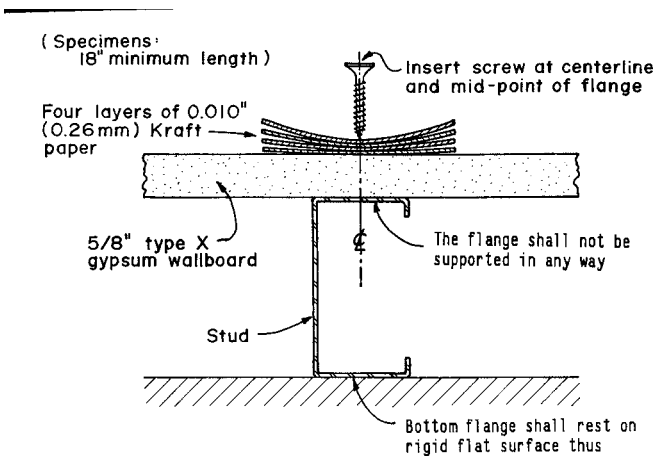

FIG. 1 Studs

6.5 Members shall be manufactured within the limits as shown in Table 2 and Fig. 2.

6.6 Bracing and bridging shall have configuration and steel thickness to provide secondary support for the studs in accordance with the AISI Specification for the Design of Cold-Formed Steel Structural Members.

7. Workmanship, Finish, and Appearance

7.1 The steel members shall be free of defects that interfere with the purpose for which they are intended.

8. Penetration Test

8.1 *Significance and Use*—This test method provides a procedure for evaluating the member's ability to pull the head of a screw below the surface of the gypsum panel product. It shall be used to determine compliance with this specification. The degree of performance of this test method with service performance has not been determined.

8.2 *Apparatus shall satisfy the following*:

TABLE 2 Manufacturing Tolerances

Dimension[A]	Item Checked	Structural Studs, in. (mm)	Structural Track, in. (mm)
A	length	+ 3/32 (2.38) – 3/32 (2.38)	+ ½ (12.7) – ¼ (6.35)
B[B]	web width	+ 1/32 (0.79) – 1/32 (0.79)	+ 1/32 (0.79) + ⅛ (3.18)
C	flare overbend	+ 1/16 (1.59) – 1/16 (1.59)	+ 0 (0) – 3/32 (2.38)
D	hole center width	+ 1/16 (1.59) – 1/16 (1.59)	NA
E	hole center length	+ ¼ (6.35) – ¼ (6.35)	NA
F	crown	+ 1/16 (1.59) – 1/16 (1.59)	+ 1/16 (1.59) – 1/16 (1.59)
G[C]	camber	⅛ (3.2) max per 10 ft	1/32 per ft (0.79) ½ max (12.7)
H[C]	bow	⅛ (3.2) max per 10 ft	1/32 per ft (0.79) ½ max (12.7)
I	twist	1/32 per ft (0.79) ½ max (12.7)	1/32 per ft (0.79) ½ max (12.7)

[A] All measurements shall be taken not less than 1 ft (305 mm) from the end.
[B] Outside dimension for stud; inside for track.
[C] ⅛ in. (3 mm) max per 10 ft (3000 mm) represents L/960 maximum for overall camber and bow. Thus a 20 ft (6000 mm) long member would have ¼ in. (6 mm) permissible maximum; a 5 ft (1500 mm) long member would have 1/16 in. (1.5 mm) permissible maximum.

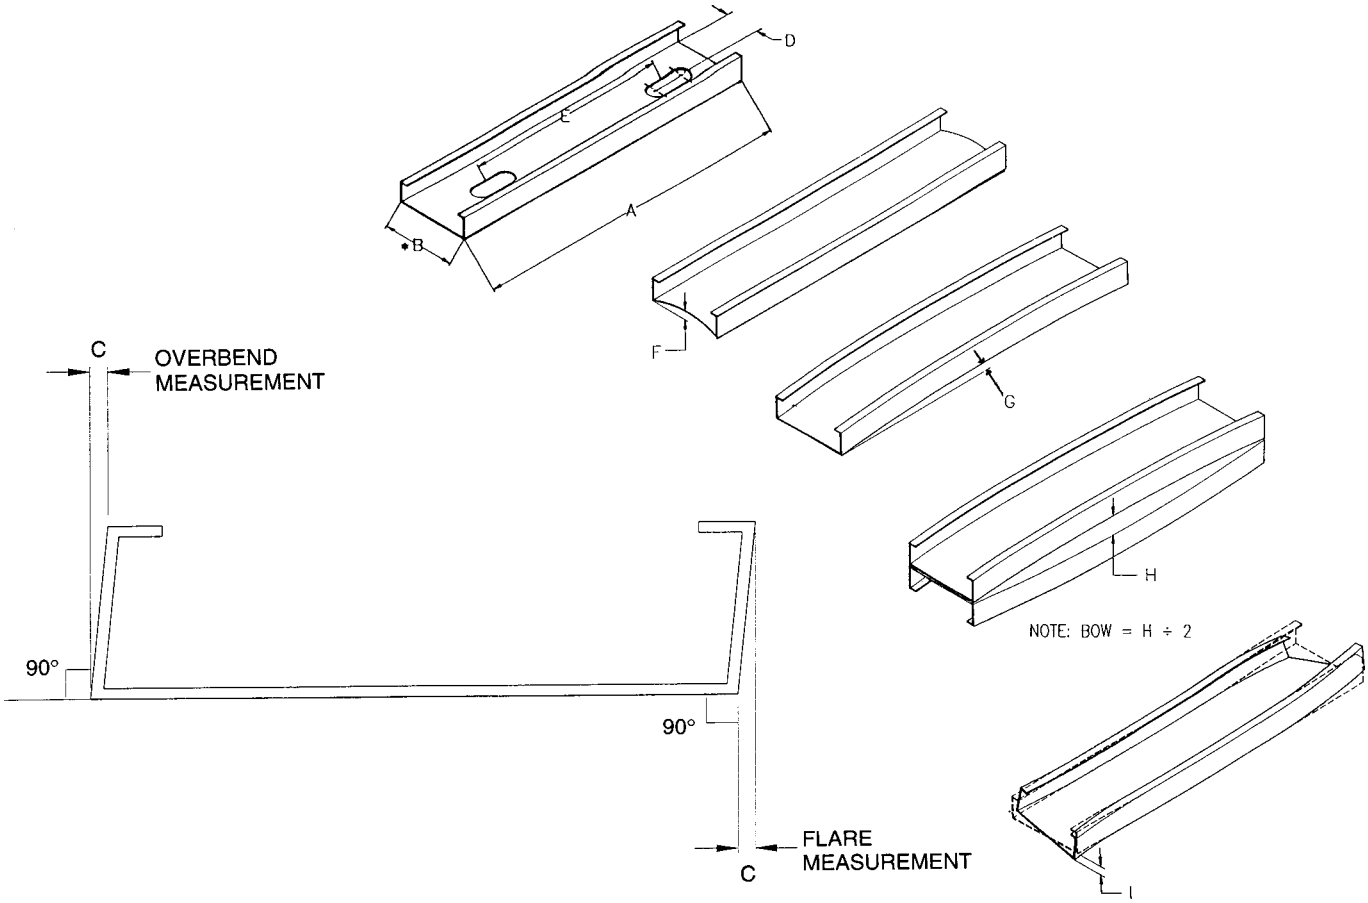

FIG. 2 Manufacturing Tolerances

8.2.1 *Electric Drill* capable of 2500 r/min (free spindle speed), supplied with a screw driving bit to fit the screw used in the test.

8.3 *Materials shall satisfy the following*:

8.3.1 *Gypsum Board*, Type X, ⅝ in. (16 mm) thick.

8.3.2 *Screws*—Specification C 954, 1 in. (25.4 mm) long.

8.3.3 *Kraft Paper*, 0.010 in. (0.25 mm) thick.

8.4 *Sampling*—One member shall be selected from each bundle or package but not more than ten from any one shipment for testing.

8.5 *Specimen Preparation*:

8.5.1 Each member to be tested shall be cut into test specimens not less than 18 in. (460 mm) long.

8.5.2 For each test, one piece of gypsum board, 6-in. (152-mm) square, shall be cut not less than 12 in. (305 mm) from the edge or end of the wallboard.

8.5.3 For each test, four pieces of kraft paper, 2-in. (51-mm) square shall be cut.

8.6 *Number of Tests and Retests*:

8.6.1 Five specimens of members shall be tested.

8.6.2 If more than one test specimen fails to meet the requirements, two more test specimens shall be chosen for retesting.

8.7 *Report*—Report shall indicate all specimens meeting the requirements of this specification if the screw penetrated the steel and the screw did not spin out; or shall indicate all specimens failing if the screw did not penetrate the steel, or the screw spun out.

8.8 *Precision and Bias*—No statement is made about either the precision or bias of this test method since the result merely states whether or not there is conformance to the criteria for success specified in the procedure.

9. Inspection

9.1 Inspection of the members shall be agreed upon between the purchaser and the producer or supplier as part of the purchase agreement.

10. Rejection

10.1 When specified in the purchase agreement, members that fail to conform to the requirements of this specification shall be rejected. Rejection shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the member has failed to conform to the requirements of this specification and the purchase agreement.

11. Certification

11.1 When specified in the purchase agreement, a producer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

12. Marking and Identification

12.1 Groups of like members shall be marked with a label, or a tag attached thereto. Marking shall include the rollformer's identification (name, logo, or initials), length, quantity, and rollformer's member designator including member depth, flange size, and minimum steel thickness in mils or inches exclusive of protective coating.

12.2 In addition to the marking referenced in 12.1, individual members shall have a legible label, stencil, or embossment, at a maximum distance of 96 in. (2440 mm) on center, on the member, with the following minimum information:

12.2.1 The rollformer's identification (that is, name, logo, or initials).

12.2.2 The minimum steel thickness, in mils or inches, exclusive of protective coatings.

12.2.3 The minimum yield strength in kip per square inch (megapascals).

12.2.4 The minimum protective coating shall be indicated with the appropriate coating designator in accordance with Table 1.

12.3 Where color-coding of members or bundles of like members is employed, the standard color-coding in Table 3 shall be used.

13. Protection

13.1 Material shall be protected during shipment as required. When specified in the purchase order, the members shall be packaged in accordance with the purchaser's instructions.

13.2 Material shall be received and stored in accordance with AISI COSP, paragraph F3.

14. Keywords

14.1 runners; screws; section properties; studs; thickness

TABLE 3 Color Codes for Members

Color	Minimum Base Metal Thickness, mils	Minimum Decimal Equivalent,	
		in.	(mm)
White	33	0.0329	(0.836)
Yellow	43	0.0428	(1.087)
Green	54	0.0538	(1.367)
Orange	68	0.0677	(1.720)
Red	97	0.0966	(2.454)
Blue	118	0.1180	(2.997)

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 955 – 09, that may impact the use of this specification. (Approved September 1, 2009)

(*1*) Added metric equivalents to Table 1 for Painted Metallic Minimum Coating Requirements.

(*2*) Added metric equivalents to Footnote C of Table 2.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 955 – 08a, that may impact the use of this specification. (Approved May 1, 2009)

(*1*) Revised camber and bow tolerances in Table 2.

(*2*) Added new Footnote C in Table 2.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 955 – 08, that may impact the use of this specification. (Approved September 1, 2008)

(*1*) Deleted CP40 coatings, Painted coatings, and Footnote F from Table 1.

(*2*) Deleted ISO 9223 from Referenced Documents.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 955 – 07, that may impact the use of this specification. (Approved March 1, 2008)

(*1*) Added metric equivalents in Table 1.

Designation: C 956 – 04

Standard Specification for Installation of Cast-In-Place Reinforced Gypsum Concrete[1]

This standard is issued under the fixed designation C 956; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the minimum requirements for the installation of cast-in-place reinforced gypsum concrete over permanent formboard.

1.2 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

A 82 Specification for Steel Wire, Plain, for Concrete Reinforcement

A 185 Specification for Steel Welded Wire Reinforcement, Plain, for Concrete

A 568 Specification for Steel, Sheet, Carbon, and High-Strength, Low-Alloy, Hot-Rolled and Cold-Rolled, General Requirements for

A 653/A 653M Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 317 Specification for Gypsum Concrete

C 726 Specification for Mineral Fiber Roof Insulation Board

E 72 Test Methods of Conducting Strength Tests of Panels for Building Construction

2.2 *American Concrete Institute Standard:*

ACI 318 Building Code Requirements for Reinforced Concrete[3]

2.3 *American Welding Society Standard:*

D1.1 Structural Welding Code Steel[4]

3. Terminology

3.1 Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions:*

3.2.1 *primary framing, n*—structural members provided to support the reinforced gypsum concrete roof deck assembly.

3.2.1.1 *purlin, n*—a secondary structural member that spans the primary framing members and provides support for subpurlins.

3.2.2 *subpurlin, n*—a steel member applied transversely to the primary framing and purlins to support the formboards and to transmit the dead and live loads from the gypsum concrete slab to the primary framing.

3.2.2.1 *bulb tee, n*—a subpurlin, hot-rolled formed steel, rail-shaped section.

3.2.2.2 *truss tee, n*—a subpurlin fabricated from steel wire and strip, tee-shaped section.

3.2.3 *cross tee, n*—a steel tee-shaped section used to support a formboard end at right angles to the subpurlins where a formboard end does not occur over the purlin or primary framing.

3.2.4 *formboard, n*—sheet material used as a permanent form to support the gypsum concrete.

3.2.5 *reinforcement, n*—steel wire mesh or fabric used within the gypsum concrete slab to provide longitudinal and transverse strength.

3.2.6 *double-pouring, n*—the application of gypsum concrete in more than one layer to complete the full slab thickness. See 8.7.4.3.

3.2.7 *ribbon-pouring or strip-pouring, n*—the application of narrow ribbons of gypsum concrete, about 10 to 12 in. (254 to

www.technobetar.ir

305 mm) wide by 1 to 1½ in. (25.4 to 38.1 mm) deep, across the width of the formboard at center of span between purlins.

4. Delivery of Materials

4.1 Materials shall be delivered in original packages, containers, or bundles bearing the brand name and name of producer or seller. Bulk materials shall be delivered with the brand name and name of the producer or seller shown on the accompanying bills of lading.

5. Storage of Materials

5.1 All materials shall be stored in a manner that prevents damage before use. When stored under tarpaulins, ventilation shall be provided to prevent moisture accumulation under the tarpaulin.

5.2 Formboard shall be stored flat and off the ground. Handling and stacking shall be done in such a manner to prevent damage to face, ends, and edges and keep dry until use.

5.3 When it is necessary to store gypsum concrete at the job site, the gypsum concrete shall be stored off the ground and kept dry until use.

6. Environmental Conditions

6.1 The minimum temperature at which gypsum concrete is mixed and placed is not specified. Gypsum concrete shall not be mixed with water containing ice crystals.

NOTE 1—An exothermic reaction during setting ensures complete hydration before freezing.

7. Materials

7.1 *Subpurlins*:

7.1.1 Subpurlins shall be designed to support live and dead loads of the roof deck.

7.1.2 Hot-rolled and cold-rolled steel shapes other than bulb tees or truss tees shall meet the requirements of this specification for subpurlins.

7.2 *Cross Tees*, shall be not less than 1¼ in. (31.75 mm) wide by ½ in. (12.7 mm) high, fabricated from not less than 26 gage zinc-coated steel conforming to Specifications A 653/A 653M or A 568.

7.3 *Formboard*:

7.3.1 *Mineral Fiber Formboard*, Specification C 726, not less than ¾ in. (19.0 mm) thick nor more than 3 in. (76 mm) thick. It shall sustain a uniform load of 20 lb/ft^2(97 kg/m^2).

7.3.1.1 Mineral fiber formboard shall be tested in accordance with the transverse loading test of Test Methods E 72.

7.3.1.2 The test specimen shall be uniformly loaded and supported at both edges and ends. The test specimens shall be supported at the perimeter with a frame providing 1 in. (25.4 mm) bearing on ends and ½ in. (12.7 mm) bearing on edges and 7 in. (177.8 mm) nominal clearance from the bed of the apparatus.

7.3.1.3 For formboards ¾ in. (19.0 mm) thick, test specimens shall be 48 in. (1200 mm) long by 24 in. (600 mm) wide.

7.3.1.4 For formboards 1 in. (25.4 mm) thick or greater, test specimens shall be 48 in. (1200 mm) long by 32 in. (800 mm) wide.

7.4 *Reinforcement*, Specification A 82, shall be fabricated from zinc-coated (galvanized) welded or woven steel wire mesh or fabric having an effective cross-sectional area of not less than 0.026 in.^{2} (16.77 mm)^2 per foot of slab width. Reinforcement shall be free of rust, scale, or other materials that reduce bond to the gypsum concrete.

7.4.1 *Hexagonal Reinforcing Mesh*, shall be fabricated from 2 in. (50.8 mm) hexagonal mesh formed of not less than 0.0410 in. (1.04 mm) diameter wires with longitudinal wires not less than 0.0625 in. (1.59 mm) in diameter, spaced not more than 3 in. (76.2 mm) on centers. Steel wire for fabricating wire mesh and fabric—Specification A 82.

7.4.2 *Rectangular Reinforcing Fabric*, Specification A 185, shall be fabricated from longitudinal wires not less than 0.1055 in. (2.68 mm) in diameter spaced not more than 4 in. (102 mm) on centers and transverse wires not less than 0.0800 in. (2.03 mm) in diameter spaced not more than 8 in. (203 mm) on centers.

7.5 *Gypsum Concrete*, Specification C 317, Class A.

7.6 *Water*, shall be potable and free of substances that could adversely affect the gypsum concrete.

7.7 *Expansion Filler Strip*, shall be not less than ¾ in. (19 mm) thick and equal in height to the abutting gypsum concrete and of the type specified by the producer of the gypsum concrete.

8. Installation

8.1 *Installation of Subpurlins*:

8.1.1 *Installation, Normal*:

8.1.1.1 *Subpurlins*—The subpurlins shall be placed transversely to the purlins and primary framing and shall be spaced to suit the size of the formboards specified. Subpurlins shall be of sufficient length so that their joints occur over purlins or primary framing. Subpurlin joints shall be alternated so that the joints are staggered one purlin space.

8.1.1.2 Subpurlins shall be welded to purlins and steel primary framing with ⅛ in. (3.2 mm) fillet welds not less than ½ in. (12.7 mm) long on alternate sides of the subpurlin at each intersection with purlins. Except as otherwise specified, welding shall be in accordance with AWS D1.1. Where primary framing is of wood, nails not less than 16d shall be used on each side of the subpurlins at each intersection. The nails shall be bent over approximately ¾ in. (19 mm) to securely clinch the flange of the subpurlin.

8.1.2 *Installation Seismic*:

8.1.2.1 *Subpurlins*—The subpurlins shall be welded at each intersection with the purlins with ⅛-in. (3.2-mm) fillet welds not less than 1 in. (25.4 mm) long, on one side. Both sides of the subpurlin shall be welded with ⅛-in. fillet welds not less than 2 in. (50.8 mm) long where subpurlin joints occur over the purlin. Both sides of the subpurlin shall be welded with ⅛-in. fillet welds not less than 2 in. long at shear transfer points and at intersections with exterior frame.

8.1.3 *Maximum Spans*—Refer to X2.1.3.

8.2 *Cross Tees*—Cross tees shall be provided where formboard ends are supported by purlins or the primary framing.

8.3 *Formboards*—Formboards shall be located face down on the flanges of the supporting members and with the ends on top of the purlins.

8.3.1 Gypsum concrete shall not be poured over formboards which have been wetted by rain or snow.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:41:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.3.2 The gypsum concrete shall be poured on the same day the formboards are installed.

8.4 *Reinforcement*—The mesh of wire fabric shall be located with the main longitudinal wires at right angles to the subpurlins and adjacent to the formboard at midspan between the purlins. Ends of the reinforcement shall be lapped not less than 4 in. (102 mm) or one mesh, whichever is greater.

8.4.1 Edges shall be butted, not lapped, unless required for fire rated or horizontal diaphragm construction. Reinforcement shall be cut to fit at walls, curbs, and openings, folded over on to itself, and extended into all areas when gypsum concrete is to be placed.

8.5 *Expansion Filler Strips*—Expansion filler strips shall be placed continuously against the walls, curbs, nailers, or other rigid surfaces that gypsum concrete will abut.

8.6 *Expansion Joints*—Expansion joints shall be located at expansion joints found in the main structure, at a maximum of 200 ft (61 m) on center in a direction parallel to the subpurlins on large buildings, at intersections of wings on L-, U-, T-, and H-shaped buildings and, wherever the roof framing changes direction. See X1.5.5.

8.7 *Gypsum Concrete Mixing and Placement*:

8.7.1 *General*—All equipment, including mixers, pumps, hoses, tools, and screeds shall be kept clean and free of set gypsum concrete throughout the placement operation.

8.7.2 *Proportioning*—The ratio of water to gypsum concrete shall be that specified by the producer of the gypsum concrete; additional water is prohibited. Volumetric or metering devices shall be used to ensure accurate measurement.

8.7.3 *Mixing*—Mixing shall be thorough but not overmixed. The slurry shall be discharged into placement equipment immediately after completion of mixing to avoid buildup of set material.

8.7.3.1 Calcium chloride or other admixtures shall not be added to the gypsum concrete.

8.7.4 *Placement*:

8.7.4.1 *General*—To avoid exposure to inclement weather and physical abuse, gypsum concrete shall be placed the same day as the installation of the formboard and reinforcement materials.

8.7.4.1.1 The deck shall be poured in sections of similar size.

8.7.4.2 *Screeds Grounds*—Screeds, such as metal bars or wood strips, shall be spaced approximately 10 ft (3050 mm) apart at right angles on top of the subpurlins at a height that will allow the gypsum concrete slurry to be leveled at the specified thickness.

8.7.4.2.1 Gypsum concrete cants, curbs, and drainage slopes shall be placed to the design thickness. Curbs around openings shall be permitted to be formed with the formboard.

8.7.4.3 The gypsum concrete shall be discharged into placement equipment immediately after completion of mixing.

8.7.4.3.1 The slurry shall be poured or discharged not more than 24 in. (600 mm) off the formboard to minimize impact and allowed to build to full thickness in one continuous operation. Double pouring shall not be permitted.

8.7.4.3.2 As soon as the slurry has stiffened enough to hold a full level, it shall be screeded to a true, even surface using a smooth, rigid straight-edge.

8.7.4.4 Place gypsum concrete cants, curbs, and drainage slopes to the design thickness. Curbs around openings shall be permitted to be formed with the formboard.

8.8 *Roof Overhangs*—Gypsum concrete shall not be placed on roof overhangs, eaves, or other similar locations, on formboards unless the underside is protected against direct wetting by a suitable facia drip cap overhang.

8.9 *Drying*—Construction moisture shall be removed from the building to permit drying of completed gypsum concrete slab, providing heat and ventilation where required. See X1.3.

8.10 *Protection of Completed Slab*—Gypsum concrete is not a finished traffic or weather protective surface. The top side of the completed gypsum concrete slab shall be protected with a permanent waterproof covering.

9. Keywords

9.1 calculation of diaphragm shear; gypsum concrete; gypsum roof deck

APPENDIXES

(Nonmandatory Information)

X1. GENERAL INFORMATION

X1.1 Limitations of Use

X1.1.1 *Roof Shapes and Designs*—Gypsum roof decks meeting this specification can be installed on flat, warped, sawtooth, curved, or pitched roofs.

NOTE X1.1—On flat roofs, a minimum pitch of ⅛ in./ft (10.4 mm/m) is recommended.

X1.1.2 *Moisture Exposure*—Cast-in-place gypsum concrete is not recommended for general use in occupancies where it may be exposed to sustained relative humidity greater than 90 % or condensing moisture. The producer of the gypsum concrete should be consulted regarding limitations of use in high humidity occupancies.

X1.1.3 *Temperature Exposures*—Where intermittent or extended exposures to high temperatures are to be expected, such as in slabs directly exposed to radiant heat over furnace

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:41:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

breachings, the gypsum concrete producer should be consulted for specific recommendations.

X1.1.4 *Acid Fumes*—If acid fumes are to be encountered, the producer of the gypsum concrete should be consulted for his specific recommendations.

X1.1.5 *Surface Protection*—Gypsum concrete decks shall not be used as a finished surface to bear traffic or other loads. Protective permanent waterproof coverings shall be installed as soon as possible after completion of the slab.

X1.1.6 *Welding Precautions*—Except as modified in the body of this specification, welding shall be in accordance with AWS D1.1. Welding will not be permitted when the temperature is lower than 0°F (−18°C), when steel surfaces are wet, or under other conditions not recommended by the American Welding Society.

X1.2 Support for Suspended Ceilings

X1.2.1 Suspended ceilings should be hung from the primary framing. Ceilings may be hung from the subpurlins. A design check shall be made in accordance with applicable building codes and regulations to verify that the structural adequacy of the subpurlins and the added weight of the ceiling will not cause the subpurlins to deflect more than that allowed by the roof deck or ceiling sign or that allowed by subpurlin design. Hangers should not be fastened into or through the gypsum concrete slab or the formboards. Similar precautions should be followed for the suspension of unit heaters, light troffers, and piping.

X1.3 Drying of Slabs

X1.3.1 Subsequent to the placing of gypsum concrete, ventilation accompanied by heat is recommended below the slabs to remove the excess construction moisture resulting from the slab pouring, placement of concrete floors, masonry plastering, and other similar construction work. Where natural ventilation is inadequate, mechanical ventilation is required to remove construction moisture from the building. When suspended ceilings are installed below the slabs, provisions should be made to permanently vent the enclosed space below the deck, particularly that space above a suspended ceiling, using sufficient gravity or mechanical ventilation to remove all construction moisture and excessive moisture vapor resulting from subsequent occupancy.

X1.4 Provisions for Expansion and Contraction

X1.4.1 Provision for relief of expansion and contraction should be considered for all cast-in-place roof decks. Wherever expansion joints have been provided in the main structure, they must also be provided in the roof deck and roof covering. The use of suitable expansion strips at the junction between roof slabs and parapets is recommended for further relief of expansion and contraction stresses in the slabs. Where subpurlins are used, edge expansion strips need be used only at walls where subpurlins abut walls at right angles.

X1.5 Roof Coverings

X1.5.1 Built-up or other suitable roof coverings should be specified over poured gypsum concrete roof slabs.

X1.5.2 The application of metal or other rigid types of roof covering over poured gypsum concrete decks is not generally recommended. If sheet metal roof coverings are required over portions of a poured gypsum concrete deck, their anchoring members must be attached either by the use of toggle bolts passing entirely through the slab and formboards or by suitable fastening to the primary members. Where shingle-type roof coverings are contemplated, the gypsum concrete producer's recommendations for attachment should be followed.

X1.5.3 Provisions for furnishing and installing roof sumps should be included in other sections of the specification.

X1.5.4 The application of roof covering should follow as promptly after the placing of gypsum concrete as possible. The top surface of the slab should be reasonably hard as indicated by the disappearance of visible moisture gloss from its surface.

X1.5.5 Expansion joints should be installed in the roofing wherever they are provided in the gypsum concrete and the main structure.

X1.6 Painting Undersides of Gypsum Concrete Roof Decks

X1.6.1 The underside of the gypsum deck is usually not further decorated. If painting is desired, it should be deferred until the formboard and the slab are thoroughly dry through their total thickness.

X1.7 Framing Requirements

X1.7.1 The primary framing to receive subpurlins and the primary framing spaced to directly receive the formboards for the gypsum concrete are not part of the gypsum concrete specifications. However, it is essential that the following provisions regarding such framing be incorporated in other sections.

X1.7.1.1 Spacing of primary structural supports to receive the subpurlins of the reinforced gypsum concrete assembly must be such that design stresses in the specified subpurlins are not exceeded.

X1.7.1.2 When subpurlins are not used, the following provisions should be made to anchor the slab to the primary framing members to resist uplift forces and movements due to temperature changes.

X1.7.1.2.1 Weld steel tee sections sized from 1 by 1 by ⅛ in. (25.4 by 25.4 by 3.2 mm) to 1½ by 1½ by 3⁄16 in. (38.1 by 38.1 by 4.7 mm) across the joists at approximately 32 in. (812.8 mm) to 48 in. (1219 mm) on center depending on type of formboard used. The reinforcing mat must then be wire tied to these tee sections.

X1.7.1.2.2 Wiring of formboard to the frame as a means of providing uplift resistance is not permissible.

X1.7.1.3 Heavy concentrated loads, such as water tanks, large fan bases, cooling towers, and flag poles, must not be imposed directly on the poured gypsum concrete roof deck. Details must provide for transmitting such loads directly to the walls, primary framing or structural supports.

X1.7.1.4 The architect or engineer should assign by specification the responsibility for furnishing and installing of roof nailers and for framing at openings and expansion joints, eaves and wall angles, and similar special items.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:41:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X1.7.1.5 It is important that the gypsum concrete roof deck be designed with sufficient slope to provide adequate drainage and eliminate the possibility of free-standing water.

X1.8 Evaluation and Inspection

X1.8.1 Metal framing members should be of the sizes specified and have a factory applied coating to prevent rust.

X1.8.1.1 Welds should meet the requirements of AWS D1.1 and be correctly located and of the size specified.

X1.8.2 Formboards should be of the type, size, and thickness specified and should be free of damage rendering them unfit for their intended use.

X1.8.3 Reinforcement should have main longitudinal strands laid at right angles to subpurlins and near formboard at midspan.

X1.8.3.1 Edges should be butted. Edges should not be lapped unless required for fire rated or horizontal diaphragm construction.

X1.8.3.2 Ends should be lapped a minimum of 4 in. (101.6 mm). At slab edges, the fabric should be folded back to provide greater bond within the slab.

X1.8.4 Top surface of the gypsum concrete slab should be smooth and free of any protrusions.

X2. DESIGN

X2.1 General

X2.1.1 Reinforced gypsum concrete shall be designed to support the anticipated loads and to withstand the forces to which they may be subjected without exceeding the allowable stresses specified in X2.1.1.1. Except as otherwise specified, methods of design shall follow established principles of mechanics and principles of design for reinforced concrete in accordance with ACI 318.X2. The minimum ratio of area of reinforcement to area of portland cement concrete for shrinkage and temperature shall not apply to gypsum concrete.

X2.1.1.1 *Allowable Stresses*—not more than:

Compressive stress in bending	0.25 f_g(Note X2.1)
Axial compressive or bearing stress	0.20 f_g(Note X2.1)
Bond stress (plain reinforced bars)	0.02 f_g(Notes X2.1 and X2.2)
Bond stress (for deformed reinforced bars or electrically welded mesh)	0.03 f_g(Note X2.1)
Shear stress	0.02 f_g(Notes X2.1 and X2.2)

NOTE X2.1—f_g indicates the compressive strength of the gypsum concrete as determined in accordance with the requirements of Specification C 317, Class A.

NOTE X2.2—Gypsum concrete meets the bond and shear requirements of this section when reinforced with steel wire reinforcement conforming to the requirements of 7.4.

X2.1.2 *Minimum Thickness*—Not less than 2 in. (50.8 mm) measured at all points over the top surface of the formboard.

X2.1.3 *Maximum Spans*—Not more than 31 in. (787 mm) between supports when using subpurlins and formboards.

X2.1.4 *Maximum Spacing of Supports*—Not more than 36 in. (914 mm) for gypsum concrete slabs over formboards applied directly to primary framing members.

X2.2 *Seismic and Wind Conditions*—Where the gypsum concrete roof deck is used as a horizontal diaphragm to transmit seismic or wind loads, the subpurlins shall be installed in accordance with 9.1.2.

X2.2.1 *Diaphragm Shear*—Determine shear in poured gypsum concrete diaphragms as follows:

$$Q_e = [0.16\, f_g t C_1 + 1000\, (k_1 d_1 + k_2 d_2)] C_2 C_3 \quad \text{(X2.1)}$$

$$Q_m = [0.0000133\, f_g t C_1 + 0.175\, (k_1 d_1 + k_2 d_2)] C_2 C_3 \quad \text{(X2.2)}$$

where:

- Q_e = allowable shear on diaphragm in lb per linear ft which includes a one-third increase for short-term loading,
- Q_m = allowable shear on diaphragm in kN·m which includes a one-third increase for short-term loading,
- f_g = oven-dry compressive strength of gypsum in lbf/in.^{2}(kPa) as determined by tests conforming to this specification,
- C_1 = 1.0 for Class A gypsum concrete,
- t = thickness of gypsum concrete between subpurlins in inches (mm). For the purpose of computing diaphragm shear values, t shall be not more than 4 in. (101.6 mm),
- k_1 = number of mesh wires per ft (wires per m) passing over subpurlins,
- d_1 = diameter of mesh wires passing over subpurlins in inches (mm) except hexagonal mesh,
- k_2 = number of mesh wires per foot (wires per metre) parallel to subpurlins or 0.7 times the number of hexagonal wires,
- d_2 = diameter in inches of mesh wires parallel to subpurlins or of hexagonal wires,
- C_2 = 1.4 for Class A gypsum concrete using the truss tee and 1.0 for bulb tee, and
- C_3 = 0.85 for perlited gypsum concrete, 1.0 for gypsum concrete made with wood chips or wood shavings.

The allowable shear values are shown in Tables X2.1 and X2.2.

NOTE X2.3—k_1 = X2.5 for 2 in. (50.8 mm) hexagonal mesh woven of No. 19 gage galvanized wire with additional longitudinal No. 16 gage galvanized wires spaced every 3 in. (75.8 mm) across the width of the mesh.

Designation: C 977 – 03

Standard Specification for Quicklime and Hydrated Lime for Soil Stabilization[1]

This standard is issued under the fixed designation C 977; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification pertains to quicklime and hydrated lime, either high calcium, dolomitic, or magnesian lime, for use in stabilization of soils (See Note 2).

NOTE 1—Quicklime and hydrated lime act upon clay soils and may render such soils suitable for highway construction and for other load-bearing applications. In most cases, lime causes finely divided clay particles to agglomerate into coarser particles which improves load-bearing properties and subsequently the lime-treated soil hardens by chemical reaction.

NOTE 2—No attempt is made to present requirements for by-product lime, commercial lime slurry, etc. Specification requirements for these materials could be better determined on a local basis.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime[2]

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products[2]

C 51 Terminology Relating to Lime and Limestone (as Used by the Industry)[2]

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone[2]

D 6276 Test Method for Using pH to Estimate the Soil-Lime Proportion Requirement for Soil Stabilization[3]

3. Chemical Composition

3.1 Unless otherwise specified, for definitions of terms used in this specification, refer to Terminology C 51.

3.2 Quicklime and hydrated lime for soil stabilization shall conform to the following chemical composition:

Calcium and Magnesium Oxides (on a non-volatile basis, minimum %)	90.0
Carbon Dioxide (taken at point of manufacture, maximum %)	5.0
Free Moisture (taken at point of manufacture, maximum %)	2.0

4. Physical Properties

4.1 *Hydrated Lime*, shall have not more than 3 % retained on a No. 30 (590-µm) sieve and not more than 25 % retained on a No. 200 (75-µm) sieve.

4.2 *Quicklime*:

4.2.1 *Particle Size of Quicklime*—Quicklime shall all pass a 1.0-in. (24.4-mm) sieve.

4.2.2 Quicklime for soil stabilization shall have a temperature rise of a minimum of 30°C in 20 min as measured by Test Methods C 110.

4.2.3 *Residue of Quicklime*—Quicklime for soil stabilization shall have not more than 10 % residue as measured by Test Methods C 110.

5. Field Applications

5.1 When quicklimes are used, ensure that thorough mixing of the lime and soil is accomplished and all lime pebbles have been hydrated with additional water and distributed uniformly throughout the soil. There shall be no lime pebbles present before the compaction operation starts. Check by turning soil with a spade at representative intervals and inspect for visible lime pebbles. Care should be exercised on initial dry applications to minimize environmental dusting.

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved May 10, 2003. Published July 2003. Originally approved in 1983. Last previous edition approved in 2002 as C 977 – 02.

www.technobetar.ir

5.2 For hydrated limes, additional water shall be added to the lime-soil mixture to facilitate mixing and uniform distribution of the hydrated lime in the soil layer. There shall be no lime clumps present before the compaction operation starts. Check by turning soil with a spade at representative intervals and inspect for visible lime clumps. Care should be exercised on initial dry applications to minimize environmental dusting.[4]

6. Test Method

6.1 The chemical analysis of quicklime and hydrated lime shall be conducted in accordance with Test Methods C 25.

6.2 The particle size of hydrated lime shall be determined in accordance with the sieve analysis of hydrated lime in Test Methods C 110.

6.3 The appendix of this specification contains a nonmandatory test to approximate the lime-soil proportion for stabilization. A more detailed version of this test appears in Test Method D 6276.

7. Sampling, Inspection, Packaging, and Marking

7.1 The sampling, inspection, rejection, retesting, packaging, and marking shall be done in accordance with Practice C 50.

8. Keywords

8.1 highway construction; hydrated lime; lime treated soils; load-bearing; quicklime; soil; stabilization

APPENDIX

(Nonmandatory Information)

X1. EADES AND GRIM TEST METHOD FOR DETERMINING THE APPROXIMATE LIME/SOIL PROPORTION FOR STABILIZATION

X1.1 This test method usually provides a lime-soil proportion for stabilization. It gives an indication whether the soil in question can be stabilized. For most stabilization work, the results of this test should be verified by performance tests in a soil laboratory.

X1.2 Air dry a sufficient quantity of the soil to be tested and screen through a No. 40 (425-μm) sieve. Store in a closed container to maintain uniform moisture. Weigh to the nearest 0.1 g a series of 20-g samples of soil and place in separate 150-mL plastic containers with water-tight lids.

X1.3 In the case of quicklime, rapidly crush the lime to pass a No. 6 (3.35-mm) sieve.

X1.4 Weigh, to the nearest 0.01 g, a series of quantities of lime equivalent to 2, 3, 4, 5, and 6 % of the soil sample.

X1.5 Add the lime quantity to the soil sample, mark the container with the appropriate percentage, and mix the dry contents thoroughly.

X1.6 Add the 100 mL of 70°F carbon dioxide-free distilled water or, if possible, 70°F actual water to be used on the job to each container of soil and lime. Seal with screw-cap lid and mix the three components by shaking the bottles. Shake each bottle for 30 s every ten min for 1 h. After 1 h, shake vigorously and transfer part of the slurry into a beaker. Measure the pH with a low-sodium error glass electrode (previously standardized to pH 12.45 with an agitated calcium hydroxide slurry). Record the pH reading for each mixture.

X1.7 If the pH readings are 12.40 or higher, the lowest percentage that gives a pH of 12.40 is the % required to stabilize the soil. If the pH readings do not go beyond pH of 12.30 and two percentages give this reading, the lowest % to give a pH of 12.30 is the % required to stabilize the soil. If the highest pH reading is a pH of 12.30 and only the highest percentage lime used gives a pH of 12.30, additional testing is required using higher percentages of lime.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 979 – 05

Standard Specification for Pigments for Integrally Colored Concrete[1]

This standard is issued under the fixed designation C 979; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the basic requirement for colored and white pigments in powder form to be used as admixtures in concrete for the purpose of producing integrally colored concrete. Where the pigments are a constituent of a multicomponent admixture, this specification applies to the pigment constituent of the admixture. This specification is not intended to establish compatibility of pigments with any other concrete admixtures unless they are tested in combination in accordance with 3.7.

1.2 This specification does not include the determination of pigment stability when elevated temperature using low-pressure (atmospheric) or high-pressure (autoclave) steam is used to accelerate the curing process.

1.3 In addition to tests defining the pigments themselves, a limited number of tests on concrete are included to define the effects on setting times, air content, and compressive strength. If more extensive information is required for a particular job, additional testing criteria and procedures should be agreed upon between the seller and user.

1.4 The maximum prescribed dosage rate of a pigment, established in accordance with 3.7, shall be equal to or less than 10 mass % of cement. When a combination of pigments is used to produce the desired color and color intensity, the total dosage rate of all pigments combined shall not exceed any of the individual maximum dosage rates of the component pigments.

1.5 The values stated in SI units are to be regarded as the standard. The inch-pound units in parentheses are for information purposes only.

2. Referenced Documents

D 1208 Test Methods for Common Properties of Certain Pigments

D 1535 Practice for Specifying Color by the Munsell System

G 23 Practice for Operating Light-Exposure Apparatus (Carbon-Arc Type) With and Without Water for Exposure of Nonmetallic Materials[3]

2.2 *ACI Standards:*

211.1 Recommended Practice for Selecting Proportions for Normal and Heavyweight Concrete[4]

3. General Requirements

3.1 *Water Wettability*—The pigment shall be water wettable when tested in accordance with 7.1.

3.2 *Alkali Resistance*—The pigment treated with sodium hydroxide shall not show any significant (Note 1) change of color when tested in accordance with 7.2.

3.3 *Total Sulfates*—Calculated as SO_3, the sulfates shall not exceed 5.0 mass % of the original pigment sample when tested in accordance with 7.3.

3.4 *Water Solubility*—The total matter soluble in water shall not exceed 2.0 mass % of the original pigment sample when tested in accordance with 7.4.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

Current edition approved Jan. 1, 2005. Published January 2005. Originally approved in 1982. Last previous edition approved in 2004 as C 979–04.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

3.5 *Atmospheric Curing Stability*—The magnitude of color differences between pigmented concrete specimens cured in dry air and those cured at high relative humidity when tested in accordance with 7.5 shall not be greater than the magnitude of the color difference between two unpigmented specimens cured under the same conditions.

3.6 *Light Resistance*—The exposed portions of the specimens shall show no significant differences (Note 1) in color from the unexposed portions when tested in accordance with 7.6. While a pigment that fails this test shall not be considered light resistant, a pigment that passes this test may still be subject to fading when exposed to natural weathering conditions.

NOTE 1—A significant difference is defined as one that is readily perceptible by visual observation without close examination. Lighting and viewing conditions as described in Practice D 1535, 6.1, may be used.

3.7 *Effects on Concrete*:

3.7.1 When compared with the control mixture, the concrete that is pigmented at the maximum prescribed dosage rate shall have a 28-day compressive strength of not less than 90 % and a water-cement ratio of not greater than 110 % of that of the control mixture when prepared and tested in accordance with 7.7 (Note 2).

3.7.2 The pigment, when added to a concrete mixture at the maximum prescribed dosage rate, shall neither accelerate the initial or final set by more than 1 h nor retard the initial or final set by more than 1½ h, as compared to the uncolored concrete control mixture when tested in accordance with 7.7 (Note 2).

3.7.3 Using the same quantity of air-entraining admixture, the pigments, when added to a concrete mixture at the maximum prescribed dosage rate, shall not change the air content by more than 1.0 %, as compared to the uncolored control mixture when tested in accordance with 7.7.

NOTE 2—These values include allowance for normal variations in test results. The object of the 90 % compressive-strength requirement is to require a level of performance of the pigmented concrete comparable to that of the reference concrete when tested in accordance with 7.7.

3.8 *Color Match of Shipment*—The color produced by the shipment of pigment shall not be significantly different (Note 1) from the color produced by the standard supplied by the pigment manufacturer when samples of both the shipment and the standard are tested in accordance with 7.8. New concrete specimens containing the standard sample of the particular pigment must be prepared whenever a new shipment is evaluated. This is necessary to eliminate color variations caused by any of the other mortar ingredients, specimen preparation, or curing.

4. Rejection

4.1 The purchaser has the right to reject material that does not conform to the requirements of this specification. Rejection shall be reported to the producer or supplier in writing.

4.2 Individual packages or containers varying more than 5 % from the stated mass may be rejected. If the average weight of 50 packages taken at random is less than that stated, the entire shipment may be rejected.

5. Packaging

5.1 Packages or containers shall be clearly marked as to color designation and the net mass.

5.2 The package or container for the pigment, only when so designated by the manufacturer, shall be added to the concrete batch, provided that it is composed of disintegrating paper or soluble material which, when tested as a unit (pigment and packaging), conforms to all requirements of this specification.

6. Materials for Tests

6.1 *Cement*—For the atmospheric curing stability and the light resistance tests, using white cement is suggested. The cement used in all other tests shall be either a Type I or Type II cement conforming to Specification C 150 or the cement proposed for specific work.

6.2 *Aggregates*—The aggregates used in all tests shall conform to Specification C 33 or shall be the aggregates proposed for specific work. For the atmospheric curing stability and the light resistance tests, clean silica sand shall be used. For both the reference and the pigmented mixtures, the aggregate grading shall be controlled by determining the mass of separate fractions.

6.3 *Admixtures*—If any of the test mixtures contain any admixtures in addition to pigment other than an air-entraining admixture complying with Specification C 260, the pigment shall be considered to comply with this specification only when used in conjunction with such other admixture(s).

7. Test Methods

7.1 *Water Wettability*—Add 10.0 g of the pigment to 150 mL of deionized water in a 250-mL beaker. If the pigment does not readily mix with the water when stirred with a spatula, but instead a substantial portion of the pigment floats on the surface of the water, the pigment is repellent and not water wettable.

7.2 *Alkali Resistance*—Add two 10.0 g-portions of the pigment to separate 250-mL beakers, each containing 150 mL of deionized water. Stir until thoroughly mixed. Add 10 mL of 10 mass % sodium hydroxide solution to one beaker, and stir thoroughly once more. Let the slurries stand 1 h, then remix and filter on separate Buchner funnels. Wash the filter cake with three replacement washes of hot deionized water. Dry the cake on the filter paper in an oven at 110 ± 3 °C (230 ± 5 °F) for 4 ± 0.5 h. Remove from the oven, cool, and crush the pigment into a fine powder in a mortar. Make two small adjacent piles of the pigment powders and press them flat with a spatula. Compare the color of the control and treated pigment powders.

7.3 *Percentage of SO_3*—Perform the sulfates soluble in hydrochloric acid test and determine the percentage in accordance with Test Methods D 50.

7.4 *Water Solubility*—Perform the matter soluble in water test in accordance with Test Methods D 1208.

7.5 *Atmospheric Curing Stability*—The composition and method of preparation of the test specimens shall be in accordance with Annex A1. Pigments shall be tested at both ½ % and 6 % levels (based on the cement mass). Two sets of specimens (designated as control specimens and test specimens) shall be prepared at the same time under identical

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:42:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

conditions except for curing. Each set shall consist of two pigmented mortar specimens, one at each of the two levels of pigmentation, and one unpigmented specimen. If, for a particular pigment being tested, the specimens that contain the pigment at a dosage rate of ½ % of the cement mass do not provide a significant difference (Note 1) in color when compared to the corresponding unpigmented specimen, the pigment dosage rate shall be increased until but not beyond the rate at which the difference in color becomes significant. In addition, tests using the higher dosage rate of 6 % of the cement mass shall continue to be performed as specified. Compare for color the specimens that were cured under different conditions. For evaluating the color stability of the pigment tested, also compare the uncolored mortar specimens for color variations. Differences in the curing conditions or efflorescence, or both, can affect the color shade of any finished mortar or concrete, either colored or uncolored.

7.6 *Light Resistance*—The test shall be conducted in a Type E or EH exposure apparatus as described in Practice G 23. Type EH apparatus shall be operated without automatic humidity control. The exposure apparatus shall be operated in accordance with Practice G 23, except that no water spray or dark cycles shall be employed. The black panel temperature shall be 54± 3 °C (130 ± 5 °F). The composition and method of preparation of the test specimens shall be in accordance with Annex I. Pigments shall be tested at both ½ % (7.5) and 6 % levels (based on the cement mass). Half of each specimen shall be masked from light exposure by an aluminum foil covering. The other half of each specimen shall be exposed to light for 500 h after which time its color shall be compared to the unexposed half (3.6).

7.7 *Effects on Concrete*:

7.7.1 *Preparation of Mixtures*—Prepare concrete mixtures both with and without the pigment under test. Refer herein to the concrete mixture without the pigment as the reference or control mixture. The control mixture and the pigmented mixture shall be of the same composition and batched in the same proportions except that the pigmented mixture shall include the pigment addition at the maximum prescribed dosage rate (1.4), and the water content of each mixture shall be adjusted to produce a slump of 100 ± 13 mm (4 ± ½ in.), as determined by Test Method C 143/C 143M. Add the pigment to the first increment of coarse aggregate and water. The mixture shall be proportioned using ACI Practice 211.1. The cement content shall be either the cement content for specific work or 307 ± 3 kg/m^3(517 ± 5 lb/yd^3). If an air-entraining admixture complying with Specification C 260 is used, its dosage rate shall be the same for both the pigmented and the control mixtures.

7.7.2 *Making and Curing*—Specimens made from concrete with and without the pigment under test shall be molded and cured in accordance with Method C 192/C 192M. Three or more compression specimens shall be prepared for each mixture.

7.7.3 *Time of Setting*—Test Method C 403/C 403M shall be used. The temperature of each of the ingredients of the concrete mixtures, just prior to mixing, and the temperature at which the time of setting specimens are stored during the test period shall be 23.0± 2 °C (73 ± 3 °F).

7.7.4 *Air Content*—Test Methods C 173 or C 231 shall be used.

7.7.5 *Compressive Strength*—Test Method C 39 shall be used. Specimens shall be tested at 28 days and optionally also at 7 days. The 28-day compressive strength of the concrete containing the pigment under test shall be calculated as a percentage of the 28-day compressive strength of the reference concrete as follows: The average 28-day compressive strength of the specimens made from the concrete containing the pigment under test shall be divided by the average 28-day compressive strength of the specimens made from the reference concrete at the same age, and the quotient shall be multiplied by 100.

7.8 *Color Match of Shipment*—Samples of both the shipment of pigment and the standard supplied by the pigment manufacturer shall be prepared in concrete at both the ½ % (7.5) and 6 % levels (based on the cement mass) or at another dosage rate(s) agreed upon between the purchaser and seller. The composition and methods of preparation and color comparison of the specimens should be agreed upon between the purchaser and seller. A suggested method of specimen preparation is given in Annex I. Compare the colors of the concrete specimens. Do not compare the colors of the pigment powders as a test for color control.

8. Report

8.1 The report shall include the following:

8.1.1 The manufacturer, designation, and type of pigment,

8.1.2 Maximum prescribed dosage rate of pigment,

8.1.3 Description of additional admixtures that must be used in the concrete,

8.1.4 Water wettability of pigment,

8.1.5 Resistance to color change when treated with sodium hydroxide,

8.1.6 Percent total sulfates calculated as SO_3,

8.1.7 Percent total water-soluble matter contained in pigment,

8.1.8 Resistance to color change when concrete is cured in a high-relative-humidity atmosphere,

8.1.9 Light resistance of pigment,

8.1.10 Cement content of pigmented and control mixtures,

8.1.11 Water-cement ratios of pigmented and control mixtures and the relative percentage change due to the use of pigment,

8.1.12 Compressive strength (28-day) of pigmented concrete and control and the relative percentage change resulting from the use of pigment,

8.1.13 Initial and final setting times of pigmented and control mixtures and the changes resulting from the use of pigment,

8.1.14 Air contents of pigmented and control mixtures and the change resulting from the use of pigment, and

8.1.15 When individual shipments are tested, a color comparison of each shipment and control.

9. Keywords

9.1 color match; integrally colored concrete; light resistance; pigment

ANNEX

(Mandatory Information)

A1. METHOD FOR PREPARING MORTAR TEST SPECIMENS

A1.1 *Apparatus*:

A1.1.1 *Wooden Mold*, to form specimens approximately 230 mm (9 in.) by 76 mm (3 in.) by 13 mm (½ in.) (Note A1.1). The mold shall be coated with a non-staining coating to prevent water absorption. The mold should be held together with C-clamps for easy removal.

NOTE A1.1—The dimensions may be modified, as long as finished specimen strength is maintained, to suit the individual weatherometer used for the light resistance test.

A1.1.2 *Wooden Tamping Block*, with a working surface area of approximately 50 mm (2 in.) by 100 mm (4 in.)

A1.1.3 *Metal or Ceramic Mixing Vessel*.

A1.1.4 *Stirring Device*, such as a large spoon or spatula.

A1.1.5 *Heated Drying Cabinet*.

A1.2 *Material*:

A1.2.1 *Clean Silica Sand*,

A1.2.2 *White Cement* (Note A1.2), and

A1.2.3 *Pigment to be Tested*.

NOTE A1.2—White cement is suggested to give maximum color discrimination in judging the pigment, but other cement may be used that is representative of the intended use.

A1.3 *Formulation*:

A1.3.1 Prepare the mortar mixtures at both ½ % (7.5) and 6 % pigment levels (based on the cement mass) in accordance with formulas below:

	Control[A]	½ %	6 %
Silica sand	480.0 g	480.0 g	480.0 g
White cement	160.0 g	159.2 g	151.0 g
Pigment	0.0 g	0.8 g	9.0 g
Water[B]	72 mL	72 mL	72 mL

[A] Control specimens are required for the atmospheric curing stability test but not for the light resistance test.

[B] In order to eliminate fluctuations in the moisture content (water/cement ratio) of the fresh and cured mortar specimens, it is advisable to dry the sand at 105 ± 3 °C (221 ± 5 °F) in an oven to constant weight. The amount of water should be adjusted such that a fairly dry, non-bleeding, mortar mix is obtained. However, the water content for all batches of the same mortar mix shall be identical.

A1.4 *Procedure*:

A1.4.1 In sequence, add the sand, cement, and pigment to the mixing vessel and mix thoroughly with the stirring device until the blend is uniform. Add the water and continue to mix until all the ingredients are thoroughly wetted.

A1.4.2 Place the mold on a glass slab, a steel plate, or any other flat, waterproof surface. Slightly overfill the mold with the mortar mixture. Using the wooden block, tamp the mixture firmly and evenly and with a screed, level it to the top of the mold.

A1.4.3 As soon as the mortar has set, loosen the C-clamps and carefully remove the sides of the mold.

A1.4.4 Place the mortar specimen on a table using spacers to permit ambient air to circulate around it, and let it dry in the air at room temperature for 12–24 h.

A1.4.5 Continue the curing process as follows: Transfer each specimen for the light resistance test and each control specimen for the atmospheric curing test to the heated cabinet, and finish curing at 49 ± 3 °C (120 ± 5 °F) for 24 h at 20 ± 10 % relative humidity. Transfer each test specimen for the atmospheric curing stability test to a 100 % relative humidity atmosphere at room temperature (Note A1.3) for at least 20 days, and then dry in the heated cabinet at 49 ± 3 °C (120 ± 5 °F) for 24 h at 20 ± 10 % relative humidity.

NOTE A1.3—A sealed plastic bag can be used for this purpose. Small amounts of water may be injected periodically into the bag to maintain a saturated atmosphere.

APPENDIX

(Nonmandatory Information)

X1. TYPICAL PIGMENT TYPES MANUFACTURED FOR COLORING CONCRETE

X1.1 Typical pigment types manufactured for coloring concrete are as follows:

X1.1.1 Synthetic iron oxides, yellows, red, browns, and black,

X1.1.2 Some natural iron oxides,

X1.1.3 Chromium oxide,

X1.1.4 Cobalt blue,

X1.1.5 Titanium dioxide, and

X1.1.6 Carbon black (concrete grade).

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 989 – 09a

Standard Specification for Slag Cement for Use in Concrete and Mortars[1]

This standard is issued under the fixed designation C 989; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers three strength grades of slag cement for use as a cementitious material in concrete and mortar.

NOTE 1—The material described in this specification may be used for blending with portland cement to produce a cement meeting the requirements of Specification C 595 or as a separate ingredient in concrete or mortar mixtures. The material may also be useful in a variety of special grouts and mortars, and when used with an appropriate activator, as the principal cementitious material in some applications.

NOTE 2—Information on technical aspects of the use of the material described in this specification is contained in Appendix X1, Appendix X2, and Appendix X3. More detailed information on that subject is contained in ACI 233R-03, formerly ACI 226.1R.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 The following safety hazards caveat pertains only to the test methods described in this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this standard.

2. Referenced Documents

C 595 Specification for Blended Hydraulic Cements

C 1012 Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution

C 1038 Test Method for Expansion of Hydraulic Cement Mortar Bars Stored in Water

D 3665 Practice for Random Sampling of Construction Materials

2.2 *American Concrete Institute Reports:*

226.1R Ground Granulated Blast-Furnace Slag as a Cementitious Constituent in Concrete[3]

233R-03 Slag Cement in Concrete and Mortar[3]

3. Terminology

3.1 Definition:

3.1.1 *blast-furnace slag*—the nonmetallic product, consisting essentially of silicates and aluminosilicates of calcium and other bases that is developed in a molten condition simultaneously with iron in a blast furnace (see Terminology C 125).

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *granulated blast-furnace slag*—the glassy granular material formed when molten blast-furnace slag is rapidly

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.27 on Ground Slag.

Current edition approved July 1, 2009. Published August 2009. Originally approved in 1982. Last previous edition approved in 2009 as C 989 – 09.

www.technobetar.ir

chilled as by immersion in water (see Terminology C 125), with or without compositional adjustments made while the blast-furnace slag is molten.

3.2.2 *slag cement*—granulated blast-furnace slag, as defined and described in 3.1.1 and 3.2.1, and ground to cement fineness with or without additions meeting the requirements of the section on additions.

4. Classification

4.1 Slag cement is classified by performance in the slag activity test in three grades: Grade 80, Grade 100, and Grade 120 (see Table 1).

5. Ordering Information

5.1 The purchaser shall specify the grade of slag cement desired and the optional chemical or physical data to be reported.

6. Additions

6.1 Slag cement covered by this specification shall contain no additions except as follows:

6.1.1 It is permissible to add calcium sulfate to slag cement provided it has been demonstrated by Test Method C 1038 that a test mixture will not develop expansion in water exceeding 0.020 % at 14 days. In the test mixture, 50 % of the mass of portland cement shall be replaced by an equal mass of slag cement. The portland cement used in the test mixture shall meet the requirements of Specification C 150. When the manufacturer supplies cement under this provision, upon request, supporting data shall be supplied to the purchaser.

6.1.2 When processing additions are used in the manufacture of slag cement, the maximum amount used shall comply with the requirements of Specification C 465 when tested using a 50-50 blend by mass and the portland cement.

7. Chemical Composition

7.1 Slag cement shall conform to the chemical requirements prescribed in Table 2.

TABLE 1 Physical Requirements

Item		
Fineness:		
amount retained when wet screened on a 45-μm (No. 325) sieve, max %		20
Specific surface by air permeability, Test Methods C 204 shall be determined and reported although no limits are required.		...
Air Content of Slag Mortar, max %		12
	Average of Last Five Consecutive Samples	Any Individual Sample
Slag Activity Index, min, %		
7-Day Index

Grade 80	75	70
Grade 100	95	90
Grade 120	115	110

TABLE 2 Chemical Requirements

Sulfide sulfur (S), max, %	2.5

8. Physical Properties

8.1 Slag cement shall conform to the physical requirements of Table 1.

9. Sampling

9.1 The following sampling and testing procedures shall be used by the purchaser to verify compliance with this specification.

NOTE 3—Sulfur in granulated blast-furnace slag is present predominantly as sulfide sulfur. In most cases, instrumental analyses, such as x-ray fluorescence, cannot differentiate sulfide sulfur from sulfate. Determine and report the sulfide sulfur content separately, and do not include it in the SO_3 calculations.

9.2 Take random grab samples either from a delivery unit or at some point in the loading or unloading process so that no sample represents more than 115 Mg (125 tons) (Note 4). If samples are taken from rail cars or trucks, take at least two separate 2-kg (5-lb) portions and thoroughly mix them to obtain a test sample (Note 5). Sample by removing approximately a 300-mm (12-in.) layer of slag. Make a hole before obtaining a sample to avoid dust collector material that has discharged into the delivery unit after the predominant slag flow has ceased. Sample at a rate of one sample per month or one sample for each 2300 Mg (2500 tons) of shipments, whichever is more frequent.

NOTE 4—Standard statistical procedures are recommended for ensuring that samples are selected by a random procedure; see Practice D 3665. These procedures can be used to select the days within a month or within a week that samples will be taken. The delivery unit or time of day then should be chosen randomly.

NOTE 5—The quantity of sample specified is more than adequate for the testing required. A 2-kg (5-lb) portion should be retained in a sealed container for retesting if that is considered necessary to verify compliance.

10. Test Methods

10.1 *Slag-Activity Tests with Portland Cement*:

10.1.1 Slag activity shall be evaluated by determining the compressive strength of both portland-cement mortars and corresponding mortars made with the same mass of 50-50 mass combinations of slag cement and portland cement. Appendix X1 discusses the effects of cement, temperature, and amount of slag cement used on performance with portland cement.

10.1.2 *Reference Cement*—The portland cement used in the slag activity tests shall comply with the standard chemical and physical requirements of Specification C 150, Type 1 or Type II, and with the additional requirements of total alkali content and compressive strength limits as shown in Table 3. Sufficient cement shall be reserved to avoid changing reference cement more often than every two months. After the initial testing to determine compliance with the compressive strength requirement of Table 3, the reference cement shall be re-qualified at least every six months.

NOTE 6—Different reference cements may produce different Slag Activity Index results.

www.technobetar.ir

TABLE 3 Alkali and Strength Limits of Reference Cement for Slag Activity Tests

Total Alkalies ($Na_2O + 0.658\ K_2O$)	min %	0.60
	max %	0.90
Compressive Strength, MPa, min, 28 days[A]		35 (5000 psi)

[A]The minimum strength limit is based solely on the strength of the Test Method C 109/C 109M mortar cubes, as required in Specification C 150, regardless of the strength of the flow-controlled Specification C 989 mortar cubes.

10.1.3 *Preparation of Specimens*—Prepare mortars in accordance with Test Method C 109/C 109M, except that sufficient water shall be used in each batch to produce a flow of 110± 5 %. The proportions shall be as follows:

Reference Cement Mortar:
500 g portland cement
1375 g graded standard sand

Slag Cement-Reference Cement Mortar:
250 g portland cement
250 g slag cement
1375 g graded standard sand

10.1.3.1 Mix a reference cement batch each day that a slag cement-reference cement batch is mixed until at least five batches have been mixed with the reference cement. Thereafter, reference cement batches need not be mixed more often than once a week whenever slag cement is being produced or shipped.

10.1.4 *Test Ages*—Determine the compressive strength of mortar specimens at 7 and 28 days age in accordance with Test Method C 109/C 109M.

10.1.5 *Calculation*—Calculate the slag activity index to the nearest percent for both 7 days and 28 days as follows:

$$\text{Slag activity index, \%} = (SP/P) \times 100 \quad (1)$$

SP = average compressive strength of slag cement-reference cement mortar cubes at designated ages, MPa (psi), and

P = average compressive strength of reference cement mortar cubes at designated age, MPa (psi).

The reference cement-mortar strength used to calculate a slag activity index shall, when a reference cement mortar is mixed on the same day as a slag cement-reference cement mortar, be the result for that batch. Otherwise, the average of tests of the five most recent reference cement-mortar batches shall be used.

10.1.6 *Report*—The report should include the following:

10.1.6.1 Slag activity index, %,

10.1.6.2 Compressive strength at 7 and 28 days, of slag cement-reference cement mortar,

10.1.6.3 Compressive strength at 7 and 28 days, of portland cement mortar,

10.1.6.4 Total alkalies of the reference cement ($Na_2O + 0.658\ K_2O$),

10.1.6.5 Fineness of reference cement, and

10.1.6.6 Potential compound composition of the reference portland cement.

10.1.7 *Precision*—The following precision statements are applicable when the slag activity index with portland cement is based on results of tests of two cubes from single batches of reference cement and 50-50 slag cement-reference cement mortars mixed on the same day. They are applicable to the slag activity index determined at 7 or 28 days.

10.1.7.1 The single-laboratory coefficient of variation has been found to be 4.1 %. Therefore, the slag activity indices of properly conducted tests based on single batches of mortar mixed on the same day should not differ by more than 11.6 % of their average.

10.1.7.2 The multilaboratory coefficient of variation has been found to be 5.7 %. Therefore, the slag activity indices of properly conducted tests of single batches by different laboratories should not differ by more than 16.1 %.

10.2 *Slag Cement Density*—Determine in accordance with Test Method C 188.

10.3 *Amount of Slag Cement Retained on a 45-μm (No. 325) Sieve*—Determine in accordance with Test Method C 430.

10.4 *Slag Cement Fineness by Air Permeability*—Determine in accordance with Test Methods C 204.

10.5 *Sulfate Ion in Slag Cement Reported as SO_3*—Determine as sulfur trioxide in accordance with Test Methods C 114, except the sample need not be completely decomposed by acid.

10.6 *Sulfide Sulfur in Slag Cement*—Determine in accordance with Test Methods C 114.

10.7 *Chloride Content of Slag*—Determine in accordance with Test Methods C 114.

10.8 *Air Content of Slag Cement Mortar*—Determine in accordance with Test Method C 185, except use 350 g of slag cement instead of cement in the standard mortar batch. Calculate using the appropriate density of the slag cement.

11. Rejection and Rehearing

11.1 The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the tests, the producer or supplier is not prohibited from making a claim for retesting.

NOTE 7—In the event of a Slag Activity Index dispute, the purchaser should request a sample of the producer's reference cement for retest.

12. Certification

12.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been tested as directed in this specification and the specified requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

12.2 When specified in the purchase order or contract, test data shall be furnished on the chloride ion content of the slag cement.

13. Manufacturer's Statement

13.1 At the request of the purchaser, the manufacturer shall state in writing the nature, amount, and identity of any processing or other additions made to the slag cement.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

14. Package Marking and Shipping Information

14.1 When the slag cement is delivered in packages, the classification of the slag cement, the name and brand of the manufacturer, and the weight of the slag cement contained therein shall be plainly marked on each package. Similar information shall be provided in the shipping invoices accompanying the shipment of packaged or bulk slag cement. All packages shall be in good condition at the time of inspection.

15. Storage

15.1 The slag cement shall be stored to permit easy access for proper inspection and identification of each shipment and in a suitable weather-tight building that will protect the slag cement from dampness and minimize quality deterioration.

16. Keywords

16.1 blast furnace slag; granulated blast furnace slag; slag activity index; slag cement

APPENDIXES

(Nonmandatory Information)

X1. CONTRIBUTION OF SLAG CEMENT TO CONCRETE STRENGTH

X1.1 When slag cement is used in concrete with portland cement, the levels and rate of strength development will depend importantly on the properties of the slag cement, the properties of the portland cement, the relative and total amounts of slag cement and portland cement, and the concrete curing temperatures.

X1.2 The reference cement used to test slag activity in this specification must have a minimum 28-day strength of 35 MPa (5000 psi) and an alkali content between 0.6 and 0.9 %. Performance of the slag cement with other portland cements may be significantly different. The slag-activity test also can be used to evaluate relative hydraulicity of different slag cements with a specific cement or of different shipments of the same slag cement. Such comparisons will be improved if all tests are made with a single sample of cement. To properly classify a slag cement, the reference portland cement must conform to the limits on strength and alkali content. Even within these limits performance will depend to some extent on the particular cement used. The percentages developed in the slag activity test do not provide quantitative predictions of strength performance in concrete. Performance in concrete will depend on a large number of factors including the properties and proportions of the slag cement, the portland cement, and other concrete ingredients, concrete temperatures, and curing conditions; and other conditions.

X1.3 Concrete strengths at 1, 3, and even 7 days may tend to be lower using slag cement-portland cement combinations, particularly at low temperatures or at high slag cement percentages. Concrete proportions will need to be established considering the importance of early strengths, the curing temperatures involved and the properties of the slag cement, the portland cement, and other concrete materials. Generally a higher numerical grade of slag cement can be used in larger amounts and will provide improved early strength performance; however, tests must be made using job materials under job conditions.

X2. SULFATE RESISTANCE

X2.1 *General*—Concrete manufactured with high percentages of slag cement is generally considered to have greater resistance to attack by sulfates than do portland cements, based largely upon comparisons of these mixtures with similar mixtures containing ordinary (Type I) portlands. These high volume slag cement mixtures (containing 60 % or more slag) are widely used for sulfate and sea-water resistant concretes throughout the world.

X2.2 *Sulfate Resistance of Portland Cements*—The sulfate resistance of concrete is dependent upon a number of factors, including mortar permeability and the type and concentration of the sulfate solutions involved. Others, directly related to the cement characteristics, include calcium hydroxide concentration and the tricalcium aluminate (C_3A) content. Specification C 150 provides limits on the C_3A for sulfate-resistant cements. Specification C 150 Type V requirements provide for a limit on the tetracalcium aluminoferrite (C_4AF) plus twice the C_3A. The C150 table of Optional Physical Requirements includes a maximum limit on expansion of Type V cement in mortar bars when tested by Test Method C 452. When this option is selected, the standard limits on tricalcium aluminate and on tetracalcium aluminoferrite plus twice the tricalcium aluminate do not apply. Test Method C 1012 can be used to measure the effects of exposure to external sulfate environments on mortar or concrete.

X2.3 *Effect of Slag Cement on Sulfate Resistance*—The use of slag cement will decrease the C_3A content of the cementing materials and decrease the permeability and calcium hydroxide

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

content of the mortar or concrete. Tests have shown that the alumina content of the slag cement also influences sulfate resistance,[4,5] and that high alumina content can have a detrimental influence at low slag cement-replacement percentages. The data from these studies of laboratory exposure of mortars to sodium and magnesium sulfate solutions provide the following general conclusions.

X2.3.1 The combinations of slag cement and portland cement, in which the slag cement content was greater than 60 to 65 %, had high sulfate resistance, always better than the portland cement alone, irrespective of the Al_2O_3 content of the slag cement. The improvement in sulfate resistance was greatest for the cements with the higher C_3A contents.

X2.3.2 The low alumina (11 %) slag cement tested increased the sulfate resistance independently of the C_3A content of the cement. To obtain adequate sulfate resistance, higher slag cement percentages were necessary with the higher C_3A cements.

X2.3.3 The high alumina (18 %) slag cement tested, adversely affected the sulfate resistance of portland cements when blended in low percentages (50 % or less). Some tests indicated rapid decreases in resistance for cements in the 8 and 11 % C_3A ranges with slag cement percentages as low as 20 % or less in the blends.

X2.3.4 Tests on slag cement (7 to 8 % alumina) in Ontario[6] have shown that a 50:50 combination by mass with Type I portland cement (having up to about 12 % C_3A) is equivalent in sulfate resistance to the Type V cement used in that study.

X2.4 *Tests for Sulfate Resistance*—When the relative sulfate resistance of a specific cement-slag cement combination is desired, tests should be conducted in accordance with Test Method C 1012.[7] Studies by Subcommittee C01.29 on sulfate resistance using Test Method C 1012, as reported by Patzias [8], recommended the following limits for expansion of portland cement and slag cement combinations at six months of exposure:

Moderate sulfate resistance — 0.10 % max
High sulfate resistance — 0.05 % max

X3. EFFECTIVENESS OF SLAG CEMENT IN PREVENTING EXCESSIVE EXPANSION OF CONCRETE DUE TO ALKALI-AGGREGATE REACTION

X3.1 Tests for effectiveness of slag cement in preventing excessive expansion due to alkali-aggregate reaction are not considered necessary unless the slag cement is to be used: (*a*) with a high-alkali portland cement ($Na_2O + 0.658\ K_20 \geq 0.6$ %) or the concrete contains added water-soluble alkalies (added as an activator to improve early strength); and (*b*) with an aggregate that is regarded as deleteriously reactive with alkalies.

X3.2 It should be expected that the effectiveness of the slag cement will depend upon the amount used and the reactivity of the slag cement itself. Data suggest that slag cements used as 40 % or more of the cementitious material will generally prevent excessive expansion with cements having alkali contents up to 1.0 %; however, definitive data are not available, and tests must be made in accordance with Test Method C 441.

X3.3 When the job cement and proportions of cement to slag cement are known, test mortars should be proportioned in accordance with the job mixture requirements of Test Method C 441, and the average expansion of mortar bars at 14 days should not exceed 0.020 %.

X3.4 When the job cement and proportions of slag cement to cement are not known, tests can be made for the reduction in mortar expansion in accordance with Test Method C 441. To be considered effective the slag cement must reduce 14-day expansions of mixtures made with the required high-alkali cement by 75 %. The slag cement should be considered effective only when the ratio of slag cement to cement equals or exceeds that found effective in the tests.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 989 – 09, that may impact the use of this specification. (Approved July 1, 2009)

(*1*) Revised 6.1.1 and Table 2.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 989 – 08, that may impact the use of this specification. (Approved January 15, 2009)

(*1*) Revised terminology from "ground granulated blast furnace slag" to "slag cement" in the title of the standard and throughout the text.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 989 – 06, that may impact the use of this specification. (Approved December 1, 2008)

(*1*) Revised 10.1.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1002 – 07

Standard Specification for Steel Self-Piercing Tapping Screws for the Application of Gypsum Panel Products or Metal Plaster Bases to Wood Studs or Steel Studs[1]

This standard is issued under the fixed designation C 1002; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers steel self-piercing tapping screws for use in fastening gypsum panel products and metal plaster bases to cold-formed steel studs less than 0.033 in. (0.84 mm) in thickness and wood members and for fastening gypsum panel products to gypsum board.

1.2 This specification also covers test methods for determining performance requirements and physical properties.

1.3 The values stated in inch-pound units are to be regarded as the standard. The SI (metric) values given in parentheses are approximate and are for information only.

1.4 The following safety hazards caveat pertains only to the test methods described in this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

A 548 Specification for Steel Wire, Carbon, Cold-Heading Quality for Tapping or Sheet Metal Screws[3]

A 568/A 568M Specification for Steel, Sheet, Carbon, Structural, and High-Strength, Low-Alloy, Hot-Rolled and Cold-Rolled, General Requirements for

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 1396/C 1396M Specification for Gypsum Board

C 645 Specification for Nonstructural Steel Framing Members

C 847 Specification for Metal Lath

3. Terminology

3.1 *Definitions:* For definitions relating to gypsum and related building materials and systems, see Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *self-piercing*, *v*—the ability to penetrate without benefit of a pre-drilled hole with sharp-point angles of not more than 30°.

3.2.2 *spin-out*, *v*—for a screw, the continued rotation of a screw without further penetration into the substrate.

4. Classification

4.1 Steel screws covered by this specification are of four types of thread configurations:

4.1.1 *Type G*, course-pitch high-thread self-piercing screws for fastening gypsum board to gypsum board.

4.1.2 *Type S*, fine-thread screw for fastening gypsum board to cold formed steel members.

4.1.3 *Type W*, course-thread screw for fastening gypsum board to wood members.

4.1.4 *Type A*, course-pitch tapping screw thread for fastening metal plaster bases to wood or cold-formed steel.

5. Materials

5.1 *Steel Wire*, for manufacturing screws, Specification A 548, Grades 1013 to 1022 for Type G and Type W screws.

5.2 *Steel Wire*, for manufacturing screws, Specification A 568/A 568M, Grades 1018 to 1022 for Type S and Type A screws.

6. Physical Properties

6.1 *Hardness*:

6.1.1 The surface of Type S, Type W, and Type A screws shall be case hardened to a depth of not less than 0.002 in. (0.05 mm) with case hardness not less than 45 HRC.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved Aug. 1, 2007. Published August 2007. Originally approved in 1983. Last previous edition approved in 2004 as C 1002 – 04.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

[3] Withdrawn

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

6.1.2 The surface of Type G screws is not required to be case hardened.

6.2 *Ductility*—The screws shall have sufficient ductility to be able to withstand a 10° bend without visible signs of fracture when tested as specified in 12.6.7.

7. Performance Requirements

7.1 *Type G Screws*:

7.1.1 Screws shall be able to self-pierce and drive into gypsum panel products.

7.1.2 Screw threads shall be adequate to pull the head of the screw below the surface of the gypsum panel product when tested as specified in 12.6.2.

7.2 *Type S Screws*:

7.2.1 *General*—Screws shall be able to self-pierce and drive into cold-formed steel members in less than 2 s, when tested as specified in 12.6.3.1.

7.2.2 *Screws for Fastening Gypsum Panel Products*—Screw threads shall be adequate to pull the head of the screw below the surface of the gypsum panel product, without spin-out, when tested as specified in 12.6.3.1.

7.3 *Type W Screws*:

7.3.1 *General*—Screw threads shall be able to self-pierce and drive into wood members.

7.3.2 *Screws for Fastening Gypsum Panel Products*—Screw threads shall be adequate to pull the head of the screw below the surface of the gypsum panel product, without spin-out when tested as specified in 12.6.4.1.

7.4 *Type A Screws*:

7.4.1 *General*—Screw shall be able to pierce and drive into wood or cold-formed steel members.

7.4.2 *Screws for Fastening Metal Plaster Bases*—Screw threads shall be adequate to pull a metal plaster base tightly enough against the face of a wood or steel stud, without spin-out, so that when subjected to a steady pull, the plaster base will tear before slipping out from under the screw head, when tested in accordance with 12.6.5.1 or 12.6.5.2.

8. Dimensions and Permissible Variations

8.1 *Head Diameter*:

8.1.1 *General*—Heads shall be permitted to be out of round not more than 0.02 in. (0.51 mm).

8.1.2 *Screws for Fastening Gypsum Board*—Not less than 0.315 in. (8 mm).

8.1.3 *Screws for Fastening Metal Plaster Bases*—Not less than 0.437 in. (11.1 mm).

8.2 *Head Contour*:

8.2.1 *Screws for Fastening Gypsum Panel Products*—The top of the head shall be flat. The outer flange thickness shall be 0.025 ± 0.005 in. (0.64 ± 0.13 mm). The contour beneath the flange head shall be such that the screw head shall be able to be driven so that the head of the screw rests immediately below the surface of the gypsum panel product.

8.2.2 *Screws for Fastening Metal Plaster Bases*—The top of the screw shall be either flat or contoured. The underside of the head shall be flat or near flat. The threads shall extend to the underside of the head.

8.3 *Driving Recess*:

8.3.1 *Screws for Fastening Gypsum Board*—No. 2 "Phillips" design, depth of recess, not less than 0.104 in. (2.64 mm).

8.3.2 *Screws for Fastening Metal Plaster Bases*—No. 2 "Phillips" design, depth of recess, not less than 0.077 in. (1.95 mm).

8.3.3 Determine depth of recess with a Phillips penetration depth gage.

8.3.4 Other types of screw-driving recesses having performance values equal to those of the recesses specified are acceptable.

8.4 *Shank Diameter*—Not less than No. 6, with major diameter not less than 0.136 in. (3.45 mm).

8.5 *Length*:

8.5.1 *Nominal Length*—The nominal length shall be the minimum length.

8.5.2 Type W and Type A screws shall be long enough to penetrate wood members not less than ⅝ in. (15.9 mm).

8.6 *Threads*—Either single or multiple thread design.

8.7 *Points*—Self-piercing design.

9. Finish and Appearance

9.1 *Form*—The form shall be straight and neatly formed.

9.2 *Threads*—The threads shall be clean and smooth.

9.3 *Finish*—Screws shall have a corrosion-resistant treatment. The treatment shall not inhibit adhesion to finishing compounds nor bleed through field-applied decoration.

10. Sampling

10.1 Obtain not less than 90 screws from not less than five containers.

11. Number of Tests and Retests

11.1 Test a minimum of five screws for each test. If any of the first lot fails, test 25 more screws.

11.2 If two or more of the second lot fail the second test, then the represented lot fails to meet the specified requirements.

12. Test Methods

12.1 The following test methods set forth procedures used to determine the ability of the screws to pierce through gypsum panel and metal plaster base and into the backup material without spin-out.

12.1.1 The test methods can also be used to determine whether or not alternate screw driving recesses will have performance values equal to those of the "Phillips" recess specified.

12.2 *Significance and Use*—The test methods provide procedures for evaluating the physical properties and performance requirements of steel self-piercing screws. The degree of correlation between these tests and service performance has not been determined.

12.3 *Apparatus*:

12.3.1 *Screw Gun*—Standard manufacture electric screw gun, turning at a minimum of 2500 r/min.

12.3.2 *Timing Device*—Standard stopwatch, calibrated in ⅒ s.

12.3.3 *Vice*—Standard machinists vice, not less than 3 in. (76 mm).

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

12.3.4 *Clamp*—Locking pliers ("Vice-Grip"), 6 in. (152 mm).

12.4 *Materials*:

12.4.1 *Gypsum Wallboard*—Specification C 1396/C 1396M, Type X, 5⁄8 in. (16 mm) thick.

12.4.2 *Metal Lath*—As in Specification C 847, diamond mesh, weight 2.5 lb/yd^2(1.4 kg/m^2).

12.4.3 *Steel Stud*—As in Specification C 645, 0.0179 in. (0.455 mm) thick, hardness not less than 52 HRB, size 3 5⁄8 in. (92.1 mm).

12.4.4 *Wood Stud*—Douglas fir, construction grade, 2 by 4 or 2 by 6, nominal, containing not less than 16 % nor more than 19 % free moisture as determined by a suitable moisture meter.

12.4.5 *Kraft Paper*—0.01 in. (0.25 mm) thick, 2 in. (51 mm) square.

12.5 *Specimen Preparation*:

12.5.1 Cut 6-in. (152-mm) square specimens from a sheet of gypsum wallboard not less than 12 in. (305 mm) away from the edge or end.

12.5.1.1 Weigh the specimens to within 1 g, and then condition at a temperature of 85 ± 15 °F (29.5 ± 5.5 °C) in an atmosphere having a relative humidity of 50 ± 2 %. Individually test the specimens after constant weight is reached.

12.5.2 Cut 6 in. (152 mm) square specimens from a sheet of metal lath not less than 4 in. (102 mm) away from the edge or end.

12.5.3 Cut 12 in. (305 mm) long specimens from a length of a steel stud.

12.5.4 Cut 12 in. (305 mm) long specimens from a length of wood stud.

12.6 *Procedure*:

12.6.1 *General:* Drive the screws not closer than 5⁄8 in. (16 mm) from the edges of the gypsum wallboard and not closer than 2 in. (50 mm) from the edges of the metal lath.

12.6.2 *Type G Screw Test*—Rigidly support two pieces of gypsum board sandwiched together. With a screw gun, drive the screw specimen into the gypsum boards, so that the head of the screw is below the surface of the gypsum board.

12.6.2.1 When driving Type G screw specimens, use the force of less than 20 lbf (89 N).

12.6.2.2 *Interpretation of Results*—Observe if the screws are pulled below the surface of the gypsum board. If any of the five screws fail, the lot has failed the test. Retest in accordance with Section 11.

12.6.2.3 *Report*—Report whether the lot has passed or failed the test.

12.6.2.4 *Precision and Bias*—No information is presented about either the precision or the bias for the Type G screw test for pulling the screw head below the surface of the gypsum board because the test result is non-quantitative.

12.6.3 *Type "S" Screws Test for Fastening Board to Steel*:

12.6.3.1 When driving Type S screws use a force of 30 lbf (133N).

12.6.3.2 Rigidly support a piece of gypsum wallboard as described in 12.4.1 over a length of steel stud as described in 12.4.3. With a screw gun as described in 12.3, drive five screw specimens through the wallboard and into the steel. Measure the length of time it takes to drive each screw so that the screw head is below the surface of the gypsum board and observe if there was spin-out.

12.6.3.3 *Interpretation of Results*—Calculate the average time to drive the five screw specimens through the wallboard and into the steel. If any of the five specimens fail to pull the screw head below the surface of the gypsum board or spins out, or if the average time is more than 2 s, the lot has failed. Retest in accordance with Section 11.

12.6.3.4 *Report*—Report whether the lot has passed or failed the test and the reason for failure.

12.6.3.5 *Precision and Bias*—No information is presented about either the precision or the bias for the Type S screw test for measuring spin-out or pulling the screw head below the surface of the gypsum board, because the test result in non-quantitative. No information is presented about either the precision or the bias for the Type S screw test for measuring the time to drive the screw because no material having an acceptable reference value is available.

12.6.4 *Type A Screws for Fastening Metal Lath to Steel*:

12.6.4.1 When driving Type A screws, use a force of 30 lbf (133 N).

12.6.4.2 Rigidly support a piece of metal lath over a steel stud specimen. With a screw gun, as described in 12.3, drive the five screw specimens through each of the five pieces of metal lath, and into the steel. Measure the length of time it takes to drive the screws and observe if there was spin-out. Grasp the metal lath with the locking pliers and pull steadily in a plane parallel to the plane of the lath. Observe whether the lath tears before it slips out from under the screw head.

12.6.4.3 *Interpretation of Results*—Calculate the average time to drive the five screw specimens through the metal lath into the steel. If any of the five specimens fails to pull the screw head through the metal lath and into the steel, or spins out, or if the average time is more than 2 s, or if the metal lath fails to tear when pulled, the lot has failed.

12.6.4.4 *Precision and Bias*—No information is presented about either the precision or the bias for the Type A screw test for measuring spin-out or pulling the screw head below the surface of the gypsum board, because the test result is non-quantitative. No information is presented about either the precision or the bias for the Type A screw test for measuring the time to drive the screw because no material having an acceptable reference value is available.

12.6.5 *Type A Screws for Fastening Metal Lath to Wood*:

12.6.5.1 When driving Type A screws, use a force of 30 lbf (133 N).

12.6.5.2 Rigidly support a piece of metal lath over a length of wood stud as described in 12.4.4. With a screw gun as described is 12.3, drive the five screw specimens through each of the five pieces of metal lath and into the wood stud. Observe if there was spin-out. Grasp the metal lath with the locking pliers and pull steadily in a plane parallel to the plane of the lath. Observe whether the lath tears before it slips out from under the screw head.

12.6.5.3 *Interpretation of Results*—If any of the five specimens fails to pull the screw head through the metal lath and

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:44:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

into the wood, or spins out, or if the metal lath fails to tear when pulled, the lot has failed. Retest in accordance with Section 11.

12.6.5.4 *Precision and Bias*—No information is presented about either the precision or the bias for the Type A screw test for pulling the screw head through the metal lath and into the wood, or spin-out, or tearing of the metal lath, because the test results are non-quantitative.

12.6.6 *Type W Screw Test for Fastening Gypsum Board to Wood*:

12.6.6.1 When driving Type W screws, use a force of 30 lbf (133 N).

12.6.6.2 Rigidly support a piece of gypsum wallboard as described in 12.4.1 over a length of wood as described in 12.4.4. With a screw gun as described in 12.3, drive five screw specimens through the wallboard and into the wood so that the head of the screw is below the surface of the wallboard, and observe if there was spin-out.

12.6.6.3 *Interpretation of Results*—If any of the five specimens fails to pull the head of the screw below the surface of the wallboard or spins out, the lot has failed the test. Retest in accordance with Section 11.

12.6.6.4 *Precision and Bias*—No information is presented about either the precision or the bias for the Type G screw test for pulling the screw head below the surface of the gypsum board because the test result is non-quantitative.

12.6.7 *Ductility Test*:

12.6.7.1 Place a screw specimen into a specified hole in a hardened block having a 10° angle on its face, then strike the part on the head with a hammer. If the head separates completely from the body, the part is either too hard in its core, the case hardness is too deep, the thread has cut the underhead radius, or the recess is too deep. Any of these problems can result in screws that break during assembly. If any of the five specimens fail, retest in accordance with Section 11.

12.6.7.2 *Interpretation of Results*—If any of the five screw specimens shows signs of fracture or complications as noted in 12.6.7.1, the lot has failed. Retest in accordance with Section 11.

12.6.7.3 *Report*—Report whether the lot has passed or failed the test and the reason for failure.

12.6.7.4 *Precision and Bias*—No information is presented about either the precision or the bias of the ductility test because the test results are non-quantitative.

13. Inspection

13.1 Inspection of the screws shall be agreed upon between the purchaser and the producer or the supplier as part of the purchase agreement.

14. Rejection

14.1 Rejection of screws that fail to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the screws have failed to conform to the specification requirements.

15. Certification

15.1 When specified in the purchase agreement, a producer's or supplier's report shall be furnished at the time of shipment, certifying that the screws are in compliance with this specification.

16. Packaging and Marking

16.1 *Packaging*:

16.1.1 Screws shall be packaged in substantial commercial shipping containers, constructed so as to preserve the contents in good condition and to ensure acceptance and safe delivery by common or other carriers, to the point of delivery.

16.1.2 Individual packages shall be so constructed that the contents shall be able to be partially removed without destroying the container's ability to serve as a receptacle for the remainder of the contents.

16.2 *Marking*—Individual packages and shipping containers shall be marked with the type, size, use, and quantity of screws contained therein, the name, brand, or trademark of the producer or supplier, and the ASTM designation.

17. Keywords

17.1 drill screw; gypsum board; lath; metal plaster base; self-pierce; self-piercing screw

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1002 – 04, that may impact the use of this specification. (Approved August 1, 2007)

(*1*) Replaced Specification C 36/C 36M with Specification C 1396/C 1396M in 12.4.1 and Referenced Documents.

Designation: C 1005 – 05

Standard Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements[1]

This standard is issued under the fixed designation C 1005; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the minimum requirements for scales, balances, reference masses, and glass graduates used in the physical testing of hydraulic cements.

1.2 Requirements for analytical reference masses and balances are not included in this specification, but are to be found in Test Methods C 114. The use of restrictive terminology, classes, ranges, etc. has been intentionally avoided to allow the use of this specification by other standards-writing bodies with similar requirements for reference masses and devices for determining mass, if desired.

1.3 These requirements are not sufficiently descriptive to be used as the sole specifications for the purchase of reference masses or devices for determining mass without amplification.

1.4 Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI–10, of measurement made in other units.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 114 Test Methods for Chemical Analysis of Hydraulic Cement

E 617 Specification for Laboratory Weights and Precision Mass Standards

IEEE/ASTM SI–10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Terminology

3.1 *Definitions:*

3.1.1 *accuracy*, *n*—degree of conformity of the indication of a device for determining mass to the true value of an applied mass.

3.1.2 *balance*, *n*—a device for determining mass that compares a mass with standard masses.

3.1.3 *precision*, *n*—reproducibility of the readings of a device for determining mass when a given test mass is applied.

3.1.4 *range of mass determination*, *n*—the range of indications of a device from the minimum test load plus any aids or containers on the load-receiving elements to the maximum test load with the same aids or containers, as specified by the particular method of test being used.

3.1.5 *readability*, *n*—the smallest fraction of a division to which the index scale of a device for determining mass can be read with ease either by estimation or by use of a vernier.

3.1.6 *reference mass*, *n*—a piece of material of known specified mass for use in comparing or measuring the mass of other masses (See Note 1).

3.1.6.1 *Discussion*—The definition of "reference mass" was formerly incorrectly designated "weight;" weight is a force (See IEEE/ASTM SI–10).

3.1.7 *scale*, *n*—a device for determining mass having a load-receiving element and an index scale (possibly in combination with the use of internal masses or proportional masses), almost always calibrated to indicate mass; generally of lesser accuracy than a balance.

3.1.8 *sensitivity*, *n*—the minimum change of applied mass required to perceptibly move the indicating element of a device for determining mass.

3.1.9 *sensitivity requirement*, *n*—the minimum change in position of rest of the indicating element of a device for determining mass in response to a specified change of mass load on the load-receiving element.

3.1.10 *test load*, *n*—the mass to be determined in a single determination, exclusive of aids or containers, as specified in the test method being followed.

3.1.11 *tolerance*, *n*—precision and accuracy criteria for reference masses or devices for determining mass.

acceptance tolerance—the maximum permissible deviation from correct indication for new or newly reconditioned or adjusted reference masses or devices for determining mass; equal to ½ the maintenance tolerance.

adjustment tolerance—acceptance tolerance.

maintenance tolerance—maximum permissible deviation

[1] This specification is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.95 on Coordination of Standards.

Current edition approved July 1, 2005. Published August 2005. Originally approved in 1983. Last previous edition approved in 2000 as C 1005 – 00.

www.technobetar.ir

from correct indication for reference masses and devices for determining mass in service.

3.1.12 *total load*, *n*—the sum of the masses of materials and aids or containers applied to the load-receiving element at any one time.

4. Reference Masses

4.1 Reference masses for use in the methods of physical testing of hydraulic cement and related and similar materials shall conform at least to the requirements of Class 6 reference masses in Specification E 617, except that the maintenance tolerances given in Specification E 617 for Class 6 reference masses are to be considered acceptance tolerances for purposes of this specification and the maintenance tolerances twice these values. See Table 1. (See Note 1)

NOTE 1—Former NBS Class P and F reference masses meet this specification as do OIML Class M1 reference masses. Former NBS Class T reference masses of 100 mg and less, Class C reference masses of 1 kg and greater, and OIML Class M2 reference masses of 200 g and greater meet the specification.

4.2 A mass used strictly as a mass, whose actual value need not be known, need not meet the requirements of 4.1 (See Note 2).

NOTE 2—A tare mass for a container used in mass determination is in this category. The actual value of its mass need not be known, but it must be equal in mass to that of the container.

5. *Requirements for Scales and Balances* Requirements for Scales and Balances

5.1 *Capacity*—The capacity of a device for mass determination shall be at least equal to the maximum total load to be applied to the load-receiving element at any one time (See Note 3).

NOTE 3—In general, the capacity of a device for mass determination should not greatly exceed twice the maximum total load required for a given test because of the reduced accuracy, readability, and sensitivity with higher capacity weighing devices. There are exceptions to this generality as, for example, the high quality substitution balances.

TABLE 1 Tolerances for Reference Masses[A,B]

Mass, g	Acceptance Tolerance, ±mg	Maintenance Tolerance, ±mg
10 000	1 000	2 000
5 000	500	1 000
3 000	300	600
2 000	200	400
1 000	100	200
500	50	100
300	30	60
200	20	40
100	10	20
50	7	14
30	5	10
20	3	6
10	2	4
5	2	4
3	2	4
2	2	4
1	2	4

[A] Values from Table 1 of Specification E 617 for Class 6 metric reference masses.

[B] For reference masses with unlisted nominal values, the tolerance shall be that for the next lower denomination listed.

5.2 *Precision and Accuracy*—The maintenance tolerance for a device for mass determination shall be no greater than 0.05 % of the test load throughout the range. For balances with a capacity of 3000 g or more, the range of the test load shall be 300 to 3000 g. For balances with a capacity of less than 3000 g, the range of the test load shall be 10 % of the capacity up to the capacity of the balance. The device for mass determination shall be capable of reproducing readings with the same test mass to within at least the maintenance tolerance.

5.3 *Readability*—The index scale of a device for mass determination shall be easily readable to 0.1 g.

5.4 *Sensitivity Requirement*—The indicating element of the device for determination of mass shall show a change of at least one of the smallest divisions of the index scale for a change of 0.1 % of the test load within the range.

6. Requirements for Glass Graduates

6.1 *Glass Graduates*, of suitable capacities (large enough to measure the mixing water for paste and mortar mixtures in a single operation) shall be made to deliver the indicated volume at 20°C (68°F).

6.1.1 The permissible variation for graduates of 100 to 150-mL capacities shall be ±1.0 mL, for graduates of 200 to 300-mL capacities ±2.0 mL, and for all larger graduates ±0.5 % of the rated capacity.

6.1.2 These graduates shall be subdivided to at least 5 mL with the following exceptions:

6.1.2.1 The graduation lines may be omitted for the lowest 15 mL for a 150-mL graduate,

6.1.2.2 The graduation lines may be omitted for the lowest 25 mL for a 250-mL graduate, and

6.1.2.3 The graduation lines may be omitted for the lowest 50 mL for a 500-mL graduate.

6.1.3 The main graduation lines shall extend at least three quarters of the way around the graduate and shall be numbered (Note 4).

NOTE 4—Some graduates are manufactured with two numbering systems; one on each side of the main graduation lines. In reading from bottom to top, one system is increasing while on the other side the numbers are decreasing. Care should be taken since this could create confusion in reading the volume.

7. Rejection

7.1 New or newly reconditioned or adjusted reference masses and devices for determination of mass shall not be placed in service if they do not meet the acceptance tolerances specified in this standard.

7.2 Reference masses and devices for determination of mass in service shall be checked annually and shall be removed from service if they exceed the maintenance tolerances specified in this standard.

8. Keywords

8.1 devices for determining mass; devices for measuring volume; glass graduate; reference masses

Designation: C 1007 – 08a

Standard Specification for Installation of Load Bearing (Transverse and Axial) Steel Studs and Related Accessories[1]

This standard is issued under the fixed designation C 1007; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the installation and erection requirements for load bearing (transverse and axial) steel studs and related accessories 0.0329 in. (0.836 mm) to 0.1120 in. (2.845 mm) thick.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

2.5 *Federal Specification:*

FF-P-395 Pin, Drive, Guided and Pin Drive, Power Actuated Fasteners for Power Actuated and Hand Actuated Fastening Tools[5]

3. Terminology

3.1 Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *axial loads*, *n*—those loads applied to a member in the same plane as its major centroidal axis.

3.2.2 *cripple studs*, *n*—less than full height studs above a header or below a sill.

3.2.3 *framing members*, *n*—studs joist, runners (tracks), bridging and bracing and related accessories.

3.2.4 *header*, *n*—the stud assembly or the track assembly, or both, placed at a right angle to supporting studs that creates the top of a framed opening.

3.2.5 *jack stud*, *n*—a framing member which provides support at the end of a header.

3.2.6 *panelized construction*, *n*—fabrication of framing members into an assembly prior to erection.

3.2.7 *sill*, *n*—the stud assembly or the track assembly, or both, placed at a right angle to supporting studs that creates the bottom of a framed opening.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for the Application of Gypsum and Other Products in Assemblies.

Current edition approved Nov. 1, 2008. Published December 2008. Originally approved in 1983. Last previous edition approved in 2008 as C 1007 – 08.

www.technobetar.ir

3.2.8 *transverse loads*, *n*—those loads applied to a member in a plane perpendicular to its major centroidal axis.

4. Storage of Materials

4.1 Products shall be protected from adverse weather and job site conditions that will cause any physical damage.

4.2 Materials shall be stored on a flat plane.

4.3 Any damaged materials shall be removed from the job site immediately.

5. Materials

5.1 *Framing members*—Specification C 955.

5.2 *Zinc-rich paint*—MIL-P-21035.

5.3 *Steel drill screws*—Specification C 954. Screws shall have rust inhibitive coating suitable for the intended installation.

5.4 *Power actuated drive pins*—FF-P-395.

6. Fastenings and Attachments

6.1 Anchorage of the tracks to the structure shall be with methods designed for the specific application of sheet steel to that surface. Size, penetration, type, and spacing shall be determined by design.

6.2 Welds shall conform to the requirements of AWS D1.3, and AISI Manual, section E 2. Welds shall be butt, fillet, spot, or groove type, the appropriateness of which shall be determined by, and within, the design calculations. All welds shall be touched-up using zinc rich paint.

6.3 Steel drill screws shall be of the minimum diameter indicated by the design of that particular attachment detail. Penetration through joined materials shall not be less than three exposed threads.

6.4 Wire tying in structural applications shall not be permitted.

7. Tolerances

7.1 Vertical alignment (plumbness) of studs shall be within 1/960 (⅛ in. in 10 ft 0 in.) of the span.

7.2 Horizontal alignment (levelness) of walls shall be within 1/960 (⅛ in. in 10 ft 0 in.) of their respective lengths.

7.3 Spacing of the framing members shall not be more than ±⅛ in. (3 mm) from the designed spacing, provided that the cumulative error does not exceed the requirements of the finishing materials.

7.4 Squareness of the prefabricated panels shall be not more than ⅛ in. (3 mm) out of square within the length of that panel.

INSTALLATION

8. General Installation

8.1 Methods of construction shall be either stickbuilt or panelized.

8.2 Stud to track connections shall be designed to meet or exceed the design loads required.

8.3 Allowance for vertical deflection of the structure shall be as required by the designer.

8.4 Transversely loaded studs shall not be required to sit squarely in tracks, but shall be attached to the tracks.

8.5 Axially loaded studs shall be fabricated with the studs seated squarely within ⅛ in. (3 mm) of the web portion of the top and bottom tracks and shall be attached to the tracks.

8.6 All axially loaded members shall be aligned vertically to allow for full transfer of the loads down to the foundation. Vertical alignment shall be maintained at floor/wall intersections.

8.7 Bearing shall be provided under tracks to provide for load transfer in axially loaded assembles.

8.8 Additional corrosion protection shall not be required on edges of metallic coated steel framing members, shop or field cut, punched or drilled.

8.9 *Cutting and Splicing of Members*:

8.9.1 Cutting of steel framing members shall be accomplished with a saw or shear.

8.9.2 Torch cutting of framing members shall not be permitted.

8.9.3 Splicing of axially loaded framing members shall not be permitted.

8.9.4 Cutting of flanges in stud and joist framing members shall not be permitted.

8.9.5 Cutting of additional holes other than those provided by the manufacturer in framing members shall not be permitted.

8.10 Temporary bracing shall be provided and left in place until the work is permanently stabilized.

8.11 Bridging shall be of the size and type shown on the shop drawings and as called for in the design calculations. For further description of the shop drawings see Annex A3.

8.12 *Header and Jack Stud Installation*:

8.12.1 Headers shall be installed in all openings in axially loaded walls that are larger than the stud spacing in that wall.

8.12.1.1 Headers shall be installed so that they lie wholly within the width of the stud wall.

8.12.1.2 Insulation (equal to the job requirements) shall be placed in all jamb and header type conditions that will be in accessible after their installation into the wall.

8.12.2 Jack studs shall be securely connected to the header and must seat squarely in the lower track of the wall in accordance with 8.4.

8.12.3 If the header is designed to be installed immediately above the wall opening the cripple studs that occur over the header shall be designed to carry all superimposed loads.

8.13 Wall track (runners) shall not be used to support any load unless specifically designed for that purpose.

9. Panelized Construction

9.1 Panels shall be designed to resist all construction and handling loads as well as live loads.

9.2 Handling and lifting of prefabricated panels shall not cause permanent distortion in any member or collateral material.

9.3 All stud-to-track connections shall be installed prior to hoisting the panel.

9.4 Where splicing of the track is necessary between stud spacings, a piece of stud not less than 12 in. (305 mm) long shall be placed in the track fastened with not less than two screws per flange to each piece of track or welds shall be provided as required.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 1—Claddings may be permitted to be attached prior to panel installation.

9.5 Attachment of the panel to the structure shall be as shown on the design drawings.

9.6 All panels shall be aligned to provide continuity of any wall/floor surface.

10. Stick Built (Non-Panelized) Members

10.1 Tracks shall be aligned accurately at supporting structure and shall be fastened to the structure.

10.2 Track intersections shall butt evenly.

10.3 Doors, windows, and other items installed in the wall shall be securely anchored to the wall by means of clips, angles, screws, bolts, etc.

11. Keywords

11.1 axial; loadbearing; runners; steel; studs; tracks; transverse

ANNEXES

(Mandatory Information)

A1. DESIGN REQUIREMENTS

A1.1 Physical properties and allowable load capabilities of materials shall be developed in accordance with AISI Design Manual, as provided by Specification C 955.

A1.2 Studs shall be spaced to suit the design requirements and limitations of collateral materials.

A1.3 All applicable loads, strains, deflections, shear and web crippling, and bending of all sections shall be examined.

A1.4 All connections (member-to-member and member-to-structure) shall be examined taking into account all relevant physical strengths and properties.

A1.5 Selected walls shall be designed to provide frame stability and lateral load resistance. Diagonal steel strapping or other engineered methods shall be used to provide frame stability and lateral load resistance. Diagonal steel strapping shall be used to transfer lateral loads to the structure and foundation. Additional studs shall be provided to resist the vertical component of the loads from the diagonal bracing.

A1.6 Wall bridging shall be designed to provide resistance to minor axis bending and rotation of wall studs.

A2. INSTALLATION REQUIREMENTS

A2.1 Gypsum board shall be attached to the steel studs in accordance with the appropriate specification.

A2.2 Metal plaster bases shall be attached in accordance with Specification C 841 or Specification C 1063, except screw heads shall be of a size and type suitable for positive (no movement) attachment.

A2.3 When diaphragm rated components are substituted for bridging, they shall be installed prior to loading of the wall. If components are installed on one side of the wall only, then the other stud flanges shall be bridged with suitable bridging. Bridging is not required to be removed when diaphragm rated components are installed.

A2.4 Care shall be taken to allow for additional studs at panel intersections, corners, doors, window, control joints, etc.

A2.5 Provision for structure movement shall be provided as indicated and necessary by design or code requirements.

A2.6 Properly designed splices, cutting of flanges, and holes other than those provided by the manufacturer shall be approved in writing by the engineer of record.

A2.7 Care shall be taken to properly distribute construction materials so that they do not exceed the project design loads.

A3. SUBMITTALS

A3.1 The following items shall be considered for approval prior to delivery of materials to the site:

A3.1.1 *Shop Drawings*—Drawings shall illustrate materials; shop coatings; steel thickness; details of fabrication; details of attachment to adjoining work; size, location, spacing of fasteners for attaching framing to itself; details of attachment to the structure; accessories and their installation; and critical installation procedures. Drawings shall include plans, elevations, sections and details.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:44:17 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

A3.1.2 *Samples*—Samples shall be representative pieces of all framing component parts and accessories.

A3.1.3 *Certification*—Certification shall be a statement from the manufacturer certifying that the materials conform to the appropriate requirements as outlined in the contract documents.

A3.1.4 *Calculations*—Engineering calculations shall be prepared verifying the assembly's ability to meet or exceed design requirements as required by local codes and authorities.

A3.1.5 *Descriptive Literature*—Manufacturer's literature shall contain product and installation specifications and details.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1007 – 08, that may impact the use of this specification. (Approved November 1, 2008)

(*1*) Revised 6.2.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1007 – 04, that may impact the use of this specification. (Approved September 1, 2008)

(*1*) Revised 8.8.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C1012/C1012M – 09

Standard Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution[1]

This standard is issued under the fixed designation C1012/C1012M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of length change of mortar bars immersed in a sulfate solution. Mortar bars made using mortar described in Test Method C109/C109M are cured until they attain a compressive strength of 20.0 ± 1.0 MPa [3000 ± 150 psi], as measured using cubes made of the same mortar, before the bars are immersed.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

C109/C109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)
C114 Test Methods for Chemical Analysis of Hydraulic Cement
C150 Specification for Portland Cement
C157/C157M Test Method for Length Change of Hardened Hydraulic-Cement Mortar and Concrete
C215 Test Method for Fundamental Transverse, Longitudinal, and Torsional Resonant Frequencies of Concrete Specimens
C305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency
C348 Test Method for Flexural Strength of Hydraulic-Cement Mortars
C349 Test Method for Compressive Strength of Hydraulic-Cement Mortars (Using Portions of Prisms Broken in Flexure)
C452 Test Method for Potential Expansion of Portland-Cement Mortars Exposed to Sulfate
C490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete
C511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes
C595 Specification for Blended Hydraulic Cements
C597 Test Method for Pulse Velocity Through Concrete
C618 Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete
C684 Test Method for Making, Accelerated Curing, and Testing Concrete Compression Test Specimens
C778 Specification for Standard Sand
C917 Test Method for Evaluation of Cement Strength Uniformity From a Single Source
C989 Specification for Slag Cement for Use in Concrete and Mortars
D1193 Specification for Reagent Water
E18 Test Methods for Rockwell Hardness of Metallic Materials

2.2 *American Concrete Institute Reports:*

ACI C201-2R-01 Guide to Durable Concrete[3]

3. Significance and Use

3.1 This test method provides a means of assessing the sulfate resistance of mortars made using portland cement, blends of portland cement with pozzolans or slags, and blended hydraulic cements. Method C452 is suitable for evaluating portland cements but not blended cements or blends of portland cement with pozzolans or slags.

3.2 The standard exposure solution used in this test method, unless otherwise directed, contains 352 moles of Na_2SO_4 per

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.29 on Sulfate Resistance.

Current edition approved Dec. 15, 2009. Published January 2010. Originally approved in 1984. Last previous edition approved in 2004 as C1012–04. DOI: 10.1520/C1012_C1012M-09.

www.technobetar.ir

m^3 [50 g/L]. Other sulfate concentrations or other sulfates such as $MgSO_4$ may be used to simulate the environmental exposure of interest. Further discussion of these and other technical issues is given in the Appendix.

4. Apparatus

4.1 *Mixer*, conforming to the requirements of Practice C305.

4.2 *Cube Molds*, conforming to the requirements of Test Method C109/C109M.

4.3 *Bar Molds*, conforming to the requirements of Specification C490.

4.4 *Comparator*, conforming to the requirements of Specification C490.

4.5 *Containers*—The containers in which the bars are immersed shall be corrosion resistent such as plastic, glass, or ceramic. Support the bars so that no end or side of a bar rests against the container. Seal the container with a lid so that the sulfate solution cannot evaporate.

4.6 *Curing Tank*, conforming to the requirements of Test Method C684.

5. Reagents and Materials

5.1 *Purity of Reagents*—USP or technical grade chemicals may be used, provided it is established that any reagent used is of sufficiently high purity to permit its use without lessening the accuracy of the determination. When tests are made that are expected to produce results that are close to an acceptance-rejection value, it is recommended that reagent grade chemicals be used. Such chemicals shall conform to the specifications of the Committee on Analytical Reagents for the American Chemical Society where such specifications are available.[4]

5.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type IV of Specification D1193.

5.3 *Sodium Sulfate (Na_2SO_4)*—Check the water content by loss on ignition each time the solution is prepared. Any anhydrous or hydrated sodium sulfate may be used if the water content of the salt is checked by loss on ignition and proper corrections made to account for the specified sulfate concentration.

5.4 *Sulfate Solution*—Each litre of solution shall contain 50.0 g of Na_2SO_4 dissolved in 900 mL of water, and shall be diluted with additional distilled or deionized water to obtain 1.0 L of solution. Mix the solution on the day before use, cover, and store at 23.0 ± 2.0 °C [73.5 ± 3.5 °F]. Determine the pH of the solution before use; reject the solution if the pH range is outside 6.0 to 8.0. Maintain the volume proportion of sulfate solution to mortar bars in a storage container at 4.0 ± 0.5 volumes of solution to 1 volume of mortar bars. For mortar bars 1 by 1 by 11¼ in. (volume of 184 mL [11.25 $in.^3$]), this is 645 to 830 mL of solution per mortar bar in the storage container. For mortar bars 25 by 25 by 285 mm (volume 178 mL), this is 625 to 800 mL of solution per mortar bar in the storage container.

5.5 *Materials*:

5.5.1 *Graded Standard Sand*, as specified in Specification C778.

5.5.2 *Stainless Steel Gauge Studs*, as specified in Specification C490.

6. Hazards

6.1 **Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[5]

7. Preparing Mortars

7.1 Make mortars as described in Test Method C109/C109M, that is, 1 part cement to 2.75 parts of sand by mass. Use a water-cement ratio by mass of 0.485 for all non-air-entraining portland cements and 0.460 for all air-entraining portland cements. Use a water-cement ratio by mass of 0.485 for non-air-entraining portland-pozzolan (IP) and portland-blast furnace slag (IS) cements. For blends of portland cement with a pozzolan or slag, use a water-cement ratio that develops a flow within ±5 of that of the portland-cement mortar at a water-cement ratio of 0.485.

8. Specimen Molds

8.1 Prepare the specimen molds in accordance with the requirements of Specification C490 except the interior surfaces of the mold shall be covered with a release agent. A release agent will be acceptable if it serves as a parting agent without affecting the setting of the cement and without leaving any residue that will inhibit the penetration of water into the specimen.

NOTE 1—TFE-fluorocarbon tape complies with the requirements for a mold release agent.

9. Procedure

9.1 *Molding and Initial Curing of Specimens*—Mold the test bars in accordance with Test Method C157/C157M. Mold the cubes in accordance with Test Method C109/C109M. A set of specimens to test one cement consists of 6 bars and up to 21 cubes (Note 2). Immediately after molding, cover the molds with a rigid steel, glass, or plastic plate, seal the plate to the mold so as to be watertight, and place the mold in the curing tank in water at 35 ± 3 °C [95 ± 5 °F] for 23½ h ± 30 min, as in Test Method C684, Procedure A (Warm-Water Method). Place the sealed molds in the curing tank with the bottom of the bars as cast down, that is, in the same relative position in which the bars were cast. At 23½ h ± 30 min, remove molds from tank and demold the specimens.

NOTE 2—The set of cubes consists of 21 cubes to be tested as described herein when significant information on the strength development rate is not available. When information is available (as for example, from the use

[4] *Reagent Chemicals, American Chemical Society Specifications* , American Chemical Society, Washington, DC. www.technobetar.ir

of the procedures of Test Method C917) that would justify making fewer cubes, only those needed to confirm the time the mortar achieves 20.0 ± 1.0 MPa [3000 ± 150 psi] are needed.

9.2 *Subsequent Curing and Preparation for Test*—After demolding, store all bars and cubes, except the two to be broken, in a curing tank of saturated limewater at 23.0 ± 2.0 °C [73.5 ± 3.5 °F]. Break two cubes in compression in accordance with Test Method C109/C109M after demolding when the specimens have cooled to ambient temperature under moist cloths. If the mean strength of the two cubes is 20 MPa [2850 psi] or more, observe and record comparator readings in accordance with Specification C490 and as prescribed in the section on Measurements of Length Change and place all the bars in the sulfate solution. If 20 MPa [2850 psi] is not achieved, store the demolded cubes and mortar bars in the curing tank and test additional cubes. Predict from the first two cubes when a compressive strength of at least 20 MPa [2850 psi] will be reached. Verify the prediction, and at that time observe and record comparator readings and place all the bars in the sulfate solution (Note 3). This measurement is designated as the initial length. The storage temperature and test temperature shall be 23.0 ± 2.0 °C [73.5 ± 3.5°F].

NOTE 3—If the value for strength at 24 h is less than 20.0 MPa [2850 psi] and additional testing on the same day is not possible, or, is unlikely to yield a value over 20.0 MPa [2850 psi] and the strength is over 21 MPa [3150 psi] when tested early the next day, it is not necessary to remake the batch.

9.3 *Storage of Test Bars during Exposure to Test Solution*—Cover the container of the bars and test solution, and seal it to prevent evaporation from the inside, or dilution with water from the outside. (See Note 4.) The storage temperature and test temperature shall be 23.0 ± 2.0 °C [73.5 ± 3.5 °C]. (See Note 5.)

NOTE 4—Gaffers tape or duct tape has been found to be suitable for sealing the container.

NOTE 5—This is the same temperature and temperature range as that specified for moist rooms in Specification C511.

9.4 *Measurements of Length Change*—At 1, 2, 3, 4, 8, 13, and 15 weeks after the bars are placed in the sulfate solution, test them for length change using the length comparator in accordance with Specification C490. Review the data at 15 weeks. Make the subsequent measurements at a minimum of 4, 6, 9, and 12 months. If at any time the rate of change between readings is great, insert other readings as needed to ensure the intervals are short enough to permit observing and reporting the behavior of the bars. If compliance with ACI C201-2R-01 Class 3 exposure is required, measure the bars at 4, 6, 9, 12, 15, and 18 months (Note 6).

NOTE 6—ACI C201-2R-01 requires an 18-month limit for Class 3 exposure.

9.4.1 *Details of Measurement of Bars for Length Change*:

9.4.1.1 Clean the hole in the base of the comparator into which the gauge stud on the lower end of the bar fits (this hole tends to collect water and sand and should be cleaned after every reading). Read and record the comparator indication of the length of the reference bar. Take one bar out of immersion, blot the pins, put the bar in the comparator, read, and record the indication. Return the bar to immersion and clean the hole in the base of the comparator. Take out the second bar and treat it in a like manner. Return the second bar to immersion, record the reading, and clean the hole in the base of the comparator. Continue the procedure until all bars have been read, returned to immersion, and the readings recorded, cleaning the hole in the bottom of the comparator each time. After reading the last bar, clean the hole in the comparator base and read and record the reference-bar indication.

9.4.1.2 When the required strength of the mortar is achieved in accordance with 9.2, store the bars in fresh sulfate solution. At subsequent readings for length change, proceed as described in 9.4.1.1; cleaning the socket in the base of the comparator before reading the reference bar initially and after reading each mortar bar. Record reference bar and mortar bar readings. Read and record the reference bar again after measurement of the last bar. Blot only around the pins (Note 7). Return each bar to the used sulfate solution after reading. When all the bars have been measured, discard the used solution. Rinse the container once with water, pouring out water and debris. Replace the frame holding the bars in the container, fill the container with enough new sulfate solution to immerse bars, and secure the lid on the container.

NOTE 7—The purpose of the minimal blotting of the pins and no blotting of the bars is to avoid drying and shrinkage of the bars. It has been observed that if the pins are blotted, and the bar placed in the comparator and the dial read, and the bar is then wiped gently with a dry cloth, the bar will shrink measurably. Therefore, drying should be minimized.

9.4.2 *Examination of Specimens After Measuring Length Change*—When the bars seem to have behaved in an unusual way or when the test is part of a research study, test the specimens for warping by placing them on a plane surface so that the ends are curved down and the maximum bowing measured. Note cracking (presence, location, type); also note surface deposits, mottling, exudations (nature, thickness, type).

9.5 *Tolerance on Time*—All references to elapsed time in 9.4 are intended to have a tolerance of ±2 %.

TABLE 1 Maximum Permissible Range of Values

Remaining No. of Specimens	Blended Cements	Portland Cement
3	0.034	0.010
4	0.037	0.011
5	0.039	0.012
6	0.041	0.012

10. Calculation

10.1 Calculate the length change at any age as follows:

$$\Delta L = \frac{L_x - L_i}{Lg} \times 100 \quad (1)$$

where:

ΔL = change in length at x age, %,

L_x = comparator reading of specimen at x age—reference bar comparator reading at x age, and

L_i = initial comparator reading of specimen-reference bar comparator reading, at the same time

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:44:18 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Lg = nominal gauge length, or 250 mm [10 in.] as applicable. (See C490).

10.2 Calculate length change values for each bar to the nearest 0.001 % and report averages to the nearest 0.01 %.

11. Report

11.1 Report type of cement, and, if blending material is used, its identification and amount and whether cement and blending material, if used, meet the applicable specifications. Report the initial comparator reading of each bar at the time of immersion in sulfate solution; this is the base value for calculation of length changes. Report the subsequent length changes in percent of base value to the nearest 0.001 % for individual bars and the nearest 0.01 % for averages. Comment on the visual condition of bars at end of the test. With each report of mean length change of bars at a particular age, report number of bars (*n*), standard deviation of length change, and coefficient of variation of length change. Data from at least three bars must be available at any age to constitute a valid test at that age. Depending upon how many remaining specimens there are, the maximum permissible range of the values must not exceed the values of length change in percent in Table 1.

11.2 Report any variation from the procedure outlined in the text as it relates to solution composition, concentration, or temperature, mortar proportions, age, or maturity, and so forth.

12. Precision and Bias

12.1 The precision of this test method has been evaluated by cooperative testing and found to vary with the type of cement studied, hence separate precision statements are given.[6]

12.1.1 *Blended Cements*—The single-operator standard deviation has been found to be 0.010 % for expansions between 0.04 % and 0.07 %. Therefore, results of two properly conducted tests by the same operator on the same blended cement Type IP or IS, should not differ from each other by more than 0.028 %. The multi-laboratory standard deviation has been found to be 0.020 % for expansions between 0.04 %, and 0.07 %. Therefore, results of two properly conducted tests on the same blended cement Type IP or IS in two different laboratories, should not differ from each other by more than 0.056 %.

12.1.2 *Type II Cement*—The single-operator standard deviation has been found to be 0.005 %, for expansions between 0.04 % and 0.07 %. Therefore, results of two properly conducted tests by the same operator on the same cement, should not differ from each other by more than 0.014 %. The multi-laboratory standard deviation has been found to be 0.020 % for expansions between 0.04 % and 0.07 %. Therefore, results of two properly conducted tests on the same cement in two different laboratories, should not differ from each other by more than 0.056 %.

12.1.3 *Type V Cement*—The single-operator standard deviation has been found to be 0.003 % for expansions between 0.04 % and 0.07 %. Therefore, results of two properly conducted tests by the same operator on the same cement, should not differ from each other by more than 0.009 %. The multi-laboratory standard deviation has been found to be 0.010 % for expansions between 0.04 % and 0.07 %. Therefore, results of two properly conducted tests on the same cement in two different laboratories should not differ from each other by more than 0.028 %.

12.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

13. Keywords

13.1 acceptability; expansion; fly ash; mortars; pozzolans; precision; search report; slag; sulfate attack; sulfate-resisting cements; tests

[6] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: RR:C01-1003.

ANNEX

(Mandatory Information)

A1. Determination of Water Content of Sodium Sulfate

A1.1 *Apparatus*

A1.1.1 Porcelain crucible, 15mL,

A1.1.2 Oven, drying capable of maintaining 110 ± 5 °C

A1.1.3 Desiccator with a good desiccant, such as magnesium percholrate, or activated alumina. Calcium sulfate treated with a color-change indicator that shows when it has lost its effectiveness is also suitable.

A1.1.4 Balance as described in Section 4 of Test Method C114.

A1.2 *Determining the water content*

Determine the mass of approximately 1 g of the sodium sulfate in a tared porcelain crucible to the nearest 0.0001 g. Dry the crucible and its contents for 1 ± 0.25 h in an oven at a temperature of 110 ± 5 °C [230 ± 10 °F]. Remove the crucible and its contents from the oven and cool in a dessicator until they are at room temperature. (See Note A1.1) Record the mass of the crucible and sodium sulfate after heating.

NOTE A1.1—15-30 minutes are usually sufficient. A small Pyrex beaker could be used as long as the mass can accurately be weighed (e.g. 50 ml beaker).

A1.3 *Calculation*

Calculate the water content of the sodium sulfate to the nearest 0.1%:

$$\% \text{ WC} = \frac{(M_i - M_f) \times 100}{M_{ss}} \quad \text{(A1.1)}$$

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:44:18 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

where:

% WC = water content, %
M_i = mass of sodium sulfate + crucible before heating, g
M_f = mass of sodium sulfate + crucible after heating, g
M_{ss} = mass of sodium sulfate before heating, g

Use the % WC to correct the mass of sodium sulfate used in Section 5.4 (see Note A1.2).

NOTE A1.2—Example: Water content was determined to be 5.0 %. Thus, the corrected mass of anhydrous sodium sulfate present would be:

$$\frac{\text{Mass sodium sulfate uncorrected} \times (100 - \%\ \text{WC})}{100} \quad \text{(A1.2)}$$

or:

$$\frac{50\ \text{g}\ Na_2SO_4 \bullet \text{x}\ H_2O \times (100 - 5)}{100} = 47.5\ \text{g} \quad \text{(A1.3)}$$

or in reverse:

$$\frac{50\ \text{g}\ Na_2SO_4 \times 100}{(100 - 5)} = 52.6\ \text{g}\ Na_2SO_4 \bullet \text{x}\ H_2O \quad \text{(A1.4)}$$

APPENDIX

(Nonmandatory Information)

X1. Technical Background

X1.1 Test Method C1012 was developed to explore the suitability of a test method for sulfate resistance based on length-change measurements of molded prisms immersed in sulfate solution. This approach was taken after it was established that Test Method C452, in which the sulfate is added to the mortar as it is mixed, and the prisms stored in fresh water, was not able properly to evaluate sulfate resistance of blended cements and blends of portland cement with pozzolan or slag.

X1.2 This test method has been subjected to two rounds of cooperative testing. The first program involved five cements (Types I, II, and V of Specification C150, and Types IS and IP of Specification C595). The test solution contained both sodium sulfate and magnesium sulfate, each in the amount of 0.176 mol/L. A report of this work is available. A paper giving results using this test method has been published **(1)**.[7] The second program involved eight blends using a Type I and a Type II cement with 50 and 70 % slag, 25 % Class F, and 35 % Class C fly ash (Specification C618). Two test solutions were used: one contained 0.303 mol/L sodium sulfate and 0.049 % magnesium sulfate; the other contained 0.352 mol/L sodium sulfate only.

X1.3 This test method involves length change of hydraulic-cement mortar bars immersed in a sulfate solution. Mortar bars are placed in the sulfate solution after companion mortar cubes have reached a compressive strength of 20.0 ± 1.0 MPa [3000 ± 150 psi]. Attempts to use Test Method C452 for blended cements and blends of portland cement and slag (Specification C989) or pozzolan (Specification C618) with portland cement failed to yield results that correlate with field and laboratory experience where the mortar or concrete developed some maturity prior to being exposed to external sulfate solution **(2)**. Since some blended cements and some blends of slag and pozzolan with portland cement have been successfully used where sulfate resistance was needed, they are tested under circumstances which permit comparisons to be based on results obtained when all the sulfate exposures are begun at equivalent strength since, in practice, it is likely that the concrete will be at about the same strength when sulfate attack begins regardless of the type of cementitious medium employed. This test method is also applicable for use in evaluating portland cements.

X1.4 The solution of 0.176 mol/L of each of the two sulfates (magnesium and sodium) studied in the first cooperative program, is believed likely to adversely affect blends or blended cements containing slag, due to a magnesium ion **(3, 4)** attack, this attack being unrelated to sulfate attack. Therefore, this solution should not be used to evaluate such systems unless they are to be exposed in service to attack in which the magnesium ion (Mg^{++}) is present in amounts approaching that of the test solution (4200 ppm).

X1.5 This test method does not simulate the mechanism of sulfate attack by solutions of sulfate compositions other than that used. If evaluation of behavior due to exposure to a given sulfate solution is desired, that solution should be used.

X1.6 The user may therefore modify this test method to use any relevant compositions or concentrations of aggressive solutions, other ages or degrees of maturity as the basis for beginning the exposure, mortars of different proportions, or different or additional means of assessing the influence of the aggressive solution on the specimens. Much work was done using mortar bars of lower strength (higher porosity) in previous cooperative tests sponsored by Committee C01 **(5-7)**. A procedure in which sodium sulfate is kept at constant alkalinity/acidity has been proposed **(8)**. Other methods of assessing the influence of the aggressive solutions that have been used or proposed include (*a*) change in pulse velocity (Test Method C597), (*b*) change in resonant frequency (Test Method C215), (*c*) change in compressive strength (Test Methods C109/C109M and C349), (*d*) change in flexural strength (Test Method C348), (*e*) change in mass, and (*f*) change in hardness (Test Methods E18).

X1.7 Work reported by Polivka and Brown **(9)** in 1958 and by Mehta and Polivka in 1975 **(10)** included tests of concrete

[7] The boldface numbers in parentheses refer to the list of references at the end of this test method.

www.technobetar.ir

exposed to a mixed sulfate solution containing 5 % each of sodium and magnesium sulfate. Other relevant work is cited in the references (**1-19**).

X1.8 The second cooperative study used both a mixed sodium/magnesium sulfate solution and a sodium sulfate solution. Precision of the results and the ranking of the cements did not differ between the solutions. Hence, the simpler test, using sodium sulfate, was selected as the standard.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C1012–04, that may impact the use of this test method. (Approved December 15, 2009)

(*1*) Revised the standard as a dual units test method.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org). Designation: C 1017/C 1017M – 07

Standard Specification for Chemical Admixtures for Use in Producing Flowing Concrete[1]

This standard is issued under the fixed designation C 1017/C 1017M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers two types of chemical admixtures to be added to hydraulic cement concrete mixtures for the purpose of producing flowing concrete. The types are as follows:

1.1.1 *Type I*—Plasticizing, and

1.1.2 *Type II*—Plasticizing and retarding.

1.2 This specification stipulates tests of a chemical admixture with reference concreting materials or with concrete-making materials proposed for specific work. Unless otherwise specified by the purchaser, the tests shall be made using reference concreting materials.

1.3 If a chemical admixture has been tested and found to comply with the provisions of this specification using reference materials, and is being considered for use with other materials for specific work, additional tests for such use are allowed if agreed upon between the purchaser and the supplier and are allowed to consist of a portion of the tests described herein.

1.4 This specification provides for three levels of testing.

1.4.1 *Level 1*—During the initial approval stage, proof of compliance with the performance requirements defined in Table 1 demonstrates that the admixture meets the requirements of this specification. Uniformity and equivalence tests of the section on Lot Uniformity and Equivalence shall be carried out to provide results against which later comparisons can be made.

1.4.2 *Level 2*—Limited retesting described in the section relating to general requirements may be requested at intervals by the purchaser. Proof of compliance with the requirements of Table 1 demonstrates continued conformity of the admixture with the requirements of the specification.

1.4.3 *Level 3*—For acceptance of a lot or for measuring uniformity within or between lots, when specified by the purchaser, the uniformity and equivalence tests of the section on Lot Uniformity and Equivalence shall be used.

1.5 The values stated in SI units are to be regarded as standard. The values in inch-pound units shown in parentheses are provided for information purposes only.

NOTE 1—It is recommended that, whenever practicable, tests be made using the concrete-making materials (cement, pozzolan, slag, aggregates, air-entraining admixture), the mixture proportions, and the batching sequence and other physical conditions proposed for the specific work. The specific effects produced by chemical admixtures may vary with the properties and proportions of the other ingredients of the concrete.

NOTE 2—Temperature has a pronounced effect on time of setting of concrete. This may be exaggerated by the use of admixture Types I and II. If concrete temperatures to be expected on a particular job differ significantly from the conditions set forth in this specification, further testing may be desirable.

NOTE 3—An unusually rapid loss of workability with time, sometimes termed "slump loss", can be experienced with these admixtures. The rate of slump loss will vary with the particular concreting materials and proportions, mixing equipment and procedures, and temperatures experienced on any particular job. At elevated temperatures, the slump may be retained for a longer period if a Type II admixture is used.

NOTE 4—Admixtures that contain relatively large amounts of chloride may accelerate corrosion of prestressing steel. Compliance with the requirements of this specification does not constitute assurance of acceptability of the admixture for use in prestressed concrete (see ACI 318).

NOTE 5—Admixtures that contain relatively large amounts of alkali ($Na_2O + 0.658\ K_2O$) may contribute to reaction with some aggregates. Compliance with the requirements of this specification does not assure acceptability when used with alkali-reactive aggregates and some cements.

1.6 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.7 The following precautionary caveat pertains only to the test method sections of this specification: *This standard does not purport to address all of the safety concerns, if any,*

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

Current edition approved June 1, 2007. Published July 2007. Originally approved in 1985. Last previous edition approved in 2003 as C 1017/C 1017M – 03.

***A Summary of Changes section appears at the end of this standard.**

2.2 *American Concrete Institute Standard:*[3]

ACI 211.1-81 Recommended Practice for Selecting Proportions for Normal and Heavyweight Concrete
ACI 318-83 Building Code Requirements for Reinforced Concrete

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *flowing concrete*—concrete that is characterized by a slump greater than 7½ in. (190 mm) while maintaining a cohesive nature, and which otherwise meets the requirements of Table 1.

TABLE 1 Physical Requirements[A]

	Type I Plasticizing	Type II Plasticizing and Retarding
Time of setting, allowable deviation from Reference, h		
Initial: at least not more than	...	1 later
	1 earlier nor 1½ later	3½ later
Final: at least not more than	...	...
	1 earlier nor 1½ later	3½ later
Increase in slump, min.	90 mm (3.5 in.)	90 mm (3.5 in.)
Compressive strength, min., % of reference		
3 days	90	90
7 days	90	90
28 days	90	90
6 months	90	90
1 year	90	90
Flexural strength, min., % of reference		
3 days	90	90
7 days	90	90
28 days	90	90
Length change after 14 days drying, max. shrinkage (alternative requirements):[B]		
% of reference	135	135
Increase over reference, in.	0.010	0.010
Relative durability factor, min.[C]	80	80

[A] The values in the table include allowance for normal variation in the test results. The object of the 90 % strength requirements is to require a level of performance comparable to that of the reference concrete.

[B] *Alternative Requirements*—Percent of reference limit applies when length change of reference is 0.030 % or greater; increase over reference limit applies when length change of reference is less than 0.030 %.

[C] The requirement is applicable only when the admixture is to be used in air-entrained concrete which may be exposed to freezing and thawing while wet.

3.1.2 *plasticizing admixture*— a chemical admixture which, when added to concrete, produces flowing concrete without further addition of water and does not retard the setting of the concrete.

3.1.3 *plasticizing and retarding admixture*—a chemical admixture which, when added to concrete, produces flowing concrete without further addition of water and retards the setting of concrete.

3.1.4 *reference concrete*—concrete which contains the same amounts of cement, aggregates, water, and other concreting materials, but no plasticizing admixture.

3.1.5 *test concrete*—concrete which has a plasticizing admixture added.

4. Ordering Information

4.1 When the purchaser specifies flowing concrete, he shall also specify the type of chemical admixture desired. If not specified, the requirements of Type I will apply.

5. General Requirements

5.1 For initial compliance with this specification, test concrete in which each type of admixture shown in 1.1 is used shall conform to the respective requirements prescribed in Table 1.

5.2 The purchaser is allowed to require a limited retesting to confirm current compliance of the admixture to specification requirements. The limited retesting will cover physical properties and performance of the admixture.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

5.2.1 The physical properties retesting shall consist of uniformity and equivalence tests for infrared analysis, residue by oven drying and specific gravity.

5.2.2 The performance property retesting shall consist of water content of fresh concrete, setting time and compressive strength at 3, 7 and 28 days.

NOTE 6—Additional performance tests currently in this standard may be required by users having special requirements.

5.3 At the request of the purchaser, the manufacturer shall state in writing that the admixture supplied for use in the work is identical in all essential respects, including concentration, to the admixture tested for conformance under this specification.

5.4 At the request of the purchaser, when the chemical admixture is to be used in prestressed concrete, the manufacturer shall state in writing the chloride content of the admixture and whether or not chloride has been added during its manufacture.

5.5 Tests for uniformity and equivalence shall be made on the initial sample and the results retained for reference and comparison, with the results of tests of samples taken from elsewhere within the lot or subsequent lots of admixture supplied for use in the work.

6. Lot Uniformity and Equivalence

6.1 When specified by the purchaser, the uniformity of a lot, or the equivalence of different lots from the same source, shall be established by the use of the following requirements:

6.1.1 *Infrared Analysis*—The absorption spectra of the initial sample and the test sample, obtained as specified, shall be essentially similar.

6.1.2 *Residue by Oven Drying (Liquid Admixtures)*—When dried as specified, the oven-dried residues of the initial sample and of subsequent samples shall be within a range of variation of not greater than five percentage points.

6.1.3 *Residue by Oven Drying (Nonliquid Admixtures)*—When dried as specified, the oven-dried residues of the initial sample and of the subsequent samples shall be within a range of variation not greater than four percentage points.

6.1.4 *Specific Gravity (Liquid Admixtures)*—When tested as specified, the specific gravity of subsequent test samples shall not differ from the specific gravity of the initial sample by more than 10 % of the difference between the specific gravity of the initial sample and that of reagent water at the same temperature. If 10 % of the difference between the specific gravity of the initial sample and water is less than 0.01, use the value 0.01 as the maximum allowable difference. Reagent water conforming to Specification D 1193, Types III or IV, and prepared by distillation, ion exchange, reverse osmosis, electrodialysis, or a combination of these procedures is adequate.

6.2 When the nature of the admixture or the analytical capability of the purchaser make some or all of these procedures unsuitable, other requirements for uniformity and equivalence from lot to lot or within a lot shall be established by agreement between the purchaser and the manufacturer.

7. Sampling and Inspection

7.1 Every facility shall be provided the purchaser for careful sampling and inspection, either at the point of manufacture or at the site of the work, as specified by the purchaser.

7.2 Samples shall be either grab or composite samples, as specified or required by this specification. A grab sample is one obtained in a single operation. A composite sample is one obtained by combining three or more grab samples.

7.3 Samples will be taken for two reasons:

7.3.1 *Quality Tests*—A sample taken for the purpose of evaluating the quality of a source or lot of admixture will be required to meet all the applicable requirements of this specification. Samples used to determine conformance with the requirements of this specification shall be composites of grab samples taken from sufficient locations to ensure that the composite sample will be representative of the lot.

7.3.2 *Uniformity and Equivalence Tests*— When specified by the purchaser, a sample taken for the purpose of evaluating the uniformity of a single lot, or equivalence of different lots from one source, shall be tested as provided in Section 6. Such samples shall be composite samples from individual lots when different lots from the same source are being compared. When the uniformity of a single lot is being determined, grab samples shall be used.

7.4 *Liquid Admixtures*—Liquid admixtures shall be agitated thoroughly immediately prior to sampling. Grab samples taken for quality or uniformity tests shall represent not more than 2500 gal (9500 L) of admixture and shall have a volume of at least 1 qt (1 L). A minimum of three grab samples shall be taken. Composite samples shall be prepared by thoroughly mixing the grab samples selected and the resultant mixture sampled to provide at least 1 gal (4 L) for quality tests. Grab samples shall be taken from different locations well distributed throughout the quantity to be represented.

7.4.1 Admixtures in bulk storage tanks shall be sampled equally from the upper, intermediate, and lower levels by means of drain cocks in the sides of the tanks or a weighted sampling bottle fitted with a stopper that can be removed after the bottle is lowered to the desired depth.

7.4.2 Samples shall be packaged in impermeable, airtight containers which are resistant to corrosion.

7.5 *Nonliquid Admixtures*—Grab samples taken for quality or uniformity tests shall represent not more than 2 tons (1800 kg) of admixture and shall weigh at least 2 lb (1 kg). A minimum of four grab samples shall be taken. Composite samples shall be prepared by thoroughly mixing the grab samples selected and the resultant mixture sampled to provide at least 5 lb (2.3 kg) for the composite sample. Grab samples shall be taken from different locations well distributed throughout the quantity to be represented.

7.5.1 Samples of packaged admixtures shall be obtained by means of a tube sampler as described in Practice C 183.

7.5.2 Samples shall be packaged in moisture-proof, airtight containers.

7.6 Samples shall be thoroughly mixed before testing to ensure uniformity. When recommended by the manufacturer,

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the entire sample of a nonliquid admixture shall be dissolved in water prior to testing.

TEST METHODS

8. Scope

8.1 These test methods are based on arbitrary stipulations which make possible highly standardized testing in the laboratory and are not intended to simulate actual job conditions.

9. Apparatus

9.1 *Infrared Spectrophotometer*.

9.2 *Hydrometers*, Nos. 112H through 117H in accordance with Specification E 100.

9.3 *Water Bath*, capable of maintaining 25 ± 1 °C.

10. Reagents and Materials

10.1 *Reagents*:

10.1.1 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water as defined by Types III or IV of Specification D 1193.

10.1.2 *Potassium Bromide*, of a grade suitable for infrared analysis.

10.2 *Materials*:

10.2.1 *Cement*—The cement used in any series of tests shall be either the cement proposed for specific work or a cement conforming to the requirements of Specification C 150, Type I or Type II. If, when using a cement other than that proposed for specific work, the air content of the concrete made without admixture is more than 3.0 %, select a different cement so that the air content of the concrete will be 3.0 % or less.

10.2.2 *Aggregates*—Except when tests are made using the aggregates proposed for specific work, the fine and coarse aggregates used in any series of tests shall come from single lots of well-graded, sound materials that conform to the requirements of Specification C 33, except that the grading of the aggregates shall conform to the following requirements:

10.2.3 *Fine Aggregate*—The fine aggregate grading shall be as follows:

Sieve	Weight Percent Passing
4.75-mm (No. 4)	100
1.18-mm (No. 16)	65 to 75
300-µm (No. 50)	12 to 20
150-µm (No. 100)	2 to 5

10.2.4 *Coarse Aggregate*—The coarse aggregate grading shall meet the requirements for Size 57 grading requirements of Specification C 33. Take care in loading and delivery to avoid segregation.

10.2.4.1 Coarse aggregate used for reference concrete and test concrete shall be essentially the same. Provide sufficient coarse aggregate for the reference concrete, the test concrete, and for grading analysis.

10.2.4.2 Prepare required quantities of coarse aggregate (See Note 7) as follows: Fill tared containers, one for sieve analysis, one for a batch of reference concrete, and one for a batch of test concrete, to the required mass from the aggregate stockpile. Accomplish this by placing equal quantities into each container, successively, and repeat the procedure until all the containers have their required mass.

NOTE 7—Refer to the section on Sampling Aggregates in the Manual of Aggregate and Concrete Testing for guidance on sampling from stockpiles.

10.2.4.3 Perform sieve analyses on the coarse aggregate prepared in 10.2.4.2 by Test Method C 136. Discard any set for which the sample does not comply with Size 57. Average test results for samples that comply with Size 57 for each sieve size. Discard any set for which the sample deviates from this average by more than the amount shown in column 3 of the tabulated values shown below. Continue the process of preparation, testing, and averaging until sufficient sets of aggregate within tolerances are obtained.

Sieve	Specification C 33, No. 57 Percent Passing	Maximum variation from average/passing
37.5-mm (1.5 in.)	100	0.0
25.0-mm (1.0 in.)	95 to 100	1.0
12.5-mm (0.5 in.)	25 to 60	4.0
4.75-mm (No. 4)	0 to 10	4.0
2.36-mm (No. 8)	0 to 5	1.0

NOTE 8—All of the results required for demonstrating compliance under this specification are dependent on the uniformity of the aggregate samples prepared and used. Careful, skilled and well-supervised work is essential.

10.2.5 *20-30 Sand*—As specified in Specification C 778.

10.2.6 *Air-Entraining Admixture*—Except when tests are made using the air-entraining admixture proposed for specific work, the air-entraining admixture used, if needed in the concrete mixtures, shall be a material which when used to entrain the specified amount of air in the reference concrete mixture will give concrete of satisfactory resistance to freezing and thawing. The material to be so used will be designated by the person, or agency, for whom the testing is to be performed. If no material is designated, neutralized Vinsol resin shall be used.

NOTE 9—If unneutralized Vinsol resin is purchased, neutralization may be accomplished by treating 100 parts of Vinsol resin with 9 to 15 parts of NaOH by mass. In an aqueous solution, the ratio of water to the resinate should not exceed 12 to 1 by mass.

10.2.7 *Materials for Tests for Specific Uses*—To test a chemical admixture for use in specific work, the concreting materials used shall be representative of those proposed for use in the work. Add the chemical admixture in the same manner and at the same time during the batching and mixing sequence as it will be added on the job. Proportion the concrete mixtures to have the cement content specified for use in the work. If the maximum size of coarse aggregate is greater than 25.0 mm (1 in.), screen the concrete over a 25.0-mm (1-in.) sieve prior to fabricating the test specimens.

10.2.7.1 *Other Use Conditions*—At times, other conditions affect the overall suitability of the concrete mixture for specific intended uses. These include the temperature of the materials or the surroundings, the humidity, the length of time between mixing and placing, the amount of mixing activity and other factors. These physical conditions are allowed to be incorporated into the tests with intention for indicating the potential interactions. These tests would be only for guidance. After incorporation of such test conditions it would not be suitable to expect compliance with this specification requirement.

10.2.8 *Preparation and Weighing*—Prepare all material and make all weighings as prescribed in Practice C 192/C 192M.

www.technobetar.ir

11. Proportioning of Concrete Mixtures

11.1 *Proportions*—Except when tests are being made for specific uses, all concrete shall be proportioned using ACI 211.19 to conform to the requirements described below.

NOTE 10—The effects of a chemical admixture on the time of setting and water requirement of concrete may vary with the time of its addition. Consequently, specifications for particular work should require that the admixture be added in the same manner and at the same time as it will be added on the job, or as recommended by the manufacturer, within the restrictions imposed by the specified mixing sequence.

11.1.1 The cement content shall be 335 ± 3 kg/m ^{3}(564 ± 5 lb/yd^3).

11.1.2 For the first trial mixture, refer to the table on volume of coarse aggregate per unit volume of concrete in ACI 211.1 for guidance on the amount of coarse aggregate to use, for the nominal maximum size of aggregate, and for the fineness modulus of the fine aggregate being used (Note 11).

NOTE 11—Values in the referenced table in ACI 211.1 are intended to ensure workable mixtures with the least favorable combinations of aggregate likely to be used.

11.1.3 For the non-air-entrained mixtures, the air content used in calculating the proportions shall be 1.5 %, as shown in Table 5.3.3 of ACI 211.1-81. For the air-entrained mixtures, the air content used for this purpose shall be 5.5 %.

11.1.4 Adjust the water content of both the reference concrete and the test concrete to obtain an initial slump of 90 ± 15 mm (3½ ± ½ in.). The workability of the concrete mixtures shall be suitable for consolidation by hand rodding, and the concrete mixtures shall have the minimum water content possible. Achieve these conditions by final adjustments in the proportion of fine aggregate to total aggregate, or in the amount of total aggregate, or both, while maintaining the yield and slump in the required range.

11.2 *Conditions*—Prepare batches of the final trial mixture, one of test concrete and one of reference concrete, which are identical prior to addition of the plasticizer. Add the admixture to the test concrete in the manner recommended by the manufacturer and in the amount necessary to obtain a slump of 215 ± 25 mm (8½ ± 1 in.).

11.2.1 *Non-Air-Entrained Concrete*—When the admixture is to be tested for use only in non-air-entrained concrete, the air content of both the test concrete mixture and the reference concrete mixture shall be 3.0 % or less, and the difference between the air contents of the two mixtures shall not exceed 0.5 %. If necessary, the air-entraining admixture shall be added to the reference concrete mixtures.

11.2.2 *Air-Entrained Concrete*—When the admixture is to be tested for use only in air-entrained concrete requiring resistance to freezing and thawing, the air-entraining admixture shall be added to reference and test concrete mixtures to produce air contents in the range of 5.0 to 7.0 %. When entrained air is to be used for workability or other purposes, air contents are adjusted to 3.5 to 7.0 %. In either case, the difference between the air content of the reference concrete and that of the test concrete shall not exceed 0.5 %.

12. Mixing

12.1 Machine mix the reference concrete mixture as prescribed in Practice C 192/C 192M.

12.2 Machine mix the test concrete mixture as prescribed in Practice C 192/C 192M, except that the admixture shall be added according to the manufacturer's instructions. In the absence of such instructions, add the admixture at the start of the 2 min final mixing period described in Practice C 192/C 192M.

13. Tests and Properties of Freshly Mixed Concrete

13.1 Samples of freshly mixed concrete from at least three separate batches for each condition of concrete shall be tested in accordance with the following methods:

13.1.1 *Slump*—Test Method C 143/C 143M.

13.1.2 *Air Content*—Test Method C 231 or Test Method C 173/C 173M.

13.1.3 *Time of Setting*—Test Method C 403/C 403M, except that the temperature of each of the ingredients of the concrete mixtures just prior to mixing and the temperature at which the time of setting specimens are stored during the test period shall be 23.0 ± 2.0 °C (73 ± 3 °F).

13.1.4 *Water Content and Unit Weight*— Determine the net water content of the batch as the weight of water in the batch in excess of that present as absorbed water in the aggregates. Measure the unit weight and compute the yield, cement content, and water content as prescribed in Test Method C 138/C 138M. Determine the water–cement ratio to the nearest 0.01 by dividing the net weight of water by the weight of cement in the batch.

14. Test Specimens of Hardened Concrete

14.1 Make specimens for tests of hardened concrete from at least three separate batches representing each test and age of test from each condition of concrete being compared. The minimum number of specimens shall be as prescribed in Table 2. On a given day, make at least one specimen for each test and age of test from each condition of concrete, except make at least two specimens for the freezing and thawing test from each condition of concrete. Complete the preparation of all specimens in three days of mixing.

14.2 *Manifestly Faulty Specimens*—Visually examine each group of specimens representing a given test or a given age of test, including tests of freshly mixed concrete, before or during the test, or both, whichever is appropriate. Discard without

TABLE 2 Types and Minimum Number of Specimens and Tests

	Number of Types of Specimens	Number of Test Ages	Number of Conditions of Concrete	Number of Specimens, min.
Slump	1	1	2	[A]
Air content	1	1	2	[A]
Time of setting	1	[B]	2	6
Compressive strength	1	5	2	30
Flexural strength	1	3	2	18
Freezing and thawing	2	1	2	12
Length change	1	1	2	6

[A] Determined on each batch of concrete mixed.
[B] As prescribed in the text.

www.technobetar.ir

testing any specimen found to be manifestly faulty by such examination. Visually examine all specimens representing a given test at a given age after testing. Should any specimen be found to be manifestly faulty, the test results thereof shall be disregarded. Should more than one specimen representing a given test at a given age be found manifestly faulty either before or after testing, the entire test shall be disregarded and repeated. The test result reported shall be the average of the individual test results of the specimens tested or, in the event that one specimen or one result has been discarded, it shall be the average of the test results of the remaining specimens.

14.3 *Number of Specimens*—Six or more test specimens for the freezing and thawing test, and three or more test specimens for each other type of test and age of test specified in Table 2 shall be made for each condition of concrete to be compared.

14.4 *Types of Specimens*—Specimens made from concrete with and without chemical admixture under test shall be prepared in accordance with the following:

14.4.1 *Compressive Strength*—Make and cure test specimens in accordance with Practice C 192/C 192M.

14.4.2 *Flexural Strength*—Make and cure test specimens in accordance with Practice C 192/C 192M.

14.4.3 *Resistance to Freezing and Thawing*— Test specimens shall consist of prisms made and cured in accordance with the applicable requirements of Practice C 192/C 192M. The prisms shall be not less than 75 mm (3 in.) nor more than 130 mm (5 in.) in width and depth, and not less than 275 mm (11 in.) nor more than 410 mm (16 in.) in length. Make one set of specimens from the test concrete mixture and one from the reference concrete mixture, the air content of each mixture being as specified.

14.4.4 *Length Change*—Make and cure test specimens in accordance with Test Method C 157/C 157M. The moist-curing period, including the period in the molds, shall be 14 days.

15. Tests on Hardened Concrete

15.1 Test the specimens of hardened concrete in accordance with the following methods:

15.1.1 *Compressive Strength*—Test Method C 39/C 39M. Test specimens at ages 3 days, 7 days, 28 days, 6 months, and 1 year. Calculate the compressive strength of the concrete containing the admixture under test as a percentage of the compressive strength of the reference concrete as follows:

15.1.1.1 Divide the average compressive strength of the specimens made from the test concrete at a given age of test by the average compressive strength of the specimens made from the reference concrete at the same age of test and multiply the quotient by 100. Requirements are shown in Table 1.

NOTE 12—When tests are conducted with materials representative of those proposed for use in specific work, and if the results of the tests are required in a period of time that will not permit curing of specimens to ages of 6 months and 1 year, the tests at those ages as required in 14.1.1 may be waived.

15.1.2 *Flexural Strength*—Test Method C 78. Test specimens at ages 3, 7, and 28 days. Calculate the flexural strength of the test concrete as a percentage of the flexural strength of the reference concrete.

15.1.3 *Resistance to Freezing and Thawing*— Procedure A of Test Method C 666/C 666M. Place specimens under test at the age of 14 days unless durability at some later age is desired for specific work. Calculate the relative durability factors as shown in Specification C 260. Only air-entrained concrete designed for resistance to freezing and thawing shall be tested for resistance to freezing and thawing.

15.1.4 *Length Change*—Test specimens shall consist of molded prisms made and tested in accordance with Test Method C 157/C 157M, except that the moist curing period, including the period in the molds, shall be 14 days. Then store the specimens in air under conditions specified in Test Method C 157/C 157M for a period of 14 days, at which time determine the length change of the specimen. Consider the drying shrinkage to be the length change during the 14 day drying period, based on an initial measurement at the time of removal of the specimen from the mold, and express it as percent to the nearest 0.001 % based on the specimen gage length. Alternative requirements for length change, based on reference concrete length change, are shown in Table 1.

NOTE 13—Since the specific effects produced by chemical admixtures may vary with the properties of the other ingredients of the concrete, results of length change tests using aggregates of such a nature that the length change on drying is low may not accurately indicate relative performance to be expected from other aggregates having properties that produce concrete of high length change on drying.

16. Infrared Analysis

16.1 *Scope*—This test method is intended to compare qualitatively the composition of different samples; results should not be not interpreted quantitatively. A general procedure for the infrared analysis of admixtures is given.

NOTE 14—It is important that the same procedures be used on all samples to be compared with each other and it is preferable that they be conducted by the same analyst. Major changes in infrared spectra may result from: (*a*) water content differences due to drying variations, (*b*) water picked up by hygroscopic materials, (*c*) reaction between the potassium bromide and some other compound present, and (*d*) differences in time between formation of the disk and its use. Also, the threshold for detection of individual components by infrared absorption varies widely, depending upon the identity and concentration of accompanying substances. For example, significant amounts of saccharides may be present in a lignosulfonate admixture without their presence being indicated by this test method.

16.2 *Procedure*:

16.2.1 *Liquid Admixtures*—Determine the residue by oven drying by 17.1 and dilute an aliquot of the liquid admixture sample with distilled water to yield a dissolved solids concentration of about 0.015 g/mL: for example, a 5-mL aliquot diluted to 200 mL. Pipet 5 mL of above solution and add it to a petri dish containing 2.5 g of potassium bromide and 5 mL of distilled water. Stir and mix to dissolve. Place in a drying oven and dry for 17 ± ¼ h at 105 ± 3 °C. Cool and transfer the dried residue to a mortar and grind to a fine powder. Work quickly to avoid moisture pick-up. Weigh 0.1 g of the powder and 0.4 g of potassium bromide. Mix in an electric amalgamator for 30 s using stainless steel capsule and balls. Proceed in accordance with 16.2.3.

16.2.2 *Nonliquid Admixture*—Grind 10 g to a fine powder with mortar and pestle. Transfer the sample to a petri dish,

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

place in a drying oven and dry for 17 ± ¼ h at 105 ± 3 °C. Weigh approximately 0.005 g of the dried powder and 0.995 g of potassium bromide. Mix in an electric amalgamator for 30 s using stainless steel capsule and balls. Proceed in accordance with 16.2.3.

16.2.3 To prepare a disk for infrared analysis, weigh 0.300 g of the mixture prepared in 16.2.1 or 16.2.2 and transfer into a suitable die. If an evacuable die is used, apply vacuum for 2 min prior to pressing. Continue vacuum and press at a suitable force for 3 min, producing a disk about 1-mm thick. Remove the disk from the die, insert into the infrared spectrophotometer, and obtain infrared absorption spectra.

17. Residue by Oven Drying

17.1 *Liquid Admixtures*:

17.1.1 Place 25 to 30 g of 20–30 sand (Specification C 778) in a wide-mouth, low-form (about 60 mm inside diameter and 30 mm in height) glass weighing bottle provided with a ground-glass stopper. Place the weighing bottle and stopper, with stopper removed, in a drying oven and dry for 17 ± ¼ h at 105 ± 3 °C (Note 15). The drying oven must be either a forced circulation type or one with provision for free access of air. Precise control of temperature and time of drying is essential so that the degree of volatilization of the material other than water from sample will not vary. Transfer to a desiccator, cool to room temperature, insert the stopper in the weighing bottle, and weigh to the nearest 0.001 g. Remove the stopper and, using a pipet, evenly distribute 4 mL of the liquid admixture over the sand. Immediately insert the stopper to avoid loss by evaporation and weigh to the nearest 0.001 g. Remove the stopper and place both the bottle and stopper in a drying oven. Dry for 17 ± ¼ h at 105 ± 3 °C. At the end of the drying period, transfer to a desiccator, cool to room temperature, stopper the weighing bottle, and weigh to the nearest 0.001 g.

NOTE 15—For laboratories conducting this test as a routine operation, previously dried sand and weighing bottles can be maintained in desiccators so that they are immediately available for use when a sample is to be tested.

17.1.2 *Calculation*:

17.1.2.1 Record the following masses:

M_1 = mass of stoppered bottle with sand and sample,
M_2 = mass of stoppered bottle with sand,
M_3 = $M_1 - M_2$ = mass of sample,
M_4 = mass of stoppered bottle with sand and dried residue, and
M_5 = $M_4 - M_2$ = mass of dried residue.

17.1.2.2 Calculate the residue by using the following equation.

$$\text{Residue by oven drying (percent by mass)} = (M_5 \times 100)/M_3 \quad (1)$$

17.1.3 *Precision*—The maximum multilaboratory coefficient of variation for residue by oven drying (liquid admixtures) has been found to be 1.25 %. Therefore, results of tests by two different laboratories on identical samples of an admixture are not expected to differ from each other by more than 3.5 % of their average (Note 16). The maximum single-operator coefficient of variation has been found to be 0.6 %. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 1.7 %.

NOTE 16—The precision statements are based on the maximum variation of tests made in 18 laboratories on sets of three duplicate samples of two different admixtures.

17.2 *Nonliquid Admixtures*:

17.2.1 Place about 3 g of the nonliquid admixture into a dried and tared glass-stoppered weighing bottle. Stopper and weigh bottle and contents to the nearest 0.001 g. Remove the stopper and immediately place both bottle and stopper in a drying oven. Dry for 17 ± ¼ h at 105 ± 3°C. At the end of the drying period, transfer to the desiccator, cool to room temperature, stopper the weighing bottle, and weigh to the nearest 0.001 g.

17.2.2 *Calculation*:

17.2.2.1 Record the following masses:

M_1 = mass of tared stoppered weighing bottle and sample before drying,
M_2 = mass of empty, stoppered weighing bottle,
M_3 = $(M_1 - M_2)$ = mass of sample,
M_4 = mass of tared stoppered weighing bottle and sample after drying, and
M_5 = $(M_4 - M_2)$ = mass of oven-dried residue.

17.2.2.2 Calculate the oven dried residue by using the following equation:

$$\text{Residue by oven drying (mass percent)} = (M_5 \times 100)/M_3 \quad (2)$$

17.2.3 *Precision*—The maximum multilaboratory coefficient of variation for residue by oven drying (nonliquid admixtures) has been found to be 1.40 %. Therefore, results of tests by two different laboratories on identical samples of an admixture are not expected to differ from each other by more than 4.0 % of their average. The maximum single-operator coefficient of variation for residue by oven drying (nonliquid admixture) has been found to be 0.48 %. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 1.4 % of their average (Note 16).

18. Specific Gravity (Liquid Admixtures)

18.1 Determine the specific gravity at 25 ± 1 °C of a liquid admixture using hydrometers complying with Specification E 100. Hydrometers Nos. 112H through 117H will cover the range for most determinations. A250-mL graduated cylinder, and a water bath capable of maintaining 25 ± 1 °C will also be required.

18.2 Place a sample in the 250-mL graduated cylinder and put in the hydrometer in such a manner that it floats free and does not touch the side of the cylinder. Place the cylinder with sample and hydrometer in the constant-temperature bath until the temperature of the cylinder, hydrometer, and sample is uniform at 25 ± 1°C. If all are at the proper temperature prior to insertion of the hydrometer, approximately 10 min shall be

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:44:20 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

allowed for equilibrium. If the sample shows evidence of foaming, hydrometer reading shall be continued until constant readings are obtained. Read the hydrometer at the base of the meniscus to the nearest 0.005.

NOTE 17—If foaming is encountered during transfer of the admixture to the cylinder, sufficient time should be allowed for the foam to dissipate or rise to the surface, or both, so that it will be removed before inserting the hydrometer. Crusting of the admixture on the hydrometer stem due to evaporation during temperature adjustment should be avoided.

18.3 *Precision*—The maximum multilaboratory coefficient of variation for specific gravity (liquid admixtures) has been found to be 0.316 %. Therefore, results of tests by two different laboratories on identical samples of an admixture are not expected to differ from each other by more than 0.9 % of their average (Note 16). The maximum single-operator coefficient of variation has been found to be 0.09 %. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 0.275 %.

19. Rejection

19.1 For initial compliance testing, the purchaser is allowed to reject the admixture if it fails to meet any of the applicable requirements of this specification.

19.2 For limited retesting, the purchaser is allowed to reject the admixture if it fails to meet any of the requirements of the Uniformity and Equivalence Section and of the applicable parts of Table 1.

19.3 An admixture stored at the point of manufacture for more than 6 months prior to shipment, or an admixture in local storage in the hands of a vendor for more than 6 months after completion of tests, shall be retested if requested by the purchaser and is allowed to be rejected if it fails to conform to any of the applicable requirements of this specification.

19.4 Packages or containers varying more than 5 % from the specified weight or volume are allowed to be rejected. If the average weight or volume of 50 packages taken at random is less than that specified, the entire shipment is allowed to be rejected.

19.5 The admixture shall be rejected when the purchaser desires if the test concrete containing it has an air content greater than 3.0 % in non-air-entraining concrete; when the admixture is to be used in air-entrained concrete, it shall be rejected when the purchaser desires if the test concrete containing it has an air content greater than 7.0 %. Except when testing in accordance with 10.2.4, other concrete materials are allowed to be chosen for reference and test concretes in order to conform to these requirements.

20. Certification and Report

20.1 When specified in the purchase order or contract, the manufacturer's or supplier's certification shall be furnished to the purchaser stating that samples representing each lot have been manufactured, tested, and inspected in accordance with this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

20.2 Report the following:

20.2.1 Results of the specified tests and the relevant specification requirements with which they are compared,

20.2.2 Brand name, manufacturer's name, and lot number, character of the material, and quantity represented by the sample of the admixture under test,

20.2.3 Brand name, manufacturer's name, and other pertinent data on the material used as the air-entraining admixture,

20.2.4 Brand name, manufacturer's name, type, and test data on the portland cement or cements used,

20.2.5 Description of, and test data on, the fine and coarse aggregates used,

20.2.6 Detailed data on the concrete mixtures used, including amounts and proportions of admixtures used, actual cement contents, water-cement ratios, densities (unit weights), ratios of fine to total aggregate, slumps, and air contents, and

20.2.7 In the event that, in accordance with the provisions of Note 12, some of the tests have been waived, the circumstances under which such action was taken shall be stated.

21. Packaging and Package Marking

21.1 When the admixture is delivered in packages or containers, the proprietary name of the admixture, the type under this specification, and the net weight or volume shall be plainly marked thereon. Similar information shall be provided in the shipping documents accompanying packages or bulk shipments of admixtures.

22. Storage

22.1 The admixture shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment and adequate protection for the admixture.

23. Keywords

23.1 admixture; concrete; flowing concrete; plasticizing admixtures; plasticizing and retarding admixtures; water-reducing admixtures; water-reducing and retarding admixtures

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1017/C 1017M – 03, that may impact the use of this specification. (Approved June 1, 2007)

(*1*) Revised 10.2.4, 10.2.4.1, 10.2.4.2 and 10.2.4.3 to clarifying wording.

(*2*) Added new Note 7 and renumbered subsequent notes.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1032 – 06

Standard Specification for Woven Wire Plaster Base[1]

This standard is issued under the fixed designation C 1032; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers woven wire plaster base, flat or self-furring, with or without stiffener wires, and with or without backing, designed for use as a base to receive gypsum or portland cement based plaster.

1.2 The values stated in inch-pound units are to be regarded as the standard. The SI equivalents of inch-pound units are approximate.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

UU-P-31 B/171 Tensile Breaking Strength (Dry)[3]

3. Terminology

3.1 *Definitions*—Definitions shall be in accordance with Terminology C 11.

4. Material

4.1 In accordance with Specification A 641/A 641M and Table 1.

4.2 *Kraft Building Paper*, Federal Specification UU-B-790a.

TABLE 1 Nominal Diameter and Minimum Weight for Size of Opening

Opening Size, in. (mm)	Diameter, in. (mm)	Weight, lb/yd^2 (kg/m^2)[A]
1 (25.4)	0.035 (0.89)	0.86 (0.466)
1½ (38.0)	0.051 (1.30)	1.40 (0.760)

[A] The weight of attached backing is not included.

5. Physical Properties

5.1 *Backing*:

5.1.1 Factory attached backing shall provide a one mesh wire to wire lap joint at one end and one edge of each flat sheet or roll. Attachment of the backing shall allow lapping of wire-to-wire and backing-to-backing of one mesh at ends and edges and shall permit full embedment in not less than ¼ in. (6.4 mm) of plaster of not less than one half the total length and width of the wire.

5.1.2 Backing shall have a minimum tensile breaking strength (dry) of 20 lbf/in. (3.5 kN/m) width, as tested in accordance with Federal Specification UU-P-31 B, Method 171.

6. Dimensions, Weight, and Permissible Variations

6.1 *Openings*:

6.1.1 Woven wire plaster base shall be fabricated to provide the size of openings in accordance with Table 1, except that any single opening shall be not more than 3.0 in.^{2} (1935.5 mm^2).

6.1.2 Wire diameter for opening size shall be in accordance with Table 1.

6.2 Diameter tolerance for galvanized wire shall be in accordance with Specification A 641/A 641M.

6.3 The wire shall be zinc-coated (galvanized) in accordance with Specification A 641/A 641M.

6.4 Weight for woven wire plaster base shall be in accordance with Table 1.

6.5 When included as part of the woven wire plaster base, factory fabricated stiffener wires shall have a diameter not less than that specified in Table 1 and shall be continuous, parallel to the long dimension of the plaster base, and shall occur at not more than 6-in. (154.4-mm) intervals.

6.6 Factory fabricated crimps for self-furring woven wire plaster base shall provide a nominal ¼-in. (6.4-mm) separation between the back plane of the plaster base and the surface of solid backing to permit embedment in both directions.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved June 1, 2006. Published June 2006. Originally approved in 1985. Last previous edition approved in 2004 as C 1032 – 04.

www.technobetar.ir

6.7 Width of woven wire plaster base shall be not less than 36 in. (914 mm).

6.8 Length of woven wire plaster base shall be in accordance with Table 2.

7. Inspection

7.1 Inspection of the material shall be agreed upon between the purchaser and the producer or supplier as part of the purchase agreement.

8. Rejection and Rehearing

8.1 Material that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the product has failed to conform to the requirements of the specification.

TABLE 2 Minimum Length of Flat Sheets and Rolls[A]

Flat Sheets	100 linear in. (2.540 m)
Rolls	150 linear ft. (45.72 m)
Rolls, with backing	100 linear ft. (30.48 m)

[A] Allowable variations shall be not more than – ¾ in. (–19.0 mm) in width or length.

9. Certification

9.1 When specified in the purchase order or contract, the producer or supplier shall furnish a report certifying that at the time of shipment, the materials were in compliance with the requirements of this specification.

10. Packaging and Package Marking

10.1 *Packaging*—Woven wire plaster base shall be packaged in bundles, rolls or pallets.

10.2 *Marking*—When shipped for sale or resale, the name of the producer or the supplier and the brand and description of the contents shall be legibly marked on each pallet, bundle or roll. The quantity for bundles shall be square yards and number of sheet per bundle. The quantity for pallets, bundles or rolls shall indicate the mesh-opening size and wire thickness.

11. Keywords

11.1 backing; base; cement plaster; flat; gypsum plaster; plaster; self-furning; woven wire

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1032 – 04, that may impact the use of this specification. (Approved June 1, 2006)

(*1*) Combined Tables 1 and 2 into new Table 1.

(*2*) Changed references to old Tables 1 and 2 to new Table 1 within the text of the specification.

(*3*) Renumbered Table 3 as Table 2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1038 – 04

Standard Test Method for Expansion of Hydraulic Cement Mortar Bars Stored in Water[1]

This standard is issued under the fixed designation C 1038; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the expansion of mortar bars made using hydraulic cement, of which sulfate is an integral part.

1.1.1 **Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

1.2 The values stated in SI units are to be regarded as the standard. Values in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 778 Specification for Standard Sand

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

C 1437 Test Method for Flow of Hydraulic Cement Mortar

D 1193 Specification for Reagent Water

3. Significance and Use

3.1 This test method is used to determine the amount of expansion of a mortar bar when it is stored in water. The amount of mortar-bar expansion may relate to the amount of sulfate in the cement; expansion may become excessive when the cement contains too much sulfate.

3.2 Some cement specifications limit the amount of sulfate contained in hydraulic cement by requiring that the amount of expansion in water not exceed a specified value.

4. Apparatus

4.1 *Reference Masses and Mass-Determining Devices*, conforming to the requirements of Specification C 1005. Evaluate the device for precision and bias at a total load of 2 Kg.

4.2 *Glass Graduates, Molds, and Length Comparator*, conforming to the requirements of Specification C 490.

4.3 *Moist Cabinet or Room*, conforming to the requirements of Specification C 511.

4.4 *Mixer, Bowl, and Paddle*, conforming to the requirements of Practice C 305.

4.5 *Trowel and Tamper*, conforming to the requirements of Test Method C 109.

5. Temperature and Relative Humidity

5.1 *Molding Room, Dry Materials, and Mixing Water*—Maintain the temperature of the molding room, dry materials, and mixing water at 23.0 ± 4.0 °C, and maintain the relative humidity of the molding room at not less than 50 %.

6. Reagents and Materials

6.1 *Mixing Water*—Potable water is satisfactory for routine tests. For all cooperative tests and in case of dispute, use reagent water conforming to the numerical limits of Type III of Specification D 1193.

6.2 *Graded Sand*—Sand for making the test specimens shall conform to the requirements for graded standard sand in Specification C 778.

---

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.28 on Sulfate Content.

Current edition approved July 1, 2004. Published August 2004. Originally approved in 1985. Last previous edition approved in 2001 as C 1038 – 01ε1.

www.technobetar.ir

7. Procedure

7.1 *Number and Dimensions of Test Specimens*—Make four 25 by 25 by 285-mm, or 1 by 1 by 11¼-in. test specimens for each cement. The effective gage length of these specimens is 250 mm (10 in.).

NOTE 1—In routine tests, 25 by 25 by 160-mm, or 1 by 1 by 6¼-in. specimens may be used; however, in case of dispute, results obtained with 25 by 25 by 285-mm, or 1 by 1 by 11¼-in. specimens shall govern. The effective gage length of this specimen is 125 mm (5 in.).

7.2 *Specimen Molds*—Prepare the specimen molds in accordance with the requirements of Specification C 490, except cover the interior surfaces of the mold with a release agent. A release agent will be acceptable if it serves as a parting agent without affecting the setting of the cement and without leaving any residue which will reduce the penetration of water into the specimen.

NOTE 2—TFE-fluorocarbon tape complies with the requirements for a mold release agent.

7.3 *Proportioning, Consistency, and Mixing of Mortar*:

7.3.1 The quantity of dry materials required to prepare four 25 by 25 by 285-mm or 1 by 1 by 11¼-in. specimens is 500 g of cement and 1375 g of graded sand. Use an amount of mixing water that produces a flow of 110 ± 5 as determined by the flow table after 25 drops in 15 s as described in Test Method C 1437. Record the amount of water used to the nearest millilitre.

7.3.2 Mix the mortar in accordance with the procedure described in Practice C 305.

7.4 *Molding Test Specimens*—Immediately upon completion of mixing, remove the paddle and the bowl from the mixer and shake the excess mortar from the paddle into the bowl. Fill the mold in two layers, compacting each layer with the tamper. Work the mortar into the corners, around the gage studs, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, cut the mortar off flush with the top of the mold and smooth the surface with a few strokes of the trowel.

8. Storage of Test Specimens

8.1 *Initial Storage*—Immediately upon completion of molding, place the test specimens in the moist cabinet or moist room. Keep all test specimens in the molds in the moist cabinet or moist room for 22.5 ± 0.5 h with upper surfaces exposed to the moist air but protected from dripping water. After this time, remove the specimens from the molds, properly identify, and place in water or saturated lime water maintained at 23.0 ± 2.0 °C for at least 30 min prior to making the initial measurement.

8.2 *Subsequent Storage*—After the initial measurement, store the test specimens in saturated lime water in a tank in the moist cabinet or moist room. Cover the specimens with at least 5-mm (¼-in.) of water during storage. Keep the storage water clean by changing as necessary. Use a tank and lime water conforming to the requirements of Specification C 511.

9. Length Change Measurement

9.1 Remove the specimens from water storage, one at a time, and wipe only the gage studs with a damp cloth before measuring. Make length-comparator readings. The effective gage length of specimens is 250 mm or 10 in. for the standard mold size.

9.2 Make the first reading at the age of 24 h ± 15 min from the time the cement and water are mixed together. Make additional length-comparator readings at the age of 14 days.

NOTE 3—Additional information of value may be obtained by making length-comparator readings of the specimens at ages earlier and later than 14 days.

10. Calculation and Report

10.1 Calculate the change in length of the specimen at 24 h and at 14 days to the nearest 0.001 % of the effective gage length and report as the expansion of the specimen at that period. Report the average length of change of the four specimens to the nearest 0.001 %.

11. Precision and Bias

11.1 *Precision*—The following precision statements are applicable when replicate samples are made using the same portland cement at fixed water content.

11.1.1 The single-operator standard deviation has been found to be 0.00165 % for expansions between 0.0075 and 0.011 %. Therefore, results of two properly conducted tests by the same operator on the same material should not differ from each other by more than 0.005 %.

11.1.2 The multi-laboratory standard deviation has been found to be 0.00287 % for expansions between 0.0075 and 0.0115 %. Therefore, results of two properly conducted tests on the same material in two different laboratories should not differ from each by more than 0.008 %.

11.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in Test Method C 1038 for measuring the expansion of the bar specimens, no statement on bias is being made.

12. Keywords

12.1 hydraulic cement; mortar-bar expansion; sulfate; sulfate content

Designation: C 1040/C 1040M – 08

Standard Test Methods for In-Place Density of Unhardened and Hardened Concrete, Including Roller Compacted Concrete, By Nuclear Methods[1]

This standard is issued under the fixed designation C 1040/C 1040M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 These test methods cover the determination of the in-place density of unhardened and hardened concrete, including roller compacted concrete, by gamma radiation. For notes on the nuclear test see Appendix X1.

1.2 Two test methods are described, as follows:

	Section
Test Method A—Direct Transmission	7
Test Method B—Backscatter	8

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 29/C 29M Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate

C 138/C 138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Significance and Use

3.1 These test methods are useful as rapid, nondestructive techniques for the in-place determination of the density of unhardened concrete. The backscatter test method is also useful for the same purpose on hardened concrete. The fundamental assumptions inherent in the test methods are that Compton scattering is the dominant interaction and that the material under test is homogeneous.

3.2 These test methods are suitable for control and for assisting in acceptance testing during construction, for evaluation of concrete quality subsequent to construction, and for research and development.

NOTE 1—Care must be taken when using these test methods in monitoring the degree of consolidation, which is the ratio of the actual density achieved to the maximum density attainable with a particular concrete. The test methods presented here are used to determine the actual density. A density measurement, by any test method, is a function of the components of the concrete and may vary, to some extent, in response to the normal, acceptable variability of those components.

3.3 Test results may be affected by reinforcing steel, by the chemical composition of concrete constituents, and by sample heterogeneity. The variations resulting from these influences are minimized by instrument design and by the user's compliance with appropriate sections of the test procedure. Results of tests by the backscatter test method may also be affected by the density of underlying material. The backscatter test method exhibits spatial bias in that the apparatus's sensitivity to the material under it decreases with distance from the surface of the concrete.

NOTE 2—Typically, backscatter gauge readings represent the density in the top 75 to 100 mm [3 to 4 in.] of material.

4. Apparatus

4.1 The exact details of construction of the apparatus may vary, but the apparatus as a whole shall satisfy the requirements for system precision stated in Annex A1. The system shall consist of the following:

4.1.1 *Gamma Source*—An encapsulated and sealed radioisotopic source, such as cesium-137 (see X1.2).

[1] These test methods are under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and are the direct responsibility of Subcommittee C09.45 on Roller-Compacted Concrete.

Current edition approved Oct. 1, 2008. Published November 2008. Originally approved in 1985. Last previous edition approved in 2005 as C 1040 – 05.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

4.1.2 *Detector*—Any type of gamma detector, such as a Geiger-Müller tube, scintillation crystal, or proportional counter.

4.1.3 *Probe*—For direct transmission measurements, either the gamma source or the detector shall be housed in a probe for inserting in a preformed hole in the material to be tested. The probe shall be marked in increments of 50 mm [2 in.] for tests with probe depths from 50 to 300 mm [2 to 12 in.]. The probe shall be so made mechanically, that when moved manually to the marked depth desired, it will be held securely in position at that depth.

4.1.4 *Readout Instrument*—A suitable scaler or direct readout meter.

4.1.5 *Gauge Housing*—The source, detector, readout instrument and appropriate power supplies shall be in housings of rugged construction that are moisture and dust proof.

4.1.6 *Reference Standard*—A block of uniform, unchanging density provided for checking equipment operation, background count, and count-rate reproducibility.

4.1.7 *Guide Plate and Hole-Forming-Device*—For direct transmission measurements, a guide plate and a device, such as a pin or drill rod, having a nominal diameter slightly larger than the probe, for forming a hole normal to the concrete surface are required.

4.1.8 *Calibration Adjustment Container*— The container shall be rigid and watertight, with minimum inside dimensions large enough to allow the calibration curve adjustment procedure (5.2) to be followed with no effect of the finite size of the container on the instrument's responses. The volume of the container shall be established following the procedure outlined in Test Method C 29/C 29M.

NOTE 3—For backscatter measurements, a container 450 by 450 by 150 mm [18 by 18 by 6 in.] will meet this requirement for most equipment currently available commercially. For 50-mm [2-in.] depth direct transmission measurements, a container 600 by 600 by 100 mm [24 by 24 by 4 in.] will meet this requirement.

4.1.9 *Scale*—The scale shall be accurate to within 0.2 kg [0.5 lb] of the test load at any point within the range of use. The range of use shall be considered to extend from the weight of the calibration adjustment container empty, to the weight of the measure plus the contents at 2600 kg/m^3 [160 lb/ft^3].

4.1.10 *Strike-Off Plate or Bar*—This shall be a flat metal or glass plate or metal bar with a length at least 50 mm [2 in.] greater than the length, width, or diameter of the calibration adjustment container. The strike-off must be rigid, straight, and smooth enough to finish the concrete surface flat and flush with the edges of the calibration adjustment container.

5. Calibration

5.1 Calibration curves are established by determining the nuclear count rate of each of several materials at different and known densities, plotting the count rate (or count ratio) versus each known density, and placing a curve through the resulting points. The method used to establish the curve must be the same as that used to determine the density. The materials used for calibration must be of uniform density.

NOTE 4—Calibration curves are supplied by gauge manufacturers, or can be established using blocks of known density or prepared containers of uniform, unchanging material compacted to known densities. Materials considered satisfactory for use in blocks include granite, aluminum, chalk, limestone, and magnesium.

5.2 *Adjusting Calibration Curves*—Prior to use, adjust the instrument's calibration curve, if necessary, to compensate for chemical composition effects. Such an adjustment is necessary whenever the chemical composition of the concrete to be tested differs significantly from that for which the calibration curve was established. An adjustment is also necessary if the testing equipment has been changed. Adjustment is particularly important for backscatter test method measurements. Determine the necessary adjustments using the same mode of operation and at the same depth (if using direct transmission) as that intended for testing. A recommended procedure for making this adjustment is as follows:

5.2.1 Prepare a concrete mix similar in composition to the material to be tested subsequently.

5.2.2 Fill the calibration adjustment container with concrete and consolidate to produce a uniform, homogeneous material with approximately the density that will be achieved in the construction.

NOTE 5—Consolidation may be achieved by the procedure used for unit weight testing (Test Method C 138/C 138M) or by other methods, such as spading the concrete and then dropping the ends of the container alternately on a rigid surface.

5.2.3 Strike off the container with strike-off plate or bar. Take care to make the concrete surface flat and flush with the container edges.

NOTE 6—A 2 mm [1⁄16 in.] average difference between the concrete surface and the container edges in a 150 mm [6 in.] deep container will produce a 1 to 2 % error in the weighed density of the concrete.

5.2.4 Weigh the concrete in the container to the nearest 0.2 kg [0.5 lb] and determine the weighed density as follows:

$$W = \frac{W_c}{V} \quad (1)$$

where:

W = weighed density of concrete, kg/m^3 [lb/ft^3],
W_c = mass of the concrete, kg [lb], and
V = volume of the container, m^3 [ft^3].

5.2.5 Immediately take three automatically timed direct transmission or backscatter readings with the instrument centered on the surface of the concrete in the container. Rotate the base of the instrument 90° around the vertical axis, with subsequent rotations of 180 and 270° from the original position. Obtain three additional automatically timed counts at each position. The instrument must be centered over the surface of the concrete in each rotated position to prevent edge effects on the instrument reading.

5.2.6 Using the applicable calibration curve, determine the density from the average of the 12 counts obtained in 5.2.5.

5.2.7 Determine the difference between the two density readings obtained in 5.2.4 and 5.2.6.

5.2.8 Repeat 5.2.2-5.2.7 on two additional concrete mixes of the same proportions. Determine the adjustment factor by averaging the three values obtained in 5.2.7 and 5.2.8. If one of the three values differs from the average by more than 25

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:44:26 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

kg/m^3 [1.5 lb/ft^3], discard it as a statistical outlier and recalculate the adjustment factor as the average of the remaining two values.

5.2.9 Use the adjustment factor determined in 5.2.8 to plot a corrected count-rate calibration curve which shall be parallel to the original calibration curve and offset by the amount indicated in 5.2.8. Alternatively, the value of the adjustment factor shall be attached to the instrument and applied to all density determinations arrived at from an original (unadjusted) calibration curve.

NOTE 7—In some circumstances, for example, where chemical composition changes are minimal, calibration curve adjustments may be established on permanent, uniform, hardened concrete blocks.

6. Standardization

6.1 Standardization of the equipment on the reference standard is required at the start of each day and whenever test measurements are suspect.

NOTE 8—In some older instrument models, count rates are strongly influenced by the ambient temperature; frequent standardization may be necessary.

6.2 Warm-up time shall be in accordance with the manufacturer's recommendations.

6.3 Take at least five readings on the reference standard, more if recommended by the manufacturer, or take one 4 min or longer count if the instrument is equipped with automatic standard count storage.

6.4 If more than one of the individual readings is outside the limit set by Eq 2, repeat the standardization. If the second attempt does not satisfy Eq 2, check the system for a malfunction. If no malfunction is found, establish a new N_o(average count) by taking the average of a minimum of 10 counts on the reference standard.

$$|N_s - N_o| < 1.96\sqrt{N_o} \quad (2)$$

where:

N_s = count currently measured in checking the instrument operation, and

N_o = average count previously established on the reference standard.

In instruments where the count has been prescaled, that is, divided by a constant factor k before it is displayed, Eq 2 shall be replaced by the following:

$$|N_s - N_o| < 1.96\sqrt{N_o/k} \quad (3)$$

6.4.1 If automatic standard count storage is used and the newly established count is outside the limit set by Eq 2, repeat the standardization.

6.4.2 If the second attempt does not satisfy Eq 2, check the system for a malfunction.

6.4.3 If no malfunction is found, establish a new N_o equal to the average count found in 6.4.2.

6.5 If a new N_o differs by more than 10 % from the standard count at which the calibration curve (5.1) was established, recalibrate the instrument.

TEST METHOD A—DIRECT TRANSMISSION (FOR UNHARDENED CONCRETE)

7. Procedure

7.1 Select a test location such that, when the gauge is placed in test position:

7.1.1 Any point on the source-detector axis shall be at least 230 mm [9 in.] from any pavement edge or object.

7.1.2 Reinforcing steel shall not be present in the volume bounded by the extended probe and the detector tubes.

7.1.3 The test location shall contain concrete to a depth 25 mm [1 in.] greater than that to which the probe will be inserted. In thin concrete overlay projects, this may require the removal of the underlying (original) concrete 25 to 50 mm [1 to 2 in.] down over a small area before placement of the overlay.

7.2 Smooth the surface with a wood float. If necessary, use the guide plate and hole-forming device (4.1.7) to make a hole slightly larger than the probe and perpendicular to the surface. In some concretes, the probe may be inserted directly into the concrete without the use of the guide plate and hole-forming device.

7.3 Insert the probe so that the side of the probe facing the center of the gauge is in intimate contact with the side of the hole. Keep all other radioactive sources at such a distance from the gauge that the readings will not be affected.

NOTE 9—The recommended minimum distance from other nuclear density gauges is 10 m [30 ft].

7.4 Use the same warm-up time as in standardization. Take automatically timed readings, for a minimum of 1 min, and determine the in-place density from the adjusted calibration curve. Alternatively, determine the in-place density from the unadjusted calibration curve and then apply the calibration adjustment factor (5.2.9). If the instrument has a direct reading display which is not programmed to apply the calibration adjustment factor (5.2.8), correct the displayed density by applying that factor.

TEST METHOD B—BACKSCATTER (FOR UNHARDENED OR HARDENED CONCRETE)

8. Procedure

8.1 Select a test location such that, when the gauge is placed in test position:

8.1.1 Any point on the source-detector axis shall be at least 230 mm [9 in.] from any pavement edge or object, and

8.1.2 No reinforcing steel with less than 75 mm [3 in.] of concrete cover shall lie directly under the source - detector axis, except as indicated in Note 10.

NOTE 10—The user may find that certain instrument models and operating modes allow gauges to operate over steel with as little as 40 mm [1½ in.] of concrete cover.

8.2 Prepare the test site in the following manner:

8.2.1 On unhardened concrete, smooth the surface with a wood float.

8.2.2 For best results on hardened concrete, find as smooth a surface as possible. Remove all loose material. The maximum void beneath the gauge shall not exceed 3 mm [⅛ in.].

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:44:26 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Use fine sand to fill these voids and smooth the surface with a rigid plate or other suitable tool.

8.3 Seat the gauge firmly. Keep all other radioactive sources at such a distance from the gauge that the readings will not be affected (Note 9).

8.4 Use the same warm-up time as in standardization. Take automatically timed readings, for a minimum of 1 min, and determine the in-place density from the adjusted calibration curve (5.2.9). Alternatively, determine the in-place density from the unadjusted calibration curve and then apply the calibration adjustment factor. If the instrument has a direct reading display which is not programmed to apply the calibration adjustment factor (5.2.8), correct the displayed density by applying that factor.

NOTE 11—On lifts less than 75 mm [3 in.] thick, readings may be erroneous if the density of the underlying material differs significantly from that of the concrete being placed. Correction procedures are available for some gauge models.

9. Report

9.1 Report the following information:

9.1.1 Test method (direct transmission or backscatter),

9.1.2 Nature of concrete (hardened or unhardened),

9.1.3 Depth of probe, if using direct transmission,

9.1.4 Thickness of layer tested,

9.1.5 Identification of raw materials,

9.1.6 Mixture proportions,

9.1.7 Count rate for standardization, and

9.1.8 Count rate for each test reading and the converted mean density value, or the corrected direct reading density value, in kg/m^3 [lb/ft^3].

10. Precision and Bias

10.1 *Precision*:

10.1.1 *Round Robin Test Program*—A round robin program was executed involving five instruments and five operators. All tests were done on a single placement of RCC. Twelve sites were prepared for measurements, relying on the natural variation in the as-placed material among the sites to generate twelve different material properties. Each instrument-operator combination determined the density at each location three times. The instrument was removed and re-inserted before each new determination. The study resulted in 60 sets of three determinations. All instruments were of the same manufacture. A report of results and calculations is on file at ASTM.[3] The data used to develop the precision statement were obtained using the inch-pound version of this test method. The precision indices shown in SI units are exact conversions of the values in parentheses.

10.1.2 *Single-Operator, Single-Instrument Precision*—The single-instrument and single-operator standard deviation was found to be 8.0 kg/m^3 [0.5 lb/ft^3].[4] Therefore, results of two properly conducted tests by the same operator are not expected to differ by more than 22.4 kg/m^3 [1.4 lb/ft^3].[4]

10.1.3 *Multi-Operator, Multi-Instrument Precision*—The multi-operator and multi-instrument standard deviation was found to be 16.0 kg/m^3 [1.0 lb/ft^3].[4] Therefore, results of two properly conducted tests by the same operator are not expected to differ by more than 44.9 kg/m^3 [2.8 lb/ft^3].[4]

10.2 *Bias*—No statement on bias is being made because no standard reference concrete of known density is available.

11. Keywords

11.1 acceptance testing; backscatter measurement; concrete-density; density; direct transmission measurement; gamma radiation; in-place density; nuclear testing; roller-compacted concrete

[3] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1031.

[4] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

ANNEX

(Mandatory Information)

A1. DETERMINING PRECISION OF APPARATUS

A1.1 Instrument Count Precision:

A1.1.1 Instrument count precision is defined as the change in density that corresponds to a one standard deviation change in the count due to the random decay of the radioactive source. Instrument count precision is determined from the slope of the calibration curve and the statistical standard deviation of the count rate, as follows:

$$P = \sigma/S \quad \text{(A1.1)}$$

where:

P = instrument count precision, kg/m^3 [lb/ft^3],

σ = standard deviation, cpm (counts/minute), and

S = slope, cpm/kg/m^3 [cpm/lb/ft^3].

A1.1.2 The slope of the calibration curve is determined at the 2240 kg/m^3 [140 lb/ft^3] point and the standard deviation is calculated from ten individual automatically-timed readings taken on material with a density of 2240 ± 80 kg/m^3 [140 ± 5 lb/ft^3]. The gauge is not moved after seating for the first count. For a direct reading gauge, the instrument count precision, P, in kg/m^3 [lb/ft^3], is the standard deviation of ten individual automatically-timed density readings.

A1.1.3 The value of P shall be determined at least once every three months. The value of P shall be less than 16 kg/m^3 [1.0 lb/ft^3] for backscatter and less than 8 kg/m^3 [0.5 lb/ft^3] for direct transmission measurements.

APPENDIX

(Nonmandatory Information)

X1. NOTES ON THE NUCLEAR TEST

X1.1 It should be noted that the volume of concrete represented in the measurements is indeterminate and will vary with (*1*) the source-detector geometry of the equipment used, and (*2*) with the characteristics of the material tested. In general, and with all other conditions constant, the denser the material, the smaller the volume involved in a backscatter measurement. The density so determined is not necessarily the average density within the volume involved in the measurement. Typically, backscatter gauge readings are influenced by 75 to 125 mm [3 to 5 in.] of material; the top 25 mm [1 in.] of the material determines 50 to 70 % of the measured count rate, and the top 50 mm [2 in.] determines 80 to 95 %. Where these materials are of uniform density, this characteristic of this test method is of no effect. However, reinforcing steel and underlying concrete are both often within the volume in which they may influence gauge readings. Also, the extent of the influence of vertical density variations, such as those caused by reinforcing steel, depends on the depth at which the steel is located.

X1.2 The use of cesium-137 and other radioisotope sources in density gauges is regulated and licensed by the U.S. Nuclear Regulatory Commission or, in agreement states, by state regulatory agencies. The primary objective of these regulations is the use of these materials in a manner safe to the operator, to other workers, and to the general public. While detailed safety procedures are beyond the scope of these test methods, the originating committee emphasized its support of these objectives. In order to meet regulatory agency requirements, gauge owners must establish effective operator instruction and use procedures, together with routine safety procedures, such as source leak tests, recording and evaluation of film badge data, the use of survey meters, etc., in connection with the operation of this type of equipment. Likewise, individual users of the equipment must complete a formal training program and must be familiar with possible safety hazards. Users should be particularly concerned about developing safe procedures for removing mortar while cleaning the source rod after direct transmission measurements.

X1.3 The determination of density in these test methods by the nuclear means is indirect. The relationship between nuclear gauge count rate and density necessarily is determined by correlation tests on materials at known average densities. Calibration curves established in this manner do not necessarily hold for all concretes because of differences in chemical composition. This effect is particularly significant for backscatter method measurements. Because of these considerations, provisions are included in these test methods for adjusting calibration curves on a project-by-project basis.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to these test methods since the last issue, C 1040 – 05, that may impact the use of these test methods. (Approved October 1, 2008)

(*1*) The standard was revised as a combined standard with SI units listed first.
(*2*) Revised 1.3.
(*3*) Added new Note 2 and renumbered subequent notes.
(*4*) Revised 10.1.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1047 – 09

Standard Specification for Accessories for Gypsum Wallboard and Gypsum Veneer Base[1]

This standard is issued under the fixed designation C 1047; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers accessories used in conjunction with assemblies of gypsum wallboard and gypsum veneer base to protect edges and corners and to provide architectural features (see Fig. 1).

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

A 463/A 463M Specification for Steel Sheet, Aluminum-Coated, by the Hot-Dip Process

A 653/A 653M Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process

A 879/A 879M Specification for Steel Sheet, Zinc Coated by the Electrolytic Process for Applications Requiring Designation of the Coating Mass on Each Surface

B 69 Specification for Rolled Zinc

B 117 Practice for Operating Salt Spray (Fog) Apparatus

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 475/C 475M Specification for Joint Compound and Joint Tape for Finishing Gypsum Board

C 587 Specification for Gypsum Veneer Plaster

D 1788 Specification for Rigid Acrylonitrile-Butadiene-Styrene (ABS) Plastics[3]

D 2092 Guide for Preparation of Zinc-Coated (Galvanized) Steel Surfaces for Painting[3]

D 3678 Specification for Rigid Poly(Vinyl Chloride) (PVC) Interior-Profile Extrusions

3. Terminology

3.1 *Definitions:*

3.1.1 Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *accessories*, *n*—cornerbeads, edge trims, and control joints, such as casing beads, bull noses, and stops.

3.2.2 *control joint*, *n*—a formed product used for designed or required separations between adjacent surfaces of gypsum boards or gypsum veneer base.

3.2.3 *cornerbead*, *n*—a formed metal, plastic, or metal and paper angle for outside corners of gypsum boards or gypsum veneer base.

3.2.4 *edge trim*, *n*—typically "J"- or "L"-shaped strip, as shown in Fig. 1, formed of metal, plastic, or metal and paper to cover exposed ends or edges of gypsum board or gypsum veneer base.

3.2.5 *flange*, *n*—that portion of the accessory used for the attachment to gypsum wallboard, gypsum veneer base, or a framing member.

4. Materials and Manufacture

4.1 Steel accessories and steel components of accessories manufactured from steel and paper in combination shall be manufactured from zinc-coated cold-roll (coil or cut length) sheet steel not less than 0.012-in. (0.30-mm) thick before application of coating.

4.1.1 Sheet steel, zinc-coated by the hot-dip process, shall be in accordance with Specification A 653/A 653M, minimized spangle, minimum G-30 coating.

4.1.2 Sheet steel, zinc-coated by the electrolytic process shall be in accordance with Specification A 879/A 879M, minimum coating on surface side to be 0.000140 in. (0.00356 mm), minimum coating on reverse side to be 0.00010 in. (0.00254 mm).

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved May 1, 2009. Published May 2009. Originally approved in 1992. Last previous edition approved in 2005 as C 1047 – 05.

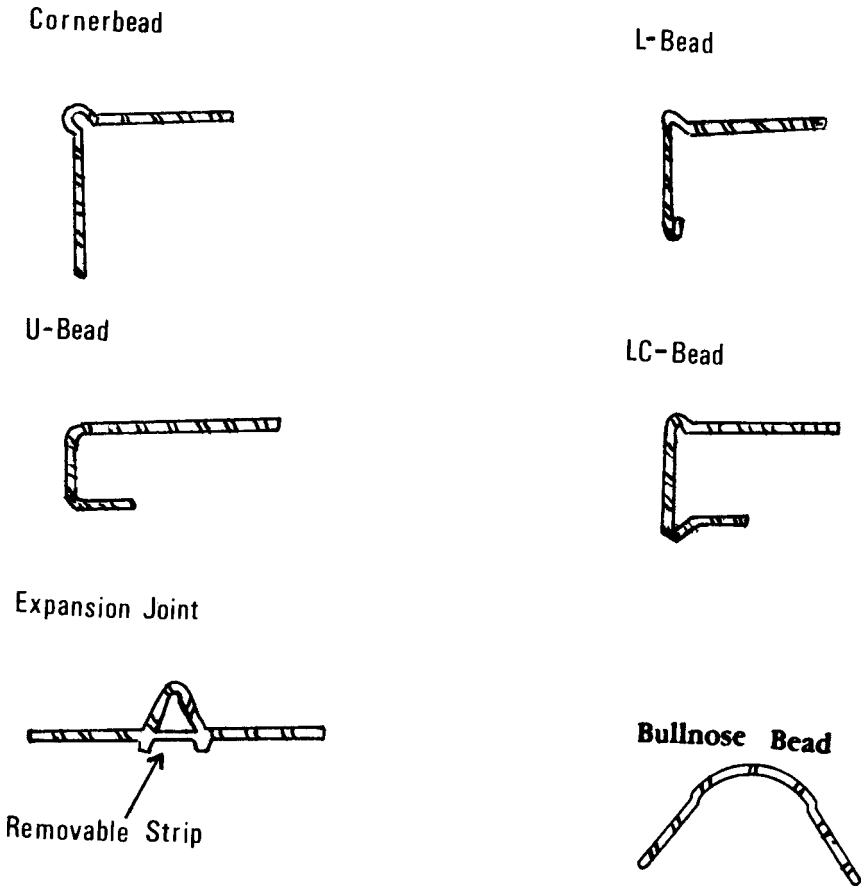

FIG. 1 Accessories for Gypsum Wallboard and Gypsum Veneer Base

4.1.3 Sheet steel, aluminum-coated, shall be in accordance with Specification A 463/A 463M minimum T1-40 coating.

4.1.4 Phosphatizing (as specified in Method A of Guide D 2092) or other surface treatments may be used to ensure compatibility and bond as specified in Section 5.

4.2 Zinc accessories shall be manufactured from rolled zinc in accordance with Specification B 69, Type I, not less than 0.012-in. (0.305-mm) thick.

4.3 Plastic for accessories shall be manufactured from rigid PVC or ABS plastic not less than 0.012 in. (0.305 mm).

4.3.1 PVC, Specification D 3678, Class II or III.

4.3.2 ABS, Specification D 1788 – 81, all limits 5-3-3-1-1.

4.4 Paper components of accessories manufactured from steel and paper in combination shall comply with requirements for thickness, tensile strength, dimensional stability, and bond of joint tape to joint compound as specified in Specification C 475/C 475M.

5. Physical Properties

5.1 *Compatibility and Bond*—Accessories shall be compatible with and provide a surface bond to the materials specified in Specifications C 475/C 475M and C 587.

5.2 *Test Performance*—Steel accessories and steel components of accessories shall not show any red oxidation when tested as specified in Practice B 117 for 192 h.

6. Dimensions and Permissible Variations

6.1 Cornerbeads shall have an interior angle between the flanges no greater than 89°.

6.2 Accessories shall be free of twist or camber of a degree that will prevent their use in the assembly for which they are intended.

6.3 Length tolerances shall be ±3⁄16 in. (±4.8 mm).

6.4 The size of the edge trim shall suit the thickness of the gypsum board used.

6.5 The minimum width of the flange shall be 7⁄8 ± 1⁄32 in. (22 ± 0.8 mm).

7. Appearance

7.1 Edges of accessories shall be free of burrs and sharp edges.

8. Configuration

8.1 Flanges of accessories, when required to be attached to framing members, shall have punch outs to accommodate fastening to the framing members. When required to meet performance requirements, the flanges shall be either knurled, made of mesh, deformed, expanded, or otherwise shaped to meet the performance requirements and intended use. Fig. 1 depicts the most commonly used shapes.

NOTE 1—Other types of accessories designed for special finish application (bull-nose, cove, and so forth) shall be manufactured in accordance

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:44:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

with the general requirements of this specification.

9. Sampling

9.1 At least 0.25 % of the number of each type of accessory in a shipment, but not less than three pieces, shall be selected to represent the shipment and shall constitute a sample for the purpose of tests by the purchaser or user.

10. Inspection

10.1 Inspection of the accessories shall be agreed upon between the purchaser and the supplier as part of the purchase order.

11. Rejection and Rehearing

11.1 Rejection of accessories that fail to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing within 10 working days from receipt of shipment by the purchaser. The notice of rejection shall contain a specific statement of the respect in which the accessories have failed to conform to the requirements of this specification. In case of dissatisfaction with the results of the test, at the request of the producer or supplier, such notice of rejection shall be supported by results of a test conducted by a mutually agreeable independent laboratory.

12. Certification

12.1 When specified in the purchase order, a producer's or supplier's certification that the product meets the requirements of this specification shall be furnished to the purchaser.

13. Packaging and Package Marking

13.1 Accessories shall be packaged to ensure safe delivery by common or other carriers.

13.2 When shipped for resale, the name of the manufacturer or seller and the brand and contents shall be legibly marked on each package.

14. Keywords

14.1 accessories; bead; corner; cornerbead; edge

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1047 – 05, that may impact the use of this specification. (Approved May 1, 2009)

(*1*) Replaced reference to Specification A 591/A 591M with Specification A 879/A 879M in 4.1.2 and Referenced Documents.

Designation: C 1059/C 1059M – 99 (Reapproved 2008)

Standard Specification for Latex Agents for Bonding Fresh To Hardened Concrete[1]

This standard is issued under the fixed designation C 1059/C 1059M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers latex bonding agents, suitable for brush, broom, or spray application, to bond fresh concrete to hardened concrete.

1.2 These bonding agents are intended for bonding new concrete to old concrete such as interior surfaces, floors, roadways, bridge decks, ramps, runways, walks, and curbs.

1.3 The values stated in either inch-pound units or SI units shall be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents, therefore, each system must be used independently of the other without combining values in any way.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 1042 Test Method for Bond Strength of Latex Systems Used With Concrete By Slant Shear

3. Classification and Use

3.1 This specification provides for the classification of the latex bonding agents in accordance with use.

3.1.1 *Type I (Redispersable)*, is restricted for use in interior work not subject to water immersion or high humidity.

3.1.2 *Type II (Non-redispersable)*, may be used for areas subject to high humidity or immersion in water and is suitable for use in other areas.

4. Ordering Information

4.1 Purchase orders for these materials shall identify:

4.1.1 The number of this specification and the required type, and

4.1.2 Supplementary requirements if necessary.

5. Physical Properties

5.1 The material shall conform to the requirements of Table 1 when tested in accordance with Test Method C 1042.

6. Sampling

6.1 For sampling of bulk quantities, a batch or lot shall be considered a unit of manufacture as prepared for shipment or may consist of a blend of two or more production runs of material. A composite sample shall be taken and it shall provide a volume of at least 1 gal [4 L].

6.2 When the bonding agent to be sampled is in containers, the sample shall be obtained by taking a portion out of the containers that is equal in number to the next integer larger than the cube root of the total number of containers in the lot. Grab samples shall be taken from each container and they shall have a volume of at least ½ pt. [0.25 L].

6.3 All the sample containers shall be sealed to prevent leakage or dilution and shall be properly marked for identification and correlation.

7. Rejection

7.1 The purchaser has the right to reject the bonding agent if it fails to meet the bond strength requirement, appears curdled or otherwise nonuniform, or if it has a rank odor.

8. Packaging and Package Marking

8.1 The proprietary name and type of the organic bonding agent and the net quantity in gallons or litres shall be plainly marked on the containers in which the material is delivered. Similar information shall be provided in the shipping advices accompanying packaged or bulk shipments of admixtures.

9. Keywords

9.1 adhesives; bonding agents; latex

4.1.2 Supplementary requirements if necessary.

5. Physical Properties

5.1 The material shall conform to the requirements of Table 1 when tested in accordance with Test Method C 1042.

6. Sampling

6.1 For sampling of bulk quantities, a batch or lot shall be considered a unit of manufacture as prepared for shipment or may consist of a blend of two or more production runs of material. A composite sample shall be taken and it shall provide a volume of at least 1 gal [4 L].

6.2 When the bonding agent to be sampled is in containers, the sample shall be obtained by taking a portion out of the containers that is equal in number to the next integer larger than the cube root of the total number of containers in the lot. Grab samples shall be taken from each container and they shall have a volume of at least ½ pt. [0.25 L].

6.3 All the sample containers shall be sealed to prevent leakage or dilution and shall be properly marked for identification and correlation.

7. Rejection

7.1 The purchaser has the right to reject the bonding agent if it fails to meet the bond strength requirement, appears curdled or otherwise nonuniform, or if it has a rank odor.

8. Packaging and Package Marking

8.1 The proprietary name and type of the organic bonding agent and the net quantity in gallons or litres shall be plainly marked on the containers in which the material is delivered. Similar information shall be provided in the shipping advices accompanying packaged or bulk shipments of admixtures.

9. Keywords

9.1 adhesives; bonding agents; latex

Designation: C 1059/C 1059M – 99 (Reapproved 2008)

Standard Specification for Latex Agents for Bonding Fresh To Hardened Concrete[1]

This standard is issued under the fixed designation C 1059/C 1059M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers latex bonding agents, suitable for brush, broom, or spray application, to bond fresh concrete to hardened concrete.

1.2 These bonding agents are intended for bonding new concrete to old concrete such as interior surfaces, floors, roadways, bridge decks, ramps, runways, walks, and curbs.

1.3 The values stated in either inch-pound units or SI units shall be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents, therefore, each system must be used independently of the other without combining values in any way.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 1042 Test Method for Bond Strength of Latex Systems Used With Concrete By Slant Shear

3. Classification and Use

3.1 This specification provides for the classification of the latex bonding agents in accordance with use.

3.1.1 *Type I (Redispersable)*, is restricted for use in interior work not subject to water immersion or high humidity.

3.1.2 *Type II (Non-redispersable)*, may be used for areas subject to high humidity or immersion in water and is suitable for use in other areas.

4. Ordering Information

4.1 Purchase orders for these materials shall identify:

4.1.1 The number of this specification and the required type, and

4.1.2 Supplementary requirements if necessary.

5. Physical Properties

5.1 The material shall conform to the requirements of Table 1 when tested in accordance with Test Method C 1042.

6. Sampling

6.1 For sampling of bulk quantities, a batch or lot shall be considered a unit of manufacture as prepared for shipment or may consist of a blend of two or more production runs of material. A composite sample shall be taken and it shall provide a volume of at least 1 gal [4 L].

6.2 When the bonding agent to be sampled is in containers, the sample shall be obtained by taking a portion out of the containers that is equal in number to the next integer larger than the cube root of the total number of containers in the lot. Grab samples shall be taken from each container and they shall have a volume of at least ½ pt. [0.25 L].

6.3 All the sample containers shall be sealed to prevent leakage or dilution and shall be properly marked for identification and correlation.

7. Rejection

7.1 The purchaser has the right to reject the bonding agent if it fails to meet the bond strength requirement, appears curdled or otherwise nonuniform, or if it has a rank odor.

8. Packaging and Package Marking

8.1 The proprietary name and type of the organic bonding agent and the net quantity in gallons or litres shall be plainly marked on the containers in which the material is delivered. Similar information shall be provided in the shipping advices accompanying packaged or bulk shipments of admixtures.

9. Keywords

9.1 adhesives; bonding agents; latex

Designation: C 1063 – 08

Standard Specification for Installation of Lathing and Furring to Receive Interior and Exterior Portland Cement-Based Plaster[1]

This standard is issued under the fixed designation C 1063; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers the minimum requirements for lathing and furring for the application of exterior and interior portland cement-based plaster as in Specification C 926 or Specification C 841.

1.2 Where a fire resistance rating is required for plastered assemblies and constructions, details of construction shall be in accordance with reports of fire tests of assemblies that have met the requirements of the fire rating imposed.

1.3 Where a specific degree of sound control is required for plastered assemblies and constructions, details of construction shall be in accordance with official reports of tests conducted in recognized testing laboratories in accordance with the applicable requirements of Test Method E 90.

1.4 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

2. Referenced Documents

C 1032 Specification for Woven Wire Plaster Base

D 1784 Specification for Rigid Poly(Vinyl Chloride) (PVC) Compounds and Chlorinated Poly(Vinyl Chloride) (CPVC) Compounds

D 4216 Specification for Rigid Poly(Vinyl Chloride) (PVC) and Related PVC and Chlorinated Poly(Vinyl Chloride) (CPVC) Building Products Compounds

E 90 Test Method for Laboratory Measurement of Airborne Sound Transmission Loss of Building Partitions and Elements

3. Terminology

3.1 *Definitions*—For definitions relating to Ceilings and Walls, see Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *control joint*, *n*—a joint that accommodates movement of plaster shrinkage and curing along predetermined, usually straight, lines.

3.2.2 *expansion joint*, *n*—a joint that accommodates movement beyond plaster shrinkage and curing.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for the Application of Gypsum and Other Products in Assemblies.

Current edition approved May 15, 2008. Published June 2008. Originally approved in 1986. Last previous edition approved in 2007 as C 1063 – 07.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

NOTE 1—For design consideration of control and expansion joints, see Annex A2.3.1.2 of Specification C 926.

3.2.3 *hangers*, *n*—wires or steel rods or straps used to support main runners for suspended ceilings beneath floor or roof constructions.

3.2.4 *inserts*, *n*—devices embedded in concrete structural members to provide a loop or opening for attachment of hangers.

3.2.5 *saddle tie*, *n*—see Figs. 1 and 2.

3.2.6 *self-furring*, *adj*—a metal plaster base manufactured with evenly-spaced indentations that hold the body of the lath approximately ¼ in. (6.4 mm) away from solid surfaces to which it is applied.

3.2.7 *framing member*, *n*—studs, joist, runners (track), bridging, bracing, and related accessories manufactured or supplied in wood or light gauge steel.

4. Delivery of Materials

4.1 All materials shall be delivered in the original packages, containers, or bundles bearing the brand-name and manufacturer's (or supplier's) identification.

5. Storage of Materials

5.1 All materials shall be kept dry. Materials shall be stacked off the ground, supported on a level platform, and protected from the weather and surface contamination.

5.2 Materials shall be neatly stacked with care taken to avoid damage to edges, ends, or surfaces.

5.3 Paper backed metal plaster bases shall be handled carefully in delivery, storage, and erection to prevent puncturing or removal of paper.

6. Materials

6.1 *Metal Plaster Bases*:

6.1.1 *Expanded Metal Lath*—Specification C 847, galvanized.

6.1.2 *Wire Laths*:

6.1.2.1 *Welded Wire Lath*—Specification C 933.

6.1.2.2 *Woven Wire Lath*—Specification C 1032.

6.1.2.3 *Paper Backed Plaster Bases*—Specification C 847.

6.2 *Accessories*:

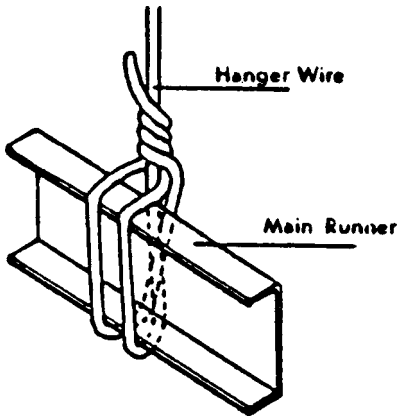

FIG. 1 Saddle Tie

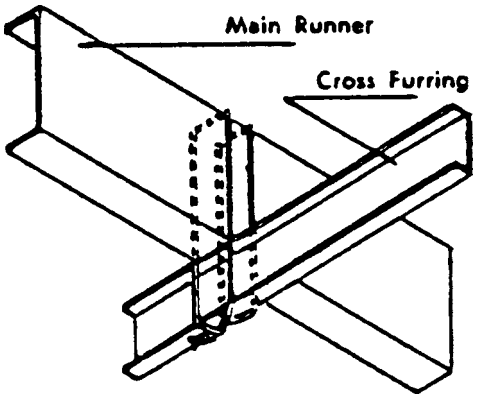

FIG. 2 Saddle Tie

6.2.1 *General*—All accessories shall have perforated or expanded flanges or clips shaped to permit complete embedment in the plaster, to provide means for accurate alignment, and to secure attachment of the accessory to the underlying surface. Accessories shall be designed to receive application of the specified plaster thickness.

6.2.2 Accessories shall be fabricated from Zinc Alloy (99 % pure zinc), galvanized (zinc coated) steel, rigid PVC or CPVC plastic, or anodized aluminum alloy. See Specification B 221. (See Table 1 for minimum allowable thicknesses).

NOTE 2—The selection of an appropriate type of material for accessories shall be determined by applicable surrounding climatic and environmental conditions specific to the project location, such as salt air, industrial pollution, high moisture, or humidity.

6.2.3 *Steel*—Specification A 653/A 653M and shall have a G60 coating.

6.2.4 *PVC Plastic*—Specification D 1784 or D 4216.

6.2.5 *Zinc Alloy*—Specification B 69, 99 % pure zinc.

6.2.6 Thickness of base material shall be as shown in Table 1.

6.2.7 *Cornerite*—1.75 lb/yd^2(0.059 kg/m^2), galvanized expanded metal lath, galvanized, 1.7 lb/yd^2(0.057 kg/m^2) galvanized woven or welded wire fabric of 0.0410 in. (1.04 mm) wire. When shaped for angle reinforcing, it shall have outstanding flanges (legs) of not less than 2 in. (51 mm).

6.3 *Channels*—Shall be cold-formed from steel with minimum 33 000 psi (228 MPa) yield strength and 0.0538 in. (1.37 mm) minimum bare steel thickness. Channel shall have a protective coating conforming to Specification A 653/A 653M–G60, or have a protective coating with an equivalent corrosion resistance for exterior applications, or shall be coated with a rust inhibitive paint, for interior applications, and shall have the following minimum weights in pounds per 1000 linear feet (kg/m).

TABLE 1 Minimum Thickness of Accessories

Accessory	Base Material, in. (mm)		
	Steel	Zinc Alloy	P.V.C.
Corner Beads	0.0172 (0.44)	0.0207 (0.53)	0.035 (0.89)
Casing Beads	0.0172 (0.44)	0.0207 (0.53)	0.035 (0.89)
Weep Screeds	0.0172 (0.44)	0.0207 (0.53)	0.050 (1.27)
Control Joints	0.0172 (0.44)	0.018 (0.46)	0.050 (1.27)

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Sizes, in. (mm)	Weight, lb/1000 ft (kg/m)	Flange Width, in. (mm)
¾ (19)	277 (0.412)	½ (13)
1½ (38)	414 (0.616)	½ (13)
2 (51)	506 (0.753)	½ (13)
2½ (64)	597 (0.888)	½ (13)

NOTE 3—Channels used in areas subject to corrosive action of salt air shall be hot-dipped galvanized, G60 coating.

6.3.1 *External Corner Reinforcement*—Expanded lath, welded wire, or woven wire mesh bent to approximately 90° used to reinforce portland cement stucco at external corners. This accessory shall be fully embedded in the stucco.

6.3.2 *Foundation Weep Screed*—Accessory used to terminate portland cement based stucco at the bottom of exterior walls. This accessory shall have a sloped, solid, or perforated, ground or screed flange to facilitate the removal of moisture from the wall cavity and a vertical attachment flange not less than 3½ in. (89 mm) long.

6.4 *Wire*—As specified in Specification A 641/A 641M with a Class I zinc coated (galvanized), soft temper steel. Wire diameters (uncoated) specified herein correspond with United States Steel Wire Gauge numbers as follows:

Wire Gauge (US Steel Wire Gauge)	Diameter (in.)	mm
No. 20	0.0348	.88
No. 19	0.0410	1.04
No. 18	0.0475	1.21
No. 17	0.0540	1.37
No. 16	0.0625	1.59
No. 14	0.0800	2.03
No. 13	0.0915	2.32
No. 12	0.1055	2.68
No. 11	0.1205	3.06
No. 10	0.1350	3.43
No. 9	0.1483	3.77
No. 8	0.1620	4.12

6.5 *Rod and Strap Hangers*—Mild steel, zinc or cadmium plated, or protected with a rust-inhibiting paint.

6.6 *Clips*—Form from steel wire, Specification A 641/A 641M zinc-coated (galvanized), Specification A 641/A 641M or steel sheet, Specification A 653/A 653M, depending on use and manufacturer's requirements.

6.7 *Fasteners*:

6.7.1 *Nails*—For attaching metal plaster bases to wood supports, 0.1205-in. 11 gauge (3.06-mm) diameter, 7/16-in. (11.1-mm) head, barbed, galvanized roofing nails or galvanized common nails.

6.7.1.1 Nails for attaching metal plaster bases to solid substrates shall be not less than ¾ in. (19 mm) long.

6.7.2 Screws for attaching metal plaster base shall be fabricated in accordance with either Specification C 954 or C 1002 and shall have a 7/16 in. (11.1 mm) diameter pan wafer head and a 0.120 in. (3.0 mm) diameter shank. Screws used for attachment to metal framing members shall be self-drilling and self-tapping. Screws used for attachment to wood framing members shall be sharp-point.

7. Installation

7.1 *Workmanship*—Metal furring and lathing shall be erected so that the finished plaster surfaces are true to line (allowable tolerance of ¼ in. [6.4 mm] in 10 ft [3.05 m]), level, plumb, square, or curved as required to receive the specified plaster thickness.

7.2 *Hangers and Inserts*:

7.2.1 Hangers shall be of ample length and shall conform to the requirements of Table 2 both as to size and maximum area to be supported, except as modified in this section.

7.2.2 When 1 by 3/16-in. (25 by 4.8-mm) flat inserts and hangers are used, 7/16-in. (11.1-mm) diameter holes shall be provided on the center line at the lower end of the insert and upper end of the hanger to permit the attachment of the hanger to the insert. The edge of the holes in both the inserts and the hangers shall be not less than 3/8 in. (9.5 mm) from the ends.

7.2.3 In concrete, hangers shall be attached to inserts embedded in the concrete or to other attachment devices designed for this purpose and able to develop full strength of the hanger.

7.2.4 Flat, steel hangers shall be bolted to 1 by 3/16-in. (25 by 4.8-mm) inserts with 3/8-in. (9.5-mm) diameter round-head stove bolts. (See Fig. 3.)

7.2.5 The nuts of the bolts shall be drawn up tight.

NOTE 4—Hangers required to withstand upward wind pressures shall be of a type to resist compression. Struts of formed channels shall be permitted.

7.3 *Installation of Hangers for Suspended Ceilings Under Wood Constructions*—Hangers shall be attached to supports by any of the following methods:

7.3.1 A hole shall be drilled through the wood member not less than 3 in. (76 mm) above the bottom with the upper end of the wire hanger passed through the hole and twisted three times around itself. See Fig. 4.

7.3.2 Three 12d nails shall be driven, on a downward slant, into the sides of the wood member with not less than 1¼ in. (31.8 mm) penetration and not less than 5 in. (127 mm) from the bottom edges, and not more than 36 in. (914 mm) on the center with the upper end of the wire hanger wrapped around the nails and twisted three times around itself. See Fig. 5.

7.3.3 A loop shall be formed in the upper end of the wire hanger and secured to the wood member by four 1½-in. (38.1-mm), not less than 9 gauge, 0.1483-in. (3.77-mm) diameter wire staples driven horizontally or on a downward slant into the sides of the wood members, three near the upper end of the loop and the fourth to fasten the loose end. See Fig. 6.

7.3.4 Where supports for flooring are thicker than 1½ in. (38.1 mm) and are spaced more than 4 ft (1.2 m) on center, 1½ in. (38.1-mm) No. 1/0 (0.3065 in.) (7.78 mm) eye screws, or equivalent, spaced not more than 3 ft (0.9 m) on centers shall be screwed into the flooring supports with the upper end of the wire hanger inserted through the eye screws and twisted three times around itself.

7.3.5 Two holes shall be drilled in the upper end of the flat hangers and nailed to the sides of the wood members with 12d nails driven through the holes and clinched. Nails shall be not less than 3 in. (76 mm) above the bottom edge of the framing member. See Fig. 7.

7.4 *Attachment of Hangers to Main Runners*:

7.4.1 Wire hangers shall be saddle-tied to the runners. See Fig. 1.

7.4.2 Smooth or threaded rod hangers shall be fastened to the runners with special attachments appropriate to the design.

Allowable Spans Notes:
[1] Bare metal thickness of cold-rolled main runners shall be not less than 0.0538 in. (1.367 mm).
[2] Inside corner radii shall not be greater than ⅛ in. (3.19 mm).
[3] Spans based on upper flange of main runners laterally unbraced.
[4] Maximum deflection limited to 1/360 of the span length.
[5] Steel yield stress, Fy, shall be not less than 33 000 psi (228 MPa).
[6] Uniform load 12 psf (dry density) shall be used for portland cement plaster ceilings with plaster thicknesses up to ⅞ in. (22 mm) and 15 psf shall be used for ceilings with plaster thicknesses over ⅞ in. (22 mm) and not more than 1-¼ in. (32 mm).
[7] "2 or More" spans refers to two or more continuous, equal spans.
[8] For the "2 or More" span condition, listed spans represent the center-to-center distance between adjacent supports.
[9] These tables are designed for dead loads. Specific conditions such as exterior installations in high wind areas require additional engineering.
[10] Where uplift resistance is required for suspended ceilings to resist negative forces, the architect or engineer of record shall select the method to be used.

7.4.3 The lower ends of flat hangers shall be bolted to the main runners, or bent tightly around the runners and carried up and above the runners and bolt to the main part of the hanger. Bolts shall be ⅜-in. (9.5-mm) diameter, round-head stove bolts. See Fig. 3.

7.5 *Installation of Main Runners*:

7.5.1 Minimum sizes and maximum spans and spacings of main runners for the various spans between hangers or other supports shall be in accordance with the requirements of Table 2.

7.5.2 A clearance of not less than 1 in. (25 mm) shall be maintained between the ends of the main runners and the abutting masonry or the concrete walls, partitions, and columns. Where special conditions require that main runners let into abutting masonry or concrete construction, within such constructions maintain a clearance of not less than 1 in. (25 mm) from the ends and not less than ¼ in. (6.4 mm) from the tops and sides of the runners.

7.5.3 A main runner shall be located within 6 in. (152 mm) of the paralleling walls to support the ends of the cross furring. The ends of main runners shall be supported by hangers located not more than 6 in. (152 mm) from the ends.

7.5.4 Where main runners are spliced, the ends shall be overlapped not less than 12 in. (305 mm) with flanges of channels interlocked and securely tied near each end of the splice with double loops of 0.0625 in. (1.59 mm) or double loops of twin strands of 0.0475-in. (1.21-mm) galvanized wire. However, when the splice occurs at an expansion/control joint, the channel shall be nested and loosely tied to hold together but still allow movement.

7.5.5 Hanger wires shall hang straight down. If an obstacle prevents this, a trapeze type device shall be used to allow hanger wires to hang straight.

7.6 *Installation of Cross Furring*:

7.6.1 Minimum size and maximum spans and spacings of various types of cross furring for various spans between main runners and supports shall conform to the requirements of Table 2.

7.6.2 Cross furring shall be saddle-tied to main runners with 0.0625-in. 16 gauge (1.59-mm) galvanized wire, or a double strand of 0.0475-in. 18 gauge (1.21-mm) galvanized wire or with special galvanized clips, or equivalent attachments. (See Fig. 2.)

7.6.3 Where cross furring members are spliced, the ends shall be overlapped not less than 8 in. (203 mm), with flanges of channels interlocked, and securely tied near each end of the splice with double loops of 0.0625-in. 16 gauge (1.59-mm) galvanized wire or twin strands of 0.0475-in. 18 gauge (1.21-mm) galvanized wire.

7.6.4 Cross furring shall not come into contact with abutting masonry or reinforced concrete walls or partitions except, where special conditions require that cross furring be let into abutting masonry or concrete construction, the applicable provisions of 7.5.2 shall apply.

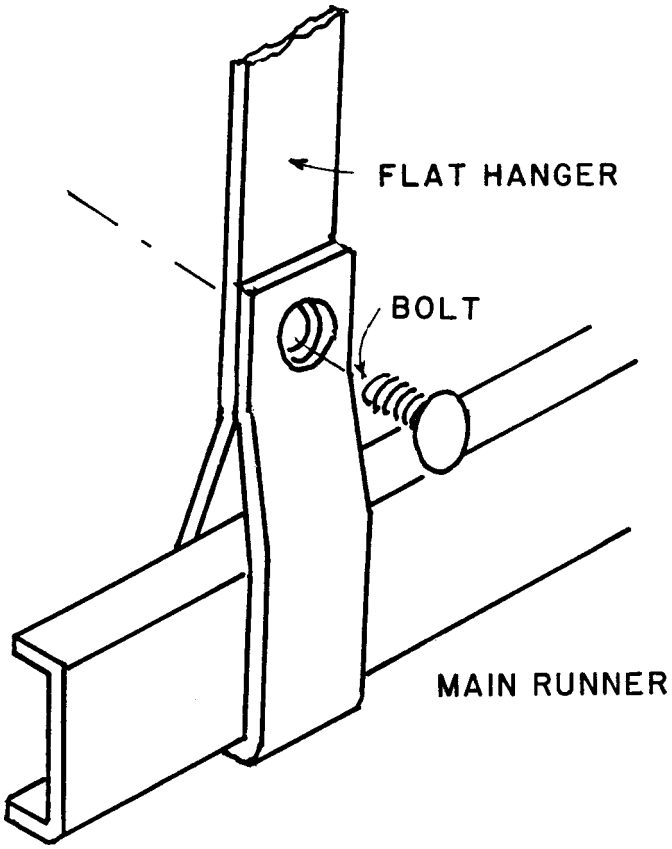

FIG. 3 Flat Hanger Attached to Main Runner Using Round-Head Stove Bolt

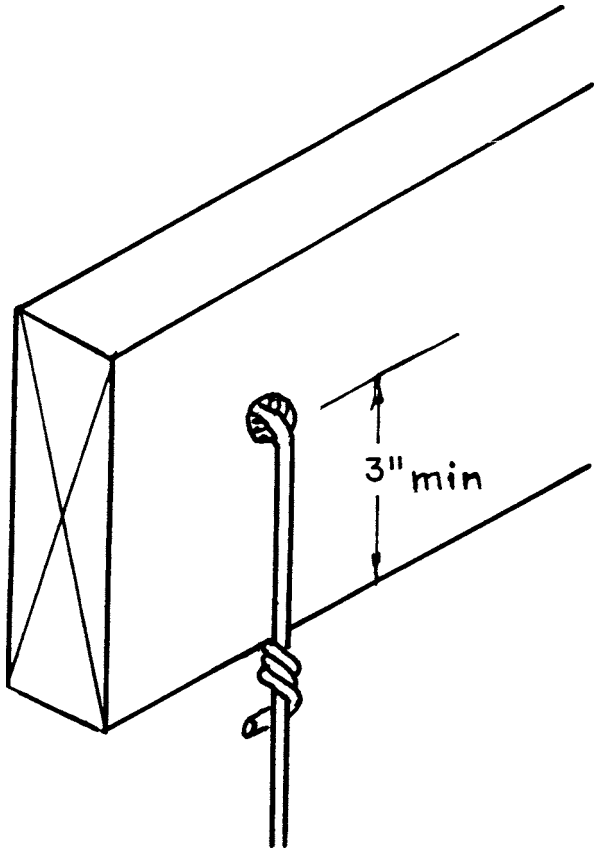

FIG. 4 Hanger Attached to Support Through a Drilled Hole

7.6.5 Main runners and cross running shall be interrupted at control (expansion) joints. However, when the splice occurs at an expansion/control joint, the channel shall be nested and loosely tied to hold together but still allow movement.

7.7 *Metal Furring for Walls*:

7.7.1 Attachments for furring shall be concrete nails driven securely into concrete or into masonry joints, short pieces of ¾-in. (19.1-mm) channels used as anchors driven into masonry joints, or other devices specifically designed as spacer elements, spaced horizontally not more than 2 ft (0.6 m) on centers. They shall be spaced vertically in accordance with horizontal stiffener spacing so that they project from the face of the wall in order for ties to be made.

7.7.2 Horizontal stiffeners shall be not less than ¾ in. (19.5-mm) cold-rolled channels, spaced not to exceed 54 in. (1372 mm) on centers vertically, with the lower and upper channels not more than 6 in. (152 mm) from the ends of vertical members and not less than ¼ in. (6.4 mm) clear from the wall face, securely tied to attachments with three loops of galvanized, soft-annealed wire, or equivalent devices. Approved furring is not prohibited from use in this application.

7.7.3 Vertical members shall be not less than ¾ in. (19.5-mm) cold-rolled channels in accordance with the requirements of Table 3. Vertical members shall be saddle-tied to horizontal stiffeners with three loops of 0.0475-in. (1.21-mm) galvanized soft-annealed wire, or equivalent devices, at each crossing, and securely anchored to the floor and ceiling constructions. Where furring is not in contact with the wall, channel braces shall be installed between horizontal stiffeners and the wall, spaced horizontally not more than 2 ft (600 mm) on centers.

7.7.4 Where dampproofing has been damaged during installation of attachments, the dampproofing shall be repaired with the same material before proceeding with the installation of the furring.

7.8 *Lapping of Metal Plaster Bases*:

7.8.1 Side laps of metal plaster bases shall be secured to framing members. They shall be tied between supports with 0.0475-in. (1.21-mm) wire at intervals not more than 9 in. (229 mm).

7.8.2 Metal lath shall be lapped ½ in. (12.7 mm) at the sides, or nest the edge ribs. Wire lath shall be lapped one mesh at the sides and the ends. Lap metal lath 1 in. (25 mm) at ends. Where end laps occur between the framing members, the ends of the sheets of all metal plaster bases shall be laced or wire tied with 0.0475-in. (1.21-mm) galvanized, annealed steel wire.

7.8.3 Where metal plaster base with backing is used, the vertical and horizontal lap joints shall be backing on backing and metal on metal.

7.8.3.1 Backing shall be lapped not less than 2 in. (50 mm). On walls, the backing shall be lapped so water will flow to the exterior. Backing shall not be placed between plaster base (lath) and flanges of accessories. Metal lath to metal flange contact shall be required to ensure that flanges are mechanically locked together.

7.9 *Spacing of Attachments for Metal Plaster Bases*—Attachments for securing metal plaster bases to framing

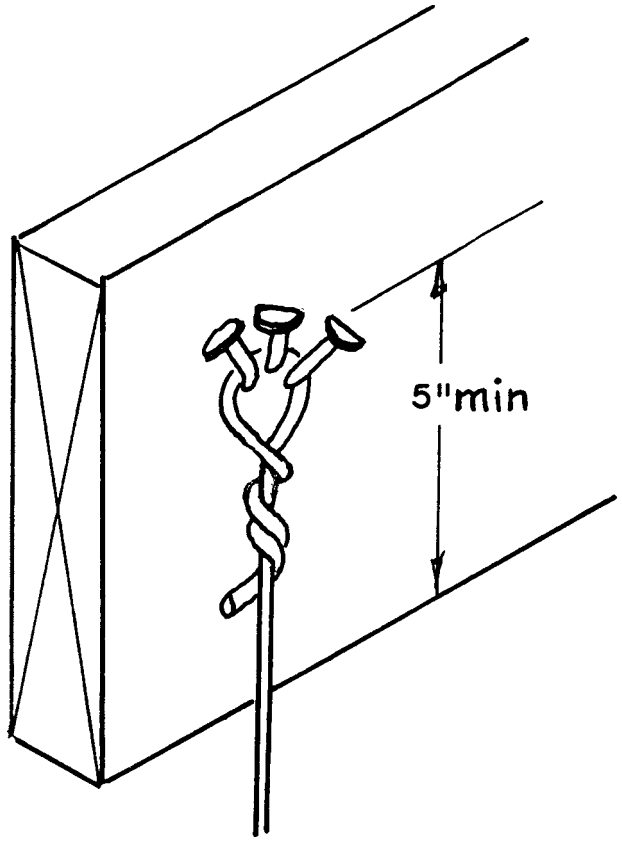

FIG. 5 Hanger Attached to Support Using Nails

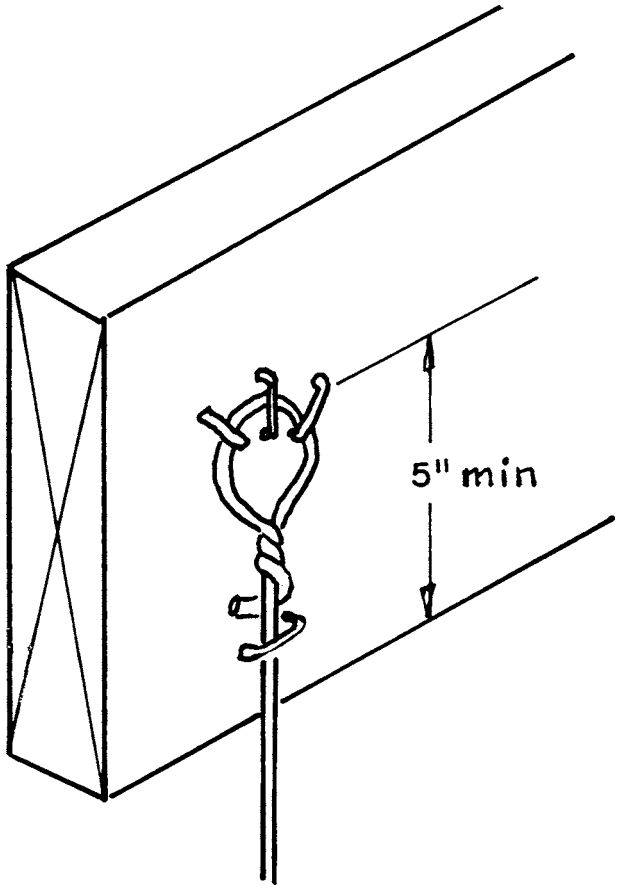

FIG. 6 Hanger Attached to Support Using Staples

members shall be spaced not more than 7 in. (178 mm) apart for diamond mesh and flat rib laths and at each rib for ⅜ in. (9.5-mm) rib lath.

7.10 *Application of Metal Plaster Bases*:

7.10.1 *General*:

7.10.1.1 The spacing of framing members for the type and weight of metal plaster base used shall conform to the requirements of Table 3. Metal plaster bases shall be attached to framing members at not more than 7 in. (178 mm) along framing members except for ⅜-in. (9.5-mm) rib metal lath that shall be attached at each rib.

7.10.1.2 Lath shall be applied with the long dimension at right angles to the supports, unless otherwise specified.

7.10.1.3 Ends of adjoining plaster bases shall be staggered.

7.10.1.4 Lath shall not be continuous through control joints but shall be stopped and tied at each side.

7.10.1.5 Where furred or suspended ceilings butt into or are penetrated by columns, walls, beams, or other elements, the edges and ends of the ceiling lath shall be terminated at the horizontal internal angles with a casing bead, control joint, or similar device designed to keep the edges and ends of the ceiling lath and plaster free of the adjoining vertically oriented, or penetrating elements. Cornerite shall not be used at these locations. A clearance of not less than ⅜ in. (9.5 mm) shall be maintained between the bead and all such elements.

7.10.1.6 Where load bearing walls or partitions butt into structural walls, columns, or floor or roof slabs, the sides or ends of the wall or partition lath shall be terminated at the internal angles with a casing bead, expansion/control joint, or similar device designed to keep the sides and ends of the wall or partition lath free of the adjoining elements. Cornerite shall not be used at these internal angles. A clearance of not less than ⅜ in. (9.5 mm) shall be maintained from all abutting walls, columns, or other vertical elements.

7.10.2 *Attachments for Metal Plaster Bases to Wood Framing Members*:

7.10.2.1 Lath shall be attached to framing members with attachments spaced not more than 7 in. (178 mm) on centers along supports.

7.10.2.2 Diamond-mesh expanded metal lath, flat-rib expanded metal lath, and wire lath shall be attached to horizontal wood framing members with 1½-in. (38.1-mm) roofing nails driven flush with the plaster base and attached to vertical wood framing members with 6d common nails, or 1-in. (25-mm) roofing nails driven to a penetration of not less than ¾ in. (19.1 mm), or 1-in. (25-mm) wire staples driven flush with the plaster base. Staples shall have crowns not less than ¾ in. (19.05 mm) and shall engage not less than three strands of lath and penetrate the wood framing members not less than ¾ in. (19.05 mm). When metal lath is applied over sheathing, use fasteners that will penetrate the structural members not less than ¾ in. (19 mm).

7.10.2.3 Expanded ⅜ in. (9.5 mm) rib lath shall be attached to horizontal and vertical wood framing members with nails or staples to provide not less than 1¾-in. (44.5-mm) penetration into horizontal wood framing members, and ¾-in. (19.1-mm) penetration into vertical wood framing members.

www.technobetar.ir

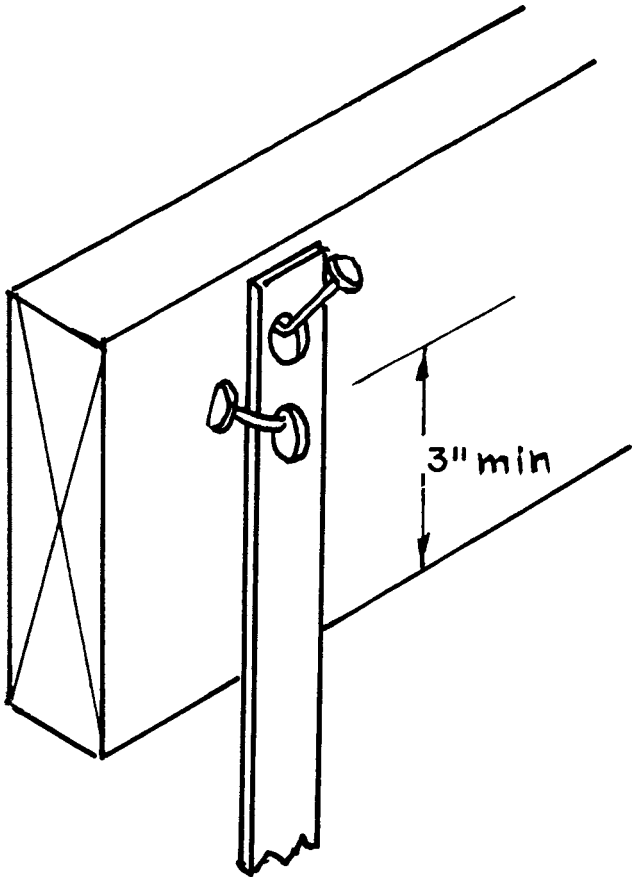

FIG. 7 Flat Hanger Attached to Support Using Nails

7.10.2.4 Common nails shall be bent over to engage not less than three strands of lath, or be bent over a rib when rib lath is installed.

7.10.2.5 Screws used to attach metal plaster base to horizontal and vertical wood framing members shall penetrate not less than ⅝ in. (15.9 mm) into the member when the lath is installed and shall engage not less than three strands of lath. When installing rib lath, the screw shall pass through, but not deform, the rib.

7.10.3 *Attachments for Metal Plaster Bases to Metal Framing Members*:

7.10.3.1 Except as described in 7.10.3.2, all metal plaster bases shall be securely attached to metal framing members with 0.0475-in. 18 gauge (1.21-mm) wire ties, clips or by other means of attachment which afford carrying strength and resistance to corrosion equal to or superior to that of the wire.

7.10.3.2 Rib metal lath shall be attached to open-web steel joists by single ties of galvanized, annealed steel wire, not less than 0.0475 in. (1.21 mm), with the ends of each tie twisted together 1½ times.

7.10.3.3 Screws used to attach metal plaster base to metal framing members shall project not less than ⅜ in. (9.5 mm) through the metal framing member when the lath is installed and shall engage not less than three strands of lath. When installing rib lath, the screw shall pass through, but not deform, the rib.

7.10.4 *Attachments for Metal Plaster Bases to Concrete Joists*—Rib metal lath shall be attached to concrete joists by loops of 0.0800-in. (2.03-mm) galvanized, annealed steel wire, with the ends of each loop twisted together.

7.10.5 Metal plaster bases shall be attached to masonry or concrete with power or powder actuated fasteners or a combination of power or powder actuated fasteners and hardened concrete stub nails. One power or powder actuated fastener shall be located at each corner and one at the mid point of the long dimension adjacent to the edge of the metal plaster base sheet. The balance of the sheet shall be fastened with power or powder actuated fasteners or hardened concrete stub nails. The fasteners shall be installed in rows not more than 16 in. (406 mm) on center and spaced vertically along each row not more 7 in. (178 mm) on center. All fasteners shall be corrosion resistant and shall be not less than ¾ in. (19 mm) long, with heads not less than ⅜ in. (9.5 mm) wide.

7.11 *Application of Accessories*:

7.11.1 *General*—All metal accessories shall be installed in such a manner than flanges and clips provided for their attachment are completely embedded in the plaster.

7.11.1.1 Accessories shall be attached to substrate in such a manner as to ensure proper alignment during application of plaster. Flanges of accessories shall be secured at not more than 7 in. (178 mm) intervals along supports.

7.11.2 *Corner Beads*—Corner beads shall be installed to protect all external corners and to establish grounds.

7.11.2.1 *External Corner Reinforcement*—External corner reinforcement shall be installed to reinforce all external corners where corner bead is not used. Where no external corner reinforcement or corner bead is used, lath shall be furred out and carried around corners not less than one support on frame construction.

7.11.3 *Casing Beads*—Nonload-bearing members shall be isolated from load-bearing members, and all penetrating elements, with casing beads or other suitable means, to avoid transfer of structural loads, and to separate from dissimilar materials.

7.11.4 *Control Joints-General*—Control joints shall be formed by using a single prefabricated member or fabricated by installing casing beads back to back with a flexible barrier membrane behind the casing beads. The separation spacing shall be not less than ⅛ in. (3.2 mm) or as required by the anticipated thermal exposure range and shall be in conformance with 7.10.1.4.

7.11.4.1 *Control Joints*—Control (expansion and contraction) joints shall be installed in walls to delineate areas not more than 144 ft^2(13.4 m^2) and to delineate areas not more than 100 ft^2(9.30 m^2) for all horizontal applications, that is, ceilings, curves, or angle type structures.

7.11.4.2 The distance between control joints shall not exceed 18 ft (5.5 m) in either direction or a length-to-width ratio of 2½ to 1. A control joint shall be installed where the ceiling framing or furring changes direction.

7.11.4.3 A control joint shall be installed where an expansion joint occurs in the base exterior wall.

7.11.4.4 Wall or partition height door frames shall be considered as control joints.

7.11.5 *Foundation Weep Screed*—Foundation weep screed shall be installed at the bottom of all steel or wood framed

TABLE 3 Types and Weights of Metal Plaster Bases and Corresponding Maximum Permissible Spacing of Supports

Type of Metal Plaster Base	Minimum Weight of Metal Plaster Base, lb/yd^2(kg/m^2)	Maximum Permissible Spacing of Supports Center to Center, in. (mm)				
		Walls (Partitions)			Ceilings	
		Wood Studs or Furring	Solid Partitions[A]	Steel Studs or Furring	Wood or Concrete	Metal
U.S. Nominal Weights:						
Diamond Mesh[B]	2.5 (1.4)	16 (406)[C]	16 (406)	16 (406)[C]	12 (305)	12 (305)
	3.4 (1.8)	16 (406)[C]	16 (406)	16 (406)[C]	16 (406)	16 (406)
Flat Rib	2.75 (1.5)	16 (406)	16 (406)	16 (406)	16 (406)	16 (406)
	3.4 (1.8)	19 (482)	24 (610)	19 (482)	19 (482)	19 (482)
Flat Rib (large opening)	1.8 (0.95)	24 (610)	24 (610)	24 (610)	16 (406)	16 (406)
⅜ in. Rib	3.4 (1.8)	24 (610)	N/A[D]	24 (610)	24 (610)	24 (610)
	4.0 (2.1)	24 (610)	N/A	24 (610)	24 (610)	24 (610)
¾ in. Rib	5.4 (2.9)	24 (610)	N/A	24 (610)	36 (914)	36 (914)
Welded Wire[B]	1.14 (0.62)	16 (406)	16 (406)	16 (406)	16 (406)	16 (406)
	1.95 (1.1)	24 (610)	24 (610)	24 (610)	24 (610)	24 (610)
Woven Wire[B]	1.4 (0.6)	24 (610)	16 (406)	16 (406)	24 (610)	16 (406)
Canadian Nominal Weights:						
Diamond Mesh[B]	2.5 (1.4)	16 (406)	12 (305)	12 (305)	12 (305)	12 (305)
	3.0 (1.6)	16 (406)	12 (305)	12 (305)	12 (305)	12 (305)
	3.4 (1.8)	16 (406)	16 (406)	16 (406)	16 (406)	16 (406)
Flat Rib	2.5 (1.4)	16 (406)	12 (305)	12 (305)	12 (305)	12 (305)
	3.0 (1.6)	16 (406)	16 (406)	16 (406)	16 (406)	13½ (343)
⅜ in. Rib	3.0 (1.6)	19 (482)	N/A	16 (406)	16 (406)	16 (406)
	3.5 (1.9)	24 (610)	N/A	19 (482)	19 (482)	19 (482)
	4.0 (2.1)	24 (610)	N/A	24 (610)	24 (610)	24 (610)

[A] Where plywood is used for sheathing, a minimum of ⅛ in. (3.2 mm) separation shall be provided between adjoining sheets to allow for expansion.
[B] Metal plaster bases shall be furred away from vertical supports or solid surfaces at least ¼ in. Self-furring lath meets furring requirements; except, furring of expanded metal lath is not required on supports having a bearing surface of 1⅝ in. or less.
[C] These spacings are based on unsheathed walls. Where self-furring lath is placed over sheathing or a solid surface, the permissible spacing of supports shall be no more than 24 in. (610 mm).
[D] Not applicable.

TABLE 4 Spans and Spacing of Cold-Rolled Channel Cross-Furring Members[A, B, C, D, E, F]

Design Load, 12 psf (575 Pa)		Allowable Span, Main Runners or Supports Ft-in. (mm)	
Member Depth	Spacing, in. (mm)	Simple Span	Two or More Spans[G,H]
¾ (19)	13.5 (343)	2-9 (840)	3-5 (1040)
	16 (406)	2-7 (790)	3-3 (990)
	19 (483)	2-7 (740)	3-0 (910)
	24 (610)	2-3 (690)	2-10 (860)
1½ (38)	13.5 (343)	4-6 (1370)	5-8 (1730)
	16 (406)	4-3 (1300)	5-5 (1650)
	19 (483)	4-0 (1220)	5-1 (1550)
	24 (610)	3-8 (1120)	4-9 (1450)

[A] Bare metal thickness of cold-rolled members shall not be less than 0.0538 in. (1.367 mm).
[B] Inside corner radii shall not be greater than ⅛ in. (3.17 mm).
[C] Spans based on upper flange of cross-furring laterally unbraced.
[D] Maximum deflection limited to $1/360^{th}$ of span length unbraced.
[E] Steel yield stress, *Fy*, shall not be less than 33 000 psi (228 MPa).
[F] Tabulated spans apply only to cross-furring with webs oriented vertically.
[G] "Two or more" spans refers to two or more continuous, equal spans.
[H] For the "two or more" span conditions, listed spans represent the center-to-center distance between adjacent supports.

exterior walls to receive lath and plaster. Place the bottom edge of the foundation weep screed not less than 1 in. (25 mm) below the joint formed by the foundation and framing. The nose of the screed shall be placed not less than 4 in. (102 mm) above raw earth or 2 in. (51 mm) above paved surfaces. The weather resistive barrier and lath shall entirely cover the vertical attachment flange and terminate at the top edge of the nose or ground flange.

ANNEX

(Mandatory Information)

A1. GENERAL INFORMATION

A1.1 All wood-based sheathing shall be installed with a minimum ⅛-in. (3.2-mm) gap around all panel edges and between openings for doors and windows.

NOTE A1.1—This ⅛-in. (3.2-mm) gap is intended to accommodate expansion. Linear expansion that is not accommodated by an expansion gap can cause stress on the stucco membrane resulting in stucco cracks.

A1.2 **Expansion Joints** shall be used to accommodate some degree of movement in the stucco membrane caused by movement of the building or its components to minimize damage to the stucco and weather resistive barrier. **Control Joints** shall be installed to minimize stress due to stucco curing and drying shrinkage and minor movement, along predetermined, usually straight lines and as a screed to aid in stucco thickness control.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1063 – 07, that may impact the use of this specification. (Approved May 15, 2008)

(*1*) Revised Table 3.
(*2*) Added new 3.2.1 and 3.2.2 and renumbered subsequent paragraphs. Added new Note 1 and renumbered subsequent notes.
(*3*) Added new Annex A1.2.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1063 – 06, that may impact the use of this specification. (Approved November 1, 2007)

(*1*) Added Annex A1.
(*2*) Replaced references to Specification A 526/A 526M with Specification A 653/A 653M throughout.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1063 – 03, that may impact the use of this specification. (Approved December 1, 2006)

(*1*) The minimum weights in Table 3 for Welded and Woven wire were changed to be brought in line with Specification C 933 and Specification C 1032, respectively.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1064/C 1064M – 08

Standard Test Method for Temperature of Freshly Mixed Hydraulic-Cement Concrete[1]

This standard is issued under the fixed designation C 1064/C 1064M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of temperature of freshly mixed hydraulic-cement concrete.

1.2 The values stated in either SI or inch-pound units are to be regarded separately as standard. Within the text, SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 172 Practice for Sampling Freshly Mixed Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Significance and Use

3.1 This test method provides a means for measuring the temperature of freshly mixed concrete. The measured temperature represents the temperature at the time of testing and may not be an indication of the temperature of the freshly mixed concrete at a later time. It may be used to verify conformance to a specified requirement for temperature of concrete.

3.2 Concrete containing aggregate of a nominal maximum size greater than 3 in. [75 mm] may require up to 20 min for the transfer of heat from aggregate to mortar. (See ACI Committee 207.1R Report.[4])

4. Apparatus

4.1 *Container*, shall be large enough to provide at least 3 in. [75 mm] of concrete in all directions around the sensor of the temperature measuring device; concrete cover must also be at least three times the nominal maximum size of the coarse aggregate.

4.2 *Temperature Measuring Device*, shall be capable of accurately measuring the temperature of the freshly mixed concrete to ±1 °F [± 0.5 °C] throughout a range of 30° to 120 °F [0° to 50 °C]. The design of the temperature measuring device shall be such that it allows 3 in. [75 mm] or more immersion during operation.

4.3 Partial immersion liquid-in-glass thermometers (and possibly other types) shall have a permanent mark to which the device must be immersed without applying a correction factor.

4.4 *Reference Temperature Measuring Device*, shall be readable and accurate to ± 0.5 °F [0.2 °C] at the verification points in 5.1. A certificate or report that verifies the accuracy shall be available in the laboratory for review. Accuracy of liquid-in-glass reference temperature measuring devices shall be verified once. Verification of direct-reading resistance reference temperature measuring devices shall be performed every twelve months. The certificate or report shall provide documentation that the reference standard used in the verification is traceable to the National Institute of Standards and Technology (NIST).

5. Calibration of Temperature Measuring Device

5.1 Each temperature measuring device used for determining temperature of freshly mixed concrete shall be calibrated

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.60 on Testing Fresh Concrete.

Current edition approved July 1, 2008. Published August 2008. Originally approved in 1986. Last previous edition approved in 2005 as C 1064 – 05.

annually, or whenever there is a question of accuracy. This calibration shall be performed by comparing the readings of the temperature measuring device at two temperatures at least 30 °F [15 °C] apart.

5.2 Calibration of the temperature measuring devices may be made in oil or other suitable baths having uniform density if provision is made to:

5.2.1 Maintain the bath temperature constant within 0.5 °F [0.2 °C] during the period of the test.

5.2.2 Have both the temperature and reference temperature measuring devices maintained in the bath for a minimum of 5 min before reading temperatures.

5.2.3 Continuously circulate the bath liquid to provide a uniform temperature.

5.2.4 Slightly tap thermometers containing liquid to avoid adhesion of the liquid to the glass if the temperature exposure is being reduced.

6. Sampling Concrete

6.1 It is acceptable to measure the temperature of freshly mixed concrete in either the transporting equipment or the forms after discharge provided the sensor of the temperature measuring device has at least 3 in. [75 mm] of concrete cover in all directions.

6.2 If the transporting equipment or placement forms are not used as the container, a sample shall be prepared as follows:

6.2.1 Immediately, prior to sampling the freshly mixed concrete, dampen (with water) the sample container.

6.2.2 Sample the freshly mixed concrete in accordance with Practice C 172, except that composite samples are not required if the only purpose for obtaining the sample is to determine temperature.

6.2.3 Place the freshly mixed concrete into the container.

7. Procedure

7.1 Position the temperature measuring device so that the end of the temperature sensing portion is submerged a minimum of 3 in. [75 mm] into the freshly mixed concrete. Close the void left by the placement by gently pressing the concrete around the temperature measuring device at the surface of the concrete to prevent ambient air temperature from affecting the reading.

7.2 Leave the temperature measuring device in the freshly mixed concrete for at least 2 min but not more than 5 min, then read and record the temperature to the nearest 1 °F [0.5 °C]. Do not remove the device from the concrete when reading the temperature.

8. Report

8.1 Report the measured temperature of the freshly mixed concrete to the nearest 1 °F [0.5 °C].

9. Precision and Bias

9.1 The single operator standard deviation for measurement of concrete temperature has been found to be 0.5 °F.[5] Therefore, results of two properly conducted tests by the same operator on the same sample of material should not differ by more than 1.3 °F.[5]

9.2 The multi-operator standard deviation for the measurement of concrete temperature on the same sample has been found to be 0.7 °F.[5] Therefore, two tests properly conducted by different operators but on the same material should not differ by more than 1.9 °F.[5]

9.3 The precision values given were derived from an interlaboratory study using 11 operators on two concrete batches at around 75 °F.[6]

9.4 Since there is no accepted reference material suitable for determining the bias of this test method, no statement on bias is being made.

10. Keywords

10.1 freshly mixed concrete; temperature; temperature measuring device

[5] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

[6] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1028.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1064/C 1064M – 05, that may impact the use of this specification. (Approved July 1, 2008)

(*1*) Revised 3.1 to clarify what the recorded temperature represents.

(*2*) Revised 7.2 and 8.1.

(*3*) Deleted 7.3 and Note 4.

Designation: C 1067 – 00 (Reapproved 2007)

Standard Practice for Conducting A Ruggedness or Screening Program for Test Methods for Construction Materials[1]

This standard is issued under the fixed designation C 1067; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers a procedure for detecting sources of variation in a test method. The procedure should be used during the development of a test method, before the interlaboratory study is executed, such as those in Practices C 670, C 802, and E 691. Interlaboratory studies can be expensive to execute. Resources will probably be more efficiently used if sources of variation in a test method are eliminated prior to performing the interlaboratory study. The procedure also is useful for determining sources of variation in an existing test method that has been found to have poor precision.

1.2 This practice covers, in very general terms, techniques for planning, collecting data, and analyzing results from a few laboratories. Annex A1 provides the details of the procedure with an example and Annex A2 gives the theoretical background.

1.3 The practice does not give information pertinent to estimating within- or between-laboratory precision.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 802 Practice for Conducting an Interlaboratory Test Program to Determine the Precision of Test Methods for Construction Materials

E 456 Terminology Relating to Quality and Statistics

E 691 Practice for Conducting an Interlaboratory Study to Determine the Precision of a Test Method

E 1169 Guide for Conducting Ruggedness Tests

3. Terminology

3.1 *Definitions:*

3.1.1 *determination value*, *n*—numerical quantity calculated as directed in the test method using direct measurements obtained in accordance with the procedures given in the test method.

3.1.2 *replication*, *n*—the act of obtaining two or more determination values under specified conditions. The number of replications must be finite and the scope of the replication operation may be narrow or broad, but must be specified.

3.1.3 For definitions of other statistical terms used in this standard, refer to Terminology E 456.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *factor*, *n*—an element in the test procedure or laboratory environment that is a potential source of variation in test results.

3.2.2 *ruggedness*, *adj*—the characteristic of a test method that produces test results that are not influenced by small differences in the testing procedure or environment.

3.2.3 *screening*, *n*—the detection of significant sources of variation as compared to chance variation.

3.2.4 *variable*, *n*—a number or quantity that varies.

4. Summary of Practice

4.1 The practice requires that the user develop, from theoretical or practical knowledge, or both, a list of factors that plausibly would cause significant variation in test results if the factors were not controlled. The technique is limited to the analysis of the effects seven factors and requires considerably less effort than would be required to collected data for seven

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates . This practice was developed jointly by ASTM Committees C01, C09, D04, and D18, and is endorsed by all four committees.

Current edition approved June 1, 2007. Published October 2007. Originally approved in 1987. Last previous edition approved in 2000 as C 1067 – 00.

www.technobetar.ir

factors in a full factorial study. Procedures exist for analysis of smaller and larger numbers of factors (see Guide E 1169), but seven is a convenient number for many test methods for construction materials. The seven-factor analysis requires 16 determinations by each laboratory. The procedure can be usefully executed by a single laboratory, but sometimes additional information can be obtained if it is repeated in one or two additional laboratories.

4.2 The procedure requires that two levels of each factor be identified, then 16 determinations be done on a prescribed combinations of factor levels. The levels assigned to a factor may be quantitative or qualitative (for example, brass versus steel).

4.3 The disadvantage of this type of analysis is that the method only estimates simple effects of each factor and does not detect interactive effects among factors.

5. Significance and Use

5.1 The purpose of a ruggedness evaluation is to determining how sensitive the test method is to changes in levels of pertinent operating factors. Normally, operating conditions for a test method are defined along with an allowable tolerance. A ruggedness analysis determines that effect of worst-case variation in operating conditions within this tolerance range. The method then can be revised with smaller tolerances on operating conditions to improve the precision.

5.2 A major reason for poor precision in test methods is the lack of adequate control over the sources of variation in testing procedures or testing environments. These sources of variation often are not controlled adequately because they were not identified during the development of the test procedures.

5.3 All new test methods must be subjected to an interlaboratory program for purposes of developing a precision and bias statement. These programs can be expensive and lengthy, and the result may be that the determination is made that the method is too variable to be published without further revision. Interlaboratory studies typically give the subcommittee an indication that the method is too variable, but they do not usually give a clear picture of what is causing the variation. Application of this ruggedness practice using one or a few laboratories may be a much more economical way to determine these causes.

5.4 Many existing test methods were published before there was a requirement that precision and bias statements be developed. Since this became a requirement, most of these test methods have developed precision and bias statements, and the result is that many have been found to suffer from relatively large amount of variation. Use of this practice represents a relatively simple way to investigate the causes of variation in test methods, so that a subcommittee will have some guidance as to which parts of the test method need to be studied further for revision.

5.5 The procedure can be used for a program within a single laboratory, but involvement of at least three laboratories is recommended, particularly if the single laboratory were to be the one in which the test method was developed. This is particularly important for new test methods. The originating laboratory is so much a part of the development of the test method that it is difficult for it to be objective in spotting any problems in the clarity of the test method directions. Two additional laboratories will probably contribute fresh critical review of the validity of the test method and provide assistance in clarifying the instructions of the test method when needed.

6. Materials

6.1 The number and types of material shall cover the range of material properties to which the test method is applicable. The test method does not apply to material types or property values outside the range evaluated. Three to five materials will usually be sufficient.

6.1.1 Some preliminary testing may help the laboratories involved determine the materials that shall be used in the screening program.

7. Procedure

7.1 Determine the number of laboratories that will participate in the program and which materials each will use in the program. The maximum amount of information is obtained if all laboratories include all materials in their part of the program, however cost can be reduced by each laboratory using a different material. Caution must be exercised in interpreting the results since laboratory-dependent cannot be separated from material-dependent effects.

7.2 Factors that are likely to have the greatest effect on the variability in the test results are selected for study. Levels of these factors are determined, selecting the minimum and maximum levels that would plausibly occur in the execution of the test method if there were no particular efforts to control them. Only two levels are allowed. Levels often represent quantitative properties, such as temperature, pressure, etc, but they may also represent nonquantitative values, such as old vs new, wet vs dry, etc. In this standard, factors are assigned letter designations, $A - G$, and the two levels of each factor are designated with upper and lower cases of these letters, as in Table 1.

7.3 Assign combinations of factor levels to experimental determinations according to Table 1. The 8 determinations will be done in duplicate, therefore, the full study on each material will require 16 determinations.

7.4 Construct a 16 row by 16 column results matrix from the 16 determinations values ($d_1 - d_{16}$) as shown in Table 2. The absolute values of the determinations in each row are identical, only the signs vary. Calculate Z and W statistics as shown in the equations below.

$$Z_r = \sum_1^{16} d_i, \text{ where } d_i\text{'s are the 16 results in each row (r).} \quad (1)$$

7	d_1	$-d_2$	$-d_3$	d_4	d_5	$-d_6$	$-d_7$	d_8	d_9	$-d_{10}$	$-d_{11}$	d_{12}	d_{13}	$-d_{14}$	$-d_{15}$	d_{16}	Z_7	W_7
8	d_1	$-d_2$	$-d_3$	d_4	$-d_5$	d_6	d_7	$-d_8$	d_9	$-d_{10}$	$-d_{11}$	d_{12}	$-d_{13}$	d_{14}	d_{15}	$-d_{16}$	Z_8	W_8
9	d_1	d_2	d_3	d_4	d_5	d_6	d_7	d_8	$-d_9$	$-d_{10}$	$-d_{11}$	$-d_{12}$	$-d_{13}$	$-d_{14}$	$-d_{15}$	$-d_{16}$	Z_9	W_9
10	d_1	d_2	d_3	d_4	$-d_5$	$-d_6$	$-d_7$	$-d_8$	$-d_9$	$-d_{10}$	$-d_{11}$	$-d_{12}$	d_{13}	d_{14}	d_{15}	d_{16}	Z_{10}	W_{10}
11	d_1	d_2	$-d_3$	$-d_4$	d_5	d_6	$-d_7$	$-d_8$	$-d_9$	$-d_{10}$	d_{11}	d_{12}	$-d_{13}$	$-d_{14}$	d_{15}	d_{16}	Z_{11}	W_{11}
12	d_1	$-d_2$	d_3	$-d_4$	d_5	$-d_6$	d_7	$-d_8$	$-d_9$	d_{10}	$-d_{11}$	d_{12}	$-d_{13}$	d_{14}	$-d_{15}$	d_{16}	Z_{12}	W_{12}
13	d_1	d_2	$-d_3$	$-d_4$	$-d_5$	$-d_6$	d_7	d_8	$-d_9$	$-d_{10}$	d_{11}	d_{12}	d_{13}	d_{14}	$-d_{15}$	$-d_{16}$	Z_{13}	W_{13}
14	d_1	$-d_2$	d_3	$-d_4$	$-d_5$	d_6	$-d_7$	d_8	$-d_9$	d_{10}	$-d_{11}$	d_{12}	d_{13}	$-d_{14}$	d_{15}	$-d_{16}$	Z_{14}	W_{14}
15	d_1	$-d_2$	$-d_3$	d_4	d_5	$-d_6$	$-d_7$	d_8	$-d_9$	d_{10}	d_{11}	$-d_{12}$	$-d_{13}$	d_{14}	d_{15}	$-d_{16}$	Z_{15}	W_{15}
16	d_1	$-d_2$	$-d_3$	d_4	$-d_5$	d_6	d_7	$-d_8$	$-d_9$	d_{10}	d_{11}	$-d_{12}$	d_{13}	$-d_{14}$	$-d_{15}$	d_{16}	Z_{16}	W_{16}

$$W_r = \frac{Z_r^2}{16} \tag{2}$$

7.5 The W statistic for row 1 represents the simple sum of the determinations and are not used in this analysis. Statistics for rows 2–8 ($W_2 - W_8$) represent the effects of the seven factors. The statistic for row 9 (W_9) represent the total variation between the two replicate sets and is not used in this analysis. Statistics for rows 10 through 16 ($W_{10} - W_{16}$) are used to calculate the error variance (X), which then is used to calculate the test criterion (F) for each factor, as shown by the equations below. Calculations are summarized in Table 3.

$$X = (\sum_{r=10}^{16} W_r^2)/7 \tag{3}$$

$F_f = \frac{W_r^2}{X}$, where F_f is the F statistic for the effect of factor f (1–7, represented by $W_2 - W_8$, respectively)

7.6 A F value of ≥5.59 represents a significant effect for factor f at a probability of 5 % for drawing an erroneous conclusion.

TABLE 3 Summary of Statistics for Seven Factors and Random Error

Factor	W	F
A	W_2	W_2^2/X
B	W_3	W_3^2/X

8.1 precision; ruggedness; test method; variation

ANNEXES

(Mandatory Information)

A1. EXAMPLE OF A RUGGEDNESS PROGRAM

A1.1 This annex describes the procedure for conducting a ruggedness evaluation using as an example a description of the ruggedness evaluation on a test method for the measurement of the viscosity of asphalt.

A1.2 As the first step in the ruggedness evaluation, each of the laboratories critically examined the procedure in the proposed test method. The objectives of the examination were as follows:

A1.2.1 To determine if the instructions are clear, concise, and complete,

A1.2.2 To decide which factors are likely to influence test results and therefore should be included in the study,

A1.2.3 To pick materials that cover the range of the property of interest for the range of physical forms of the materials to be tested, and

A1.2.4 To determine the proper levels to be evaluated for each of the chosen variables.

A1.3 In this example, representatives of the three laboratories, after familiarizing themselves with the test method as specified in A1.2, met and tried to improve the instructions for the viscosity method. They selected variables, materials, and levels that showed the effect of the variation. One of the laboratories measured viscosity at 24 °C, 25 °C, and 26 °C and found that there was about a 10 % variation with a change of

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

1 °C. This was considered too large so 24.6 and 25.4 °C were selected as the lower and upper temperature levels for the ruggedness test. In the same manner, the effect of the other variables were evaluated and the two levels to be evaluated were determined.

NOTE A1.1—Seven variables were selected and placed in a systematic procedure called an incomplete Latin Square or a Youden Square (**1**).The variables are listed below and shown in a Youden Square in Table A1.1. This plan can evaluate the seven variables with eight determinations. Table A1.2 shows the variables and the levels selected for this example.

A1.4 Four materials were selected to cover the range of the test method and the viscosities were determined by each of the three laboratories with one replication. The results are displayed in Table A1.3. This plan required 16 determinations by each laboratory on each material or 64 determinations by each laboratory.

A1.5 Table A1.4 specifies the experimental plan for a Youden Square for seven factors. The theory of its use is covered in Annex A2. Table A1.4 consists of 16 rows and 16 columns of coefficients each equal to ±1 and arranged in a definite pattern.

A1.6 To obtain Table A1.5, first copy one row from Table A1.3 16 times in the general format of Table A1.5 and then multiply each entry in the new table by the corresponding entry in Table A1.4. Table A1.5 is just such a table derived from the data for Material 1 and Laboratory 1 in Table A1.3.

A1.7 To obtain Table A1.6, add, with due regard to sign, each row of Table A1.5 to obtain the first column of Table A1.6 containing Z_1–Z_{16}. Next, square each entry in column one of Table A1.6 to obtain the corresponding entry in column two and then divide each entry in column two of Table A1.6 by 16 to obtain the corresponding entry in column three. The first row, Z_1, represents the sum of all viscosities for the first row in Table A1.5 and will not be used in this analysis. The second row, Z_2, is the algebraic addition of the second row in Table A1.5 and measures the effect of temperature. In the same manner, the third row, Z_3, measures the effect of the age of the viscometer. The fourth row, Z_4, measures the effect of vacuum level. The fifth row, Z_5, measures the effect of stirring. The sixth row, Z_6, measures the effect of the viscometer being slanted. The seventh row, Z_7, measures the effect of variation in meniscus level. The eighth row, Z_8 measures the effect of variation in time in the bath of the viscometer prior to testing. The ninth row, Z_9, measures the variation between the first and second replication. Rows 10 through 16 (Z_{10}–Z_{16}) measure the factor differences that yield the estimate of error variance. By adding W_{10} through W_{16} we can estimate the error variance with seven degrees of freedom using Eq A1.1:

$$\chi = \sum_{i=10}^{16} W^2{}_i /7\sigma^2 \qquad \text{(A1.1)}$$

where:

χ = pooled sum of squares for error,
$W^2{}_i$ = sum of squares for error in ith row, and
σ^2 = true, but unknown error variance.

A1.7.1 By dividing χ into $W^2{}_j/\sigma^2$, representing the sums of squares for the main factors, we can test for the significance of the *j*th factor difference as shown in Eq A1.2:

$$F_j = W^2{}_j /\sigma^2 / \sum_{i=10}^{16} W^2{}_i /7\sigma^2 = W^2{}_j / \sum_{i=10}^{16} W^2{}_i /7 \qquad \text{(A1.2)}$$

A1.7.2 Eq A1.2 will have an *F*-distribution with 1 and 7 degrees of freedom.

A1.8 The pooled sum of squares for error was determined and compared with the sums of squares for each of the main factors or treatments. The ratio that is significant at the 0.05 level is 5.59.

A1.9 *F* values for each of the main factors were calculated for Tables A1.6-A1.17. The results of these calculations are shown for all factors in Table A1.18. All ratios that were less than 5.59 are shown in the table as NS to show that they are not significant. Z_2 or the effect of temperature was found highly significant for every material and every laboratory indicating the importance of improved control of temperature. Z_4 or the effect of variation in vacuum showed five significant values indicating a need for tightened controls on vacuum. Z_6 or the effect of the viscometer deviating from the vertical position was significant in six of the laboratory-material combinations indicating the need for tightened controls on the position of the viscometer. Z_3, Z_5, Z_7, and Z_8 showed some scattering of barely significant values but these were not judged to be of sufficient importance to require tighter controls.

TABLE A1.1 Pattern for Assigning Levels to Seven Factors

	Determination Number							
Variable	1	2	3	4	5	6	7	8
A or a	a	a	a	a	A	A	A	A
B or b	b	b	B	B	b	b	B	B
C or c	C	c	C	c	C	c	C	c
D or d	D	D	d	d	d	d	D	D
E or e	e	E	e	E	E	e	E	e
F or f	F	f	f	F	F	f	f	F
G or g	G	g	g	G	g	G	G	g

a = 24.6°, the lower level of temperature.
A = 25.4°, the higher level of temperature.
b = New viscometer tube.
B = Worn viscometer tube.
C = 290-mm Hg, lower vacuum.
c = 310-mm Hg, higher vacuum.
d = Charge viscometer without stirring sample.
D = Charge viscometer after stirring for 1 min.
e = Mount the viscometer vertically.
E = Mount the viscometer 3° from vertical.
f = Charge with meniscus 1 mm above line.
F = Charge with meniscus 1 mm below line.
g = Hold viscometer in bath 10 min less than normal before testing.
G = Hold viscometer in bath 10 min longer than normal before testing.

A1.10 Representatives of the three laboratories met after completion of the laboratory work and the subsequent analysis. After discussion of the results, the decision was made that it was practical and desirable to control temperature, vacuum, and the angle of the viscosity tube to the following limits:

Temperature 25 ± 0.1, °C
Vacuum 300 ± 2, mm (Hg) and
Angle with Horizontal 90 ± 1°

With these changes an interlaboratory study was made on the method.

A2. THEORY OF THE RUGGEDNESS ANALYSIS

A2.1 Any mathematical analysis depends on assumptions. It is particularly difficult to make valid assumptions when there is little experience on which to make the assumptions. Since a ruggedness or screening program is usually run on a new test method, there is very little history or experience to validate the necessary assumptions. An extensive study could yield the experience to validate the assumptions, but it would also increase the cost of the ruggedness program to the point that few such programs could be undertaken. This practice seeks to balance these risks to make the practice practical and useful.

A2.2 A ruggedness program attempts to identify the important factors or variables which cause variability of results obtained using the test method. It is important that all of the major factors be included in the study, since, if one is left out, the study will not help in identifying its significance. The example in Annex A1 evaluates seven factors. This is usually sufficient to cover the major sources of variability. Design for both fewer and more factors are given in statistical texts for use when needed **(5).**

A2.2.1 It is unusual for more than seven or for less than five factors to be required. When only five factors are considered significant, two other factors can nearly always be selected about which there may be some doubt. A seven factor analysis is usually suitable for most ruggedness evaluations.

A2.2.2 A full factorial experiment for seven factors at two levels would require 2^7 or 128 runs or determinations for each laboratory and each material. If this design had been followed in Annex A1, 128 runs times 3 laboratories times 4 materials times 2 replications equals 3072 determinations instead of the 192 determinations actually required in the example.

A2.2.3 A full factorial experiment identifies not only significant effects of the main factors but also those of the interactions. An interaction is a source of variability due to the combination of main factors that cannot be explained by the individual variability of those main factors. There are instances where the effect of an interaction is greater than the sum of the effects of the main factors that create the interaction. However, interactions are usually regarded as being smaller sources of variation; particularly three and four factor interactions. In this standard, the effect of all interactions are assumed to be negligible. This is done to permit testing of the significance of a large number of main effects while holding the size of the experiment down to manageable levels. The effect of interactions will not always be negligible and there are times when an estimate of a main effect will include an interaction.

A2.2.4 The assumption is also made that the random errors are normally distributed. Since a new method is being evaluated, there is no data available to show that the errors are normally distributed. However, the assumption appears reasonable based on experience with other ASTM test methods.

A2.2.5 While the risks inherent in adopting these assumptions are real, it is thought that despite the risks the ruggedness program will serve a useful purpose in improving the precision of most test methods.

A2.3 Two levels have been chosen for this study. Three or more levels could have been used. The higher number of levels would have given information about the shape of the curves that could be derived by plotting the viscosity versus each of the main factors at the levels chosen. Increasing the levels would also increase the number of runs or determinations. For example, seven factors at three levels would require 2187 runs compared with 128 at two levels. Since each of the factors vary by a small amount, the curves would be substantially straight and there would be little gained by measuring at a higher number of levels than two.

A2.4 A linear model or equation for the seven main factor ruggedness program would be:

$$Z = B_0 + B_1X_1 + B_2X_2 + B_3X_3 + B_4X_4 + B_5X_5 + B_6X_6 + B_7X_7 + e \quad \text{(A2.1)}$$

where:

X_1 = through X_7 are the main effects,
B_0 = through B_7 are the unknown parameters, and
e = is random error.

A2.4.1 A Youden Square, which is the basis for this ruggedness program, is in turn part of a Hadamard matrix an example of which is shown in Table A2.1. The Youden Square would be Table A2.1 with the top or Z_1 line removed. Table A2.1 represents the values of B that equate each of the Z's to the X_0, X_1, X_2, through X_7 in eight linear equations. The fact

TABLE A2.1 Values for the coefficients B_o through B_7

	X_0	X_1	X_2	X_3	X_4	X_5	X_6	X_7
Z_1	1	1	1	1	1	1	1	1
Z_2	1	1	1	1	−1	−1	−1	−1
Z_3	1	1	−1	−1	1	1	−1	−1
Z_4	1	−1	1	−1	1	−1	1	−1
Z_5	1	1	−1	−1	−1	−1	1	1
Z_6	1	−1	1	−1	−1	1	−1	1
Z_7	1	−1	−1	1	1	−1	−1	1
Z_8	1	−1	−1	1	−1	1	1	−1

that Hadamard matrices are orthogonal makes each row of Table A2.1 an independent vector in the transformation matrix which is Table A2.1. This also means that when any line in the table is multiplied by any other line the sum is always zero. The B_0 through B_7 are represented by numbers + 1 or − 1 shown on each line of Table A2.1.

A2.4.2 It should be noted that Z_2 divided by 4 is the difference between average results when temperature is at a high level and the average results when temperature is at a low level. The design of the experiment based on the characteristic of Hadamard matrices, is such that when determinations of temperature are at a high level all other factors are twice at a high level and twice at a low level. When determinations of temperature are at a low level, all other factors are twice at a high level and twice at a low level. Measurement of temperature is freed of the effect of the level of the factors other than temperature leaving only the effect of the temperature and of random error, *e* of the other factors.

A2.4.3 A close examination of Table A2.1 shows that what is true for temperature is also true for each of the other factors. With the experimental design in Table A2.1, separate assessments of each of the effects of seven factors can be made with only eight tests.

A2.4.4 There is no separate estimate of the error variance by which the statistical significance of the factor effects can be tested.

A2.5 An estimate of error variance can be obtained by replicating the experiment. It is important in experiments of this kind to keep the amount of work and therefore the cost as low as possible while obtaining valid results. The amount of work would be halved if the work of each laboratory is regarded as a replication of the experiment. Experience in ASTM interlaboratory studies shows that there usually are significant differences between laboratories. Therefore, the recommendation is that the experiment be replicated in each laboratory according to the experimental design shown in Table A1.4 and used in Annex A1.1.

A2.6 The first eight rows in Table A1.4 are the same as in Table A2.1 except that they are repeated in the second replication. Z_9 shows the differences between replications. The coefficients in Z_{10} through Z_{16} are exactly the same as those in Z_2 through Z_8 but in the replication all signs are reversed in Z_{10} through Z_{16}. It is these differences from replicate to replicate that yield the necessary estimate of error variance. The assumption as already stated is made that there are no real interactions between factor differences and replications.

A2.7 The transformation matrix for the 16 determinations is shown in Table A1.4. A column containing values for $W_i^2 = Z_i^2/D_1$ appears in Table A1.6 and Table A1.7 where: Z_i equals the sum of the Z's in the ith row squared, and D_i equals the sum of squares of the coefficients in the ith row.

In all instances for an Hadamard matrix D_i equals the number of columns in the matrix since both 1 and $-1^2 = 1$. All rows in Table A1.4 sum to 16 so $D_i = 16$ for every row.

If σ^2 is the true, but unknown error variance, then on the assumption that the errors are normally distributed each W_i^2/σ^2 will have an independent χ^2–distribution with 1° of freedom. The sum $\Sigma_{i=10}^{16} W_i^2/7\sigma^2$ represents the pooled sums of squares for error divided by the error variance that will have a χ^2 distribution with 7° of freedom. For the ith row of Table A1.4, j = 2 to 8, the ratio will have an F-distribution with 1 and 7° of freedom.

$$F_j = W_j^2/\sigma^2 / \sum_{i=10}^{16} W_i^2/7\sigma^2 = W_j^2/\sum_{i=10}^{16} W_i^2/7 \qquad \text{(A2.2)}$$

A2.8 Annex A1 consists of a detailed example using the theory of Annex A2. It is recommended that the test of significance be carried out at the probability level of 0.05 of the F-distribution. The ratio that is significant at the 0.05 probability level can be obtained from tables of the F-distribution that are in most standard statistical text books.

Designation: C 1073 – 97a (Reapproved 2003)

Standard Test Method for Hydraulic Activity of Ground Slag by Reaction with Alkali[1]

This standard is issued under the fixed designation C 1073; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the rapid determination of hydraulic activity of ground-granulated iron blast-furnace slag. This test method measures the accelerated strength development of the slag by using sodium hydroxide solution as mixing water and curing at elevated temperature.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* A specific warning statement is given in Section 6.

1.4 The text of this standard references notes and footnotes which provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this standard.

C 125 Terminology Relating to Concrete and Concrete Aggregates[3]

C 219 Terminology Relating to Hydraulic Cement[2]

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency[2]

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials[3]

C 778 Specification for Standard Sand[2]

C 989 Specification for Ground Blast-Furnace Slag for Use in Concrete and Mortars[3]

3. Terminology

3.1 *Definitions:*

3.1.1 Definitions are given in Terminology C 125 and C 219.

3.2 *Description of Term Specific to This Standard:*

3.2.1 *slag, n*—granulated blast-furnace slag as defined in Terminology C 125 and ground to cement fineness.

4. Significance and Use

4.1 This test method can be used as a quality-control test for slag production from a single source after adequate correlation with tests stipulated in Specification C 989.

4.2 This test method may be used as an evaluation technique for slag, when an appropriate correlation with various finenesses of slags from a specific source ground in a specific laboratory mill has been previously developed.

4.3 The hydraulic activity as measured by this test method on ground-slag samples can provide guidance to a manufacturer as to fineness level required to maintain a certain level of hydraulic activity.

4.4 While this test method is intended primarily as a quality control test, some studies have shown that the test method is capable of evaluating the hydraulic activity of slags from different sources.

5. Apparatus

5.1 *Three-Gang Molds for 2-in. or 50-mm Cubes and Compression Test Machine*, as specified in Test Method C 109/C 109M (Note 1).

NOTE 1—Silicone grease is recommended for protection of mold surfaces from the caustic solution in this test.

5.2 *Mixer*, as specified in Method C 305.

5.3 *Curing Chamber*, capable of maintaining a temperature of air or water bath of 55 ± 2°C.

5.4 *Containers*, capable of holding one three-cube mold in an essentially vapor-tight condition. If polyethylene or other plastic bags are used, they shall have a closure of the zip type. If rigid containers are used, they shall have tight sealing covers (Note 2). The acceptability of containers shall be determined by measuring the water loss after curing in air or the gain after curing in water bath. Water loss shall be less than 15 mL in air curing or gain less than 5 mL in water-bath curing.

NOTE 2—Plastic boxes designed for household storage of celery with a bottom grid have given good service.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.27 on Ground Slag .

Current edition approved August 10, 2003. Published September 2003. Originally approved in 1985. Last previous edition approved in 1997 as C 1073 – 97a.

6. Materials

6.1 *Graded Standard Sand*—The sand used for making test specimens shall be natural silica sand conforming to the requirements for graded standard sand in Specification C 778.

6.2 *Reagent Sodium Hydroxide Solution* (20 %):

6.2.1 Prepare fresh daily using boiled distilled water and reagent grade sodium hydroxide (NaOH).

6.2.2 Dissolve 200 g of sodium hydroxide in 1 L of distilled water and cool to room temperature. **Warning—**All work with this highly caustic solution should be completed with the use of gloves, apron, and face mask.

NOTE 3—One litre will provide enough solution for eight three-cube batches. More or less solution in these proportions should be made depending on the number of batches to be mixed during the day.

7. Procedure

7.1 *Batch*—The quantities of materials to be mixed at one time in the batch of mortar for making three or six specimens shall be as follows:

	Number of Specimens	
	3	6
Slag, g	250	500
Sand, g	687.5	1375
NaOH solution, mL	112.5	225

7.2 *Preparation of Specimens*—Prepare specimens in accordance with Test Method C 109/C 109M, except that the mixing water shall be replaced by the volume of NaOH solution equal to the volume of water which would give a water/slag ratio of 0.45 by mass.

7.3 *Curing*—Immediately upon completion of molding place each three-cube mold in a container. Add approximately 50 mL of water into the container at the mold base in order to assure 100 % relative humidity during the curing cycle. In the case where plastic bags are employed, special care should be exercised to avoid tearing the plastic during handling. Place the container and molds in the curing chamber maintained at 55 ± 2°C. If water curing is used, rigid containers shall be required and the water temperature shall be controlled to the prescribed temperature and a minimum 5 mL of water shall cover the containers. At the end of 23 ± ¼ h remove the molds from the curing chamber and examine each container for leaks. If more than 15 mL of water has escaped or more than 5 mL of water has entered, discard the specimens and retest. Remove the specimens from the mold and store in room air until tested.

7.4 *Determination of Compressive Strength*—Test the specimens for compressive strength at 24 ± ½ h in accordance with Test Method C 109/C 109M.

8. Calculation

8.1 Calculate the compressive strength of the specimens in accordance with Test Method C 109/C 109M.

9. Faulty Specimens and Retests

9.1 Faulty specimens and the need for retest shall be determined in accordance with Test Method C 109/C 109M.

10. Report

10.1 The average strength in MPa rounded to the nearest 0.1 MPa at 24 h shall be reported as the hydraulic activity of the sample. For example, Hydraulic Activity with NaOH: 7.3 MPa.

11. Precision and Bias

11.1 *Precision*—The following precision statements were developed using data generated from an interlaboratory test program. Nine laboratories participated in the program and tested three slags with varied hydraulic activity. Duplicate tests were performed on different days. Revisions to the precision statements shall be made as more comprehensive data become available.

11.1.1 The precision statements are applicable when a test result is the average of compressive strengths of three cubes molded from a single batch of mortar and tested at the same age.

11.1.2 The multilaboratory coefficient of variation has been found to be 8.1 % (Note 4). Therefore, results of properly conducted tests of single batches by two different laboratories should not differ by more than 22.9 % of their average (Note 4).

11.1.3 The single-laboratory coefficient of variation has been found to be 4.6 % (Note 4). Therefore, results of two properly conducted tests of single batches of mortar made with the same materials either on the same day or within the same week should not differ from each other by more than 13.0 % of their average (Note 4).

NOTE 4—These numbers represent respectively the (Is) and (d2s) limits as described in Practice C 670.

11.2 *Bias*—The procedure in this test method has no bias since the hydraulic activity is defined only in terms of the test method.

12. Keywords

12.1 ground slag; hydraulic activity; slag

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1074 – 04

Standard Practice for Estimating Concrete Strength by the Maturity Method[1]

This standard is issued under the fixed designation C 1074; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice provides a procedure for estimating concrete strength by means of the maturity method. The maturity index is expressed either in terms of the temperature-time factor or in terms of the equivalent age at a specified temperature.

1.2 This practice requires establishing the strength-maturity relationship of the concrete mixture in the laboratory and recording the temperature history of the concrete for which strength is to be estimated.

1.3 The values stated in SI units are to be regarded as the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *datum temperature*—the temperature that is subtracted from the measured concrete temperature for calculating the temperature-time factor according to Eq 1.

3.1.2 *equivalent age*—the number of days or hours at a specified temperature required to produce a maturity equal to the maturity achieved by a curing period at temperatures different from the specified temperature.

3.1.3 *maturity*—the extent of the development of a property of a cementitious mixture.

3.1.3.1 *Discussion*—While the term is used usually to describe the extent of relative strength development, it can also be applied to the evolution of other properties that are dependent on the chemical reactions that occur in a cementitious mixture. At any age, maturity depends on the curing history.

3.1.4 *maturity function*—a mathematical expression that uses the measured temperature history of a cementitious mixture during the curing period to calculate an index that is indicative of the maturity at the end of that period. Refer to Appendix X1 for additional discussion of this term.

3.1.5 *maturity index*—an indicator of maturity that is calculated from the temperature history of the cementitious mixture by using a maturity function.

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.64 on Nondestructive and In-Place Testing.

Current edition approved June 1, 2004. Published July 2004. Originally approved in 1987. Last previous edition approved in 1998 as C 1074 – 98.

www.technobetar.ir

3.1.5.1 *Discussion*—The computed index is indicative of maturity provided there has been a sufficient supply of water for hydration or pozzolanic reaction of the cementitious materials during the time used in the calculation. Two widely used maturity indexes are the *temperature-time factor* and the *equivalent age*.

3.1.6 *maturity method*—a technique for estimating concrete strength that is based on the assumption that samples of a given concrete mixture attain equal strengths if they attain equal values of the maturity index **(1, 2, 3)**.[4]

3.1.7 *strength-maturity relationship*—an empirical relationship between compressive strength and maturity index that is obtained by testing specimens whose temperature history up to the time of test has been recorded.

3.1.8 *temperature-time factor*—the maturity index computed according to Eq 1.

4. Summary of Practice

4.1 A strength-maturity relationship is developed by laboratory tests on the concrete mixture to be used.

4.2 The temperature history of the field concrete, for which strength is to be estimated, is recorded from the time of concrete placement to the time when the strength estimation is desired.

4.3 The recorded temperature history is used to calculate the maturity index of the field concrete.

4.4 Using the calculated maturity index and the strength-maturity relationship, the strength of the field concrete is estimated.

5. Significance and Use

5.1 This practice can be used to estimate the in-place strength of concrete to allow the start of critical construction activities such as: (*1*) removal of formwork and reshoring; (*2*) post-tensioning of tendons; (*3*) termination of cold weather protection; and (*4*) opening of the roadways to traffic.

5.2 This practice can be used to estimate strength of laboratory specimens cured under non-standard temperature conditions.

5.3 The major limitations of the maturity method are: (*1*) the concrete must be maintained in a condition that permits cement hydration; (*2*) the method does not take into account the effects of early-age concrete temperature on the long-term strength; and (*3*) the method needs to be supplemented by other indications of the potential strength of the concrete mixture.

5.4 The accuracy of the estimated strength depends, in part, on determining the appropriate maturity function for the particular concrete mixture.

6. Maturity Functions

6.1 There are two alternative functions for computing the maturity index from the measured temperature history of the concrete.

6.2 One maturity function is used to compute the *temperature-time factor* as follows:

$$M(t) = \Sigma(T_a - T_o)\,\Delta t \quad (1)$$

where:

$M(t)$ = the temperature-time factor at age t, degree-days or degree-hours,
Δt = a time interval, days or hours,
T_a = average concrete temperature during time interval, Δt, °C, and
T_o = datum temperature, °C.

6.3 The other maturity function is used to compute *equivalent age* at a specified temperature as follows **(4)**:

$$t_e = \Sigma e^{-Q\left(\frac{1}{T_a} - \frac{1}{T_s}\right)}\,\Delta t \quad (2)$$

where:

t_e = equivalent age at a specified temperature T_s, days or h,
Q = activation energy divided by the gas constant, K,
T_a = average temperature of concrete during time interval Δt, K,
T_s = specified temperature, K, and
Δt = time interval, days or h.

NOTE 1—Temperature in kelvin (K) equals approximately temperature °C + 273 °C.

6.4 Approximate values of the datum temperature, T_o, and the activation energy divided by the gas constant, Q, are given in Appendix X1. Where maximum accuracy of strength estimation is desired, the appropriate values of T_o or Q for a specific concrete mixture are determined according to the procedures given in Annex A1.

7. Apparatus

7.1 A device is required to monitor and record the concrete temperature as a function of time. Acceptable devices include thermocouples or thermistors connected to strip-chart recorders, or digital data-loggers, or embedded digital devices that measure temperature and record and store the data. The recording time interval shall be ½ h or less for the first 48 h and 1 h or less thereafter. The temperature recording device shall be accurate to within ±1 °C.

7.2 Alternative devices include commercial maturity instruments that automatically compute and display either temperature-time factor or equivalent age.

NOTE 2—Commercial maturity instruments use specific values of datum temperature or activation energy in evaluating the maturity index; thus the displayed maturity index may not be indicative of the true value for the concrete mixture being used. Refer to Appendix X1 for information on correcting the displayed values.

8. Procedure to Develop Strength-Maturity Relationship

8.1 Prepare at least 15 cylindrical specimens according to Practice C 192/C 192M . The mixture proportions and constituents of the concrete shall be similar to those of the concrete whose strength will be estimated using this practice. If two batches are needed to prepare the required number of cylinders, cast an equal number of cylinders from each batch, and test one cylinder from each batch at the test ages given in 8.4.

8.2 Embed temperature sensors to within ±15 mm of the centers of at least two specimens. Immediately connect the

[4] The boldface numbers in parentheses refer to the list of references at the end of this practice.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

sensors to maturity instruments or to temperature-recording devices such as data-loggers or strip-chart recorders.

NOTE 3—A method to assist in the proper positioning of the sensor is to insert a small diameter rigid rod into the center of the freshly made cylinder. The rod will push aside any interfering aggregate particles. The rod is removed and the sensor is inserted into the cylinder. The side of the cylinder mold should be tapped with a rubber mallet or the tamping rod to ensure that the concrete comes into contact with the sensor.

8.3 Moist cure the specimens in a water bath or in a moist room meeting the requirements of Specification C 511.

8.4 Unless specified otherwise, perform compression tests at ages of 1, 3, 7, 14, and 28 days in accordance with Test Method C 39/C 39M. Test two specimens at each age and compute the average strength. If the range of compressive strength of the two specimens exceeds 10 % of their average strength, test another cylinder and compute the average of the three tests. If a low test result is due to an obviously defective specimen, discard the low test result.

NOTE 4—For concrete mixtures with rapid strength development, or when strength estimates are to be made at low values of maturity index, tests should begin as soon as practicable. Subsequent tests should be scheduled to result in approximately equal increments of strength gain between test ages. At least five test ages should be used.

8.5 At each test age, record the average maturity index for the instrumented specimens.

8.5.1 If maturity instruments are used, record the average of the displayed values.

8.5.2 If temperature recorders are used, evaluate the maturity index according to Eq 1 or Eq 2. Unless specified otherwise, use a time interval (Δt) of ½ h or less for the first 48 h of the temperature record. Longer time intervals are permitted for the relatively constant portion of the subsequent temperature record.

NOTE 5—Judgement should be used in selecting the initial time intervals to record temperature in mixtures that result in rapid changes in early-age temperature due to rapid hydration. Appendix X2 gives an example of how to evaluate the temperature-time factor or equivalent age from the recorded temperature history of the concrete.

8.6 Plot the average compressive strength as a function of the average value of the maturity index. Draw a best-fit curve through the data. The resulting curve is the strength-maturity relationship to be used for estimating the strength of the concrete mixture cured under other temperature conditions. Fig. 1 is an example of a relationship between compressive strength and temperature-time factor, and Fig. 2 is an example of a relationship between compressive strength and equivalent age at 20 °C.

NOTE 6—The strength-maturity relationship can also be established by using regression analysis to determine a best-fit equation to the data. Possible equations that have been found to be suitable for this purpose may be found in Ref. **(3)**. A popular equation is to express strength as a linear function of the logarithm of the maturity index (see Fig. 3).

8.7 When specified, a flexural strength versus maturity index relationship is permitted. Prepare at least 15 beam specimens in accordance with Practice C 192/C 192M. If two batches are needed to prepare the required number of specimens, cast an equal number of beams from each batch, and test one beam from each batch at the test ages given in 8.4. Embed

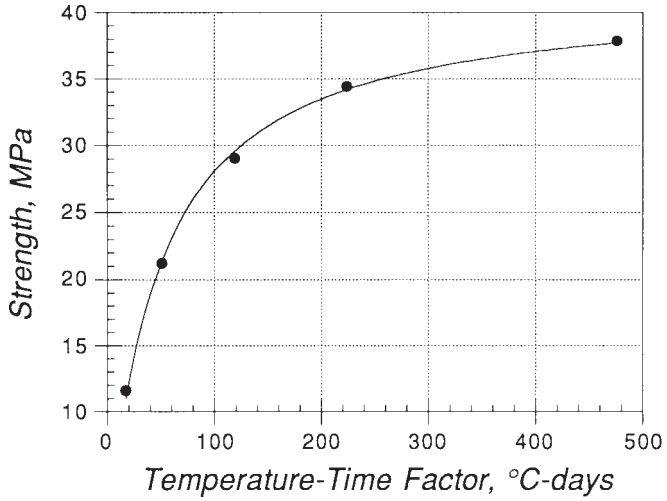

FIG. 1 Example of a Relationship Between Compressive Strength and Temperature-Time Factor

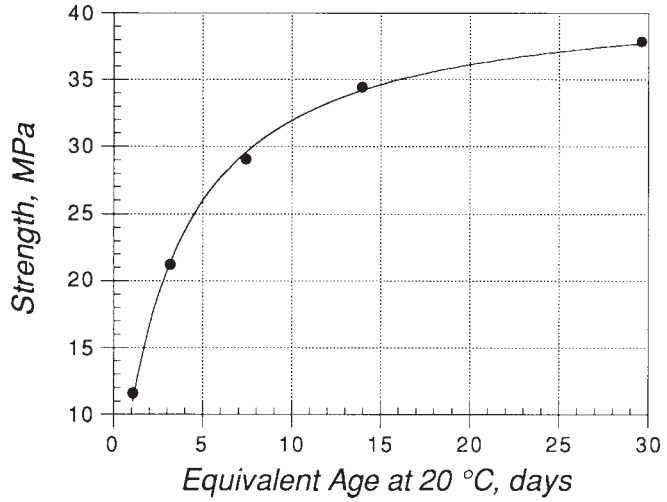

FIG. 2 Example of a Relationship Between Compressive Strength and Equivalent Age at 20 °C

temperature sensors in two specimens, one from each batch if two batches are made. Connect the sensors to maturity instruments or temperature recording devices, and moist cure the specimens in a water bath or in a moist room meeting the requirements of Specification C 511. Measure flexural strength in accordance with Test Method C 78 at time intervals of 1, 3, 7, 14 and 28 days, or as specified otherwise (See Note 4). Test two specimens at each age and compute the average strength. If the range of flexural strength of the two specimens exceeds 15 % of their average strength, test another beam and compute the average of the three tests. If a low test result is due to an obviously defective specimen, discard the low test result. Use the same procedures as in 8.5 and 8.6 to develop the flexural strength-maturity relationship.

9. Procedure to Estimate In-Place Strength

9.1 As soon as is practicable after concrete placement, embed temperature sensors into the fresh concrete. When using this practice to allow critical construction operations to begin,

www.technobetar.ir

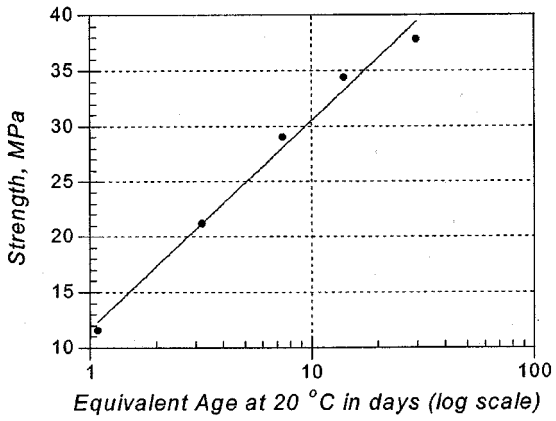

FIG. 3 Example of Compressive Strength as a Function of Logarithm of Equivalent Age

install sensors at locations in the structure that are critical in terms of exposure conditions and structural requirements.

NOTE 7—In building construction, exposed portions of slabs and slab-column connections are typically critical locations. The advice of the Engineer should be sought for critical locations in the particular structure under construction.

9.2 Connect the sensors to maturity instruments or temperature-recording devices and activate the recording devices as soon as is practicable. Use the same value of datum temperature or activation energy, whichever is applicable, as was used in computing the maturity index during development of the strength-maturity relationship (See Section 8).

9.3 When the strength at the location of a sensor is to be estimated, read the value of the maturity index from the maturity instrument or evaluate the maturity index from the temperature record.

9.4 Using the strength-maturity relationship developed in Section 8, read off the value of compressive (or flexural) strength corresponding to the measured maturity index.

9.5 Prior to performing critical operations, such as formwork removal or post-tensioning, supplement determination of the concrete maturity with other tests to ensure that the concrete in the structure has a potential strength that is similar to that of the concrete used to develop the strength-maturity relationship. Appropriate techniques include:

9.5.1 In-place tests that give indications of strength, such as Test Method C 803/C 803M, Test Method C 873, or Test Method C 900.

9.5.2 Early-age compressive strength tests in accordance with Test Method C 918 of standard-cured specimens molded from samples of the concrete as-delivered, or

9.5.3 Compressive strength tests on specimens molded from samples of the concrete as-delivered and subjected to accelerated curing in accordance with Test Method C 684.

9.5.4 Early-age tests of field-molded cylinders instrumented with maturity instruments. The measured strengths are compared with the strengths estimated from the established strength-maturity relationship. If the difference consistently exceeds 10 %, a new strength-maturity relationship is to be developed.

10. Precision and Bias

10.1 This practice is used to estimate the in-place strength of concrete based on the measured thermal history at a point in the structure and a previously established strength-maturity relationship. The accuracy of the estimated strength depends on several factors, such as the appropriateness of the maturity function for the specific mixture, the early-age temperature history, and the actual mixture proportions. For this reason, it is not possible to write statements about the precision and bias of the estimated strength.

11. Keywords

11.1 in-place strength; maturity method; nondestructive testing; temperature

ANNEX

(Mandatory Information)

A1. DETERMINATION OF DATUM TEMPERATURE OR ACTIVATION ENERGY

A1.1 Procedure

A1.1.1 The testing required to determine experimentally the datum temperature or the activation energy can be performed using mortar specimens, and the results are applicable to the concrete under investigation **(5, 6, 7)**. The basic approach is to establish the compressive strength versus age relationships for mortar specimens cured in water baths maintained at three different temperatures. Two baths are at the maximum and minimum concrete temperatures expected for the in-place concrete during the period when strengths are to be estimated. The third bath temperature is midway between the extremes. Depending on the data analysis procedure that is used, the final setting times of the mortar at the three temperatures may also have to be measured.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:19 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

A1.1.2 Proportion a mortar mixture having a fine aggregate-to-cement ratio (by mass) that is the same as the coarse aggregate-to-cement ratio of the concrete mixture under investigation **(6)**. The paste shall have the same water-cementitious materials ratio and the same amounts of admixtures that will be used in the concrete.

A1.1.3 If the strength data will be analyzed using the reciprocal plotting procedure in A1.1.7, final setting times must be measured. Prepare three mortar specimens using containers specified in Test Method C 403/C 403M. Carefully submerge each specimen into its corresponding temperature bath. Determine the time of final setting for each temperature in accordance with Test Method C 403/C 403M. The specimens are removed from the water baths and excess water is removed prior to making penetration measurements. If the data will be analyzed using the regression procedures in A1.1.8, it is not necessary to measure times of final setting.

A1.1.4 Prepare three sets of 50-mm mortar cubes, with 18 cubes per set. Mold the cubes in accordance with Test Method C 109/C 109M and carefully submerge each set into one of the temperature baths. For each set, remove the molds and return the specimens to their respective baths approximately 1 h before the first series of compression tests.

A1.1.5 For each set of cubes, determine the compressive strength of three cubes in accordance with Test Method C 109/C 109M at an age that is approximately twice the time of final setting. If final setting times were not measured, perform the first test when the compressive strength is approximately 4 MPa. Perform subsequent tests on three cubes from each set at ages that are approximately twice the age of the previous tests. For example, if the time of the first test was 12 h, successive compressive strength tests would be performed at 1, 2, 4, 8, 16, and 32 days.

A1.1.6 The strength versus age data obtained at the three curing temperatures are analyzed to determine the relationship between the rate constant for strength development (*k*-value) and the curing temperature. Different procedures can be used depending on the available computational tools. If the user has the capability to perform only linear regression analysis, use the procedure in A1.1.7 or A1.1.8.2. If the user has a computer program that can perform regression analyses with a general function, use the procedure in A1.1.8.1.

A1.1.7 To use this procedure, the final setting times at the three temperatures must be measured. Prepare a graph with the reciprocal of strength as the *y*-axis and the reciprocal of age as the *x*-axis. For each curing temperature, plot the reciprocal of the average cube strength along the *y*-axis and the reciprocal of the age beyond the time of final setting along the *x*-axis. An example of such a plot is shown in Fig. A1.1. Determine the slope and the intercept of the best-fitting straight line through the data for each curing temperature. For each straight-line, divide the value of the intercept by the value of the slope. These quotients are the *k*-values that are used to calculate the datum temperature or the activation energy.

A1.1.8 As an alternative to the procedure in A1.1.7, the *k*-values can be estimated by either of the following methods. In these cases, the final setting times do not have to be measured.

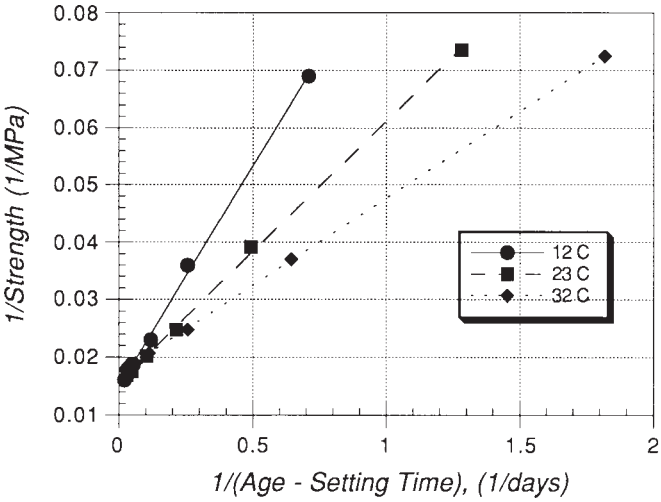

FIG. A1.1 Reciprocal of Strength Versus Reciprocal of Age Beyond Time of Final Setting

A1.1.8.1 If the user has access to a computer program that will permit the fitting of a general equation to a set of data, determine the *k*-values by fitting the following equation to the strength-age data for each curing temperature:

$$S = S_u \frac{k(t - t_o)}{1 + k(t - t_o)} \quad \text{(A1.1)}$$

where:

S = average cube compressive strength at age t,
t = test age,
S_u = limiting strength,
t_o = age when strength development is assumed to begin, and
k = the rate constant.

The computer program will calculate the best-fit values of S_u, t_o, and k.

A1.1.8.2 The *k*-values can also be estimated by the following method **(5, 8)**.

(1) Using the strength-age data for the last four test ages, plot the reciprocal of strength (*y*-axis) versus the reciprocal of age (*x*-axis). Determine the *y*-axis intercept. The inverse of the intercept is the limiting strength, S_u. Repeat this procedure for each curing temperature.

(2) For each curing temperature, use the strength-age data at the four earliest test ages and the value of S_u to compute the values of *A* for each strength, where *A* is given by the following equation:

$$A = \frac{S}{(S_u - S)} \quad \text{(A1.2)}$$

(3) For each curing temperature, plot the values of *A* versus age. Determine the slopes of the best-fit straight lines for each curing temperature. These slopes are the *k*-values.

A1.2 Determination of Datum Temperature

A1.2.1 Plot the *k*-values as a function of the water bath temperatures (Fig. A1.2). Determine the best-fitting straight line through the three points and determine the intercept of the line with the temperature axis. This intercept is the datum

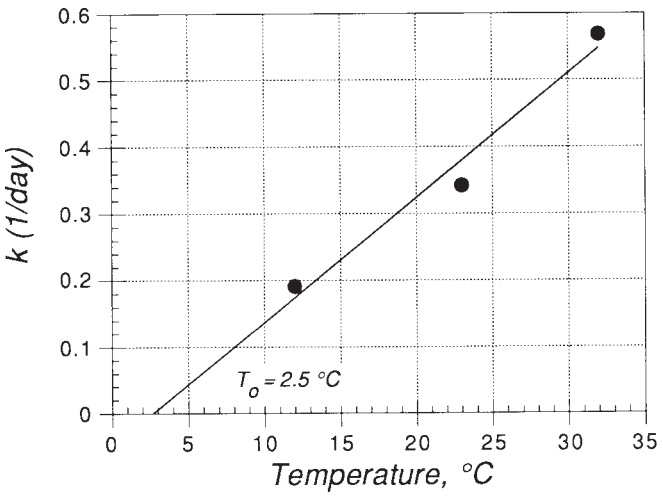

FIG. A1.2 Example of Plot of *k*-Values Versus Curing Temperature for Determining the Datum Temperature

temperature, T_o, that is to be used in computing the temperature-time factor according to Eq 1.

A1.3 Determination of Activation Energy

A1.3.1 Calculate the natural logarithms of the *k*-values, and determine the absolute temperatures (in kelvin) of the water baths (kelvin = Celsius + 273).

A1.3.2 Plot the natural logarithm of the *k*-values as a function of the reciprocal absolute temperature (Fig. A1.3). Determine the best-fitting straight line through the three points. The negative of the slope of the line is the value of the activation energy divided by the gas constant, *Q*, that is to be used in computing equivalent age according to Eq 2.

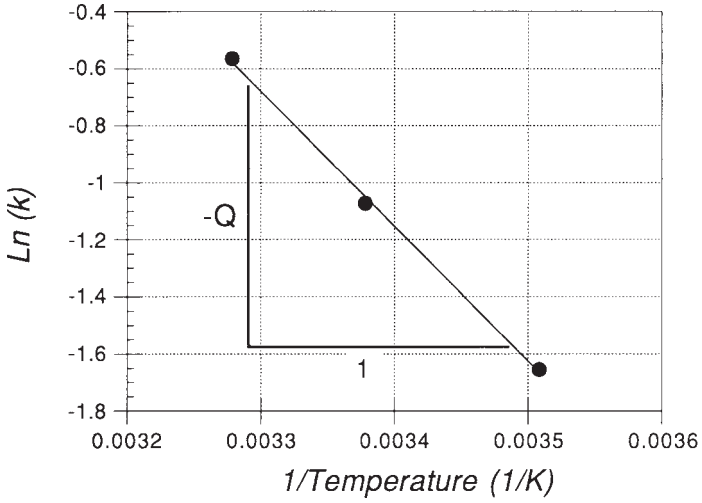

FIG. A1.3 Example of Plot of the Natural Logarithm of *K*-Values Versus the Inverse Absolute Temperature for Determining the Value of *Q* used in Calculating Equivalent Age

APPENDIXES

(Nonmandatory Information)

X1. MATURITY FUNCTIONS

X1.1 General

X1.1.1 A maturity function is a mathematical expression to account for the combined effects of time and temperature on the strength development of a cementitious mixture. The key feature of a maturity function is the representation of how temperature affects the rate of strength development. There are two widely-used approaches; one assumes that the rate of strength development is a linear function of temperature, and the other assumes that rate of strength development obeys the exponential Arrhenius equation **(3, 4, 5)**.

X1.2 Temperature-Time Factor

X1.2.1 The assumption that the rate of strength development is a linear function of temperature leads to the maturity function given in Eq 1, which is used to compute the temperature-time factor. To compute the temperature-time factor, it is necessary to know the appropriate value of the datum temperature for the specific materials and conditions. The datum temperature may depend on the type of cement, on the type and the dosage of admixtures or other additives that affect hydration rate, and on the temperature range that the

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

concrete will experience while hardening **(5, 7)**. For Type I cement without admixtures and a curing temperature range from 0 to 40 °C, the recommended datum temperature is 0 °C **(5)**. For other conditions and when maximum accuracy of strength estimation is desired, the appropriate datum temperature can be determined experimentally according to the procedures in Annex A1.

X1.2.2 Some types of maturity instruments that compute temperature-time factor may not employ the appropriate datum temperature, and therefore may not indicate the true value of the factor. The value of the temperature-time factor displayed by the instrument can be corrected for the datum temperature as follows:

$$M_c = M_d - (T_o - T_d)\, t \qquad \text{(X1.1)}$$

where:

M_c = the corrected temperature-time factor, degree-days or degree-hours,
M_d = the temperature-time factor displayed by the instrument, degree-days or degree-h,
T_o = the appropriate datum temperature for the concrete, °C,
T_d = the datum temperature incorporated into the instrument, °C, and
t = the elapsed time from when the instrument was turned on to when a reading was taken, days or h.

X1.3 Equivalent Age

X1.3.1 The assumption that the rate of strength development obeys the Arrhenius equation leads to the maturity function given in Eq 2, which is used to compute equivalent age at a specified temperature. Note that in using Eq 2, the temperature must be in kelvin (kelvin = Celsius + 273). To compute equivalent age it is necessary to know the activation energy for the specific materials and conditions. It has been shown that the activation energy depends on the type of cement, the type and the dosage of admixtures that affect the rate of strength development, and the water-cementitious materials ratio **(7)**. In general, for Type I cement without admixtures or additions, values of activation energy in the range of 40 000 to 45 000 J/mol have been reported **(6)**. Thus an approximate value of Q, the activation energy divided by the gas constant for use in Eq 2, is 5000 K. (The value of the gas constant is 8.31 J/(K·mol)). For other conditions and when maximum accuracy of strength estimation is desired, the appropriate value for Q can be determined experimentally according to the procedures in Annex A1.

X1.3.2 The calculation of equivalent age also requires a specified temperature, T_s. Traditionally, a value of 20 °C has been used **(4)**, but any other convenient temperature, such as 23 °C, is permissible provided that it is reported along with the value of the equivalent age.

X1.3.3 Maturity instruments that compute equivalent age according to Eq 2, are based on specific values of activation energy. The displayed readings cannot be corrected for the appropriate activation energy value of the concrete being used. The user should recognize this limitation when the in-place concrete has an activation energy that is widely different from that incorporated into the instrument. Refer to **(3)** for information on the effect of the activation energy on the computed value of equivalent age.

X2. EXAMPLE MATURITY CALCULATIONS

X2.1 Temperature Record

X2.1.1 Fig. X2.1 shows a hypothetical temperature history for concrete that will be used to illustrate the calculations of temperature-time factor and equivalent age. The temperature values at half-hour intervals are tabulated in column 2 of Table X2.1.

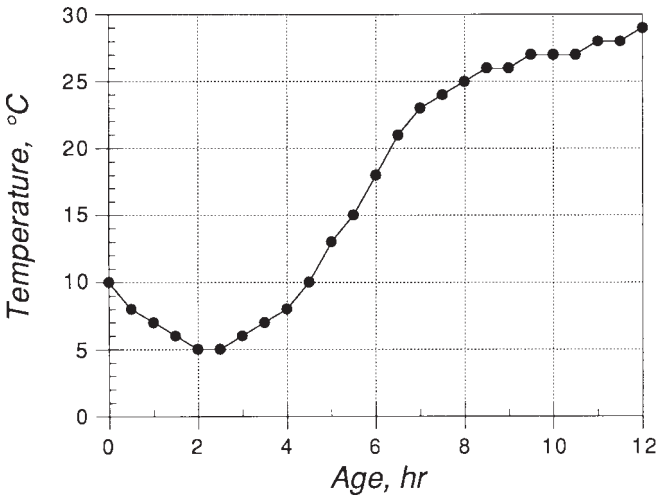

FIG. X2.1 Hypothetical Temperature History used to Illustrate Computations of Temperature-Time Factor and Equivalent Age

X2.2 Calculation of Temperature-time Factor

X2.2.1 The value of the datum temperature, T_o, is required to compute the temperature-time factor according to Eq 1. For this example, a value of 2.5 °C is assumed as indicated in Fig. A1.2.

X2.2.2 The average temperature during each half-hour interval is computed and the results are given in column 4 of Table X2.1. The datum temperature is subtracted from the average temperature, and the difference is multiplied by the age interval, which in this example is 0.5 h. The product gives the incremental value of the temperature-time factor for that age interval. The incremental values are shown in column 5 of Table X2.1.

7.0	23	0.5	22	9.8	55	1.11	0.56	4.3
7.5	24	0.5	23.5	10.5	66	1.21	0.60	4.9
8.0	25	0.5	24.5	11.0	77	1.27	0.64	5.5
8.5	26	0.5	25.5	11.5	88	1.34	0.67	6.2
9.0	26	0.5	26	11.8	100	1.38	0.69	6.9
9.5	27	0.5	26.5	12.0	112	1.42	0.71	7.6
10.0	27	0.5	27	12.3	124	1.45	0.73	8.3
10.5	27	0.5	27	12.3	137	1.45	0.73	9.0
11.0	28	0.5	27.5	12.5	149	1.49	0.75	9.8
11.5	28	0.5	28	12.8	162	1.53	0.77	10.5
12.0	29	0.5	28.5	13.0	175	1.57	0.79	11.3

X2.2.3 The summation of the incremental temperature-time factors gives the cumulative temperature-time factor at each age. For example, at an age of 12 h the temperature-time factor is 175 °C-h.

X2.3 Calculation of Equivalent Age

X2.3.1 The value of Q and the value of the specified temperature, T_s, are required to compute the equivalent age according to Eq 2. For this example, the value of Q is assumed to be 4700 K, and the specified temperature is assumed to be 20 °C (293 K).

X2.3.2 Using the average temperature, in kelvin, during each age interval, the values of the exponential function in Eq 2 are calculated. These values are given in column 7 of Table X2.1 under the heading Age Factor. The product of each of the age factors and the age interval (0.5 h) gives the incremental equivalent ages at 20 °C; the incremental equivalent ages are shown in column 8 of Table X2.1.

X2.3.3 The summation of the incremental equivalent ages gives the cumulative equivalent age at 20 °C (column 9 of Table X2.1). For example, at an age of 12 h the equivalent age at 20 °C is 11.3 h. Note that because the concrete temperature is less than 20 °C for the first six hours, the equivalent age at 6 h is only 3.2 h.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1074 – 98, that may impact the use of this practice. (Approved June 2004)

(*1*) Added a warning about chemical burns in 1.4
(*2*) Added new Note 1.
(*3*) Updated 7.1 to include other embedded devices for recording temperature data.
(*4*) Revised 8.1 to provide guidance on the use two batches to prepare test cylinders.
(*5*) Revised 8.4 and added new Note 4 to provide guidance on test ages for concrete mixtures with rapid strength development.
(*6*) Revised Note 5 to provide guidance on time intervals to record temperature in mixtures with rapid hydration.
(*7*) Revised Note 6 to refer to semi-log strength-maturity relationship and provided new Fig. 3.
(*8*) Added new section 8.7 to permit development of flexural strength versus maturity relationship.
(*9*) Revised 9.2 to clarify that same values of datum temperature or activation energy must be used in the field as during development of the strength-maturity relationship.
(*10*) Added 9.5.4 on the use of instrumented field cylinders to verify the strength-maturity relationship.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1077 – 09b

Standard Practice for Laboratories Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation[1]

This standard is issued under the fixed designation C 1077; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This practice identifies and defines the duties, responsibilities, and minimum technical requirements of testing laboratory personnel and the minimum technical requirements for laboratory equipment utilized in testing concrete and concrete aggregates for use in construction.

1.2 This practice provides criteria for the evaluation of the capability of a testing laboratory to perform designated ASTM test methods on concrete and concrete aggregates. It can be used by an evaluation authority in the inspection or accreditation of a laboratory or by other parties to determine if the laboratory is qualified to conduct the specified tests.

NOTE 1—Specification E 329 provides criteria for the evaluation of laboratories that perform the inspection of concrete during placement.

1.3 If the laboratory requires external technical services to conduct tests, the external agency shall be subject to separate evaluation.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

E 1301 Guide for Proficiency Testing by Interlaboratory Comparisons

2.2 *ACI Standards:*

ACI 214-77 Recommended Practice for Evaluation of Strength Test Results of Concrete[3]

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this practice, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *evaluation authority*, *n*—an independent entity, apart from the testing laboratory being evaluated, that has the capability to provide an unbiased evaluation of the professional and technical activities of concrete and concrete aggregates testing laboratories.

3.2.1.1 *Discussion*—Two acceptable methods of evaluation are inspection and accreditation, and these evaluations are offered by many evaluation authorities. An inspection is an evaluation of equipment and procedures based on the Test Methods and Procedures section, along with a review of the quality system. An inspection report is the final step in the process for an inspection agency. The testing laboratory being evaluated performs corrective actions for any deficiencies noted, and these corrections are to be placed with the other inspection documentation as part of the permanent record of the inspection. An accreditation agency uses the results of the inspection report or the results of their own onsite assessment as one phase of the accreditation process. As a separate phase, the accreditation agency also reviews the testing laboratory's corrective actions for the deficiencies noted and issues a certificate of accreditation once all of the deficiencies have been corrected. There is no universally accepted evaluation authority in the construction materials testing field; therefore, testing laboratories should give careful consideration when selecting an evaluation authority to gain the most benefit from the evaluation. In most cases, a testing laboratory will select an evaluation authority as a result of requirements in a project specification, or contract, or in response to local codes, or other industry requirements. In those circumstances, the requirements will stipulate the acceptable evaluation authorities. If there are no specific requirements and the evaluation is in anticipation of future work or to compete with other local testing laboratories, then the laboratory should contact the organization(s) most likely to use their services for a list of acceptable evaluation authorities. A list of evaluation authorities is provided in the Qualification of Personnel and Laboratory Evaluation section of the Manual of Aggregate and Concrete Testing.[4] The list is merely a collection of organizations willing to provide this service and is not an endorsement of any particular organization. Other organizations may also be available to provide this service.

3.2.2 *external technical services*, *n*—those services required by a testing laboratory that are provided by another organization.

3.2.3 *field technician*, *n*—an employee of the laboratory who is assigned to perform sampling and testing functions outside the laboratory.

3.2.4 *laboratory technician*, *n*—an employee of the laboratory who is assigned to perform the actual testing operations primarily conducted in the laboratory.

3.2.5 *quality systems*, *n*—those internal procedures and practices that a laboratory utilizes to ensure continued compliance with applicable testing standards for concrete and concrete aggregates.

3.2.6 *testing laboratory*, *n*—an organization that measures, examines, performs tests, or otherwise determines the characteristics or performance of materials or products. This may include organizations that offer commercial testing services, an in-house quality control function, an academic institution, or any other organization providing the required testing services.

4. Significance and Use

4.1 The testing and inspection of concrete and concrete aggregates are important elements in obtaining quality construction. A testing laboratory providing these services must be selected with care.

4.2 A testing laboratory shall be deemed qualified to perform and report the results of its tests if the laboratory meets the requirements of this practice. The testing laboratory services shall be provided under the technical direction of a registered professional engineer.

4.3 This practice establishes essential characteristics pertaining to the organization, personnel, facilities, and quality systems of the laboratory. This practice may be supplemented by more specific criteria and requirements for particular projects.

5. Organization

5.1 The following information shall be readily available for review:

5.1.1 Description of the organization, including:

5.1.1.1 Complete legal name and address of the main office and each laboratory location,

5.1.1.2 Names and positions of the principal officers and the responsible, registered professional engineer in charge, and

5.1.1.3 Description of the organization management structure.

5.1.2 Listing of the relevant technical services offered, and

5.1.3 All external technical services normally utilized.

5.2 The laboratory shall designate an individual with access to management who has the responsibility of seeing that procedures required in this document are being carried out.

6. Personnel Qualifications

6.1 Information shall be made available to substantiate personnel qualifications as follows:

6.1.1 All relevant testing services are provided under the full-time technical direction of a registered professional engineer with at least 5 years experience in construction materials testing.

[3] Available from American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333-9094, http://www.aci-int.org.

www.technobetar.ir

6.1.2 Supervising laboratory technicians shall possess a minimum of 3 years relevant experience and current technician certification. The technician certification program must include a written examination and performance examination of relevant tests. Relevant tests that must be covered by the certification program are: Practice C 31/C 31M, Test Methods C 39/C 39M, C 40, C 117, C 127, C 128, C 136, C 138/C 138M, C 143/C 143M, Practice C 172, Test Methods C 173/C 173M, C 231, and Test Method C 1064/C 1064M. In cases where the supervising laboratory technician is supervising technicians who only test concrete, the applicable relevant tests are the concrete tests listed in the group. Where the supervising laboratory technician is supervising technicians who only test aggregates, the applicable relevant tests are the aggregate tests listed in the group.

6.1.3 Supervising field technicians shall possess a minimum of 3 years relevant experience and current technician certification. The technician certification program must include a written examination and performance examination of relevant tests. Relevant tests that must be covered by the certification program are: Practice C 31/C 31M, Test Methods C 138/C 138M, C 143/C 143M, Practice C 172, Test Methods C 173/C 173M, C 231, and C 1064/C 1064M.

6.1.4 Concrete laboratory technicians shall possess current technician certification. The technician program must include a written examination and performance examination of relevant tests. Relevant tests that must be covered by the certification program are: Test Method C 39/C 39M and Practice C 617 or C 1231/C 1231M.

6.1.5 Aggregate laboratory technicians shall possess current technician certification. The technician certification program must include a written examination and performance examination of relevant tests. Relevant tests that must be covered by the certification program are: Test Methods C 40, C 117, C 127, C 128, and C 136.

6.1.6 Concrete field technicians shall possess current technician certification. The technician certification program must include a written examination and performance examination of relevant tests. Relevant tests that must be covered by the certification program are: Practice C 31/C 31M, Test Methods C 138/C 138M, C 143/C 143M, Practice C 172, Test Methods C 173/C 173M, C 231, and C 1064/C 1064M.

6.1.7 The technician certification program shall meet the following criteria:

6.1.7.1 The written examination shall be of sufficient length and detail to cover the entire test method,

6.1.7.2 The performance examination shall adequately cover procedures of the test method, and

6.1.7.3 The written and performance examinations shall include all relevant test methods that are listed in the section above for the type of technician being certified.

NOTE 2—A list of technician certification programs is provided in the Qualification of Personnel and Laboratory Evaluation section of the Manual of Aggregate and Concrete Testing.[4] The list is merely a collection of certification programs and is not an endorsement of any particular program. Other programs may also be available.

7. Test Methods and Procedures

7.1 The testing laboratory shall be capable of performing the required ASTM test methods, guides, or practices in 7.2 and may request additional evaluation for the optional methods in 7.3 to the extent that those services are provided by the laboratory.

7.2 *Required Test Methods and Practices*:

7.2.1 *For Laboratories Testing Concrete*:

7.2.1.1 *Sampling*, Practice C 172,

7.2.1.2 *Slump*, Test Method C 143/C 143M,

7.2.1.3 *Unit Weight, Yield, and Air Content*, Test Method C 138/C 138M,

7.2.1.4 *Air Content*, Test Method C 173/C 173M (volumetric method), or Test Method C 231 (pressure method), or both.

7.2.1.5 *Temperature*, Test Method C 1064/C 1064M,

7.2.1.6 *Making and Curing Test Specimens*, Practice C 31/C 31M,

7.2.1.7 *Compressive Strength*, Test Method C 39/C 39M,

7.2.2 *For Laboratories Testing Concrete Aggregates*:

7.2.2.1 *Sieve Analysis*, Test Method C 136,

7.2.2.2 *Material Finer Than 75-μm (No. 200) Sieve*, Test Method C 117,

7.2.2.3 *Specific Gravity and Absorption*, Test Method C 127 (Coarse Aggregate) and Test Method C 128 (Fine Aggregate), and

7.2.2.4 *Organic Impurities in Fine Aggregate*, Test Method C 40.

7.3 *Optional Test Methods or Practices*:

7.3.1 Some laboratories conduct other tests on concrete and concrete aggregates in addition to those listed in The *Required Test Methods and Practices* Section. These optional test methods and practices could include any of the test methods or practices developed by Committee C09 and contained in volume 04.02, as well as other related standards such as Practice D 75 and Test Method D 2419. The laboratory shall have evidence of proper facilities, equipment, and trained personnel to comply with the applicable test method or practice, if it is included in the scope of services as defined by the laboratory. The laboratory and the evaluation authority will mutually agree upon which optional test methods or practices will be included in the laboratory's evaluation. The evaluation authority shall then select which of the optional test methods or practices offered by the laboratory need to be demonstrated by the personnel.

7.4 The laboratory shall use the latest version of each referenced method within one year of its publication unless an earlier version of the standard is required by the client.

7.5 Laboratory personnel shall have convenient access to applicable standards.

8. Facilities, Equipment, and Supplemental Procedures

8.1 *General*—The laboratory shall have facilities and equipment conforming to the requirements of the applicable test method. This section contains equipment requirements and procedures that clarify certain provisions of the test methods.

8.2 *Procedures Related to Required Test Methods*—In addition to standard test method requirements, the conditions listed in 8.3 and 8.4 must be met.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:24 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.3 *For Laboratories Testing Concrete*:

8.3.1 *Compressive Strength Testing Machines*, shall conform to the applicable requirements of Test Method C 39/C 39M and have a capacity, loading range, and the appropriate heads for specimens to be tested. Testing machines shall be verified at least annually in accordance with Practices E 4 and a report giving details of the verification shall be readily available.

8.4 *For Laboratories Testing Concrete Aggregates*:

8.4.1 *Sieve Accuracy*—Verification of sieve accuracy shall be performed at least annually on each sieve used in the test for sieve analysis (Test Methods C 117 and C 136). Any one of the following three methods of verification is acceptable. Each method of sieve verification shall include an inspection of the sieve cloth for punctures or obvious defects.

8.4.1.1 Verification of each sieve used according to the procedures prescribed in the Annex of Specification E 11.

8.4.1.2 A comparison of the results of a split sample sieved on different sieve sets. Results shall be verified for single operator precision to be within the acceptable range of two results stated in the test method.

8.4.1.3 Participation in the sieve analysis test in an aggregate proficiency sample program, as described in the Quality Systems section. Results shall be verified for multilaboratory precision to be within the acceptable range of two results stated in the test method.

8.4.2 *Mechanical Sieve Shaker*—When mechanical sieving devices are used, the period of mechanical agitation shall be checked at least annually for adequacy of sieving as described in Test Method C 136. Mechanical agitation periods must be established for each different type of aggregate tested.

NOTE 3—Different types of aggregate refer to shape and composition, not supplier. For example, agitation periods for elongated materials may need to be extended, while softer materials that break down easily may require a shorter period to minimize alteration of the particle size distribution.

8.4.3 *Relative Density (Specific Gravity) and Absorption Tests*—When performing the procedures of Test Methods C 127 and C 128, duplicate tests shall be made at least once every 6 months. Results shall be verified for single operator precision within the tolerance stated in the respective test method. Participation in a proficiency sample program with relative density (specific gravity) and absorption testing is an acceptable alternative.

8.4.4 Balances or scales for all concrete and aggregate tests shall be calibrated annually.

8.5 *Procedures Related to Optional Test Methods*:

8.5.1 If the applicable test method requires equipment calibration and does not specify a frequency, then the laboratory shall establish a frequency in its quality assurance program and conform thereto.

8.5.2 In the event that the laboratory borrows or rents equipment to perform an optional test method, the laboratory must be able to document that it obtained the appropriate equipment and that the equipment was calibrated, standardized, or verified.

8.6 All equipment listed in this section shall be calibrated or verified before being placed in service. Equipment not in operating condition or out of tolerance shall be marked as such and taken out of service until corrected.

9. Laboratory Records and Reports

9.1 The laboratory shall maintain a system of records that permits verification of any issued report.

9.2 The records of the laboratory shall contain the following information:

9.2.1 Standard operating procedures for the following:

9.2.1.1 Identification of the test sample,

9.2.1.2 Transfer of the sample from the field to the laboratory, and

9.2.1.3 Recording of test results.

9.2.2 Calibrations or verifications of equipment required by the test method for all of the tests offered in the scope of the laboratory's services. The records shall include:

9.2.2.1 The identification of the specific piece of equipment,

9.2.2.2 The identification of the equipment used to perform the calibration or verification,

9.2.2.3 The name of the individual who performed the calibration or verification,

9.2.2.4 The date the calibration or verification was performed,

9.2.2.5 The quantity measured by the equipment (such as length, force, or mass), and

9.2.2.6 The associated accuracy of the measurement or a comparison of the measured quantity with the associated allowable tolerances, as necessary to verify that the equipment complies with the requirements in the relevant standards. Where additional calibration or verification requirements have been listed in the *Facilities, Equipment, and Supplemental Procedures* Section, this information shall also be included in the records.

9.2.3 Records on laboratory personnel that document work experience, education, on-the-job training, and methods used to ensure continued competence in performing the required test methods,

9.2.4 Audits and inspections by outside agencies and all reports or certifications, with applicable dates, of any evaluation or accreditations issued by any evaluating authorities,

9.2.5 The laboratory shall retain results of participation in proficiency sample programs, including data sheets, summary reports and, if low proficiency sample ratings are received, a record of the laboratory's investigation into the reason for the low ratings and corrective action taken.

9.2.6 Current standard test methods and other pertinent reference material in a library,

9.2.7 Identification of the person performing the field tests, and

9.2.8 Documents that establish the traceability to an acceptable reference standard or a national standard for load cells, proving rings, thermometers, test weights, and test equipment used for verification or calibration of laboratory equipment.

9.3 Laboratory test reports shall accurately and clearly present the specified test results and all pertinent data.

9.4 Test reports shall include the following information:

9.4.1 Name and address of the laboratory,

9.4.2 Identification of the report and the date issued,

9.4.3 Name of the client,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:24 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.4.4 Project identification,

9.4.5 Sample identification,

9.4.6 Identification of the standard test method used, a notation of all known deviations from the test method, and all requirements of the test method that were not performed by the laboratory (Note 5),

9.4.7 Test results and other pertinent data required by the standard,

9.4.8 Name of the registered professional engineer or his designee, and

9.4.9 Identification of results obtained from tests performed by other laboratories.

9.5 Corrections or additions to reports shall clearly reference the report being amended.

9.6 All records required by this standard shall be stored safely for at least 3 years, unless otherwise required by law or governing specifications. Those records that are confidential in nature, including test reports and other records generated as required by contract with the client, shall be stored safely in confidence to the client, unless otherwise required by law, governing specification, or client requirements.

NOTE 4—There are circumstances when a longer retention period may be advantageous to the laboratory. Records concerning the calibration, verification, and standardization of equipment are an example. Records of this type are often held throughout the useful life of the equipment.

NOTE 5—Deviation from standard test methods may adversely affect results.

10. Quality Systems

10.1 The laboratory shall maintain a quality manual of written procedures for ensuring the quality of the services offered (Note 8). In addition to the following information, each page in the manual shall contain a preparation or revision date to ensure the latest procedure is being followed.

10.1.1 Internal quality assurance program, including:

10.1.1.1 Personnel evaluation including the method of evaluation, the frequency of the review, the criteria used, and the title or name of the individual responsible for administering the evaluations; and technician training including a description of the levels of training, the testing used to determine when a level has been reached and the title or name of the individual responsible for administering the training,

10.1.1.2 Equipment calibration and maintenance,

10.1.1.3 A current library including all relevant test methods, and

10.1.1.4 Inventory of all test equipment requiring both an initial and a subsequent periodic calibration or verification that is used by the laboratory to perform the test methods covered by this standard and within the laboratory's scope of services. The inventory shall include the equipment description, identification number, and next date of calibration or verification.

NOTE 6—The inventory should include equipment such as scales, compression machines, and slump cones. Equipment such as tamping rods and expendable supplies such as single-use cylinder molds need not be included on the inventory.

10.1.1.5 Participation in proficiency sample programs (PSP). The laboratory shall participate in concrete or aggregate proficiency sample programs or both if the laboratory performs testing in both areas. The PSP used must meet the following criteria: (1) include a minimum of 10 participants, (2) issue a report that includes the laboratory's results, the average of all results, the standard deviation of the results, and rating(s) based on the number of standard deviations that the laboratory's results vary from the grand average for the test method(s) covered, (3a) include at least one of the following methods if the laboratory tests concrete: C 39/C 39M, C 138/C 138M, C 143/C 143M, C 173/C 173M, or C 231; and, (3b) include at least one of the following methods if the laboratory tests concrete aggregates: C 136, C 127, or C 128, (4) be independent of the participating laboratories, (5) distribute samples at least once annually, and (6) maintain a record of all sample test results from participants for at least 3 years.

NOTE 7—For additional guidance in selecting a proficiency sample program the laboratory may wish to consult Guide E 1301.

10.1.2 The laboratory shall establish procedures for responding to low proficiency sample program ratings. Ratings are considered to be low if the laboratory's result is beyond two standard deviations from the grand average on the final report.

10.1.3 The laboratory shall establish procedures for handling technical complaints from clients that includes the title or name of the individual responsible for handling the complaint, the review system in the laboratory and the type of reply to be issued.

10.1.4 The laboratory shall establish procedures for ensuring the quality of external technical services, such as: calibration services used by the laboratory, equipment and materials procured by the laboratory from vendors, and subcontractors (that is, a laboratory contracted to perform a standard test method or part of a test method). The laboratory should be able to demonstrate that the subcontractor is competent and is in compliance with the requirements of the test methods. The laboratory should maintain records of the subcontractor and vendor evaluations. The selection and evaluation criteria for the subcontractor should include a review of external audits, inspections, certifications, and laboratory accreditations held by the laboratory.

NOTE 8—Other recommended quality programs for a laboratory include: (*1*) Conducting within-laboratory statistical computations on concrete tests. Randomly selecting 10 tests per month and determining the within-test standard deviation (see ACI 214-77 and Practice C 802 for statistical methods); (*2*) Participation in an interlaboratory proficiency program on concrete tests. A quarterly exchange of samples between laboratories in accordance with Practice C 802 will provide excellent quality assurance data.

11. Laboratory Evaluation

11.1 The testing laboratory shall have its facilities, equipment, personnel, and procedures evaluated at intervals of approximately 24 months by an evaluation authority to confirm its ability to perform the required tests. The personnel and equipment used by the laboratory during the evaluation shall be representative of the personnel and equipment available during the period between evaluations. Temporary acquisition of personnel or equipment to enhance the results of the evaluation shall not be permitted.

11.2 Deficiencies noted in the final report provided to the laboratory by the evaluation authority shall be corrected within 30 days of receipt of the report.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:24 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11.3 The laboratory shall (*1*) report deficiency corrections to the accrediting body who will issue a certificate of accreditation when their requirements are satisfied, or (*2*) if an inspection service is used, supplement copies of the final report with a statement of corrective actions taken signed by the laboratory's professional engineer.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1077 – 09a, that may impact the use of this practice. (Approved August 1, 2009)

(*1*) Removed the certification agency names in 6.1.2-6.1.6. Revised 6.1.7. Added new Note 2.

(*2*) Replaced "performance evaluation" with "performance examination" in Section 6.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1077 – 09, that may impact the use of this practice. (Approved July 1, 2009)

(*1*) Revised 9.2.1 and 9.2.2. Deleted old 9.2.3 and 9.2.4 and renumbered subsequent paragraphs.

(*2*) Revised 9.6 to clarify requirements for the retention of records. Added new Note 4 and renumbered subsequent notes.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1077 – 08a, that may impact the use of this practice. (Approved June 1, 2009)

(*1*) Revised the title of Section 6 from "Human Resources" to "Personnel Qualifications."

(*2*) Revised Section 3 and deleted 3.1.7.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1077 – 08, that may impact the use of this practice. (Approved December 1, 2008)

(*1*) Revised 4.1.

(*2*) Revised 11.1.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1077 – 07a, that may impact the use of this practice. (Approved November 1, 2008)

(*1*) Revised 3.1.1.1.

(*2*) Revised 10.1.1.5.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1084 – 02

Standard Test Method for Portland-Cement Content of Hardened Hydraulic-Cement Concrete[1]

This standard is issued under the fixed designation C 1084; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of portland-cement content of a sample of hardened hydraulic-cement concrete.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Disposal of some or all of the chemicals used in this method may require adherence to EPA or other regulatory guidelines.

2. Referenced Documents

2.1 *ASTM Standards:*

C 42 Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete[2]

C 114 Test Methods for Chemical Analysis of Hydraulic Cement[3]

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials[3]

C 702 Practice for Reducing Samples of Aggrgate to Testing Size[2]

C 823 Practice for Examination and Sampling of Hardened Concrete in Constructions[2]

C 856 Practice for Petrographic Examinations for Hardened Concrete[2]

D 1193 Specification for Reagent Water[4]

E 11 Specification for Wire-Cloth and Sieves for Testing Purposes[2]

E 832 Specification for Laboratory Filter Papers[5]

3. Significance and Use

3.1 This test method consists of two independent procedures: an oxide-analysis procedure that consists of two subprocedures and an extraction procedure. Each procedure requires a substantial degree of chemical skill and relatively elaborate chemical instrumentation. Except for the influence of known interferences, determined cement contents are normally equal to, or slightly greater than, actual values except for the Maleic Acid procedure where results can also be significantly low when the paste is carbonated (Note 1).

NOTE 1—With certain limitations, the procedure is also applicable for estimating the combined content of portland cement and pozzolan or slag in concretes made with blended hydraulic cement and blends of portland cement with pozzolans or slags. The results of this test method when applied to concretes made with blended cements or pozzolans depend on the composition of the pozzolan, the age of the concrete, the extent of reaction of the pozzolan and the fact that this test method may determine only the portland-cement component of a blended cement. The test method should be applied to determination of the blended cement content or the pozzolanic content only by use of calibration concrete samples or other information. Earlier versions of this test method can provide useful information as detailed by Hime[6] and Minnick.[7]

4. Interferences

4.1 Many constituents of concrete may interfere with the analysis of the concrete for portland-cement content. The following limited lists of materials have been provided as a guide. The rocks, minerals or mineral admixtures listed will interfere with the cement content determination to the extent of their solubility during the dissolution procedure used. The solubility of rocks, minerals or mineral admixtures may depend on the fineness of the test sample, the water-cement ratio of the concrete, the extent of hydration, and the age of the concrete (extended exposure to the high pH of the concrete may affect the solubility of some minerals).

[1] This method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.69 on Miscellaneous Tests.

Current edition approved Jan. 10, 2002. Published March 1997. Originally published as C 1084 – 87. Last previous edition C 1084 – 97.

www.technobetar.ir

4.2 *Substances Affecting Calcium Oxide Sub-procedure*:

4.2.1 The following are soluble in even the cold dilute hydrochloric acid of this procedure and will contribute a high bias to the cement content calculated from the soluble calcium oxide: limestone, marble, dolomitic limestone, calcareous sandstone, calcareous chert, and caliche encrusted and calcite or dolomite coated rocks.

4.2.2 The following may be soluble depending on the age and pH of the concrete; whether the mineral present is glassy or crystalline, or weathered or strained; and the fineness of the mineral present, and, if soluble, will bias the cement content calculated from the soluble calcium oxide high depending on the calcium content of the minerals: weathered or altered plagioclase feldspar, caliche-encrusted rocks, altered volcanic rocks (with calcareous inclusions), and many other calcium containing rocks.

4.2.3 Every percent of soluble calcium oxide that is contributed by soluble aggregate or mineral admixtures will bias the cement content high by approximately 1.6 %.

4.2.4 Silica fume may lower the acid solubility of the sample and hence bias the result low.

4.3 *Substances affecting the Soluble Silica Sub-procedure*:

4.3.1 The following may be soluble depending on the age and pH of the concrete; whether the aggregate is glassy or crystalline, or weathered or strained; and the fineness of the mineral: chert, opal, chalcedony, glassy volcanic rock, strained quartz (highly strained), quartzite, cataclastic rocks (mylonite, phyllonite), gneiss, schist, metagraywacke, and many other soluble silicon containing rocks or minerals.

4.3.2 Every percent of soluble SiO_2 contributed by aggregates or mineral admixtures will bias the reported cement content high by approximately 4.7 %.

4.3.3 Silica fume may lower the acid solubility of the sample and hence bias the result low. If the digestion time or temperature are sufficient to digest all of the portland cement, the silica fume will also be solubilized and bias the calculated cement content high.

4.4 *Substances affecting the Maleic Acid Procedure*:

4.4.1 The same substances that are soluble in the soluble calcium or the soluble silica subprocedures may be soluble in the maleic acid procedure. (See 4.2.1, 4.2.2 and 4.3.1.)

4.4.2 Every 1 % of the sample that is aggregate or mineral admixture dissolved by the maleic acid will bias the cement content high by 1 %.

4.4.3 Carbonated cement paste may not be soluble in the maleic acid-methanol dissolution and thus may bias the cement content results low.

4.4.4 The unhydrated iron and aluminum phases of the portland cement may not be soluble in the maleic acid and, if not soluble, will bias the cement content low. This may be significant at early ages and less significant at later ages.

5. Apparatus

5.1 Choose the apparatus from applicable items given in Test Methods C 114 and from the following:

5.1.1 Chipmunk (jaw ore crusher).

5.1.2 Disk Pulverizer.

5.1.3 Rotary Mill (rotating puck).

5.1.4 Sieve, 300 um (No. 50), 1.18-mm (No. 16) and 4.75-mm (No. 4).

5.1.5 Ice Bath or electric cooling apparatus.

5.1.6 Steam Bath.

5.1.7 Funnel, Buchner-type porcelain funnel.

5.1.8 Filter Paper, Type II, Class F and Class G as described in Specification E 832.

5.1.9 Beakers, 1000 and 250 mL.

5.1.10 Magnetic stirrer, variable speed, with a TFE-fluorocarbon-coated magnetic stirring rod, or an overhead stirrer with a propeller.

5.1.11 Volumetric flask, 1000 mL and 500 mL.

5.1.12 Filtering flask, 2000 mL.

5.1.13 Vacuum pump.

5.1.14 Watch glass, 125 mm.

6. Reagents and Materials

6.1 *Soluble Silica Sub-procedure*:

6.1.1 *Hydrochloric Acid*, reagent grade, density 1.19 Mg/m^3.

6.1.2 *Hydrochloric Acid (1:3)*—Mix 300 mL of hydrochloric acid into 900 mL of water.

6.1.3 *Hydrochloric Acid (1:9)*—Mix 100 mL of hydrochloric acid into 900 mL of water.

6.1.4 *Sodium Hydroxide (10 g/L)*—Dissolve 5 g of reagent grade sodium hydroxide in 200 mL of water and dilute to 500 mL.

6.1.5 *Hydrofluoric Acid*, 48 %, reagent grade.

6.1.6 *Sulfuric Acid*, density 1.84 Mg/m^3, reagent grade.

6.2 *Calcium Oxide Sub-procedure*—Use reagents as required in Test Methods C 114.

6.3 *Maleic Acid Procedure*:

6.3.1 *Maleic acid*, technical grade.

6.3.2 *Methanol*, technical grade, anhydrous.

6.3.3 *Maleic acid solution*—prepare a fresh solution of 15 % maleic acid in methanol by dissolving and diluting 180 + 1 g of maleic acid with methanol to a final solution volume of 1200 millilitres. Prepare this solution fresh daily. Care must be taken to use methanol only in well ventilated areas, preferably under a hood, to avoid skin contact and breathing vapors. Disposal of the maleic acid/methanol solution shall be according to applicable regulations.

6.3.4 *Fuller's earth*—a clay-like material consisting of a porous colloidal aluminum silicate. Its high adsorptivity has been found very beneficial for decolorizing and purifying materials.

6.4 *Water*—All references to water shall be understood to mean reagent water Types I through IV of Specification D 1193.

7. Sampling

7.1 Choose the concrete sample in accordance with the purposes of the investigation (Note 2).

NOTE 2—A standard procedure for sampling hardened concrete is given in Practice C 823 and a standard procedure for obtaining cores is given in Test Method C 42.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.2 Both the sample for cement content and for density shall have a minimum length and diameter of four times the nominal maximum size of the aggregate (Note 3).

NOTE 3—A single concrete core taken through the entire depth of the concrete is ordinarily an appropriate sample. This sample may be sawed or split lengthwise to provide samples for cement content, density, and petrographic examination, provided that the length and thickn ess of the split samples for cement content and density meet the minimum size specified in 7.2. If the split sample would not meet the minimum size requirement, perform the density measurement first, and then crush the entire dry sample for cement content determination. The recommended mass of concrete for cement content determination is 4.5 kg (10 lb). This mass should be obtained from more than one core when the concrete depth is small and one core will not supply a mass of 4.5 kg (10 lb). If the concrete sample did not have a mass of 4.5 kg (10 lb) it should be so stated in the final report for the cement content result.

7.3 For cement content determination, crush the sample to pass a 4.75-mm (No. 4) sieve, mix thoroughly, and obtain a representative subsample for analysis by coning and quartering or by riffle splitting as described in Practice C 702. The subsample should have a mass of 0.45 kg (1 lb).

8. Cement Content Procedure

8.1 *Oxide Analysis Procedure*:

8.1.1 Crush or grind the subsample prepared as described in 7.3 using a chipmunk (jaw ore crusher), a disk pulverizer, or a rotary mill (rotating-puck) device, so that all of the material passes a 300-μm (No. 50) sieve. To minimize production of very fine material, use several passes of the sample through the equipment, removing the portion passing the sieve before regrinding the remainder of the sample. Thoroughly mix by coning ten times from one paper to another.

8.1.2 Dry the crushed or ground material in an oven at 105 to 115°C (220 to 240°F) for 3 h and retain the sample in a sealed container.

8.1.3 *Sub-procedure to be used*:

8.1.3.1 The soluble silica sub-procedure shall be performed in all cases except where a petrographic examination has indicated there are siliceous aggregates or mineral admixtures that will be soluble in cold hydrochloric acid.

8.1.3.2 The calcium oxide sub-procedure shall also be employed unless the aggregate contains a significant amount of calcareous components.

8.1.3.3 All analyses shall be done in triplicate and the average of the three values used in calculating cement content.

8.1.4 *Soluble Silica Sub-procedure*:

8.1.4.1 Introduce 100 mL of dilute hydrochloric acid (1:3) into each of three 250-mL beakers. Cool until within the range of 3 to 5°C (38 to 41°F), using an ice bath or electric cooling apparatus.

8.1.4.2 Weigh a 2 g sample to 0.001 g and slowly, over a 1-min period, add it to the cold hydrochloric acid. Maintain the 3 to 5°C (38 to 41°F) temperature for a 5-min period, and stir the mixture either continuously or at least several times during this period (Note 4).

NOTE 4—Observation of the solution during the introduction of the sample may provide useful information. Considerable effervescence indicates a substantial amount of calcite or carbonated paste. Delayed effervescence suggests a dolomitic aggregate. Lack of effervescence suggests the applicability of the calcium oxide sub-procedure.

8.1.4.3 Decant through a Buchner-type porcelain funnel fitted snugly with two disks of a quantitative filter paper for fine precipitates, Type II, Class G filter paper. Once the filtration has begun, take care so that the mat and accumulated residue do not dry completely until the filtration process is complete. Regulate the suction so as to maintain a rapid rate of dripping during the greater part of the filtration. Retain as much of the residue in the beaker as possible. Wash twice by decantation with hot water. Save the filtrate. Transfer the filter paper from the funnel to the beaker containing the balance of the residue, being careful that no residue is lost. Add 75 mL of hot sodium hydroxide solution (10 g/L) to the residue while stirring, macerate the filter paper, and digest, covered, on a steam bath for 15 min. During the digestion, occasionally stir the mixture. Filter all solids, and wash twice with hot water until the filtrate is neutral to litmus. Combine the filtrates.

8.1.4.4 The filtrate now contains the silica in the form of silicic acid, either in true solution or in suspension in the hydrochloric acid medium. To ensure analysis of only the soluble silicon, refilter any filtrate that is cloudy. (Allowing the filtrate to stand overnight will usually permit suspended silica to settle.) The soluble silica may be analyzed by either of the following procedures 8.1.4.4.1 or 8.1.4.4.2.

8.1.4.4.1 *Analysis of soluble silica by conversion to silicon tetrafluoride with hydrofluoric acid*—In the case where the aggregate of the original sample contains substantial amounts of material that yields calcium oxide (CaO) on acid treatment, add 10 mL of hydrochloric acid (density 1.19 Mg/m^3) to the solution from 8.1.4.4. Transfer to a suitable beaker, with several rinsings of the filter flask. Evaporate to dryness with great care to minimize spattering, bake at not over 120°C (248°F) for 1 h, moisten with hydrochloric acid (density 1.19 Mg/m^3), evaporate and bake again, and take up for filtration in 75 mL of hydrochloric acid (1:3). Heat to boiling, filter through an ashless filter paper, and wash the residue with 50 mL of hot hydrochloric acid (1:9) and then with hot water until the washings are free of chlorides. Determine the silica present in the sample by treatment with hydrofluoric acid and sulfuric acid in accordance with the procedure given in Test Methods C 114.

8.1.4.4.2 *Instrumental analysis of soluble silica*—Transfer the filtrate from 8.1.4.4 to a 500-mL volumetric flask with several rinsings of the filtration flask and bring the volume in the volumetric flask to 500 mL with water. Analyze the soluble silica by any instrumental method found acceptable for cement analysis in accordance with the performance requirement for rapid methods of Test Methods C 114, provided it can be applied to the filtrate. Suitable instrumental techniques may include atomic absorption or inductively coupled plasma spectroscopy.

8.1.4.5 *Calculation*—Calculate the cement percentage, C_s, by dividing the percent silica (SiO_2) in the concrete by the percent silica (SiO_2) in the cement, and multiplying by 100. If the cement silica value is unknown, assume 21.0 %.

8.1.5 *Calcium Oxide Sub-procedure*—Calcium oxide may be determined by either of the following procedures. Omit the determination if it is known that the aggregate contains substantial amounts of calcareous components.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:26 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.1.5.1 *Oxalate precipitation of calcium*— Using the filtrate from the removal of silica (8.1.4.4), separate the ammonium hydroxide group and then determine the calcium oxide, both in accordance with Test Methods C 114, or proceed as described in 8.1.5.2.

8.1.5.2 *Instrumental analysis of calcium oxide*—Any calcium method found acceptable for cement analysis in accordance with the performance requirements for rapid methods of Test Methods C 114 may be used, provided that the method may be applied to the filtrate of . Further, the method must be acceptable for cement analysis in the same silica-present or silica-absent condition as is the case for the state of analysis of the concrete.

8.1.5.3 *Calculation*—Calculate the cement percentage, C_c, by dividing the percentage calcium oxide in the concrete by the percentage calcium oxide in the cement, and multiplying by 100. If the cement calcium oxide value is unknown, assume 63.5 %.

8.2 *Maleic Acid Extraction Procedure*:

8.2.1 Crush or grind and dry the sample as described in 8.1.1 and 8.1.2 except that the material shall pass a 1.18-mm (No. 16) sieve meeting Specification E 11.

8.2.2 *Combined water*—Measure 10 g of the dried crushed sample to the nearest 0.001 g into a tared pre-heated crucible, and dry at 520 ± 5°C for 3 h or to constant mass (Note 5). Cool in a desiccator and determine the mass.

NOTE 5—The temperature of 540°C should not be exceeded to avoid the decomposition of calcitic or dolomitic carbonates in certain aggregates.

8.2.2.1 Calculate the percentage of combined water as follows:

$$L_c\,\% = \frac{(C - D) \times 100}{C} \quad (1)$$

where:

L_c = percent combined water, dry basis,
C = mass of dried sample, g, and
D = mass after heating at 520°C, g.

8.2.3 *Extraction*—Determine the mass of a 20-g sample of the ground dried concrete and a 2.5-g sample of Fuller's earth, dried at 105 to 115°C (220 to 240°F), to 0.001 g, and transfer both to a 1000-mL beaker or flask. Add 800-mL of maleic acid solution, and stir with a magnetic stirrer (or overhead stirrer equipped with a propeller) for 60 min. Allow the mixture to settle for 60 min. Filter the solution by carefully decanting through a Whatman 41 filter paper or equivalent of known mass fitted into a 100-mm Buchner funnel, using suction, and collect the filtrate in a 2000-mL vacuum filtering flask. Allow the residue to remain in the beaker.

8.2.3.1 Add 400-mL of maleic acid solution to the residue in the beaker, and stir for 10 min. Allow the mixture to settle for 30 min, and filter the entire contents of the beaker through the original filter paper. Rinse the beaker thoroughly with methanol to insure complete transfer. Wash the residue contained on the filter paper 4 to 5 times with approximately 50 mL portions of methanol to remove any residual maleic acid. Also wash any iron fillings that may be attached to the magnetic stir bar into the Buchner funnel. The filtrate should be clear.

8.2.3.2 Transfer the filter paper and residue onto a 125-mm watch glass, and place in an oven at 105°C (220°F). Dry to a constant mass, and determine the mass of the residue and filter paper to the nearest 0.001 g.

8.2.4 *Calculation*—Calculate the percentage of insoluble residue as follows:

$$R,\,\% = \frac{(F - G) \times 100}{E} \quad (2)$$

where:

R = percent insoluble residue,
E = mass of sample used, g,
F = combined mass of residue, filter paper, and Fuller's earth, g, and
G = combined mass of filter paper and Fuller's Earth, g.

8.2.5 *Calculation*—Calculate the percent cement content, C_m by subtracting R and L_c from 100.

9. Unit Weight and Loss of Free Water

9.1 Determine the density of a separate sample of the concrete, of a minimum dimension four times the maximum size of the aggregate and a sample mass of at least 0.45 kg (1 lb), as follows:

9.1.1 *Saturated surface dry density*— For saturated surface dry density, which will usually correlate well with the density of the concrete as placed. Immerse the concrete in water and soak it for a minimum of 24 h or to constant weight. (Constant weight may take 48 h for ½ of a 100-mm (4-in.) diameter core.) Determine the mass of the sample while immersed in the water to the nearest 0.1 g (0.001 lb). Remove from the water, surface dry, and determine the mass to the nearest 0.1 g (0.001 lb). Calculate the density, D_{SSD}, in kilograms per cubic metre (or alternately in pounds per cubic foot), as:

$$D_{SSD} = \frac{W_1 \times \rho}{W_1 - W_2} \quad (3)$$

where:

D_{SSD} = saturated surface dry unit weight, kg/m^3(or alternately lb/ft ^{3}),
W_1 = saturated surface dry (SSD) mass in air after the 48 h soak, kg,
W_2 = SSD mass suspended and immersed in water, kg, and
ρ = density of water, 997 kg/m ^{3}(62.3 lb/ft^3).

9.1.2 *Dry unit weight and free water*— Dry the sample from 9.1.1 for a minimum of 24 h or to constant weight at 105 to 115°C (220 to 240°F). Cool. Determine the mass to the nearest 0.1 g (0.001 lb). Calculate the density, D_{SSD}, in kilograms per cubic metre (pounds per cubic foot), and the free water, L_f, as:

$$D_{dry} = \frac{D_{SSD} \times W_3}{W_1} \quad (4)$$

$$L_f = \frac{(W_1 - W_3) \times \rho}{(W_1 - W_2)}$$

where:

D_{SSD} = saturated surface dry unit weight, kg/m^3(or alternately lb/ft ^{3}),
W_1 = saturated surface dry (SSD) mass in air after the 48 h soak, kg,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:26 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

W_3 = dry mass, kg, and
L_f = free water, kg/m^3(or alternately lb/ft^3).

10. Additional Calculations

10.1 *Cement Content*—Calculate the cement content of the concrete from the data for each procedure used, as follows:

$$\text{Cement content, kg/m}^3 = \frac{C \times D_1}{100} \quad (5)$$

$$\text{Cement content, lb/yd}^3 = \frac{C \times D_2 \times 27}{100} \quad (6)$$

where:
C = determined cement percentage, percent by mass, either as C_s, C_c, or C_m,
D_1 = D_{dry}, kg/m^3,
D_2 = D_{dry}, lb/ft^3.

11. Report

11.1 Report the cement percentage, and if required, the cement content, to the nearest kg/m^3(lb/yd^3), as follows:

11.1.1 If two or more procedures or subprocedures have been performed, report the lowest result and report the procedure used.

12. Precision and Bias

12.1 *Precision*—The precision of the cement content test procedures is dependent upon the composition of the concrete.[8]

12.1.1 The use of the soluble silica procedure may lead to erroneously high results for concretes that contain siliceous aggregates, pozzolans, or other cementitious components.

12.1.2 The use of the calcium oxide procedure will lead to erroneously high results if calcareous aggregates or other cementitious materials are present, and may do so with many pozzolanic materials.

12.1.3 The use of the maleic acid procedure may lead to erroneously low or high results, depending upon the solubility of the aggregates in the maleic acid solution, the amount of unhydrated aluminate and ferrite phases in the cement which are insoluble, and the carbonation of the paste.

12.1.4 For these reasons, precision data obtained on one concrete may not be useful in estimating that obtainable for another concrete.

12.1.5 The following sections on the soluble silica and calcium oxide procedures are based on results of cooperative analyses of a suite of three samples (Note 6), one having an aggregate providing a calcium interference, one an aggregate providing a silica interference, and one providing both interferences.

NOTE 6—These precision statements are based on tests of samples that were ground to pass a 600-mm (No. 30) sieve by a single laboratory. For this reason, interlaboratory tests did not include any variation in results that will occur because of sampling and sample preparation.

12.1.6 The section on maleic acid extraction is based on results of cooperative analyses from eleven laboratories on a suite of four concrete samples (Note 7), one with a limestone coarse aggregate, one with dolomite, and two with siliceous aggregates. One specimen contained fly ash. Total cementitious material contents ranged from 250 to 355 kg/m^3(400 to 600 lb/yd^3).

NOTE 7—This precision statement is based on tests of samples that were ground to pass a 1.18 mm (No. 16) sieve by a single laboratory. For this reason, interlaboratory tests did not include any variation in results that will occur because of sampling and sample preparation.

12.1.7 *Soluble Silica Procedure*—The single laboratory standard deviation has been found to be 15.6 kg/m^3(26.3 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests in the same laboratory on the same material should not differ by more than 44.1 kg/m^3(74.3 lb/yd^3) (Note 8).

12.1.7.1 The miltilaboratory standard deviation has been found to be 25.1 kg/m^3(42.3 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests from two different laboratories on samples of the same material should not differ by more than 71.4 kg/m ^{3}(120.3 lb/yd^3) (Note 8).

12.1.8 *Calcium Oxide Procedure*—Where applicable, the single laboratory standard deviation has been found to be 2.8 kg/m ^{3}(4.7 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests in the same laboratory on the same material should not differ by more than 7.8 kg/m^3(13.2 lb/yd^3) (Note 8).

12.1.8.1 The multilaboratory standard deviation has been found to be 10.0 kg/m^3(16.9 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests from two different laboratories on samples of the same material should not differ by more than 28.4 kg/m ^{3}(47.9 lb/yd^3) (Note 8).

NOTE 8—These numbers represent, respectively, the 1s and d2s limits as described in Practice C 670.

12.1.9 *Maleic Acid Procedure*—The single laboratory standard deviation has been found to be 14 kg/m^3(24 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests in the same laboratory on the same material should not differ by more than 40 kg/m^3(67 lb/yd^3) (Note 8).

12.1.9.1 The multilaboratory standard deviation has been found to be 22 kg/m^3(37 lb/yd^3) (Note 8). Therefore, results of two properly conducted tess from two different laboratories on samples of the same material should not differ by more than 62 kg/m ^{3}(104 lb/yd^3) (Note 8).

12.2 *Bias*—The bias of the test procedures is dependent upon the composition of the concrete for reasons described in 12.1.1-12.1.3. For these reasons, bias data obtained on one concrete may be useless in estimating that obtainable for another concrete. Refer to 12.1.5 for a description of the test program on which the following is based.

12.2.1 *Soluble Silica Subprocedure*—For the soluble silica procedure, determined values may be expected to be from about 20 kg/m^3(50 lb/yd^3) below the true value to 10 kg/m^3(25 lb/yd^3) above for no silica interference, to 45 kg/m^3(100 lb/yd^3) or more above for severe silica interferences (for example, for samples containing slag or volcanic aggregate, or a fly ash addition).

12.2.2 *Calcium Oxide Subprocedure*—Where the calcium procedure is applicable, determined values should be within 10 kg/m^3(25 lb/yd^3) of the true value.

12.2.3 The use of either of the oxide determination procedures may lead to error to the extent that the oxide content used

[8] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR:C09-1003 and RR:C09-1012.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:26 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

for calculations differs from the true value for the cement. Errors greater than 4 % relative are unusual for this parameter.

12.2.4 Bias may be reduced by analysis of separate samples of calcareous aggregates representing those used in the concrete, employing the same procedures and applying corrections based on mix design data or estimates of aggregate proportion as based on petrographic studies. Where corrected values are 45 kg/m^3(100 lb/yd^3) or more below uncorrected values, the method is probably inapplicable.

12.2.5 *Maleic Acid Procedure*—The bias of the maleic acid procedure is dependent upon the composition of the concrete for reasons stated in 12.1.3. Based on the mean values from the interlaboratory test program described under Precision, the values determined should be within – 10 to + 4 kg/m^3(–17 to + 6 lb/yd^3) of the actual values.

12.2.5.1 Approximately 40 % of the fly ash in the interlaboratory test program was consumed in the extraction and contributed to the determined cement content of the concrete. Other sources have found that variable amounts of fly ash can be consumed in some cases. This demonstrates the need for caution and compensation for induced bias when testing concretes containing fly ash, slag, silica fume, or natural pozzolans. Various sources of these materials will have highly variable effects on the results from this test.

12.2.5.2 Concrete samples that have deeply carbonated should be tested with caution as the maleic acid test results can be significantly affected, producing erroneously low cement content values.

12.2.6 Particular aggregate sources have been found to significantly affect the bias of this test method. Therefore, the separate testing of aggregate materials may be useful to indicate the solubility of the materials and possible significant contribution from the aggregate to the cement content results.

12.2.7 Petrographic studies such as those performed according to Practice C 856 can be useful in indicating potential interferences to each of the cement content procedures.

13. Keywords

13.1 cement content; concrete; hardened

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1090 – 01 (Reapproved 2005)ε1

Standard Test Method for Measuring Changes in Height of Cylindrical Specimens of Hydraulic-Cement Grout[1]

This standard is issued under the fixed designation C 1090; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—Footnotes 4 and 5 were removed editorially June 2005.

1. Scope

1.1 This test method covers measurement of the changes in height of hydraulic-cement grout by the use of 75 by 150-mm (3 by 6-in.) cylinders, when the cylinders are protected so that the tendency to change in height does not include evaporation so as to cause drying, uptake of moisture, carbonation, or exposure to temperatures outside the range 23 ± 2.0 °C (73 ± 3 °F) or, optionally, to another specified temperature controlled within ± 2.0 °C (± 3 °F).

1.2 If desired, this test method can be adapted to studies of changes in height involving either schedules or environmental treatment different from the standard procedures prescribed by this test method.

1.3 The values stated in SI units are to be regarded as the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 172 Practice for Sampling Freshly Mixed Concrete

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 827 Test Method for Change in Height at Early Ages of Cylindrical Specimens from Cementitious Mixtures

C 939 Test Method for Flow of Grout for Preplaced-Aggregate Concrete (Flow Cone Method)

3. Terminology

3.1 *Definition of Term Specific to This Standard:*

3.1.1 *change in height*—either an increase or decrease in the vertical dimension of a test specimen, provided the change has been caused by factors other than externally applied forces, changes in ambient temperature not conforming to the specified range, drying caused by evaporation, carbonation, or uptake of moisture.

4. Significance and Use

4.1 This test method is intended to provide a means of assessing the ability of a hydraulic-cement grout to retain a stable volume during the stipulated testing period of 28 days, provided that the tendency to change height does not include the effects of drying caused by evaporation, uptake of moisture, carbonation, or exposure to temperatures outside the range 23.0 ± 2.0 °C (73 ± 3 °F) (Note 1). An exception is made when the options described in the section on test conditions are exercised.

NOTE 1—This test method does not measure the change in height before hardening (see Test Method C 827).

5. Apparatus

5.1 *Cylinder Molds* steel cylindrical molds with minimum wall thickness of 6 mm (¼ in.) fitted with clamp assemblies for closing, 75 mm (3 in.) ± 1 % in inside diameter by 150 mm (6 in.) ± 2 % in height (Note 2)), fitted with a removable 6-mm (¼-in.) steel base plate that can be clamped in place with the cylinder molds, top edge machined to a narrow rim as shown in Fig. 1.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.68 on Volume Change of Concrete.

Current edition approved June 10, 2001. Published September 2001. Originally approved in 1988. Last previous edition approved in 1996 as C 1090 – 96.

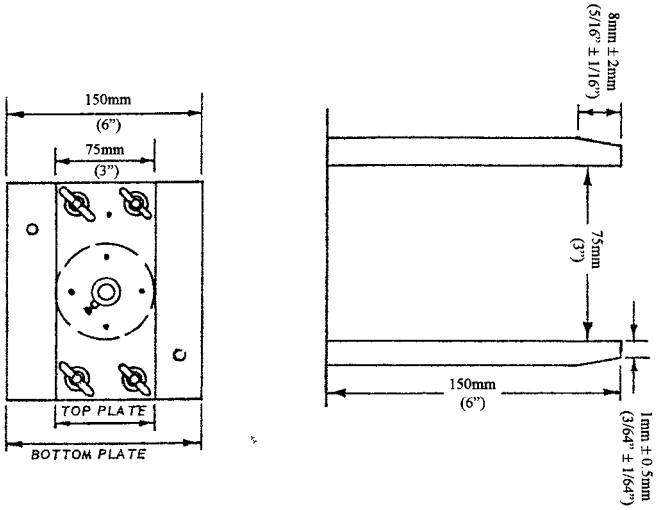

FIG. 1 Cylinder Mold with Machined (Tapered) Top Edge

NOTE 2—Satisfactory molds can be made from lengths of steel tubing or pipe that is slit on one side parallel to the longitudinal axis and fitted with a means of closing the vertical slit as well as a means of attaching a base plate.

5.2 *Glass Plate* approximately 100 mm (4 in.) square by 6 mm (¼ in.) thick, coated as thinly as possible on one surface with a silicone-base spray or other inert material such as mineral oil, and permitted to dry before use.

5.3 *Hold-Down Weight* having a mass of 1.5 kg (3 lb.) ± 1 %.

5.4 designed to support and hold one cylinder in a level, firm position (Fig. 2), with steel rods, and a top made of noncorroding metal, not more than 1 mm (3⁄64 in.) larger than the diameter of the measuring shaft of the micrometer depth gage, and numbered 1 to 4 (Note 3).

NOTE 3—The four holes should be 30 ± 2 mm (1¼ ± 1⁄16 in.) from the center of the hold-down device.

5.5 *Micrometer Depth Gage* having a range from 25 to 50 mm. (1.000 to 2.000 in) graduated in units not larger than 0.02 mm (0.001 in.) (Note 4).

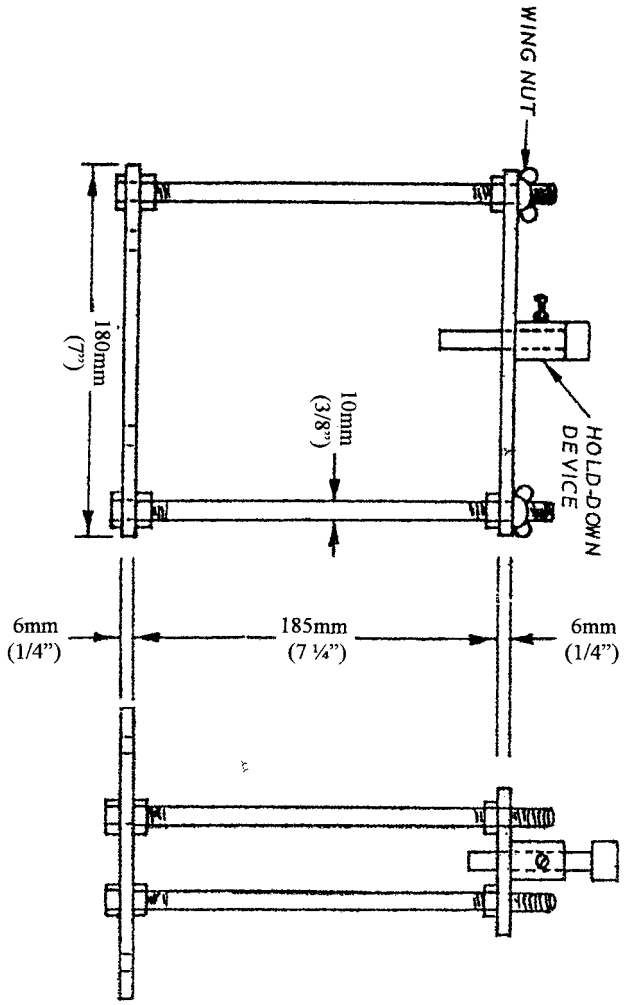
NOTE 4—The diameter of the shaft of the depth micrometer should be 3.0 ± 0.4 mm (⅛ ± 1⁄64 in.).

5.6 *Outside Micrometer Caliper*, used to measure the thickness of the plate, with a capacity of at least 12 mm (½ in.) and graduated in units not larger than 0.02 mm (0.001 in.) having throat depth of at least 50 mm (2.0 in.).

5.7 *Tamping Rod*, a straight steel rod with at least the tamping end rounded to a hemispherical tip of the same diameter as the rod, 10 mm (⅜ in.) in diameter and at last 250 mm (10 in.) long.

5.8 *Mechanical Mixer*, as described in Practice C 305 (Note 5).

NOTE 5—This mixer has clearances between paddle and bowl that are suitable only for mortars made with fine aggregates that are finer than the 850-µm (No. 20) sieve. Mortars made with aggregates containing particles coarser than the 850-µm sieve may require special clearance or a different type of paddle to permit the mixer to operate freely and avoid damage to the paddle and bowl.



NOTE 1—All parts of this bridge shall be made of a noncorroding metal.
NOTE 2—The diameter of the measuring shaft of the depth micrometer shall be 3.0 ± 0.4 mm (⅛ ± 1⁄64 in. The four holes should be 25 ± 1 mm (1 ± 1⁄16 in. from the center of the cylinder as shown in Fig. 1.

FIG. 2 Dimensions of Micrometer Bridge

6. Preparation of Sample

6.1 Take a sample of the freshly mixed grout to be tested either in accordance with Practice C 172 or prepared in sufficient quantity to permit molding at least one test specimen for height-change measurements and such additional tests as may be required or specified.

6.2 If the grout to be tested is blended from individual components, mix in accordance with Practice C 305 (Note 6). If the grout is made using a packaged product, proceed as follows, unless otherwise recommended by the manufacturer.

6.2.1 Use 3000 to 3500 g of dry material as required and the proportionate amount of water required for the test. Record amounts used.

6.2.2 Place mixing water in mixing bowl.

6.2.3 Add dry material during the first 30-s period while mixing at slow speed, 140 ± 5 r/min.

6.2.4 Continue mixing for 3 min, stopping the mixer for not over 15 s after 1 min to scrape down into the batch any grout that may have collected on the side of the bowl.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 6—If the grout contains fine aggregate, the mixing procedure for mortar is applicable; if it does not, that for paste is applicable.

6.3 Cast the sample and lock the glass plate, micrometer bridge, top plate, plunger, and weight into position within 4 min after completion of mixing. Complete the initial measurements within 3 min after completion of these operations.

6.4 If it is required or desired to cast the specimen after a longer holding period, continue mixing of either the whole or remaining portion, as appropriate, at slow speed for the specified time and the sample cast, apparatus locked, and take initial measurements within 3 min after completion of these operations.

7. Preparation of Apparatus

7.1 Coat the exterior seams of the cylinder mold and the exterior joint between the mold and the base plate with melted paraffin wax. Coat the interior of the cylinder mold and base plate lightly with mineral oil (Note 7). Attach the mold to the micrometer bridge.

NOTE 7—The exterior of the mold and the base plate may be coated with paraffin wax to facilitate cleanup after completion of the test.

8. Conditioning

8.1 Keep the air temperature at 23 ± 2 °C (73 ± 3 °F), and a relative humidity of not less than 50 %. Store the test specimen at a temperature of 23 ± 2 °C for the duration of the test, unless otherwise specified. When it is desired to test the height change of material that is permitted to be used in the field at temperatures either below or above 23 ± 2 °C, use such other temperatures controlled to ±2 °C (3 °F) throughout instead of 23 ± 2 °C. Record the temperature of the mixing water, other materials, and of the mixture immediately after mixing is completed. Store the height-change apparatus in air at the desired test storage temperature within ±2 °C before casting the specimen.

8.2 Protect the test specimen from loss of moisture, absorption of moisture, or reaction with carbon dioxide for the duration of the test. Store the specimen in the moist room or in laboratory air described as follows: Under either condition, the specimen shall remain protected at all times during the test for 28 days except during removal of the glass plate and the taking of measurements.

8.2.1 *Moist Room Storage*—Immediately after taking the initial measurements, cover the plunger and bridge apparatus with a plastic bag previously fitted and cut to a length that extends downward to the midpoint of the specimen mold to prevent water from dripping on the bridge, glass plate, or specimen. Then carefully place the specimen in a moist room or moist cabinet meeting the requirements of Specification C 511.

8.2.2 *Laboratory Air Storage*—Prior to casting the test specimen, place the entire apparatus in a prefitted plastic bag just large enough to be gathered and tied above the plunger and bridge. Roll down or collapse the bag so as not to interfere with the casting operation. Immediately after taking the initial measurement, place a damp, but not dripping, towel around the outside of the lower portion of the four posts supporting the bridge, inside the plastic bag. The towel shall extend upward, but not to more than half the height of the cylinder. Gather and tie the plastic bag just above the plunger and bridge.

8.2.3 *Subsequent Storage*—If after 28-days storage, as previously described, it is desired to observe height change while allowing some drying or carbonation, or both, to occur, remove the specimen from the moist room, or from being protected by the plastic bag and damp towels, exposed to air at 50 ± 4 % relative humidity and at the same temperature at which the test was previously maintained.

9. Procedure

9.1 Place the apparatus on a smooth, horizontal surface, which is free of vibration or disturbance. Remove the top of the bridge after it has been pre-leveled parallel to the top of the mold rim by using the four lower nuts.

9.2 Determine consistency in accordance with Test Method C 827. Consider mixtures having a flow of less than 100 % as "stiff plastic;" those having flows between 100 and 125 % are considered "plastic." A "flowable" mixture shall have a flow between 125 and 145 % when tested in accordance with Test Method C 827, but not less than 30 s when tested in accordance with Test Method C 939. A "fluid" mixture shall have a flow of 10 to 30 s when tested in accordance with Test Method C 939.

9.3 When testing a material that does not flow easily into the mold, fill by using three equal layers, rod each layer 15 times with the tamping rod. When testing materials that flow easily into the mold, fill the mold and tap the side of the mold lightly three times with the tamping rod. Use sufficient material so that after consolidation the mold is slightly overfilled.

9.4 Carefully place the coated surface of the glass plate on top of the test specimen as follows: Hold the plate, coated side down, with the index finger placed in the center and the thumb and other fingers on two opposite edges. Bring the plate, held at an angle of approximately 45°, to the beveled edge of the cylinder mold at a point 12 mm (½ in.) from the lower edge of the plate. Using this contact point as a fixed hinge, lower the plate in a single motion until the excess material is extruded and full contact with the rim is established. Neither slide nor use the glass plate in a screeding motion, as this will either smear the material on the glass or cover voids, thus making their detection at this time difficult. After placing the glass plate, maintain contact between the plate and the rim until the plunger and weight have been placed.

9.4.1 Quickly examine the grout surface through the glass plate for voids. If there is an area larger than 3.2 mm (⅛ in.) in diameter which lacks contact with the plate, discard the entire test specimen (Note 8).

NOTE 8—In order to keep rejected test specimens to a minimum, operators conducting this operation for the first time have found it helpful to practice several times placing the plate on a cylinder filled with an easily available plain mortar before starting the test.

9.5 Immediately after placing the glass plate, place the preleveled top plate of the micrometer bridge in position, tighten wing nuts, and lower the plunger of the hold-down device until it makes contact with the top surface of the glass plate. To ensure firm contact between the plunger and the plate, place a 1.5-kg (3-lb) mass on the top of the plunger prior to the tightening of the setscrew of the plunger. Following the

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

tightening of the setscrew, remove the mass and immediately insert the depth micrometer shaft through the four holes located on the top plate of the bridge until the finger rests are in full contact with it. Turn the shaft down and determine four initial measurements from this surface to the top surface of the glass plate covering the cylinder mold. Make measurements to the nearest 0.02 mm (0.001 in.). Calculate the average; do not round the numerical value. While the shaft is still touching the glass plate, use a glass marker to make a circle around the contact areas as the points at which later plate-thickness measurements will be taken.

9.6 Release the plunger and remove the glass plate from the top of the test specimen 24 ± ½ h after starting the mixing.

9.7 Immediately after removal, measure the thickness of the glass plate at the points of contact between the glass plate and the micrometer depth gage and record to the nearest 0.02 mm (0.001 in.).

9.8 At ages of 24 ± ½ h, 3 days ± 1 h, 14 days ± 6 h, and 28 days ± 12 h, measured from the time of contact of the dry materials and the mixing water, take four measurements directly to the top of the test specimen at the gage points. If the rod end of the depth micrometer either contacts the specimen surface within a bubble that has formed after placing the glass plate or breaks through the surface of a hidden bubble or other placing defect, discard the reading at that point. If less than three valid gage points remain, discard the test specimen. Measurements may be continued for additional specified periods of time. Calculate the average; do not round the numerical value.

9.9 On completion of measurements, carefully strip the test specimen and make careful visual examination of the cylindrical surface. Discard measurements made on a specimen that is cracked or otherwise manifestly faulty.

10. Calculation

10.1 To determine V_1, correct the initial measurements by adding the thickness of the glass plate measured at each corresponding contact point. Calculate the height change in percent for each age to the nearest 0.01 %, using non-rounded values for V_1 and V_2 as follows:

$$V = \frac{V_1 - V_2}{H} \times 100 \quad (1)$$

where:

V = height change, %,
V_1 = average of at least three adjusted micrometer depth gage readings at beginning of test, mm (in.),
H = height, 152-mm (6-in.), and
V_2 = average of at least three-micrometer depth gage readings at test age, mm (in.).

11. Report

11.1 Report the calculated height change (either positive or negative) at each test age. Also report the temperature and relative humidity at which the tests were performed, mixture proportions (if not prepackaged), as-mixed temperature, and consistency. Also report any deviations from the provisions given herein.

12. Precision and Bias

12.1 *Precision*—Based on an analysis of results of cooperative tests of three materials tested at two consistencies, stored at two storage conditions, it was concluded that separate precision statements are needed for flowable and fluid mixtures.

12.1.1 *Flowable Mixtures*—The single-operator standard deviation has been found to be 0.07 % (Note 9). This does not vary with test age (up to 28 days) or with expansion (over the range from 0.02 to 0.43 %). Therefore, results from two properly conducted tests by the same operator on the same material should not differ by more than 0.196 % (Note 9).

12.1.1.1 The multilaboratory standard deviation has been found to be 0.08 % (Note 9). This does not vary with test age (up to 28 days) or with expansion (over the range from 0.02 to 0.43 %). Therefore, results of two properly conducted tests on the same material in two laboratories should not differ by more than 0.216 % (Note 9).

12.1.2 *Fluid Mixtures*—The single-operator standard deviation has been found to be 0.11 % (Note 9). This does not vary with test age (up to 28 days) or with expansion (over the range from 0.11 to 0.33 %). Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 0.3255 % (Note 9).

12.1.2.1 The multilaboratory standard deviation has been found to be 0.11 % (Note 9). This does not vary with test age (up to 28 days) or with expansion (up to 0.43 %). Therefore, results of two properly conducted tests on the same material in two laboratories should not differ by more than 0.30 % (Note 9).

NOTE 9—These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

12.2 *Bias*—No statement on bias is being made because there is no accepted reference material suitable for determining the bias in this test method.

13. Keywords

13.1 grout; height change; hydraulic cement; nonshrink grout

Designation: C 1097 – 07

Standard Specification for Hydrated Lime for Use in Asphalt Cement or Bituminous Pavements[1]

This standard is issued under the fixed designation C 1097; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers high calcium, dolomitic and magnesian-hydrated lime for use in asphalt cement or bituminous pavement.

NOTE 1—Hydrated lime, either calcitic, dolomitic, or magnesian, improves bonding of bitumen and aggregates which reduces susceptibility to moisture damage, reduces age hardening by chemically stabilizing polar compounds found in asphalts, and increases initial stiffness of asphalt mixtures.

NOTE 2—No attempt is made to present requirements for any by-product lime.

1.2 *This standard does not purport to address the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

D 8 Terminology Relating to Materials for Roads and Pavements

D 242 Specification for Mineral Filler For Bituminous Paving Mixtures

D 546 Test Method for Sieve Analysis of Mineral Filler for Bituminous Paving Mixtures

3. Terminology

3.1 For definitions of terms used in this specification, refer to Terminology C 51 or Terminology D 8.

4. Chemical Requirements

4.1 Hydrated lime for use in bituminous paving mixtures shall conform to the following chemical composition:

Calcium and Magnesium Oxides (on an LOI-free basis, minimum %)	90.0
Carbon Dioxide (taken at point of manufacture, maximum %)	5.0
Unhydrated Calcium and Magnesium Oxides (maximum%)	5.0
Free Moisture of Dry Hydrates (taken at point of manufacture, maximum %)	2.0

4.2 The chemical analysis of the hydrated lime shall be determined in accordance with Test Methods C 25.

5. Physical Requirements

5.1 Hydrated lime, either dry or slurry form, shall not have more than 3.0 % retained on a No. 30 (600 µm) sieve and not more than 30 % retained on a No. 200 (75 µm) sieve.

NOTE 3—Specification D 242 also contains physical specifications for hydrated lime. Specification D 242 includes four size gradations, expressed as percent passing the sieve. For the two size gradations included in both Specification D 242 and Specification C 1097, the specifications are the same.

5.2 The particle size of hydrated lime shall be determined in accordance with Test Methods C 110.

NOTE 4—Some hydrated limes may require a full 30-min wash time.

NOTE 5—The Test Methods C 110 method for particle size analysis is required instead of the Test Method D 546 method because the because the Test Methods C 110 method uses a standardized spray nozzle and pressure gauge.

6. Sampling, Inspection, Packaging and Marking

6.1 The sampling, inspection, rejection, retesting, packaging, and marking shall be done in accordance with Practice C 50.

7. Keywords

7.1 additive; asphalt; bituminous; hydrated; lime; mineral filler; mixtures; modifier; pavement

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved June 15, 2007. Published July 2007. Originally approved in 1990. Last previous edition approved in 2006 as C 1097 – 06a.

SUMMARY OF CHANGES

Committee C07 has identified the location of selected changes to this specification since the last issue, C 1097 – 06a, that may impact the use of this specification. (Approved June 15, 2007)

(*1*) Revised 5.1.
(*2*) Revised Note 5.
(*3*) Added Terminology section and renumbered subsequent sections. Moved old 3.1 into new 3.1 and renumbered subsequent paragraphs.

Committee C07 has identified the location of selected changes to this specification since the last issue, C 1097 – 06, that may impact the use of this specification. (Approved November 15, 2006)

(*1*) Revised the text throughout.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Designation: C 1105 – 08a

Standard Test Method for Length Change of Concrete Due to Alkali-Carbonate Rock Reaction[1]

This standard is issued under the fixed designation C 1105; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination, by measurement of length change of concrete prisms, the susceptibility of cement-aggregate combinations to expansive alkali-carbonate reaction involving hydroxide ions associated with alkalies (sodium and potassium) and certain calcitic dolomites and dolomitic limestones.

1.2 The values stated in SI units are to be regarded as the standard. No other units of measurement are included in this standard. When combined standards are cited, the selection of measurement system is at the user's discretion subject to the requirements of the referenced standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes
C 586 Test Method for Potential Alkali Reactivity of Carbonate Rocks as Concrete Aggregates (Rock-Cylinder Method)
C 595 Specification for Blended Hydraulic Cements
C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
C 702 Practice for Reducing Samples of Aggregate to Testing Size
D 75 Practice for Sampling Aggregates

3. Terminology

3.1 Terminology used in this standard is defined in Terminology C 125 or Descriptive Nomenclature C 294.

4. Significance and Use

4.1 Two types of alkali reactivity of aggregates have been described in the literature: the alkali-silica reaction involving certain siliceous rocks, minerals, and artificial glasses (**1**),[3] and the alkali-carbonate reaction involving dolomite in certain calcitic dolomites and dolomitic limestones (**2**). This test method is not recommended as a means to detect combinations susceptible to expansion due to alkali-silica reaction since it was not evaluated for this use in the work reported by Buck (**2**). This test method is not applicable to aggregates that do not contain or consist of carbonate rock (see Descriptive Nomenclature C 294).

4.2 This test method is intended for evaluating the behavior of specific combinations of concrete-making materials to be used in the work. However, provisions are made for the use of substitute materials when required. This test method assesses the potential for expansion of concrete caused by alkali-carbonate rock reaction from tests performed under prescribed

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.26 on Chemical Reactions.

Current edition approved Dec. 1, 2008. Published January 2009. Originally approved in 1989. Last previous edition approved in 2008 as C 1105 – 08.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

[3] The boldface numbers in parentheses refer to the list of references at the end of this test method.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

laboratory curing conditions that will probably differ from field conditions. Thus, actual field performance will not be duplicated due to differences in wetting and drying, temperature, other factors, or combinations of these (see Appendix X1).

4.3 Use of this test method is of particular value when samples of aggregate from a source have been determined to contain constituents that are regarded as capable of participation in a potentially deleterious alkali-carbonate rock reaction either by petrographic examination, Guide C 295, by the rock cylinder test, Test Method C 586, by service record; or by a combination of these.

4.4 Results of tests conducted as described herein should form a part of the basis for a decision as to whether precautions be taken against excessive expansion due to alkali-carbonate rock reaction. This decision should be made before a particular cement-aggregate combination is used in concrete construction (see Note 1).

NOTE 1—Other elements that may be included in the decision-making process for categorizing an aggregate or a cement-aggregate combination with respect to whether precautions are needed, and examples of precautions that may be taken, are described in Appendix X1.

4.5 While the basic intent of this test method is to develop information on a particular cement-aggregate combination, it will usually be very useful to conduct control tests in parallel using the aggregate of interest with other cements or the cement of interest with other aggregates.

5. Apparatus

5.1 The molds, the associated items for molding test specimens, and the length comparator for measuring length change shall conform to the applicable requirements of Test Method C 157/C 157M and Practice C 490, and the molds shall have nominal 75-mm square cross sections.

6. Materials

6.1 *Maximum Size of Coarse Aggregate*—Coarse-aggregate fractions larger than the 19.0-mm sieve shall not be tested as such. When petrographic examination using Guide C 295 reveals that the material making up the size fractions larger than the 19.0-mm sieve is of such a composition and lithology that no differences should be expected compared with the smaller size material to be tested, or when tests, made in accordance with Test Method C 586, of material in such sizes reveal no significant differences from the sizes to be tested, then no further attention need be paid to the larger sizes. If results of petrographic examination or tests made in accordance with Test Method C 586 suggest that the larger size material should be studied for its effects in concrete, one or the other of two alternative procedures described herein may be used.

6.1.1 *Proportional Testing*—Material larger than the 19.0-mm sieve shall be crushed to pass the 19.0-mm sieve and material larger than the 4.75-mm sieve shall be proportioned to include the same proportion by mass of the crushed material originally retained on the 19.0-mm sieve and that originally passing this sieve, as may be expected to be used in the field concrete.

6.1.2 *Separated Size Testing*—Material larger than the 19.0-mm sieve shall be crushed to pass this sieve and shall be used in concrete as a second aggregate.

6.1.2.1 In the case of construction where several size ranges coarser than the 19.0-mm sieve are contemplated, each of these may, if desired, be separately crushed to pass this sieve and may be tested separately.

6.2 *Job Cement*—When it is desired to evaluate a particular cement-aggregate combination for use in particular work, the cement or cements used shall meet the requirements for the work and shall be from the source or sources and in the amounts expected to be used in the work. If several cements may be used in the work, it is desirable that tests be made using each cement separately.

6.3 *Reference Cements*—When it is desired to evaluate aggregates for general use or to compare aggregates for investigational purposes, the cement used shall be of the highest alkali content representative of the general use intended, or available to the laboratory making the tests. The cement or cements selected should comply with Specification C 150 or Specification C 595. Additional information of value may be obtained by conducting parallel tests with cements of different alkali content, of different sodium oxide to potassium oxide ratio, or blended with pozzolan or ground blast-furnace slag, or both.

6.4 *Substitute Fine Aggregate*—If the test aggregate is to be used only as coarse aggregate and the fine aggregate that it will be used with is not available, a fine aggregate that is not expected to participate in an expansive reaction with alkalies (see Note 2) shall be used.

NOTE 2—Advice on judging the expansive reactivity of aggregate is given in Appendix XI of Specification C 33.

7. Sampling

7.1 Obtain the sample in accordance with Practice D 75 and reduce it to test portion size in accordance with Practice C 702.

8. Test Specimens

8.1 Prepare six specimens, of the type required for concrete Test Method C 157/C 157M, from one batch of concrete. The concrete mixture shall be the mixture in which the aggregates are proposed for use. In the event that no specific concrete mixture is being considered, that described in Test Method C 233 shall be used.

8.2 If control or comparison mixtures are made, specimens shall be made from those mixtures as described in 8.1.

9. Conditioning

9.1 Cure, store, and remove molds in accordance with Test Method C 157/C 157M. Thereafter, keep the specimens in moist storage in accordance with Specification C 511 but do not immerse in water.

10. Procedure

10.1 Follow the procedure of Test Method C 157/C 157M, except that the specimens shall be stored in a moist room or moist cabinet meeting the requirements of Specification C 511 and length measurements shall be made at ages 7, 28, and 56 days, and 3, 6, 9, and 12 months.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:32 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11. Calculation

11.1 Calculate the change in length of each of the prisms at each of the ages at which determinations are made and express as a percentage change based on the length at the time of removal from the mold at an age of 23½ ± ½ h. Calculate the average length change in percentage for the group of prisms.

11.2 Data from at least three bars must be available at any age to constitute a valid test at that age.

12. Report

12.1 Report the following information:

12.1.1 Pertinent details about materials and mixtures used,

12.1.2 The length change in percentage for each specimen and for the group of prisms at each test age, and

12.1.3 Description of the circumstances under which results on any one of the specimens are not included in the average.

13. Precision and Bias [4]

13.1 *Precision*:

13.1.1 *Single-Operator Precision*—The precision statement is based on calculations made using data reported by Buck (**2**). The particular within-laboratory variability for which precision is reported was obtained by a single operator, using the same materials and equipment over a short period of time. The single-operator standard deviation (1s[A]) does not vary appreciably with age over the range of 90 through 365 days. Standard deviation varies with the magnitude of the expansion described as follows:

	Average % Expansion	
	<0.040 %	≥0.040 %
Single-operator standard deviation (1s) among individual bars	0.003 %	0.005 %
Maximum difference (d2s[A]) between extreme values within a set of bars in a properly conducted test should not exceed:		
number of bars in set		
6	0.013 %	0.021 %
5	0.012 %	0.020 %
4	0.012 %	0.019 %
3	0.011 %	0.017 %
Calculated expected 1S associated with a mean of 3 bars	0.002 %	0.003 %
Maximum permissible difference between two such means in properly conducted tests should not exceed	0.005 %	0.008 %

[A] As described in Practice C 670.

13.1.2 *Multilaboratory Precision*—In studies involving 12 and 20 laboratories (**8**,9), testing three specimens rather than the six specified in this test method, and testing nominal 19 mm maximum size coarse aggregates known to be susceptible to alkalicarbonate rock reaction, in concrete mixtures with a cement content of 310 kg/m^3 , the multilaboratory precision was found to be as follows:

13.1.2.1 For concrete with an average expansion less than 0.014 % the multilaboratory standard deviation of a single test result (mean of measurements on three prisms) for average expansion less than 0.014 % has been found to be 0.0032 %. Therefore, results of two properly conducted tests in different laboratories using the same aggregate should not differ by more than 0.009 %.[5]

13.1.2.2 For concrete with an average expansion greater than 0.014 % the multilaboratory coefficient of variation of a single test result (mean of measurements on three prisms) for average expansion greater than 0.014 % has been found to be 23 %. Therefore, results of two properly conducted tests in different laboratories using the same aggregate should not differ from each other by more than 65 % of their average.[5]

13.2 *Bias*—A statement on bias has not been developed since no reference materials are available.

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1002.

[5] These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

APPENDIX

(Nonmandatory Information)

X1. GENERAL INFORMATION

X1.1 The question of whether or not criterion based on the results obtained using this test method should be used for acceptance of materials for use as concrete aggregate will be dealt with, if deemed appropriate, in Specification C 33.

X1.2 Work has been reported from which it may be inferred that a cement-aggregate combination might reasonably be classified as potentially deleteriously reactive if the average expansion of six concrete specimens is equal to or greater than: 0.015 % at 3 months; 0.025 % at 6 months; or 0.030 % at 1 year (**1**,**2**). Data for later ages are preferred but the 3-month or 6-month average may be used if necessary.

X1.3 If this test method has been performed on a cement-aggregate combination involving an aggregate that has not been examined petrographically using Practice C 295, or that has not been measured by the rock prism expansion in Test Method C 586, it is recommended that one or both of those

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:32 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

procedures be performed.

X1.4 When it has been concluded from the results of tests performed using this test method and supplementary information from petrographic examination, rock-prism testing, service records, or combinations of these, that a given cement-aggregate combination is potentially deleteriously expansive, additional studies may be appropriate to develop information on the potential expansion of other combinations containing the same cement with other aggregates, the same aggregate with other cements, or the same cement-aggregate combination with a pozzolan or slag.

X1.5 If a cement-aggregate combination tested using this test method is judged by the results to be "non-reactive," no restrictions on the use of the aggregate with the cement used in the test are necessary in order to protect against probable alkali-carbonate rock reaction. If the combination is judged to be "reactive," measures to control the effects of the reaction (**3**,**4**) include:

X1.5.1 The use of the smallest nominal maximum size coarse aggregate that is practical.

X1.5.2 A maximum of 20 % reactive rock in the coarse aggregate, 20 % reactive rock in the fine aggregate, or a total of 15 % reactive rock if the coarse and fine aggregate both contain reactive rock.

X1.5.3 Use of a cement having no greater an alkali content than a cement tested using test method for which the results are judged to be "non-reactive."

X1.5.4 Additional useful information about this chemical reaction is included in (**5-7**).

Designation: C 1107/C 1107M – 08

Standard Specification for Packaged Dry, Hydraulic-Cement Grout (Nonshrink)[1]

This standard is issued under the fixed designation C 1107/C 1107M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers packaged dry, hydraulic cement grout (nonshrink) intended for use under applied load (such as to support a structure, a machine, and the like) where a change in height below initial placement height is to be avoided.

1.2 Grouts covered are composed of hydraulic cement, fine aggregate, and other ingredients. They require only the addition of mixing water for use.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 The following safety hazards caveat pertains only to the test method portion of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 138/C 138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

C 157/C 157M Test Method for Length Change of Hardened Hydraulic-Cement Mortar and Concrete

C 185 Test Method for Air Content of Hydraulic Cement Mortar

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 702 Practice for Reducing Samples of Aggregate to Testing Size

C 827 Test Method for Change in Height at Early Ages of Cylindrical Specimens of Cementitious Mixtures

C 939 Test Method for Flow of Grout for Preplaced-Aggregate Concrete (Flow Cone Method)

C 1090 Test Method for Measuring Changes in Height of Cylindrical Specimens of Hydraulic-Cement Grout

C 1437 Test Method for Flow of Hydraulic Cement Mortar

3. Terminology

3.1 *Definitions*—For definitions of terms used in this specification, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *consistency, flowable*, *n*—a grout consistency having a flow of 125 to 145 by the flow test in accordance with the applicable provisions of Test Method C 1437; the flow after 5 drops of the flow table in 3 s.

3.2.2 *consistency, fluid*, *n*—a grout consistency having a time of efflux of 10 to 30 s when tested by the flow cone procedure of Test Method C 939.

3.2.3 *consistency, plastic*, *n*—a grout consistency having a flow of 100 to 125 by the flow test in accordance with the applicable provisions of Test Method C 1437; the flow after 5 drops of the flow table in 3 s.

4. Ordering Information

4.1 When the purchaser specifies that properties of the packaged, dry grout meet the requirements of this specification, also specify which, if any, of the optional requirements apply.

4.2 When the grout is to be used in contact with stressed tendons or other corrosion-sensitive, load-bearing structural members, the purchaser shall supply this information to the manufacturer and obtain assurances that the material meets

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.43 on Packaged Dry Combined Materials.

Current edition approved Oct. 1, 2008. Published November 2008. Originally approved in 1991. Last previous edition approved in 2007 as C 1107 – 07a.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

relevant chloride, nitrite, nitrate, sulfide, and sulfate requirements, and any other material limitations imposed by the applicable codes and standards (See Note 1).

4.3 When the grout is to be used in abnormal or aggressive environments, the purchaser shall supply this information to the manufacturer and obtain assurance that the grout has a successful history of performance in the same or similar exposures.

NOTE 1—Since all conditions of use cannot be anticipated, this specification requires nonshrink grout to exhibit no shrinkage when tested in a laboratory-controlled, moist-cured environment, and requires only the reporting of the observed height change, usually shrinkage, when test specimens are subjected to some degree of drying. It is suggested that users consult with manufacturers on specific applications to determine the applicability of specific test results.

5. Materials

5.1 The materials used as ingredients in packaged, dry, grout include hydraulic cement, fine aggregate, and other ingredients.

6. Performance Requirements

6.1 Specimens shall be made from freshly mixed grout and from grout that has been retained in the mixer for the maximum usable working time allowed by the manufacturer. Specimens from both conditions shall meet the requirements prescribed in Table 1.

6.2 Specimens shall be prepared using materials and equipment at temperatures representing the maximum and minimum usable temperatures specified by the manufacturer for his product. Specimens from both conditions shall meet the requirements prescribed in Table 1, except that the compressive-strength requirements do not have to be met at minimum usable temperature.

6.3 Specimens for testing shall be prepared by combining the use of grout retained in the mixer as in 6.1 with the minimum and maximum as mixed and curing temperatures used in 6.2. Specimens from these combinations of conditions shall meet the requirements of Table 1, except that the compressive-strength requirements do not have to be met at minimum usable temperature.

6.4 All test specimens for performance evaluation shall be prepared using the highest water to solids ratio, maximum flow, or most fluid consistency stated on the package.

TABLE 1 Performance Requirements

Compressive Strength, min	MPa	[psi]
1 day[A]	7.0	[1000]
3 day	17.0	[2500]
7 day	24.0	[3500]
28 day	34.0	[5000]
Early Age Height Change Max % @ Final Set		+ 4.0
Height Change of Moist Cured Hardened Grout at 1, 3, 14 and 28 Days		
Maximum, %		+ 0.3
Minimum, %		0.0

[A] When required, the purchaser must so specify in the purchase contract.

7. Sampling

7.1 Use whole packages of grout selected at random from the lot of grout to be examined.

7.2 Where lesser quantities of grout will serve the purpose, select 3000 g [7 lb] of dry grout from a whole package in accordance with the mechanical-splitter method in Practice C 702. For high-density grouts, adjust the mass to provide an equivalent volume.

8. Batching

8.1 Grout mixtures shall be produced in the following conditions:

8.1.1 Batch grout mixtures at temperature conditions corresponding to the maximum recommended temperature limit and at a temperature corresponding to the minimum temperature stated by the manufacturer.

8.1.2 For standard temperature testing, maintain the grout mixture and the testing equipment at a temperature of 23 ± 2 °C [73.5 ± 3.5 °F].

8.2 Bring all materials and equipment to be used in preparing test specimens to the specified test temperature, ± 3 °C [± 5 °F] prior to use.

8.2.1 When the controlled-environment test room is too small to accommodate large equipment, immediately prior to use, bring the mixer to the desired testing temperature by filling it with water at the appropriate temperature and agitating it by turning the mixer on. When this water has stabilized at the desired temperature, discard it and start preparing the batch immediately.

8.3 The manufacturer is not prohibited from including, in the package instructions, procedures for adjusting the mixing water temperature to achieve limitations imposed on the grout use temperatures. Use of this technique shall not abrogate the extended mixing time requirement of this specification.

9. Proportioning

9.1 The minimum and maximum amount of water recommended by the manufacturer on the package shall be used to determine conformance with the requirements of this specification. If the manufacturer provides maximum flow (thinnest consistency) information on the package, conduct consistency tests to an accuracy of ±5 % to determine the amount of water to be added for testing. In either case, express the weight of water so determined as a ratio of water to dry grout material by weight. If both are given, make tests at whichever involves the larger amount of water by ratio of dry grout mixture.

10. Mixing

10.1 Either the mixer described in Practice C 305 or the mortar mixer described in 10.1.2 shall be used for performance qualifications. In the event of a dispute, the mixer described in 10.1.2 shall be used for the referee test.

NOTE 2—The referee test is a test made to settle disagreement as to the conformance to the specified requirements.

10.1.1 *Bench Scale Epicyclic Mixer*—The mortar-mixing apparatus shall be as specified in Practice C 305. However, the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:35 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

mixer shall be provided with a bowl positioner to enable clearance of the largest sized aggregate in the mixture being tested.

10.1.2 *Mortar Mixer*—A 110 to 125-L [4 to 4½-ft^3] capacity horizontal shaft stationary drum mortar mixer (See Note 3) is required. The mortar mixer shall have a metal shell with horizontal mixing blades. The mixing blades shall be angled so that adjacent paddle arms reverse the flow of the grout in the mixing drum during rotation of the horizontal shaft. The mixing blades shall have adjustable wiper blades that wipe the inner surfaces of the mixing chamber. The wiper blades shall be rubber or other flexible, wear-resistant material that does not deleteriously react with the grout mixture. The wiper blades shall be adjusted to continuously wipe the curved inner surface of the mixing chamber below the grout level and the ends of the chamber. The horizontal shaft shall rotate the mixing paddles at 28 to 35 r/min. The mixer shall be clean, pre-wetted, and drained and essentially free of hardened mortar and other foreign material that can be removed with a trowel or by reasonably striking with a hammer.

NOTE 3—An electric motor-driven mixer is preferable in the laboratory to avoid noise and exhaust fumes. For greater safety, the mixer should be equipped with a lever-operated clutch. While these comments are selected safety precautions, it is the user's responsibility to see that any equipment in use is not hazardous in a physical or mechanical way to operators and attendant personnel, and that safe work practices are required at all times.

10.2 *Mixing Procedure for Bench Scale Mixing*:

10.2.1 Use a 3000-g [7-lb] sample to determine the consistency classification and to determine the water content of grout tested at maximum flow or most fluid consistency.

10.2.2 Weigh all grout on a balance or on a platform scale to the nearest 0.1 %.

10.2.3 Measure the water by mass or volume to the nearest 0.1 %. If the manufacturer recommends maximum water content, calculate the percent water from the packaging information and use that amount of water to prepare the grout mixture. If the manufacturer recommends maximum flow or most fluid consistency, use the suggested water content as a starting point and adjust water as necessary to achieve the maximum flow or most fluid consistency stated on the package. If the required consistency has not been met, make additional adjustments to estimate the water content to use for the next batch. Discard current batch and repeat with newly established water content.

10.2.4 Place water in the bowl. Start the mixer at speed 1. Add the dry grout material to the water over approximately 30 sec. After 1 min, stop the mixer for 15 sec and scrape into the batch any grout that may have collected on the side of the bowl. Switch to speed 2 and mix for a total of 5 min as measured from first contact of dry material with water. Use other mixing procedures if recommended by the manufacturer.

NOTE 4—It is advisable to cover the bowl with a lid while mixing. A metal disc in which a slit has been cut to accommodate the mixer shaft has been found suitable. If excessive splash-over occurs, a larger mixer should be used.

10.2.5 Prepare required specimens from additional batches of grout as needed. Use the water content established above for all successive batches. When testing grout at the end of its working time, a separate batch of grout shall be mixed continually until the time of test unless otherwise recommended by the manufacturer.

10.3 *Procedure for Using The Mortar Mixer*:

10.3.1 Prepare all specimens from a single batch of grout using the horizontal shaft stationary drum mortar mixer. Perform tests to verify compliance with performance requirements.

10.3.2 With materials and equipment brought to the testing temperature, use enough whole bags of material to produce at least 56 L [2 ft^3] of mixed grout. Use this batch for both freshly-mixed and delayed-mixed testing at one specified temperature. Place the total required amount of mixing water in the mixer (See Note 5).

10.3.2.1 When testing a grout to a maximum water to solids ratio, use the weighed contents of the packages to determine the amount of water to be used.

10.3.2.2 When testing a grout to a maximum recommended flow or most fluid consistency, adjust the water content at the time of mixing to achieve the recommended consistency. With the mixer running, add the grout material to the water in a steady flow, sliding it into the mixer along the side away from the discharge. After mixing for 1 min, stop the mixer for not more than 30 s and scrape down the sides and blades. Mix for an additional 5 min after all the dry material has been added, unless otherwise recommended by the manufacturer. If the required consistency has not been met, make additional adjustments to estimate the water content to use for the next batch. Discard current batch and repeat with newly established water content.

NOTE 5—Extensive lumping generally occurs during the procedure for adding grout to water. If it occurs repeatedly, try adding about 80 % of the water, then add all of the dry grout material. Add the remaining water after about 1 min of mixing. If lumping persists, contact the grout manufacturer for recommendations.

10.3.3 After completely mixing, discharge a portion of the material through a 9.5-mm [⅜-in.] mesh screen into a clean, pre-wetted container. If lumps or balls of partially mixed material remain on the screen, reject the entire batch and start over.

10.3.4 Leave the portion of grout to be tested later in the mixer with the mixer running, unless otherwise recommended by the manufacturer, for the period recommended by the manufacturer as the maximum usable working time.

10.3.5 If the manufacturer requires other equipment or a different mixing procedure, or both, when using a particular grout, they shall be used if adequately detailed in the manufacturer's instructions.

11. Test Methods

11.1 *Consistency*:

11.1.1 Determine the consistency of the grout mixture in accordance with Test Method C 827, Preparation of Mixtures, with the exception of temperature. To adjust for consistency, repeat the procedure starting with dry material. Do not add water or dry material to an existing mixture.

11.1.2 Determine the consistency with the required water content, at the temperature extremes allowed by the manufacturer, both with freshly mixed grout and grout mixed to the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:45:35 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

maximum allowed usable working time. The consistency at the end of the maximum allowed usable working time at each of the allowed temperature extremes shall remain within the specified flow ranges.

11.1.3 Do not adjust the water at extreme conditions unless recommended by the manufacturer. When water adjustment is recommended, perform tests required by this specification to verify that the water-adjusted grout meets the requirements of this specification.

11.2 *Yield*—Determine the yield of the grout using the 400-mL cylindrical measure described in Test Method C 185.

11.2.1 *Calculation*—Calculate the density of the grout in accordance with Test Method C 138 and calculate the yield of freshly mixed grout per package of specified mass as follows:

$$Y = (1 + A)\frac{W_t}{W} \quad (1)$$

where:

Y = Yield of grout, L [ft^3] (expressed to nearest 0.5 L [0.01 ft^3]),

W = Unit weight of grout, kg/m^3 [lb/ft^3],

A = Fraction of water added to grout,

$$\frac{\text{Mass of Water}}{\text{Mass of Dry Grout}}$$

W_t = Net weight marked on package, kg [lb].

11.3 *Early Age Height Change*—Determine the early-age height change of grout in accordance with the applicable portions of Test Method C 827.

11.4 *Height Change of Hardened Grout*:

11.4.1 Determine height change of hardened grout at 1, 3, 14, and 28 days in accordance with Test Method C 1090 and report.

11.4.2 At 28 days age, leave specimens in the apparatus and expose to 50 % relative humidity air, in accordance with Test Method C 157, until 56 days age. Determine the net change in specimen height after 28 days of moist curing followed by 28 days of storage in 50 % relative humidity air at 23 ± 2 °C [73 ± 5 °F].

11.5 *Compressive Strength*—Determine compressive strength in accordance with the applicable portions of Test Method C 109/C 109M except as modified in this section.

11.5.1 For fluid or flowable grouts, fill each mold in the set halfway. Puddle each with a gloved finger five times to consolidate. Fill the mold and puddle again. When filling the mold, use sufficient material so that after the final consolidation the mold is slightly overfilled. Bring the excess grout to the center and finish the surface by cutting off the excess with the straight edge of a trowel held vertically and drawn across the top of the mold with a sawing motion. Plastic grouts shall be consolidated as described in Test Method C 109/C 109M.

11.5.2 Clamp a cover plate over the cube molds using two C-clamps, taking care that the grout does not prevent seating of the plate. The cover plate shall be rigid, nonreactive and not less than 6 mm [¼ in.] thick. The cover plate shall overlap the cube mold by not less than 6 mm [¼ in.]. Immediately place test specimens in moist room.

11.5.3 For 1 day compressive strength specimen, strip molds at 24 ± ½ h after molding. Strip remaining molds at 72 ± 1 h after molding and place specimens in moist cabinet or moist room protected from dripping water. Three cubes shall be tested at each age—1, 3, 7, and 28 days.

12. Report

12.1 Report the following information:

12.1.1 Source and identification of grout tested,

12.1.2 Details of any variations and options practiced by the tester that are recommended or allowed by the manufacturer or others. Also, designate by whom exceptions are allowed or recommended,

12.1.3 Number and size of each grout specimen and the date molded,

12.1.4 Consistency at the time the specimens were molded and the water to dry solids ratio,

12.1.5 Mixing temperature and curing temperature,

12.1.6 Identify the usable working time, and temperature range within which the grout specimens were prepared, placed, cured, and tested,

12.1.7 Height change from placement to time of final setting, %,

12.1.8 Height change of hardened, moist-cured grout at specimen age of 1, 3, 14, and 28 days, %,

12.1.9 Height change of hardened grout at 56 days of age when exposed to air drying for 28 days after 28 days of moist-curing, %,

12.1.10 Compressive strength of cubes at 1, 3, 7, and 28 days, and

12.1.11 Yield, determined in 11.2.

13. Inspection and Rejection

13.1 Inspection of the dry grout material shall be agreed upon between the purchaser and the manufacturer as part of the purchase contract.

13.2 Any material that fails to conform to any of the requirements in this specification shall be designated as nonconforming material. In the event of a failure to conform to any part of the requirements of this specification when using the mixer described according to Practice C 305, the mortar mixing procedure as described in 10.1.2 shall be used to resolve compliance with the specification. The purchaser has the right to reject any nonconforming material. Rejection shall be reported to the producer or supplier in writing.

14. Certification

14.1 The manufacturer shall, at the time of purchase, provide the purchaser, on request, a certification under terms of the purchase contract, that the product meets the requirements of this standard.

15. Product Marking

15.1 All packages shall show at least the following information in clearly legible form:

15.1.1 Brand name, usable working time for high and low temperatures within which the grout will meet the requirements of this specification, net weight,

15.1.2 Date of manufacture and the recommended use expiration date, and

15.1.3 Lot identification number.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

15.2 The following additional information shall be either marked on package or attached to it:

15.2.1 Surface preparation, mixing, placing, and curing instructions,

15.2.2 Maximum amount of mixing water to be used, or maximum recommended consistency,

15.2.3 Yield at maximum mixing water content, or maximum consistency. The yield claimed shall not be greater than that measured in 11.2,

15.2.4 Recommended maximum usable working time, "pot-life," and approximate consistency at end of that time. Usable working time shall not exceed the time after initial mixing that grout retains properties required in this specification, and

15.2.5 High and low temperatures during preparation and placement within which the grout will meet the requirements of this specification.

16. Keywords

16.1 dry hydraulic cement grout; grout; nonshrink hydraulic cement grout; packaged dry grout; shrinkage compensated grout

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1107 – 07a, that may impact the use of this specification. (Approved October 1, 2008)

(*1*) Made major revisions to Sections 6, 10, and 13 to permit the use of either a mortar mixer or a bench scale mixer to prepare samples for qualification testing.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1107 – 07, that may impact the use of this specification. (Approved July 15, 2007)

(*1*) Revised 8.1.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1116/C 1116M – 09

Standard Specification for Fiber-Reinforced Concrete[1]

This standard is issued under the fixed designation C 1116/C 1116M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers all forms of fiber-reinforced concrete that are delivered to a purchaser with the ingredients uniformly mixed, and that can be sampled and tested at the point of delivery. It does not cover the placement, consolidation, curing, or protection of the fiber-reinforced concrete after delivery to the purchaser.

1.2 Certain sections of this specification are also applicable to fiber-reinforced concrete intended for shotcreting by the dry-mix process when sampling and testing of concrete is possible only at the point of placement. In this case, the sections dealing with batching plant, mixing equipment, mixing and delivery, and measurement of workability and air content, are not applicable.

1.3 This specification does not cover thin-section glass fiber-reinforced concrete manufactured by the spray-up process that is under the jurisdiction of ASTM Subcommittee C27.40.

1.4 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.5 The following precautionary statement pertains only to the test method portion, Sections 15 and 18, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

211.1 Standard Practice for Selecting Proportions for Normal, Heavyweight, and Mass Concrete[3]
211.2 Standard Practice for Selecting Proportions for Structural Lightweight Concrete[3]
506.2 Specification for Materials, Proportioning and Application of Shotcrete[3]

3. Terminology

3.1 *Definitions*

3.1.1 For definitions of terms used in this specification, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *manufacturer*, *n*—the producer who furnishes the fiber-reinforced concrete.

3.2.2 *purchaser*, *n*—the owner, or representative thereof, who buys the fiber-reinforced concrete.

4. Classification

4.1 This specification classifies fiber-reinforced concrete by the material type of the fiber incorporated.

NOTE 1—The performance of fiber-reinforced concrete depends upon the susceptibility of the fibers to physical damage during mixing or shotcreting and to chemical damage on exposure to the cement paste solution, which is highly alkaline and may also contain carbon dioxide, chlorides, sulfates or oxygen. Improper methods of fiber addition to a concrete mix can lead to balling of some types of fiber; consult manufacturer for advice as to correct method before use. The magnitude of improvements in the mechanical properties of the concrete or shotcrete imparted by fibers can also reflect the material characteristics, geometry, and design of the fiber type.

4.1.1 *Type I Steel Fiber-Reinforced Concrete*—Contains stainless steel, alloy steel, or carbon steel fibers conforming to Specification A 820/A 820M.

4.1.2 *Type II Glass Fiber-Reinforced Concrete*—Contains alkali-resistant (AR) glass fibers conforming to Specification C 1666/C 1666M.

4.1.3 *Type III Synthetic Fiber-Reinforced Concrete*—Contains synthetic fibers for which documentary evidence can be produced confirming their resistance to deterioration when in contact with the moisture and alkalis present in cement paste and the substances present in admixtures throughout the anticipated useful life of the structure (see Note 2 and 4.2).

NOTE 2—Fibers such as polyolefins (polypropylene and polyethylene), nylon, and carbon have been shown to be durable in concrete.

4.1.4 *Type IV Natural Fiber-Reinforced Concrete*—Contains natural fibers for which documentary evidence can be produced confirming their resistance to deterioration when in contact with the moisture and alkalis present in cement paste and the substances present in admixtures throughout the anticipated useful life of the structure. When Type IV fiber-reinforced concrete contains cellulose fibers they shall conform to Specification D 7357.

NOTE 3—The classification, natural fibers, refers to a population of fibers that are manufactured from natural fibrous resources and are used for the first time in concrete. Depending on the initial raw material and the manufacturing process employed to produce the fiber, the final physical and chemical fiber properties in this general classification can vary greatly. Some natural fibers are susceptible to deterioration from exposure to alkalis; Test Method D 6942 may be used to determine the susceptibility of these fibers to deterioration as a result of exposure to alkalis in concrete. Conversely, many other natural fiber types are highly resistant to alkalis and can remain in concrete with no degradation for the complete product life cycle.

4.2 When the purchaser chooses to permit the use of fibers other than those complying with the classifications in 4.1, the manufacturer or supplier shall show evidence satisfactory to the purchaser that the type of fiber proposed for use shows resistance to deterioration when in contact with the moisture and alkalis present in cement paste and the substances present in admixtures throughout the anticipated useful life of the structure.

5. Basis of Purchase

5.1 The basis of purchase for fiber-reinforced concrete shall be in accordance with the *Basis of Purchase* Sections of Specification C 94/C 94M or Specification C 685/C 685M.

6. Ordering Information

6.1 In the absence of designated applicable general specifications, the purchaser shall specify the following:

6.1.1 Type of fiber-reinforced concrete required. See Section 4.

6.1.2 Type of cement at the purchaser's option, otherwise the cement shall be Type 1 meeting the requirements of Specification C 150;

6.1.3 Designated size, or sizes, of coarse aggregates;

6.1.4 Slump required at the point of delivery, or when appropriate the point of placement, subject to the tolerances hereinafter specified;

6.1.5 Air content when air-entrainment is required, based on the air content of samples taken at the point of discharge, or when appropriate the point of placement, subject to the tolerances hereinafter specified;

NOTE 4—In selecting the specified air content, the purchaser should

[3] Available from American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333-9094, http://www.aci-int.org.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

consider the exposure conditions to which the concrete will be subjected. Air contents less than shown in Table 1 may not produce adequate durability. Air contents higher than the levels shown may reduce strength without contributing further to freeze-thaw resistance.

6.1.6 When structural lightweight concrete is specified, the purchaser shall specify the density as freshly mixed density, equilibrium density, or oven-dry density.

NOTE 5—The freshly mixed density of lightweight concrete, that is the only density determinable at the time of delivery, is always higher than the equilibrium density or oven-dry density. Definitions of, and methods for determining or calculating freshly mixed, equilibrium, and oven-dry densities of lightweight concrete are covered in Test Methods C 138/C 138M and C 567.

6.1.7 If desired, any of the optional requirements of Table 2 of Specification C 1602/C 1602M.

6.1.8 One of the following Options A, B, or C, shall be used as the basis for determining the proportions of the fiber-reinforced concrete of the quality required.

6.2 *Option A*:

6.2.1 When the purchaser assumes responsibility for mixture proportioning, the following parameters shall also be specified by the purchaser:

6.2.1.1 The cement content in kilograms per cubic metre [pounds per cubic yard],

6.2.1.2 If supplementary cementitious materials are required, the type, and amounts to be used in kilograms per cubic metre [pounds per cubic yard], or in percentages by mass of cement,

6.2.1.3 The maximum allowable amount of mixing water in litres per cubic metre [gallons per cubic yard], including surface moisture on the aggregates, but excluding water absorbed by the aggregate,

6.2.1.4 If air-entraining admixtures are required, the type, name, and dosage range to be used to achieve the specified air content, (see 6.1.4),

6.2.1.5 If chemical admixtures are required, the type, name, and dosage range to be used, and:

6.2.1.6 The type of fibers to be used and the amount in kilograms per cubic metre [pounds per cubic yard], (see Classification Section 4).

NOTE 6—The dosage of air-entraining, water-reducing (including high-range), accelerating, and retarding admixtures needed to satisfy the material performance requirements varies. Therefore, dosage ranges should be specified to ensure that the material performance requirements can be met.

NOTE 7—The purchaser, in selecting requirements for which he assumes responsibility should give consideration to requirements for workability, placeability, durability, surface texture, and density. The purchaser is referred to ACI Practices 211.1 and 211.2 for selecting proportions that will result in concrete suitable for various types of structures and conditions of exposure, and to ACI Report 544.3R[4] for selecting concrete and fiber parameters suitable for fiber-reinforced concrete. For guidance on selecting proportions for fiber-reinforced shotcrete, the purchaser is referred to ACI Reports 506.1R[5] and 506.R[6] and ACI Specification 506.2.

6.2.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of concrete, furnish a statement to the purchaser giving the sources, relative densities, sieve analyses, and saturated surface-dry masses of fine and coarse aggregates, and the amount of mixing water per cubic metre [per cubic yard] that will be used in the manufacture of each class of concrete ordered by the purchaser.

6.3 *Option B*:

6.3.1 When the purchaser requires the manufacturer to assume full responsibility for mixture proportioning (see Note 7), the purchaser shall also specify the following:

6.3.1.1 Requirements for flexural performance determined in accordance with one of the following: Test Method C 1399, C 1550 or C 1609/C 1609M, using samples obtained at the point of discharge, or when appropriate at the point of placement. At the option of the purchaser, compressive strength (Test Method C 39/C 39M) shall be specified when the flexural requirements are considered inadequate for ensuring the quality of the matrix of the fiber-reinforced concrete. Unless accelerated curing and testing in accordance with the warm water or boiling water procedures of Test Method C 684 is specified, tests shall be performed after standard moist curing in accordance with Practices C 31/C 31M at 28 days, or such other ages as are specified by the purchaser.

NOTE 8—While flexural strength at first peak is affected by the type and amount of fibers, it is more dependent on the characteristics of the mortar or concrete matrix, so it is recommended that the purchaser, when specifying flexural strength at first peak, consider factors known to influence the strength of normal concrete such as, water-cement ratio, aggregate maximum size, and the presence of chemical or supplementary cementitious materials.

6.3.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of concrete, furnish a statement to the purchaser giving the sources, relative densities, sieve analyses, and saturated surface-dry masses of fine and coarse aggregates, the dry masses of cement and supplementary cementitious materials, the type, dimensions, and weight of fibers, the quantities, types and names of chemical and air-entraining admixtures (if any), and the amount of mixing water per cubic metre [per cubic yard] that will be used in the manufacture of each class of concrete ordered by the purchaser. The manufacturer shall also furnish evidence satisfactory to the purchaser that the materials to be used and the proportions selected will produce fiber-reinforced concrete of the quality specified.

6.4 *Option C*:

6.4.1 When the purchaser requires the manufacturer to assume responsibility for mixture proportioning with the minimum allowable cement content specified (see Note 7), the purchaser shall also specify the following:

6.4.1.1 Requirements for flexural performance determined in accordance with one of the following: Test Method C 1399, C 1550, or C 1609/C 1609M, using samples obtained at the point of discharge, or when appropriate the point of placement. At the option of the purchaser, compressive strength (Test

[4] ACI 544.3R-08, "Guide for Specifying, Proportioning and Production of Fiber-Reinforced Concrete," American Concrete Institute (ACI), PO Box 9094 Farmington Hills, MI 48333-9094.

[5] ACI 506.1R-08, "Guide to Fiber-Reinforced Shotcrete," American Concrete Institute (ACI), PO Box 9094 Farmington Hills, MI 48333-9094.

[6] ACI 506R-05, "Guide to Shotcrete," American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333-9094.

www.technobetar.ir

Method C 39/C 39M) shall be specified when the flexural requirements are considered inadequate for ensuring the quality of the matrix of the fiber-reinforced concrete. Unless accelerated curing and testing in accordance with the warm water or boiling water procedures of Test Method C 684 is specified, tests shall be performed after standard moist curing in accordance with Practices C 31/C 31M at 28 days, or such other ages as are specified by the purchaser (see Note 8).

6.4.1.2 Minimum cement content in kilograms per cubic metre [pounds per cubic yard].

6.4.1.3 If admixtures are required, the type, name, and dosage to be used. The cement content shall not be reduced when admixtures are used.

NOTE 9—Option C can be distinctive and useful only if the designated minimum cement content is at about the same level that would ordinarily be required for the mechanical properties, aggregate size, and workability specified. It must be an amount that will be sufficient to ensure durability under expected service conditions, as well as satisfactory surface texture and density. For additional information refer to ACI Practices 211.1 and 211.2.

6.4.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of the concrete, furnish a statement to the purchaser giving the sources, relative densities, sieve analyses and saturated surface-dry masses of fine and coarse aggregates, the dry masses of cement and supplementary cementitious materials, the type, dimensions, and weight of fibers, the quantities, types and names of chemical and air-entraining admixtures (if any), and the amount of mixing water per cubic metre [per cubic yard] that will be used in the manufacture of each class of concrete ordered by the purchaser. The manufacturer shall also furnish evidence satisfactory to the purchaser that the materials to be used and the proportions selected will produce fiber-reinforced concrete of the quality specified.

6.5 The proportions arrived at by Options A, B, or C for each class of fiber-reinforced concrete approved for use in a project shall be assigned a designation to facilitate identification of each mixture delivered to the project. A certified copy of the proportions of all mixtures as established in Options A, B, or C shall be kept on file by the manufacturer.

6.6 The purchaser shall ensure that the manufacturer is provided copies of all reports of tests performed on concrete samples taken to determine compliance with specification requirements. Reports shall be provided on a timely basis.

7. Materials and Manufacture

7.1 In the absence of designated applicable specifications covering requirements for quality of materials, the following specifications shall govern:

7.1.1 Except for fibers, materials for the manufacture of fiber-reinforced concrete shall conform to Specification C 94/C 94M and materials for the manufacturer of fiber-reinforced concrete intended for shotcreting shall conform to Specification C 1436.

7.1.2 *Fibers*—Fibers shall be capable of producing fiber-reinforced concrete meeting the requirements of this specification. Steel fibers shall conform to Specification A 820/A 820M, alkali-resistant (AR) glass fibers shall conform to Specification C 1666/C 1666M, and cellulose fibers shall conform to Specification D 7357.

8. Measuring Materials

8.1 Except as otherwise specifically permitted by the purchaser, cement, supplementary cementitious materials, fine and coarse aggregates, mixing water, and admixtures shall be measured in accordance with the applicable requirements of Specification C 94/C 94M or Specification C 685/C 685M.

8.2 Fibers shall be batched by mass or volume with an accuracy of –3 % and +5 % of the amount required per batch.

8.3 Fibers shall be measured by mass when fiber-reinforced concrete is produced in accordance with Specification C 94/C 94M, and by volume when the fiber-reinforced concrete is produced in accordance with Specification C 685/C 685M. When the fibers are to be measured by mass, bags, boxes, or like containers are acceptable provided that such like containers are sealed by the fiber manufacturer and have the mass contained therein clearly marked. No fraction of a container delivered unsealed, or left over from previous work, shall be used unless weighed.

8.4 Prepackaged, dry, combined materials, including fibers, shall comply with the packaging and marking requirements of Specification C 387 or C 1480 and shall be accepted for use provided that after addition of water, the resulting fiber-reinforced concrete meets the performance requirements of this specification.

9. Batching Plant

9.1 Batching plant used for the preparation of batch-mixed fiber-reinforced concrete shall comply with the applicable requirements of Specification C 94/C 94M.

NOTE 10—A vibrating screen or other device for separating fibers may be required to avoid clumping of some types of fibers prior to mixing with concrete.

9.2 Batching plant used for the preparation of continuously-mixed fiber-reinforced concrete shall comply with the applicable requirements of Specification C 685/C 685M.

10. Mixing Equipment

10.1 Mixers or agitators for batch-mixed fiber-reinforced concrete shall comply with the applicable requirements of Specification C 94/C 94M.

10.2 Mixers for continuously mixed fiber-reinforced concrete shall comply with the applicable provisions of Specification C 685/C 685M.

11. Mixing and Delivery

11.1 Batch-mixed fiber-reinforced concrete, whether prepared on site or at a location remote from the site, shall be mixed and delivered to the point designated by the purchaser in accordance with the applicable requirements of Specification C 94/C 94M including the requirements for uniformity in the Annex.

11.2 Continuously mixed fiber-reinforced concrete, whether prepared on site or at a location remote from the site, shall be mixed and delivered to the point designated by the purchaser in

www.technobetar.ir

TABLE 1 Recommended Total Air Content for Air-Entrained Concrete[A,B]

Exposure Condition[C]	Total Air Content, %						
	Nominal Maximum Sizes of Aggregate, mm [in.]						
	9.5 [⅜]	12.5 [½]	19.0 [¾]	25.0 [1]	37.5 [1½]	50.0 [2]	75.0 [3]
Mild	4.5	4.0	3.5	3.0	2.5	2.0	1.5
Moderate	6.0	5.5	5.0	4.5	4.5	4.0	3.5
Severe	7.5	7.0	6.0	6.0	5.5	5.0	4.5

[A] For air-entrained concrete, when specified.
[B] Unless exposure conditions dictate otherwise, air contents recommended above may be reduced by up to 1 % for concretes with specified compressive strength, f'_c, of 34.5 MPa [5000 psi] or above.
[C] For description of exposure conditions, refer to ACI 211.1, Table number 5.3.3 with attention to accompanying footnotes.

accordance with the applicable requirements of Specification C 685/C 685M including the requirements for uniformity in the Annex.

11.3 Fiber-reinforced concrete shall be free of fiber balls when delivered.

12. Batch Ticket Information

12.1 The manufacturer of the fiber-reinforced concrete shall furnish to the purchaser a delivery ticket or statement of particulars on which is printed, stamped, or written, information in one of the following two alternative formats:

12.1.1 *Batch-Mixing Format*—The details identified in the applicable requirements of Specification C 94/C 94M, and details of the type, brand, and amount of fibers used.

12.1.2 *Continuous Mixing Format*—The details identified in the applicable requirements of Specification C 685/C 685M, and details of the type, brand, and amount of fibers used.

13. Inspection of Materials, Production, and Delivery

13.1 The manufacturer shall afford the inspector all reasonable access, without charge, for making necessary checks of the production facilities and for securing necessary samples to determine if the materials used in the fiber-reinforced concrete comply with the requirements of this specification. Inspection, sampling, and testing shall not interfere unnecessarily with the manufacturing and delivery operations.

14. Sampling

14.1 The contractor shall afford the inspector all reasonable access, without charge, for the procurement of samples of freshly mixed fiber-reinforced concrete at the time of placement to determine compliance with the requirements of this specification.

14.2 Samples of batch-mixed fiber-reinforced concrete shall be obtained in accordance with Practice C 172 or C 1385/C 1385M as appropriate, except that wet-sieving shall not be permitted. Sampling for uniformity tests shall be in accordance with Specification C 94/C 94M.

14.3 Samples of continuously mixed fiber-reinforced concrete shall be obtained in accordance with the applicable requirements of Specification C 685/C 685M, except that wet-sieving shall not be permitted. Sampling for uniformity tests shall be in accordance with Specification C 685/C 685M.

15. Slump and Air Content Tests

15.1 Make tests for slump and air content at the time of placement at the option of the inspector as often as necessary for control checks and acceptance purposes, and always when specimens for tests on hardened concrete are made. When water is added in accordance with the requirements of this specification (see Tolerances in Slump Section 16), repeat all tests, and use the results of the second set of tests to establish whether or not the requirements of this specification are met.

15.2 If the measured slump or air content fall outside the limits permitted by this specification, make a check test immediately on another portion of the same sample. If the results again fall outside the permitted limits, the material represented by the sample fails to meet the requirements of this specification.

16. Tolerances in Slump

16.1 Unless other tolerances are included in the project specifications, the following shall apply to all forms of fiber-reinforced concrete except dry-mix shotcrete.

16.1.1 When the project specifications for slump are written as a "maximum" or "not to exceed" requirement:

	Specified Slump	
	If 75 mm [3 in.] or less	If more than 75 mm [3 in.]
Plus Tolerance	0	0
Minus Tolerance	40 mm [1½ in.]	65 mm [2½ in.]

These tolerances apply only if one addition of water is permitted on the job provided such addition does not increase the water-cement ratio above the maximum permitted by the project specifications.

NOTE 11—The slump of a fiber-reinforced concrete is less than the slump of an otherwise identical concrete without fibers. The magnitude of the difference depends strongly on the amount and type of fibers, so it is recommended that trial mixtures representing the amount and type of fibers to be used in the work be prepared and tested to ensure that the specified slump requirements are met.

16.1.2 When the project specifications for slump are not written as a "maximum" or "not to exceed" requirement:

Tolerances for Nominal Slumps

For Specified Slump of	Tolerance
50 mm [2 in.] and less	±15 mm [½ in.]
50 to 100 mm [2 to 4 in.]	±25 mm [1 in.]
more than 100 mm [4 in.]	±40 mm [1½ in.]

16.2 Fiber-reinforced concrete shall be available within the permissible range of slump for a period of 30 min starting either on arrival at the job site or after the permitted slump adjustment, whichever is later. The first and last ¼ m^3 [¼ yd^3] discharged are exempt from this requirement. If the user is unprepared for discharge of the material at the job site, the manufacturer shall not be responsible for failure to meet slump

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:46:14 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

requirements after 30 min have elapsed beyond either the actual arrival time at the job site or the requested delivery time, whichever is later.

17. Tolerance in Air Content

17.1 When air-entrainment is specified, the total air content measured using Test Method C 173/C 173M or Test Method C 231 shall be within a tolerance of ±1.5 of the specified value in percent.

18. Acceptance Testing of Hardened Fiber-Reinforced Concrete

18.1 Obtain material for the preparation of test specimens in accordance with the sampling section of this specification.

18.2 When post-crack flexural performance is used as the basis for acceptance of fiber-reinforced concrete, make, condition, and test sets of test specimens in accordance with Test Method C 1399, C 1550 or C 1609/C 1609M as specified.

18.3 When flexural strength is used as the basis for acceptance, make and test sets of at least three test specimens in accordance with the requirements for sampling and conditioning given in Test Method C 1609/C 1609M. Test specimens representing thin sections, as defined in Test Method C 1609/C 1609M, or specimens representing fiber-reinforced shotcrete of any thickness, shall be tested as cast or placed without being turned on their sides before placement on the support system. Acceptance shall not be based on flexural strength alone when post-crack performance is important.

NOTE 12—Test Method C 1609/C 1609M provides for the determination of first peak flexural strength when required by the purchaser. For many type-amount fiber combinations, the first peak flexural strength is not significantly greater than the peak strength in flexure.

18.4 When compressive strength is used as part of the basis for acceptance of fiber-reinforced concrete, make sets of at least two test specimens in accordance with the applicable requirements of Practices C 31/C 31M and C 192/C 192M, or Test Methods C 42/C 42M or C 1604/C 1604M and condition and test in accordance with Test Methods C 39/C 39M, C 42/C 42M, or C 1604/C 1604M. Acceptance shall not be based on compressive strength alone.

18.5 The testing laboratory performing acceptance tests shall comply with the requirements of Practice C 1077.

19. Frequency of Tests

19.1 The frequency of tests on hardened fiber-reinforced concrete shall be in accordance with the following requirements:

19.1.1 *Batch-Mixing*—Tests shall be made with a frequency of not less than one test for each 115 m^3 [150 yd^3]. Each test shall be made from a separate batch. On each day fiber-reinforced concrete is mixed, at least one test shall be made for each class of material.

19.1.2 *Continuous Mixing*—Tests shall be made for each 19 m^3 [25 yd^3] or fraction thereof, or whenever significant changes have been made in the proportioning controls. On each day fiber-reinforced concrete is mixed, at least one test shall be made for each class of material.

19.1.3 *Shotcrete*—Tests shall be made for each 38 m^3 [50 yd^3] placed using specimens sawed or cored from the structure or from corresponding test panels prepared in accordance with Practice C 1140. On each day fiber-reinforced shotcrete is prepared, at least one test shall be made for each class of material.

19.2 The representative of the purchaser shall ascertain and record the delivery-ticket number or equivalent information and the exact location in the work at which the material represented by each test is deposited.

20. Calculation of Test Results

20.1 A test result shall be based on the mean of the property values for a set of hardened concrete test specimens constituting a test unit as defined herein or in the applicable test method.

20.2 Any individual test specimen in a set constituting a test unit, as defined herein or in the applicable test method, shall be deemed defective and discarded if it shows definite evidence of improper sampling, molding, handling, curing, or testing, and the mean of the property values for the remaining test specimens shall be considered the test result. If more than one specimen in the set is deemed defective on this basis, the test result shall be rejected.

21. Performance Requirements

21.1 Unless specifically excluded by the purchaser when ordering material in accordance with Option B or C, fiber-reinforced concrete prepared in accordance with this specification shall meet the following requirements:

21.2 For post-crack flexural performance determined in accordance with Test Method C 1399, C 1550 or C 1609/C 1609M, the test results shall equal or exceed the specified values at the applicable test age.

NOTE 13—A post-crack performance requirement should not be specified when fibers are used only to control plastic shrinkage cracking.

21.3 When first-peak and peak flexural strength, in accordance with Test Method C 1609/C 1609M, or compressive strength, in accordance with Test Method C 39/C 39M, are performance requirements, the test results shall equal or exceed the specified values at the applicable test age.

21.4 When the fiber-reinforced concrete is to be exposed to cycles of freezing and thawing, and the purchaser requires evidence of satisfactory durability, such evidence shall be provided by the manufacturer. A proven record of satisfactory freeze-thaw durability for concrete with or without fibers, made using the same air content, aggregates, and mixture proportions as the fiber-reinforced concrete specified for the work, shall be considered acceptable evidence when the concrete has been in place for at least two winters. In the absence of such a record, satisfactory durability shall be demonstrated for the fiber-reinforced concrete proposed for the work by the attainment of an average durability factor of at least 80 % for a set of three specimens tested according to Procedure A of Test Method C 666/C 666M.

22. Failure to Meet Requirements

22.1 When fiber-reinforced concrete fails to meet the requirements of this specification, the manufacturer and the purchaser shall confer to determine whether agreement can be reached as to what adjustment, if any shall be made. If

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

agreement on a mutually satisfactory adjustment cannot be reached by the manufacturer and the purchaser, a decision shall be made by a panel of three qualified engineers, one of whom shall be designated by the purchaser, one by the manufacturer, and the third chosen by these two members of the panel. The question of responsibility for the cost of such arbitration shall be determined by the panel. Its decision shall be binding, except as modified by a court decision.

23. Keywords

23.1 accuracy; average residual-strength; certification; fibers; fiber-reinforced concrete; flexural parameters; materials for; scales; testing; toughness

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1116/C 1116M – 08a, that may impact the use of this specification. (Approved June 1, 2009)

(*1*) Deleted references to Test Method C 995, which was withdrawn in 2008, in 6.1.4, 15.2, 16.1, Note 11, 16.2, and Referenced Documents. Deleted 6.1.4.1. Deleted old Note 4 and renumbered subsequent notes.
(*2*) Replaced "workability" with "slump" in Sections 15 and 16.
(*3*) Revised the order of the units in Sections 6, 16, 19, and Table 1 to comply with C09's units policy.
(*4*) Updated references in Footnotes 4 and 5.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1116/C 1116M – 08, that may impact the use of this specification. (Approved December 15, 2008)

(*1*) Revised 4.1.3, 4.1.4, and 4.2 to better define what is expected in terms of resistance to deterioration.
(*2*) Revised Note 1.
(*3*) Added new 8.2 to provide batching tolerances for fibers and renumbered subsequent paragraphs.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1116/C 1116M – 06, that may impact the use of this specification. (Approved January 1, 2008)

(*1*) Added new 9.2 to add reference to continuous batching to avoid confusion as to batching and mixing.
(*2*) Revised the Terminology Section to comply with ASTM Form and Style and revised the definitions of *manufacturer* and *purchaser*.
(*3*) Extensively revised Section 4.
(*4*) Revised 5.1 and 8.3 to accommodate production of fiber-reinforced concrete in accordance with Specification C 685/C 685M.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1137 – 05

Standard Test Method for Degradation of Fine Aggregate Due to Attrition[1]

This standard is issued under the fixed designation C 1137; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method provides a procedure for indicating the relative degree to which a fine aggregate is likely to degrade due to the mixing and agitation of hydraulic cement concrete.

1.2 The values given in SI units are to be regarded as the standard. The values given in inch-pound units are for information only.

1.3 The text of this test method references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this test method.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 33 Specification for Concrete Aggregates

C 117 Test Method for Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 295 Guide for Petrographic Examination of Aggregates for Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 702 Practice for Reducing Samples of Aggregate to Testing Size

D 75 Practice for Sampling Aggregates

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Summary of Test Method

3.1 A specimen of fine aggregate, of specified grading, is subjected to vigorous agitation under water from the action of a high-speed impeller. Degradation is measured by the decrease in fineness modulus (as defined in Terminology C 125) and the increase in amount of material finer than the 75-µm (No. 200) sieve.

4. Significance and Use

4.1 The tendency of some fine aggregates, including those that comply with the requirements of Specification C 33, to degrade from the grinding action in a concrete mixer may affect mixing water demand, entrained air, and slump. When it is suspected that degradation during mixing is a problem, this test method may be useful for evaluating the extent of the problem.

4.2 This test method is of use for preliminary screening to indicate the need for further evaluation through petrographic examination (Guide C 295) or testing the quality of mortar, or concrete, or both made from the fine aggregate in question.

4.3 This test method is of use for comparing the results obtained with unknown materials against those with materials of known performance in concrete.

5. Apparatus

5.1 *Sieves*, conforming to Specification E 11: 75-µm (No. 200), 150-µm (No. 100), 300-µm (No. 50), 600-µm (No. 30), 1.18-mm (No. 16), 2.36-mm (No. 8), 4.75-mm (No. 4), and 9.5-mm (⅜-in.).

5.2 *Balance*—A balance or scale readable and accurate to 0.1 g or 0.1 % of the test specimen mass, whichever is greater, at any point within the range of use.

5.3 *Oven*—An oven of appropriate size capable of maintaining a uniform temperature of 110 ± 5 °C (230 ± 9 °F).

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved July 15, 2005. Published August 2005. Originally approved in 1990. Last previous edition approved in 1997 as C 1137 – 97.

5.4 *Attrition Device*—A stainless steel octagonal tank, 140 mm (5½ in.) high and 110 mm (4½ in.) minimum inside width, with a motor-driven 19-mm (¾-in.) vertical shaft so mounted that it can be lowered into the desired position within the octagonal tank. Mounted on the shaft there shall be three horizontal sets of six pitched stainless steel blades[3]. A lid shall be provided with a hole for the shaft. See Figs. 1 and 2.

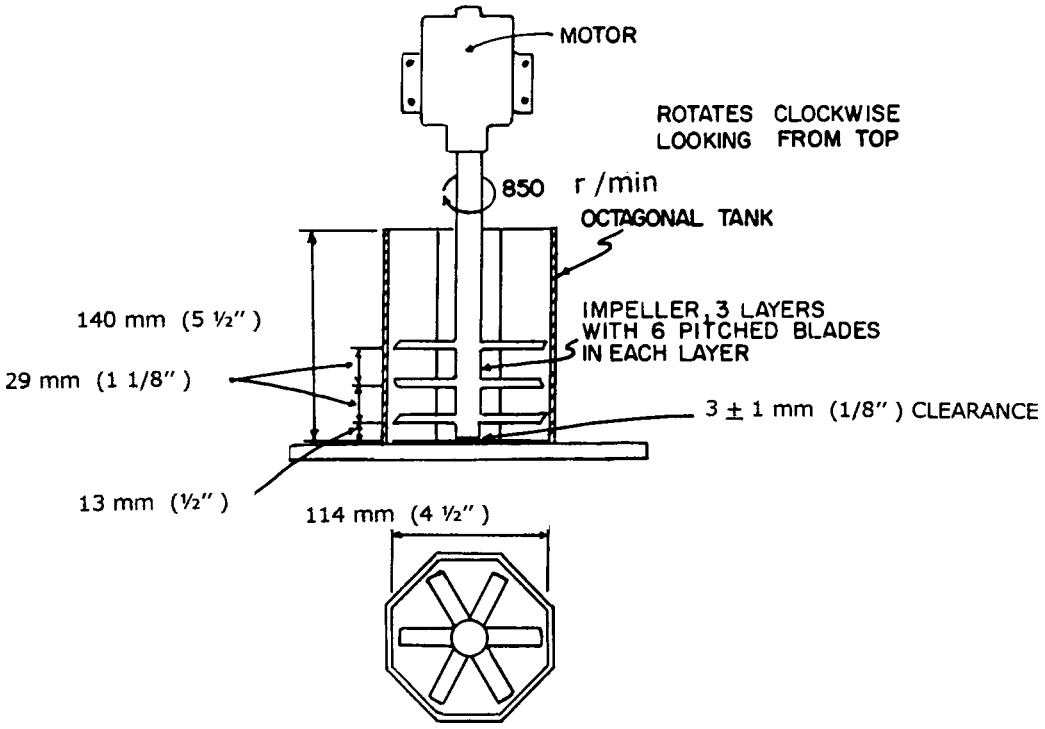

FIG. 1 Attrition Machine

5.5 *Rotating Device*—An electric motor-driven device or drill press suitable for driving the impeller clockwise as shown in Fig. 1. It shall be capable of driving the impeller at 850 ± 50 r/min with the specimen and water in the tank.

6. Sample Preparation

6.1 Sample the aggregate in accordance with Practice D 75 and reduce to test specimen size in accordance with Practice C 702.

6.2 Prepare a test specimen of 500 ± 5 g to a grading listed in Table 1. If these gradings are not practicable, it is permitted to use a grading not listed in Table 1 and compute the fineness modulus of this grading.

6.3 In preparing a test specimen, first remove material passing the 75-µm sieve by washing (in accordance with Test Method C 117), then oven dry and sieve (in accordance with Test Method C 136) into separate size fractions. Weigh and combine the fine aggregate size fractions to the selected grading.

6.4 If the test is to be performed on one of the standard gradings from Table 1, use the grading nearest that of the as-received sample. Where different fine aggregates are to be compared, use the same initial grading for each.

7. Procedure

7.1 Determine the mass of the test specimen of oven-dry fine aggregate to the nearest 0.1 g and record.

7.2 Determine the mass of the cleaned, dry impeller. Insert the container and impeller in the drill press and adjust the vertical stop on the feed to position the bottom of the impeller shaft 3 ± 1 mm (⅛ ± 1/32 in.) above the bottom of the container. Make this adjustment prior to each test before introducing the specimen. Using a funnel, place the test specimen in the container. Brush any remaining material from the funnel into the container and add 175 g ± 5 g of water. Place the lid firmly on the container to avoid loss of the fine aggregate and the water. It is permitted, as an alternative method, to add the test specimen to the container and then insert the impeller by turning the shaft by hand until the impeller penetrates through the fine aggregate.

7.3 Run the attrition device for 6 ± 1/10 min at 850 ± 50 r/min.

[3] The sole source of supply of the apparatus known to the committee at this time is Dorr-Oliver Eimco, 2850 South Decker Lake Drive, Salt Lake City, Utah, 84119, phone 801–526–2000, www.glv.com. An attrition tank with 100 mm attriting element (impeller) that can be used in a 850-r/min drill press or in a WEMCO laboratory flotation machine, parts No. 23828 (impeller), 23844 (tank), and 44519 (cover). If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

TOP VIEW—TOP IMPELLER BLADE ENDS BENT LEFT (COUNTERCLOCKWISE)

Impeller—102 mm (4 in.) diameter × 1.5 mm (No. 16 gage) thick; Three Layers Shaft—19 mm (¾ in.) diameter extending 9.5 mm (⅜ in.) below bottom layer and the ends of the blades bent to 45° pitch. Blades on the top and bottom layer bent to the left (counterclockwise) and the middle layer bent to the right (clockwise).

FIG. 2 Impeller Details

TABLE 1 Alternative Test Gradings

Sieve Size	% Passing				
	No. 1	1A[A]	No. 2	No. 2A[B]	No. 3
4.75-mm (No. 4)	100	100	100	100	100
2.36-mm (No. 8)	80	100	88	100	100
1.18-mm (No. 16)	50	60	74	80	85
600-µm (No. 30)	25	30	49	50	60
300-µm (No. 50)	10	10	20	20	30
150-µm (No. 100)	2	0	5	0	10
75-µm (No. 200)	0	0	0	0	0
Fineness Modulus	3.33	3.00	2.64	2.50	2.15

[A] Similar to No. 1 but with the fine and coarser fractions removed.
[B] Similar to No. 2 but with the fine and coarser fractions removed.

7.4 Remove the container, lid, and impeller from the drill press and place in a pan. Using a minimum amount of water, wash the test specimen from the container, impeller, and lid into the pan. Avoid loss of any portion of the test specimen.

7.5 Test the whole test specimen in accordance with Test Method C 117 and test the washed material remaining in accordance with Test Method C 136.

7.6 Determine the mass of the clean, dry impeller after the test and record its mass to detect any long-term change in the impeller.

NOTE 1—Repeated testing will cause abrasive wear to the blades of the impeller. In a study of testing 100 specimens of siliceous fine aggregate, it was found that these specimens caused sufficient wear to the impeller to result in a 14 to 25 % reduction in the ability of the apparatus to cause degradation of the aggregate[4]. Degradation was measured by the increase in amount of material passing the 75-µm (No. 200) sieve. For this reason, it is good practice to monitor change in equipment efficiency by periodically testing replicate specimens of an aggregate of known behavior in the test. Such an aggregate can be established at the time the equipment is first used and a sufficient supply retained for monitoring purposes.

8. Report

8.1 Report the following data:

8.1.1 Grading as-received,

8.1.2 Grading as-tested (from Table 1 or as otherwise specified),

8.1.3 Grading after attrition,

8.1.4 Percent finer than the 75-µm (No. 200) sieve after attrition,

8.1.5 Fineness modulus before and after attrition, and

8.1.6 The mass of the clean, dry impeller before and after the test.

9. Precision and Bias

9.1 *Within Laboratory Precision*—In a study using one test apparatus, involving six different operators, testing six specimens of three materials of different attrition loss passing the 75-µm (No. 200) sieve, the following data on repeatability were obtained:

Mean % Loss Passing 75-µm (No. 200) Sieve, by Mass	Sample Standard Deviation, % by Mass[A]	Acceptable Range of Two Results, % by Mass[A]
5.5	0.31	0.88
9.9	0.26	0.74
29.1	0.47	1.33

[A] These numbers represent, respectively, the (1s%) and (d2s%) limits as described in Practice C 670.

9.2 *Multilaboratory Precision*—Data on multi-laboratory variation are not available.

9.3 *Bias*—The procedure in this test method has no bias because the values obtained for attrition loss can be defined only in terms of the test method.

10. Keywords

10.1 agitation; attrition; concrete; degradation; fine aggregates; mixing

APPENDIX

(Nonmandatory Information)

X1. Interpretation of Results

X1.1 No specifications have been developed for results obtained with this test method. Davis et al.[5] developed the attrition test to evaluate fine aggregate degradation that might occur during mixing. Meininger[6] found that the amount of material that passed the 75-μm (No. 200) sieve might be a better indicator of fine aggregate behavior than change in fineness modulus. He found that sands that gave attrition losses [measured by material finer than 75-μm (No. 200)] greater than about 20 % were most likely to be susceptible to breakdown during concrete mixing. He also noted that such sands might still be used satisfactorily in some cases. He also found that lesser problems might be experienced with sands giving losses above about 12 %.

It has been found[4] that there is a moderate correlation between attrition loss of natural sands [material passing 75-μm (No. 200)] and the magnesium sulfate soundness loss of the sands. Crusher screenings and manufactured stone sands give considerably greater attrition losses than that obtained with natural sands of the same sulfate loss. This is due to breakage of the sharp and relatively brittle edges found in such angular products. It should be noted that for a given material, attrition loss of coarse graded sand [as measured by material passing 75-μm (No. 200)] is considerably greater than that of fine graded sand [4,6].

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1137 – 97, that may impact the use of this specification. (Approved July 15, 2005)

(*1*) Revised Section 1.
(*2*) Updated Referenced Documents.
(*3*) Revised Sections 4-10.
(*4*) Added a within laboratory precision statement.
(*5*) Added an appendix to provide guidance on the interpretation of test results.

Designation: C 1138M – 05

Standard Test Method for Abrasion Resistance of Concrete (Underwater Method)[1]

This standard is issued under the fixed designation C 1138M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers a procedure for determining the relative resistance of concrete (including concrete overlays and impregnated concrete) to abrasion under water (see Note 1). This procedure simulates the abrasive action of waterborne particles (silt, sand, gravel, and other solids).

NOTE 1—Other procedures are available for measuring abrasion resistance of concrete surfaces not under water. These include Test Methods C 418, C 779, and C 944.

1.2 The values stated in acceptable metric units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 418 Test Method for Abrasion Resistance of Concrete by Sandblasting

C 642 Test Method for Density, Absorption, and Voids in Hardened Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 779/C 779M Test Method for Abrasion Resistance of Horizontal Concrete Surfaces

C 944 Test Method for Abrasion Resistance of Concrete or Mortar Surfaces by the Rotating-Cutter Method

E 18 Test Methods for Rockwell Hardness and Rockwell Superficial Hardness of Metallic Materials

3. Significance and Use

3.1 This test method is intended to qualitatively simulate the behavior of swirling water containing suspended and transported solid objects that produce abrasion of concrete and cause potholes and related effects.

3.2 This test method should provide a relative evaluation of the resistance of concrete to such action.

3.3 The results are expected to be useful in selection of materials, mixtures, and construction practices for use where such action is to be expected.

3.4 The test method is not intended to provide a quantitative measurement of the length of service that may be expected from a specific concrete.

4. Apparatus

4.1 *Rotating Device*—A drill press or similar device with a chuck capable of holding and rotating the agitation paddle under test conditions at a speed of 1200 ± 100 rpm shall be used.

4.2 *Test Container*—A steel pipe, 305 ± 6-mm (12 ± ¼-in.) inside diameter by 450 ± 25-mm (18 ± 1-in.) high, fitted with a watertight steel base shall be used (see Fig. 1).

4.3 *Agitation Paddle*—The agitation paddle shall be as shown in Fig. 2.

4.4 *Abrasive Charges*—Seventy grade 1000 chrome steel grinding balls with nominal sizes as specified in Table 1 shall be used. The steel of which the balls are made shall have a Rockwell C-scale hardness of 65 ± 5 as determined by Test Methods E 18. The balls shall have a smooth texture and no apparent mold seam (see Note 2).

NOTE 2—An abrasive charge meeting the requirements of Table 1 will have a mass of approximately 1530 to 1900 g (3.8 to 4.2 lb). When the mass of the charge approaches the lower limit, replace the undersize or underweight balls not complying with Table 1.

4.5 *Scales*—A platform scale having a capacity of at least 45 kg (100 lb) or more and accurate to within at least 5.0 g (0.01 lb) at any point within the range used in this test shall be

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.62 on Abrasion Testing.

FIG. 1 Test Apparatus

used. The scale shall be equipped with a suitable apparatus for suspending the sample in its container in water from the center of the weighing platform.

4.6 *Weighing Basket*—A wire basket or other suitable support shall be provided for weighing the specimen in water. The weighing basket shall be constructed to prevent entrapping air when it and the specimen are submerged.

4.7 *Water Tank*—A suitable watertight tank into which the basket and the specimen can be suspended below the scale shall be furnished.

4.8 *Seating Block*—A minimum of three steel blocks 25 by 25 by 25 mm (1 by 1 by 1 in.) shall be used to support the specimen.

5. Test Specimens

5.1 The test specimen shall be cylindrical in shape, having a diameter approximately 6-mm (¼-in.) less than that of the inside diameter of the test container and a height of 100 ± 13 mm (4 ± ½ in.). It may be molded from freshly mixed concrete or cored from hardened concrete (see Note 3). Cores shall be taken in accordance with Methods C 42.

NOTE 3—Specimens should be tested at an age appropriate for the material being evaluated. Most testing done to date has been done at 28 days. Concretes containing pozzolans should be tested at an age that allows development of appropriate strength. Toppings and impregnated concretes should be tested at an age appropriate for the material and in compliance with the manufacturer's recommendations. The appropriate testing age may also depend upon when the concrete will be put into service.

5.2 If the specimen has a membrane curing compound on the surface, remove it completely by steel wire brushing prior to the soaking period.

5.3 Soak the specimen in lime-saturated water or in the water to which the concrete shall be subjected in service for a minimum of 48 h prior to testing.

5.4 Determine the average diameter of the top surface of the specimen to be tested to the nearest 2 mm (1/16 in.) by averaging two diameters measured at right angles to each other. This average diameter shall be used in calculating the top surface area.

5.5 Surface dry the specimen. Determine and record the mass in air to the nearest 25.0 g (0.05 lb). Determine and record the apparent mass of the specimen immersed in water to the nearest 25.0 g (0.05 lb). The procedure of Test Method C 642 shall be followed using water at 23 ± 1.7 °C (73.4 ± 3 °F) having a density of 997 ± 2 kg/m^3. Remove all entrapped air by shaking the specimen while it is immersed in the water for weighing.

6. Procedure

6.1 Place the specimen in the test container with the surface to be tested facing up and the seating blocks in place.

6.2 Position the specimen so that its surface is normal to the drill shaft and the center of the specimen coincides with the drill shaft.

6.3 Mount the agitation paddle in the drill press. The bottom of the agitation paddle shall be 38 ± 5 mm (1½ ± ¼ in.) above the surface of the specimen.

6.4 Determine and record the mass of the abrasive charge to the nearest 10 g (0.02 lb). Place it on the surface of the specimen and add water of the same type as used in the saturation period to 165 ± 5 mm (6½ ± ¼ in.) above the surface of the specimen.

6.5 Start the paddle rotating and check that the paddle is rotating at the required speed with the paddle immersed.

6.6 Remove the specimen from the test container at the end of every 12 h of operation. Flush off the abraded material and surface dry. Determine and record the mass of the specimen in air and in water.

6.7 The standard test shall consist of six 12-h periods for a total of 72 h (see Note 4).

NOTE 4—Testing totalling 24 h generally produces significant abrasion in most concrete surfaces, but it is recommended to extend the period of simulation if more severe abrasion is desired. Additional testing time may be required for concrete that is highly resistant to abrasion.

7. Calculation

7.1 Calculate the abrasion loss as follows:

7.1.1 Calculate the volume of the specimen at any time as follows:

$$V_t = \frac{W_{air} - W_{water}}{G_w} \quad (1)$$

TABLE 1 Abrasive Charges

Number of Balls	Nominal Size	Minimum Diameter
10	1.00 in.	25.3 mm (0.95 in.)
35	0.75 in.	19.0 mm (0.70 in.)
25	0.50 in.	12.6 mm (0.45 in.)

where:
V_t = volume of the specimen at the desired time, m^3,
W_{air} = mass of the specimen in air at the desired time, kg,
W_{water} = apparent mass of the specimen in water at the desired time, kg, and
G_w = unit weight of water kg/m^3.

7.1.2 Calculate the volume of concrete lost at the end of any time increment of testing as follows:

$$VL_t = V_i - V_t \quad (2)$$

where:
VL_t = volume of material lost by abrasion at the end of the test increment in question, m^3,
V_i = volume of specimen before testing, m^3, and
V_t = volume of the specimen at the end of the test increment in question m^3.

7.2 Should it be desired to calculate the average depth of wear at the end of any time increment of testing based on volume of abraded material, it may be done as follows:

$$ADA_t = VL_t/A \quad (3)$$

where:
ADA_t = average depth of abrasion at the end of the test increment in question, m, and
A = area of top of specimen m^2.

8. Report

8.1 The report shall include the following:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:48:55 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.1.1 A plot of time versus abrasion loss of at least three individual test specimens and the average of all specimens of a type that were tested.

8.1.2 The average diameter of each specimen. The volume of each specimen at the end of each test period.

8.1.3 Relevant data as desired on the concrete represented by the specimens.

8.1.4 Mass of the grinding balls at the beginning and end of the testing.

9. Precision and Bias

9.1 *Precision*—The single laboratory coefficient of variation among test specimens made from a single batch of concrete was found to be 14.0 %. Therefore, in a properly conducted test, the range among test results from the three specimens required by the test method should be no greater than 46.2 % of their mean. (See Note 5.)[4]

NOTE 5—This number represents the 1 S limit, as defined by Practice C 670. This limit was calculated according to paragraph 3.3.2 of Practice C 670 – 91a. The variation due to making specimens from different concrete batches was found to be too small to detect.

9.2 *Bias*—No estimate of bias is being made because there is no recognized standard material for this test method.

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1009.

APPENDIX

(Nonmandatory Information)

X1. PRECISION OF THE TEST METHOD

X1.1 This test method was originally developed and used by the Corps of Engineers.[5] When developed and during its initial use, abrasion loss as determined by the test method was expressed as a percentage of the original mass of the specimen. For tests so conducted the single-operator standard deviation (1S) was found to be 0.42 % and hence, the results of two properly conducted tests by the same operator on specimens from the same batch of concrete should not differ by more than 1.18 % (D2S). These limits were calculated as described in Practice C 670.

X1.2 The test method was revised to reflect loss in terms of volume rather than in terms of mass to eliminate differences in results resulting from the allowable variations in specimen size.

Designation: C 1138M – 05

Standard Test Method for Abrasion Resistance of Concrete (Underwater Method)[1]

This standard is issued under the fixed designation C 1138M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers a procedure for determining the relative resistance of concrete (including concrete overlays and impregnated concrete) to abrasion under water (see Note 1). This procedure simulates the abrasive action of waterborne particles (silt, sand, gravel, and other solids).

NOTE 1—Other procedures are available for measuring abrasion resistance of concrete surfaces not under water. These include Test Methods C 418, C 779, and C 944.

1.2 The values stated in acceptable metric units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 418 Test Method for Abrasion Resistance of Concrete by Sandblasting

C 642 Test Method for Density, Absorption, and Voids in Hardened Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 779/C 779M Test Method for Abrasion Resistance of Horizontal Concrete Surfaces

C 944 Test Method for Abrasion Resistance of Concrete or Mortar Surfaces by the Rotating-Cutter Method

E 18 Test Methods for Rockwell Hardness and Rockwell Superficial Hardness of Metallic Materials

3. Significance and Use

3.1 This test method is intended to qualitatively simulate the behavior of swirling water containing suspended and transported solid objects that produce abrasion of concrete and cause potholes and related effects.

3.2 This test method should provide a relative evaluation of the resistance of concrete to such action.

3.3 The results are expected to be useful in selection of materials, mixtures, and construction practices for use where such action is to be expected.

3.4 The test method is not intended to provide a quantitative measurement of the length of service that may be expected from a specific concrete.

4. Apparatus

4.1 *Rotating Device*—A drill press or similar device with a chuck capable of holding and rotating the agitation paddle under test conditions at a speed of 1200 ± 100 rpm shall be used.

4.2 *Test Container*—A steel pipe, 305 ± 6-mm (12 ± ¼-in.) inside diameter by 450 ± 25-mm (18 ± 1-in.) high, fitted with a watertight steel base shall be used (see Fig. 1).

4.3 *Agitation Paddle*—The agitation paddle shall be as shown in Fig. 2.

4.4 *Abrasive Charges*—Seventy grade 1000 chrome steel grinding balls with nominal sizes as specified in Table 1 shall be used. The steel of which the balls are made shall have a Rockwell C-scale hardness of 65 ± 5 as determined by Test Methods E 18. The balls shall have a smooth texture and no apparent mold seam (see Note 2).

NOTE 2—An abrasive charge meeting the requirements of Table 1 will have a mass of approximately 1530 to 1900 g (3.8 to 4.2 lb). When the mass of the charge approaches the lower limit, replace the undersize or underweight balls not complying with Table 1.

4.5 *Scales*—A platform scale having a capacity of at least 45 kg (100 lb) or more and accurate to within at least 5.0 g (0.01 lb) at any point within the range used in this test shall be

Designation: C 1140 – 03a

Standard Practice for Preparing and Testing Specimens from Shotcrete Test Panels[1]

This standard is issued under the fixed designation C 1140; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers procedures for preparing test panels of dry-mix or wet-mix shotcrete and for testing specimens sawed or cored from the panels.

1.2 The values stated in inch-pound units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete[2]

C 78 Test Method for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)[2]

C 138/C 138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete[2]

C 143/C 143M Test Method for Slump of Hydraulic Cement Concrete[2]

C 171 Specification for Sheet Materials For Curing Concrete[2]

C 231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method[2]

C 642 Test Method for Density, Absorption, and Voids in Hardened Concrete[2]

C 995 Test Method for Time of Flow of Fiber-Reinforced Concrete Through Inverted Slump Cone[2]

C 1018 Test Method for Flexural Toughness and First-Crack Strength of Fiber-Reinforced Concrete (Using Beam with Third-Point Loading)[2]

C 1399 Test Method for Obtaining Average Residual-Strength of Fiber-Reinforced Concrete[2]

3. Summary of Practice

3.1 Test panels of shotcrete are fabricated using the personnel, materials, equipment, and shooting positions under investigation. Specimens are core drilled or sawed from these panels for evaluation.

4. Significance and Use

4.1 Specimens obtained in accordance with the procedure section of this practice may be used for preconstruction studies of shotcrete mixtures, to qualify nozzlemen and equipment, or for quality control, or compressive or flexural strength testing, during the progress of a project.

5. Test Panels

5.1 *Forms for Panels*:

5.1.1 The form for receiving the shotcrete shall be either wood or steel construction and sufficiently rigid to prevent dislodging of the shotcrete through vibration or deformation. The form shall have a minimum width and length of 24 in. (610 mm) and a minimum depth of 3½ in. (89 mm) with either square or sloped sides. Larger panels may be desirable for qualifying nozzlemen, equipment, or mixture design.

5.1.1.1 *Wood Forms*—Wood forms shall have a back made from plywood at least ¾ in. (19 mm) thick. Side pieces shall be made of lumber with a minimum thickness of 1½ in. (38 mm).

5.1.1.2 *Steel Forms*—Steel forms shall be made using material having a minimum thickness of 3⁄16 in. (5 mm).

6. Materials

6.1 *Dry-Mix Process*—The test mixture shall be of the same materials and proportions being used or proposed for use in the structure.

6.2 *Wet-Mix Process*—The test mixture shall be of the specified slump and have the specified air content and unit weight, or, when fibers are used, the specified time of flow, air

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.46 on Shotcrete.

Current edition approved March 10, 2003. Published April 2003. Originally approved in 1989. Last previous edition approved in 2003 as C 1140-03.

www.technobetar.ir

content, and unit weight as the mixture being used or proposed for use in the structure. Determine the air content by Test Method C 231, the unit weight by Test Method C 138/C 138M, slump by Test Method C 143/C 143M and time of flow by Test Method C 995 prior to shooting the panels.

7. Procedure

7.1 *Number of Panels*—A separate panel shall be shot for each mixture representing each admixture type or dosage, fiber type or fiber volume and each shooting position anticipated in the structure (that is, slab, slopes, vertical, and overhead).

7.2 The admixture, if one is used, shall be added in the same manner and dosage as proposed for use or used in the structure.

7.3 Reinforcing bars shall be included in test specimens used for bar encapsulation studies and qualification of personnel, equipment, and application techniques. Reinforcing bars should be excluded from samples prepared for compressive, flexural, and tensile tests. If fibers are added to the shotcrete, they should be included in the respective test samples.

7.4 *Shotcreting*:

7.4.1 *Equipment*—Shotcrete shall be applied using the equipment, water pressure, and air pressure to be used on the structure.

7.4.2 *Personnel*—The operating personnel (nozzlemen and gun operator) shall be those to be used on the structure.

7.4.3 *Application of Shotcrete*—Apply the shotcrete to the panel forms in the manner as proposed for use or as is being done in the structure. Dampen wood forms just prior to shotcreting.

8. Curing

8.1 To prevent evaporation of water from the panels, the panels shall be covered and tightly wrapped (as soon after fabrication as is safe to prevent damage) with a sheet of material meeting requirements of Specification C 171 or stored in a moist room meeting the requirements of Specification C 511. Field cured specimens shall be moved to the laboratory just prior to testing.

8.2 Latex admixed shotcrete panels shall be moist-cured for 24 h and then air-dried for the balance of the curing cycle.

9. Obtaining and Testing Specimens

9.1 Specimens shall be obtained from panels by drilling cores or sawing beams in accordance with Test Method C 42/C 42M, or by sawing cubes in accordance with Test Method C 513. Samples to be cored or sawed shall be removed from the central portion of the specimen. Samples shall not be taken from the shotcrete in the space equal to the depth plus 1 in. (25.4 mm) from the outside edges. For 3½ in. (89 mm) deep, 24 × 24 in. (610 × 610 mm) forms, this corresponds to 4½ in. (114 mm) from the inside of the bottom corner formed by the base of the form, resulting in a sample area of 15 × 15 in. (381 × 381 mm). Cores and beams shall be free from corrugations and striations caused by uneven sawing or coring. It is recommended that all flat surfaces be sawed to ensure parallel and smooth surfaces. Cores shall be drilled and tested for compressive strength perpendicular to the surface of the panel. Cubes and beams may be tested either perpendicular or parallel to the surface of the panel. The direction of testing can influence the results and shall be specified. Proper handling of freshly applied specimens requires they be protected from damage due to extremes of temperature and vibrating movements, shaking, or shock during the hydration process. Beams shall be tested in accordance with Test Method C 78 except that beams of fiber-reinforced concrete shall be tested in accordance with Test Method C 1018 or Test Method C 1399.

9.1.1 *Age*—Specimens shall be obtained from panels and tested at designated ages. Unless moisture conditioning is specified, the specimens shall be obtained from panels no more than 2 h before being tested.

9.1.2 *Conditioning*—When moisture conditioning is specified, it shall be in accordance with the provisions of Test Method C 42/C 42M unless otherwise specified by the purchaser.

9.2 The density, absorption, and voids shall be determined in accordance with the provisions of Test Method C 642. Data obtained in flexural tests shall be treated in accordance with Test Methods C 78, C 1018 or C 1399.

NOTE 1—If the purchaser requests it, the air content of the hardened shotcrete may be determined by Test Method C 457.

10. Calculation

10.1 The length to diameter correction factor found in Test Method C 42/C 42M shall be applied to compressive strengths. For sawed cubes, compressive strengths shall be multiplied by a correction factor of 0.85 to obtain equivalent strength of drilled cores.

11. Report

11.1 The report shall include the following data pertinent to the variables or combinations of variables studied in the tests:

11.1.1 Type and proportions of cement and admixture, fine and coarse aggregate including maximum size and grading, free water content, in the case of wet-mix shotcrete, and temperature.

11.1.2 Type and proportion of any fibers used.

11.1.3 Position of panel as shot.

11.1.4 Type of shotcrete, that is, wet or dry.

11.1.5 Name of nozzleman and gun operator.

11.1.6 Specimen size and moisture conditioning.

11.1.7 Direction of testing relative to panel surface.

11.1.8 Unit weight, air content, absorption and voids, slump, and time of flow, if applicable.

11.1.9 Strength and other mechanical properties evaluated and test methods used, and correction factors applied.

12. Precision and Bias

12.1 The precision and bias of tests conducted on specimens prepared according to this practice will be that of the referenced test methods.

13. Keywords

13.1 beams; cores; cubes; shotcrete; test panels

Designation: C 1141 – 06

Standard Specification for Admixtures for Shotcrete[1]

This standard is issued under the fixed designation C 1141; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers materials proposed for use as admixtures to be added to a portland-cement shotcrete mixture for the purpose of altering the properties of the mixture.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in inch-pound units are to be regarded as the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 138/C 138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

C 173/C 173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C 183 Practice for Sampling and the Amount of Testing of Hydraulic Cement

C 231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method

C 260 Specification for Air-Entraining Admixtures for Concrete

C 311 Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete

C 494/C 494M Specification for Chemical Admixtures for Concrete

C 618 Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

C 979 Specification for Pigments for Integrally Colored Concrete

C 989 Specification for Ground Granulated Blast-Furnace Slag for Use in Concrete and Mortars

C 1240 Specification for Silica Fume Used in Cementitious Mixtures

C 1398 Test Method for The Laboratory Determination of the Time of Setting of Hydraulic-Cement Mortars Containing Additives for Shotcrete by the Use of Gillmore Needles

C 1438 Specification for Latex and Powder Polymer Modifiers for Hydraulic Cement Concrete and Mortar

D 98 Specification for Calcium Chloride

2.2 *ACI Documents:*

318 Building Code Requirements for Reinforced Concrete[3]

3. Terminology

3.1 The terms used in this standard are defined in Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *dry-mix shotcrete*—Shotcrete in which most of the mixing water is added at the nozzle.

3.2.2 *shotcrete*—Mortar or concrete pneumatically projected at high velocity onto a surface.

3.2.3 *wet-mix shotcrete*—Shotcrete in which most of the ingredients, including the water, are mixed prior to introduction into the delivery hose.

4. Classification

4.1 This specification recognizes grades of admixtures, used in shotcrete made by either of two processes, as follows:

4.1.1 *Type I*—Dry mix shotcrete.

4.1.1.1 *Grade 1*—Accelerating admixture, conventional.

4.1.1.2 *Grade 2*—Retarding admixture.

4.1.1.3 *Grade 3*—Pozzolanic admixture.

4.1.1.4 *Grade 4*—Metallic iron admixture.

4.1.1.5 *Grade 5*—Coloring admixture.

4.1.1.6 *Grade 6*—Organic polymer admixture.

4.1.1.7 *Grade 7*—Not applicable.

4.1.1.8 *Grade 8*—Not applicable.

4.1.1.9 *Grade 9*—Accelerating admixture, quick-setting.

4.1.2 *Type II*—Wet-mix shotcrete.

4.1.2.1 *Grade 1*—Accelerating admixture, conventional.

4.1.2.2 *Grade 2*—Retarding admixture.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.46 on Shotcrete.

Current edition approved June 1, 2006. Published June 2006. Originally approved in 1989. Last previous edition approved in 2001 as C 1141 – 01.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

4.1.2.3 *Grade 3*—Pozzolanic admixture.
4.1.2.4 *Grade 4*—Metallic iron admixture.
4.1.2.5 *Grade 5*—Coloring admixture.
4.1.2.6 *Grade 6*—Organic polymer admixture.
4.1.2.7 *Grade 7*—Water reducing admixture.
4.1.2.8 *Grade 8*—Air-entraining admixture.
4.1.2.9 *Grade 9*—Accelerating admixture, quick-setting.

4.1.3 Each of the above grades is further classified by identifying it according to the following classes:
4.1.3.1 *Class A*—Liquid.
4.1.3.2 *Class B*—Non-liquid.

5. Ordering Information

5.1 The purchaser shall include the following information in the contract or purchase order, if applicable:
5.1.1 The specification designation and date of issue,
5.1.2 Type of shotcrete, grade and class of admixture,
5.1.3 Quantity of admixture required,
5.1.4 Special packaging and package marking requirements,
5.1.5 Special sampling for inspection requirements, and
5.1.6 Any supplementary requirements.

6. Requirements

6.1 Shotcrete admixtures shall conform to the requirements for the applicable type and grade as given in Table 1.

6.2 At the request of the purchaser, the manufacturer shall state in writing that the admixture supplied is essentially identical in concentration, composition, and performance to the admixture previously tested under this specification and found to comply with the applicable requirements thereof.

6.3 Requirements for establishing compositional or chemical equivalence of a lot or of a subsequent lot relative to a previous lot that was subjected to quality tests and found to comply with the applicable requirements may be determined by agreement between the purchaser and the manufacturer. At the request of the purchaser, the manufacturer shall recommend appropriate test procedures, such as infrared spectrophotometry, pH value, and solids content, for establishing the equivalence of material from different lots or different portions of the same lot.

6.4 At the request of the purchaser, the manufacturer shall state in writing the chloride content of the admixture.

NOTE 1—Ultraviolet absorption of solutions and infrared spectroscopy of dried residues have been found to be valuable for these purposes. The specific procedures to be employed and the criteria to establish equivalence should be stipulated with due regard to the composition and properties of the sample.

NOTE 2—Admixtures containing relatively large amounts of chloride ions may make embedded metals susceptible to corrosion when moisture and oxygen are present in hardened shotcrete.

7. Sampling

7.1 Access shall be provided to the purchaser for careful sampling, either at the point of manufacture, or at the site of the work, as may be specified by the purchaser.

7.2 Samples shall be either grab or composite samples, as specified or required by this specification. A grab sample is one secured in a single operation. A composite sample is one obtained by combining three or more grab samples.

TABLE 1 Shotcrete Admixture Requirements

Type I—Dry-Mix Shotcrete

Grade	Admixture	ASTM Standard	Other Limits
1	Accelerating, conventional	D 98, C 494 Type C or E	
2	Retarding	C 494 Type B or D	
3	Pozzolanic	C 618, C 989, C 1240	
4	Metallic iron	Not established	The metallic particles shall be ground iron free from rust, oil, foreign materials, and nonferrous metal particles. The grading of the metallic aggregates shall be as follows when tested according to C 136: U.S. Sieve No. — %Passing 4.75 mm (No. 4) — 100 2.36 mm (No. 8) — 90–100 1.18 mm (No. 16) — 70–85 600 µm (No. 30) — 20–35 300 µm (No. 50) — 0–10 150 µm (No. 100) — 0–5
5	Coloring	C 979	Even when using materials conforming to C 979, it may be difficult to obtain uniformity of coloring because of the placement procedures in dry-mix shotcreting.
6	Organic Polymer	C 1438	
9	Accelerating, quick-setting	C 1398	Initial time of setting 1 to 3 min and final time of setting not more than 12 min in two of every three tests and chloride llmits of ACI 318 shall not be exceeded.

Type II—Wet-Mix Shotcrete

Grade	Admixture	ASTM Standard	Other Limits
1	Accelerating, conventional	D 98, C 494 Types C or E	
2	Retarding	C 494, Type B, D or G	
3	Pozzolanic	C 618, C 989, C 1240	
4	Metallic iron	Not established	See Type I, Grade 4
5	Coloring	C 979	
6	Organic Polymer	C 1438	
7	Water reducing	C 494, Types A, D, E, F, or G	
8	Air-entraining	C 260	
9	Accelerating, quick-setting	C 1398	See Type I, Grade 9

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.3 The sample size for each class of admixture shall be as follows:

7.3.1 *Class A Liquid Admixtures*:

7.3.1.1 Liquid admixtures shall be agitated thoroughly immediately prior to sampling. Individual grab samples shall represent not more than 2500 gal (9500 L) of admixture and shall have a volume of at least 1 qt (1 L). A minimum of four grab samples shall be taken from different locations well distributed throughout the quantity to be represented. Composite samples shall be prepared by thoroughly mixing the selected grab samples, and the resultant mixture sampled to provide at least 1 gal (4 L) for testing.

7.3.1.2 Admixtures in bulk storage tanks shall be sampled equally from the upper, intermediate, and lower levels by means of drain cocks in the sides of the tanks, or a weighted sampling bottle fitted with a stopper that can be removed after the bottle is lowered to the desired depth.

7.3.1.3 Samples shall be packaged in impermeable, airtight containers which are resistant to attack by the admixture.

7.3.2 *Class B Non-liquid Admixtures*:

7.3.2.1 Individual grab samples (except pozzolanic) shall not represent more than 2 tons (2 Mg) of admixture and shall weigh at least 2 lb (1 Kg). A minimum of four grab samples shall be taken from different locations well distributed throughout the quantity to be represented. Composite samples shall be prepared by thoroughly mixing the selected grab samples, and the resultant mixture sampled to provide at least 5 lb (2.1 Kg) for testing. Grading of composite samples shall be determined for each 2 tons (2 Mg) of Grade 4 metallic iron admixtures shipped.

7.3.2.2 Pozzolanic admixtures shall be sampled and tested in accordance with the requirements established in Test Methods C 311.

7.3.2.3 Samples of packaged admixtures shall be obtained by means of a tube sampler as described in Practice C 183.

7.3.2.4 When recommended by the manufacturer, the entire sample of an admixture shall be dissolved in water prior to testing.

7.3.2.5 Samples shall be packaged in moisture-proof, airtight containers.

8. Number of Tests and Retests

8.1 The number of tests and retests to be performed on specified materials shall be the number stipulated in the referenced ASTM standard.

9. Specimen Preparation

9.1 The specimens for tests shall be prepared as required by the particular test method referenced by the ASTM specification relating to the particular admixture.

NOTE 3—It is recommended that, whenever practicable, tests with the admixture be made using all of the ingredients of the shotcrete proposed for the specified work, because the effect produced by the admixture may vary with the properties of the other ingredients of the concrete.

10. Inspection

10.1 Inspection of the material shall be agreed upon between the purchaser and supplier as part of the purchase contract.

11. Rejection

11.1 The shotcrete admixture may be rejected if it fails to meet any of the applicable requirements of this specification. See Table 1.

11.2 An admixture stored at the point of manufacturer for more than six months prior to shipment or an admixture in local storage by a vendor for more than six months after completion of tests, may be retested before use and may be rejected if it fails to conform to any of the applicable requirements of this specification.

11.3 Packages or containers varying more than 2 % from the specified weight or volume shall be rejected. If the average weight or volume of 50 packages taken at random is less than that specified, the entire shipment shall be rejected.

11.4 When the admixture is to be used in non-air-entrained wet-mix shotcrete, it shall be rejected if the tested shotcrete containing the admixture has an air content greater than 5 %. When the admixture is to be used in air-entrained wet-mix shotcrete, it shall be rejected if the tested shotcrete containing the admixture has an air content greater than 12 % or less than 5 %. The air content shall be determined on a sample taken prior to shooting in accordance with either of Test Methods C 138, C 173 or C 231.

11.5 Rejection and reason(s) for rejection shall be reported to the producer or supplier promptly in writing.

12. Certification

12.1 When specified in the purchase order or contract, a certificate shall be furnished to the purchaser that the material has been tested in accordance with this specification and found to meet the requirements. When specified in the purchase order or contract, a report of test results on samples taken from material shipped shall be furnished. The test report requested in accordance with the purchase order shall be furnished within 60 days after shipment of the order.

13. Product Marking

13.1 When the admixture is delivered in packages or containers, the proprietary name of the admixture, the type, grade, and class under this specification, and the net weight or volume shall be plainly marked thereon. Similar information shall be provided in the shipping paper accompanying packaged or bulk materials.

14. Supplementary Requirements

14.1 Supplementary requirements may be specified by the purchaser and apply only when they appear separately on the purchase contract or order.

14.2 Quality assurance requirements shall be specified in the purchase contract or order with a reference to a pertinent document agreed upon by the supplier and purchaser.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1141 – 01, that may impact the use of this specification. (Approved June 1, 2006)

(*1*) Replaced Test Method C 1102 with Test Method C 1398 in Table 1 and Referenced Documents.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1152/C 1152M – 04ε1

Standard Test Method for Acid-Soluble Chloride in Mortar and Concrete[1]

This standard is issued under the fixed designation C 1152/C 1152M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—A typo in the equation in paragraph 9.1 was corrected editorially February 2006.

1. Scope

1.1 This test method[2] provides procedures for the sampling and analysis of hydraulic-cement mortar or concrete for chloride that is acid soluble under the conditions of test. In most cases, acid-soluble chloride is equivalent to total chloride.

1.2 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes shall not be considered as requirements of this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other.

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 114 Test Methods for Chemical Analysis of Hydraulic Cement

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 702 Practice for Reducing Samples of Aggregate to Testing Size

C 823 Practice for Examination and Sampling of Hardened Concrete in Constructions

C 1084 Test Method for Portland-Cement Content of Hardened Hydraulic-Cement Concrete

D 1193 Specification for Reagent Water

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Significance and Use

3.1 The amount of acid-soluble chloride in most hydraulic-cement systems is equal to the total amount of chloride in the system. However, some organic substances that may be introduced into mortar or concrete contain chloride that is initially acid-insoluble that can eventually ionize and thus become acid-soluble or water-soluble after a period of exposure in the very alkaline cement system.

3.2 Sulfides are known to interfere with the determination of chloride content. Blast-furnace slag aggregates and cements contain sulfide sulfur in concentrations that can cause such interference and produce erroneously high test results. Treatment with hydrogen peroxide, as discussed in Test Methods C 114, is used to eliminate such interference.

3.3 There are aggregates that contain chloride that is not available for corrosion. Such chloride will be detected by the use of this method.[4]

4. Apparatus

4.1 *Sampling Equipment*

4.1.1 The apparatus required for obtaining samples by coring or sawing is described in Test Method C 42/C 42M.

4.1.2 Use the following apparatus for sampling by drilling (pulverization):

4.1.2.1 *Rotary Impact Drill* and drill or pulverizing bits of sufficient diameter to provide a representative sample of sufficient size for testing.

4.1.2.2 *Spoon* or other suitable means to remove pulverized sample material from drill hole without contamination.

4.1.2.3 *Sample Containers* capable of maintaining samples in an uncontaminated state.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.69 on Miscellaneous Tests.

Current edition approved June 1, 2004. Published July 2004. Originally approved in 1990. Last previous edition approved in 2003 as C 1152 – 03.

[2] This test method is based on a report by Clear, K. C., and Harrigan, E. T., "Sampling and Testing for Chloride Ion in Concrete," Report No. FHWA-RD77-85, Federal Highway Administration, Washington, DC, Aug. 1977 (Available as PB 275-428/AS National Technical Information Services).

www.technobetar.ir

4.2 *Sample Processing Apparatus*—The apparatus required for processing samples shall be chosen for its suitability for the purposes of the investigation, and frequently includes a concrete saw and one or more pulverizers.

4.2.1 Samples more than 25 mm (1 in.) in maximum dimension shall be reduced in size by use of a jaw crusher or broken into smaller pieces by hammering carefully to avoid loss of smaller pieces.

4.2.2 Crush particles less than 25 mm (1 in.) in maximum dimension using a rotating puck grinding apparatus, or by using a disk pulverizer, or mortar and pestle operated to restrict to negligible levels the loss of fine particles.

4.2.3 *Sieve*, 850-µm [No. 20], which shall comply with Specification E 11.

4.3 *Chloride Determination*

4.3.1 *Balance*, shall be capable of reproducing results within 0.0002 g with an accuracy of ± 0.0002 g. Direct-reading balances shall have a sensitivity not exceeding 0.0001 g. Conventional two-pan balances shall have a maximum sensibility reciprocal of 0.0003 g. Any rapid weighing device that may be provided, such as a chain, damped motion, or heavy riders, shall not increase the basic inaccuracy by more than 0.0001 g at any reading and with any load within the rated capacity of the balance.

4.3.2 *Stirrer*, magnetic variable speed, with a TFE-fluorocarbon coated magnetic stirring bar.

4.3.3 *Chloride, Silver/Sulfide Ion Selective Electrode*, or a silver billet electrode coated with silver chloride (see Note 1) with an appropriate reference electrode.

4.3.4 *Potentiometer*, with millivolt scale readable to 1 mV or better. A digital readout is preferred but not required.

NOTE 1—See Note 67 of Test Methods C 114 for a discussion of suitable electrodes and coating methods.

4.4 *Glazed Paper*—Paper to which fine particles do not adhere, for use as described in 7.1.

5. Reagents

5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society[5]. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.1.1 *Sodium Chloride* (NaCl).

5.1.2 *Silver Nitrate* ($AgNO_3$).

5.1.3 *Potassium Chloride* (KCl), (required for silver billet electrode only).

5.1.4 *Reagent Water* conforming to the requirements of Specification D 1193 for Type III reagent water.

5.1.5 *Sodium Chloride, Standard Solution* (0.05 N NaCl)—Dry sodium chloride at 105 to 110 °C to a constant mass. Weigh 2.9222 g of dried reagent. Dissolve in water and dilute to exactly 1 L in a volumetric flask and mix thoroughly. This solution is the standard and requires no further standardization.

5.1.6 *Silver Nitrate, Standard Solution* (0.05 N ($AgNO_3$))—Dissolve 8.4938 g of silver nitrate in water. Dilute to 1 L in a volumetric flask and mix thoroughly. Standardize against 5.00 mL of standard 0.05 N sodium chloride solution diluted to 150 mL with water following the titration test method given in 8.1 beginning with the second sentence. The exact normality shall be calculated from the average of three determinations as follows:

$$N = 0.25/V, \text{ where:}$$

N = normality of $AgNO_3$ solution,
0.25 = milliequivalents NaCl (5.0 × 0.05 N), and
V = volume of $AgNO_3$ solution, mL.

Commercially available standard solutions may be used provided the normality is checked according to the standardization procedure.

5.1.7 *Methyl Orange Indicator*—Prepare a solution containing 2 g of methyl orange per litre of 95 % ethyl alcohol.

5.1.8 *Nitric Acid* (1+1).

5.1.9 *Hydrogen Peroxide* (30 %).

6. Sampling

6.1 Select the sample per Practice C 823 or as required for the purpose of the investigation.

6.1.1 Because of the small nominal maximum size of the aggregate in a mortar, pieces of mortar having a mass of 10 g or more will be representative of a rather large volume of mortar.

6.1.2 Take concrete cores in accordance with Test Method C 42/C 42M unless otherwise specified.

NOTE 2—Concrete cores taken in accordance with Test Method C 42/C 42M may be cut longitudinally to provide a 12-mm [½-in.] thick section generally representative of the core, or cut laterally into 12-mm [½-in.] thick disks representative of the concrete core at various depths. Concrete farthest from a surface into which chloride has penetrated often provides chloride data close to that of the originally placed fresh concrete. The cooling water from core cutting may dissolve some of the chloride.

6.1.3 Powdered concrete obtained by use of a rotary impact drill is frequently used in determining chloride concentration with depth in bridge decks, pavements, etc. Such samples may be unrepresentative, especially when the nominal maximum coarse aggregate size is 25 mm [1 in.] or more. Thus, several such samples should be combined, or the data used with care. Procedures for this method of sampling are as follows:

6.1.3.1 Using the rotary impact drill, drill perpendicular to the concrete surface or parallel to the axis of a cored specimen to a specified depth or a depth sufficient to obtain a representative sample of the concrete mixture of at least 20 g of powdered material. To prevent sample contamination, avoid contact of sample with hands and other sources of perspiration. Clean all sampling tools prior to each sampling operation (See Note 3). No lubricants shall be used during drilling.

NOTE 3—Sampling tools may be cleaned with a brush, cloth, ethyl

[5] *Reagent Chemicals, American Chemical Society Specifications*, American Chemical Society, Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see *Analar Standards for Laboratory Chemicals*, BDH Ltd., Poole, Dorset, U.K., and the *United States Pharmacopeia and National Formulary*, U.S. Pharmaceutical Convention, Inc. (USPC), Rockville, MD.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

alcohol rinse, water rinse, or other method that will not contaminate the sample.

6.1.3.2 Transfer powdered sample into sample container using a spoon or other suitable means.

7. Sample Preparation

7.1 Pulverize the sample so that all the material will pass a 850-µm [No. 20] sieve. Thoroughly blend the material by coning as described in Practice C 702 from one glazed paper to another at least 10 times.

8. Procedure

8.1 Determine the mass of approximately 10 g of sample to the nearest 0.01 g and transfer to a 250 mL beaker. Disperse the sample with 75 mL of water. Slowly add 25 mL of dilute (1+1) nitric acid and stir with a glass rod, breaking up any lumps of sample. If the smell of hydrogen sulfide is strongly present, add 3 mL of hydrogen peroxide (See Note 4). Add 3 drops of methyl orange indicator to the beaker and stir. Cover the beaker with a watch glass and allow to stand for 1 to 2 minutes. If the solution above the settled solids is not pink colored, add more nitric acid dropwise while stirring until a pink or reddish color persists, then add 10 additional drops of nitric acid and stir. Heat the covered beaker rapidly to boiling and remove from hot plate. Do not allow sample to boil more than a few seconds (See Note 5). Make a blank determination using 75 mL of water in place of sample.

NOTE 4—Slags and slag cements contain sulfide sulfur in concentrations that can interfere with chloride determination unless oxidized with hydrogen peroxide.

NOTE 5—To prevent loss of chloride by volatilization, it is important to keep the beaker covered during heating and digestion. Ten seconds of boiling is sufficient. Excessive amounts of acid can erode the silver chloride coating on the silver billet electrode prematurely. A slurry that is only slightly acidic is sufficient.

8.2 Filter the sample through a 9-cm coarse-textured filter paper in a 250 mL or 500 mL Buchner funnel and filtration flask using suction. Rinse the beaker and the filter paper twice with small portions of water. Transfer the filtrate from the flask to a 250 mL beaker and rinse the flask once with water. The original beaker may be used (See Note 6). Cool the filtrate to room temperature. The volume should not exceed 175 mL.

NOTE 6—It is not necessary to clean all the slurry residue from the sides of the beaker, nor is it necessary that the filter remove all the fine material. The titration may take place in a solution that contains a small amount of solid matter.

8.3 For instruments equipped with a dial readout it is necessary to establish an approximate ″equivalence point″ by immersing the electrodes in a beaker of water and adjusting the instrument to read about 20 mV lower than mid-scale. Record the approximate millivoltmeter reading. Remove the beaker and wipe the electrodes with absorbent paper.

8.4 Pipet 2.00 mL of standard 0.05 N NaCl solution into the cooled sample beaker (See Note 7). Place the beaker on a magnetic stirrer and add a TFE-fluorocarbon coated stir bar. Immerse the electrodes into the solution, taking care that the stir bar does not strike the electrodes. Begin stirring gently. Place the delivery tip of the 10 mL buret filled to the zero mark with standardized 0.05 N $AgNO_3$ in (preferably) or above the sample solution (See Note 8).

NOTE 7—It is advisable to maintain constant temperature during measurement, as the solubility of silver chloride varies markedly with temperature at low concentrations.

NOTE 8—If the tip of the buret is out of the solution, any adhering droplet should be rinsed into the beaker with a few millilitres of water following each titration increment.

8.5 Gradually titrate, record the amount of standard 0.05 N silver nitrate solution required to bring the millivoltmeter reading to -60.0 mV of the equivalence point determined in the water.

8.6 Continue the titration with 0.20 mL increments. Record the buret reading and the corresponding millivoltmeter reading. Allow sufficient time between each addition for the electrodes to reach equilibrium with the sample solution (See Note 9).

NOTE 9—Experience has shown that acceptable readings are obtained when the minimum scale reading does not change within a 5-s period.

8.7 As the equivalence point is approached, the equal additions of silver nitrate solution will cause larger and larger changes in the millivoltmeter readings. Past the equivalence point, the change per increment will decrease. Continue to titrate until three readings past the approximate equivalence point have been recorded.

8.8 Calculate the precise equivalence point of the titration (See Note 10) and subtract the results of the water blank (See Note 11)

NOTE 10—An example of recording solution, millivolt readings, and calculation of the titration equivalence point can be found in Appendix X1 of Test Methods C 114.

NOTE 11—For nonreferee analysis, the blank may be omitted.

9. Calculation

9.1 Calculate percent chloride by mass of mortar or concrete to the nearest 0.001 % as follows:

$$C1, \% = 3.545\ [(V_1\text{-}V_2)\ N]/W,$$ where:

V_1 = millilitres of 0.05 N $AgNO_3$ solution used for sample titration (equivalence point),
V_2 = millilitres of 0.05 N $AgNO_3$ solution used for blank titration (equivalence point),
N = exact normality of 0.05 N $AgNO_3$ solution,
W = mass of sample, g.

9.2 Other useful measures of chloride concentration can be obtained as follows:

9.2.1 For calculating kilograms of chloride per cubic metre [pounds of chloride per cubic yard] of concrete (see Note 12), multiply percent chloride by $D_1/100$ or $D_2/100$ to the nearest 0.1 kg/m^3[lb/yd^3], where:

D_1 = oven dry density as determined in the section on Concrete Density in Test Method C 1084, kg/m^3[lb/yd^3].
D_2 = saturated-surface-dry density as determined in the section on Concrete Density in Test Method C 1084, kg/m^3[lb/yd^3].

www.technobetar.ir

Report which density was used in the calculation.

NOTE 12—In the case of drilled samples or where the actual density can not be determined: U = density of mortar or concrete, kg/m^3[lb/yd^3]. The air dry density of normal weight concrete for most purposes can be assumed to be 2263 kg/m^3[3815 lb/yd^3].

9.2.2 For calculating percent chloride by mass of cement, multiply percent chloride by 100/*P*, where:

P = percent cement by mass in the mortar or concrete, as known or determined in accordance with Test Method C 1084.

9.2.3 For calculating equivalent flake calcium chloride (calcium chloride dihydrate) concentrations, multiply percent chloride by 2.07.

10. Precision and Bias

10.1 *Precision*[6]

10.1.1 The single laboratory standard deviation has been found to be 0.0015 % chloride (*a*). Therefore, results of two properly conducted tests in the same laboratory on the same material should not differ by more than 0.0042 % (*b*).

10.1.2 The multilaboratory standard deviation has been found to be 0.0021 % (*a*). Therefore, results of two properly conducted tests from two different laboratories on samples of the same material should not differ by more than 0.0059 % (*b*).

NOTE 13—The numbers (*a*) and (*b*) represent, respectively, the (1S) and (D2S) limits as described in Practice C 670. This precision statement applies to tests of samples prepared and ground by a single laboratory. For this reason, test results will vary depending upon the method of obtaining the sample and the size of the sample before it is crushed and reduced to pass the 850-µm [No. 20] sieve, or pulverized. The effect may be small for large concrete cores or from mortars sectioned vertically to appreciable for large aggregate concretes sampled by rotary impact drilling with small diameter drills.

10.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

[6] A copy of the research report used to develop the precision statement is available from ASTM Headquarters. Request RR:C9-1003.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1157/C 1157M – 09

Standard Performance Specification for Hydraulic Cement[1]

This standard is issued under the fixed designation C 1157/C 1157M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This performance specification covers hydraulic cements for both general and special applications. There are no restrictions on the composition of the cement or its constituents (See Note 1).

NOTE 1—There are two related hydraulic cement standards, Specification C 150 for portland cement and Specifications C 595 for blended cements, both of which contain prescriptive and performance requirements

1.2 This performance specification classifies cements based on specific requirements for general use, high early strength, resistance to attack by sulfates, and heat of hydration. Optional requirements are provided for the property of low reactivity with alkali-silica-reactive aggregates.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. Values in SI units [or inch-pound units] shall be obtained by measurement in SI units [or inch-pound units] or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units [or SI units]. Values are stated in only SI units when inch-pound units are not used in practice.

1.4 The text of this standard refers to notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) are not requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): the Modern Metric System

3. Terminology

3.1 *Definitions:*

3.1.1 Terms used in this specification are defined in Terminology C 219.

4. Classification and Use

4.1 The types of hydraulic cement covered by this specification are given in 4.2.1-4.2.6 and are classified in accordance with specific properties defined in Table 1 (See Note 2).

NOTE 2—This specification is based on hydraulic cement attributes related to concrete performance, including strength development, sulfate resistance, heat of hydration, and resistance to alkali-silica reactivity. Concrete performance is dependent on many factors such as characteristics of other concrete materials, mix design, production, handling, and environmental conditions. For performance properties of concrete, including permeability, resistance to freeze-thaw cycles and deicer salt scaling, additional information may be obtained through the use of comparative testing of concretes.

4.2 Cements conforming to this specification shall be designated in accordance with the nomenclature with special characteristics indicated by type in accordance with the types in 4.2.1-4.2.6. When the type is not specified, the requirements of type GU shall apply.

4.2.1 *Type GU*— Hydraulic cement for general construction. Use when one or more of the special types are not required.

4.2.2 *Type HE*—High Early-Strength.

4.2.3 *Type MS*—Moderate Sulfate Resistance.

4.2.4 *Type HS*—High Sulfate Resistance.

4.2.5 *Type MH*—Moderate Heat of Hydration.

4.2.6 *Type LH*—Low Heat of Hydration.

4.3 *Additional Option*—The following additional purchase option applies for any of the principal types listed. When this option is invoked, its letter designation and title shall follow

TABLE 1 Standard Physical Requirements

Cement Type	Applicable Test Method	GU	HE	MS	HS	MH	LH
Fineness	C 204	[A]	[A]	[A]	[A]	[A]	[A]
Autoclave length change, max, %	C 151	0.80	0.80	0.80	0.80	0.80	0.80
Time of setting, vicat test[B]	C 191						
Initial, not less than, minutes		45	45	45	45	45	45
Initial, not more than, minutes		420	420	420	420	420	420
Air content of mortar volume, %	C 185	[C]	[C]	[C]	[C]	[C]	[C]
Compressive strength minimum, MPa [psi][D]	C 109/C 109M						
1 day		...	12 [1740]	...	...	...	...
3 days		13 [1890]	24 [3480]	11 [1600]	11 [1600]	5 [725]	...
7 days		20 [2900]	...	18 [2610]	18 [2610]	11 [1600]	11 [1600]
28 days		28 [4060]	...	...	25 [3620]	...	21 [3050]
Heat of hydration	C 186						
7 days, max, kJ/kg [kcal/kg]		...	...	...	...	290 [70]	250 [60]
28 days, max, kJ/kg [kcal/kg]		...	...	...	...	...	290 [70]
Mortar bar expansion	C 1038						
14 days, % max		0.020	0.020	0.020	0.020	0.020	0.020
Sulfate expansion (sulfate resistance)[E]	C 1012						
6 months, max, %		...	...	0.10	0.05	...	...
1 year, max, %		...	...	...	0.10	...	...
Optionial Physical Requirements							
Option R—Low reactivity with alkali-silica-reactive aggregates[F]	C 227						
Expansion at							
14 days, max, %		0.020	0.020	0.020	0.020	0.020	0.020
56 days, max, %		0.060	0.060	0.060	0.060	0.060	0.060
Early stiffening, final penetration, min,%	C 451	50	50	50	50	50	50
Compressive strength,[D] 28 days, min, MPa	C 109/C 109M	...	...	28.0	...	22.0	...
Drying Shrinkage, %	C 596	...[G]	...[G]	...[G]	...[G]	...[G]	...[G]

[A] Both amount retained when wet sieved on the 45-μm (No. 325) sieve and specific surface area by air permeability apparatus in m^2/kg shall be reported on all certificates of test results requested from the manufacturer.

[B] Time of setting refers to initial setting time in Test Method C 191.

[C] Air content shall be reported on all certificates of test results requested from the manufacturer. A given value in mortar does not necessarily assure that the desired air content will be obtained in concrete.

[D] Cements may be shipped prior to later-age test data being available. In such cases, the test value may be left blank. Alternatively, the manufacturer can generally provide estimates based on historical production data. The report shall indicate if such estimates are provided.

[E] In the testing of HS cement, testing at one year shall not be required when the cement meets the 6 month limit. An HS cement failing the 6 month limit shall not be rejected unless it also fails the one year limit.

[F] Compliance with this requirement shall not be requested unless the cement will be used with alkali-reactive aggregate.

[G] At the request of the purchaser, data on drying shrinkage shall be supplied.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:47:35 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

immediately after the respective letter designation and title of the principal type (for example, Type MS(R)).

4.3.1 *Option R*—Low Reactivity with alkali-silica-reactive aggregates. When tested for potential activity with reactive aggregates, the cement shall meet the requirements of Table 1 for Option R.

5. Ordering Information

5.1 Orders for cement meeting the requirements of this specification shall include:

5.1.1 The specification designation ASTM C 1157, and date,

5.1.2 The type of cement required. If no type is specified, Type GU shall be supplied.

5.1.3 A statement that an option is invoked, when such is desired, and

5.1.4 Manufacturer's certification, if required.

6. Chemical Composition

6.1 The chemical composition for the cement is not specified. However, the cement shall be analyzed for informational purposes.

7. Physical Properties

7.1 Cement of the type specified shall conform to all of the applicable standard physical requirements of Table 1.

7.2 When optional requirements are specified, the cement shall conform to the applicable optional limits of Table 1.

8. Sampling

8.1 When the purchaser requires that the cement be sampled and tested to verify compliance with this specification, sample in accordance with Practice C 183. Provide adequate facilities for sampling the finished cement. Sample the finished cement at the mill or at the site of transfer of ownership as may be specified by the purchaser.

8.2 Practice C 183 is not designed for manufacturing quality control and is not required for manufacturer's certification.

9. Test Methods

9.1 When testing a cement for compliance with this specification, or for general characterization, use the following methods, with modifications or exceptions as indicated.

9.2 *Chemical Analysis*—Chemically analyze the cement using Test Methods C 114 for major and minor oxides present in greatest quantity that together, including loss-on-ignition, constitute at least 98 % of the total mass of the cement.

9.3 *Fineness*:

9.3.1 Determine fineness by Test Method C 204.

9.3.2 Determine amount retained on the 45-μm (No. 325) sieve by Test Method C 430.

9.4 Determine autoclave expansion by Test Method C 151, except that for cements with 1-day compressive strengths anticipated to be below 3.4 MPa [500 psi], store the test specimen in a moist cabinet for a period of 48 h before demolding and measuring their length.

9.5 Determine the time of setting using Test Method C 191. Only the time of initial setting is required.

9.6 Test the mortar for air content using Test Method C 185 using the actual density of the cement, as determined by Test Method C 188, if it differs from 3.15 Mg/m^3 by more than 0.05 Mg/m^3.

9.7 Determine compressive strength using Test Method C 109/C 109M. Tests shall be conducted at each age specified in Table 1.

9.8 Determine heat of hydration using Test Method C 186.

9.9 Determine sulfate resistance using Test Method C 1012.

9.10 Determine reactivity of cement with alkali-silica-reactive aggregate (Option R) using Test Method C 227 using crushed borosilicate glass, as described in Test Method C 441, as aggregate.

9.11 Determine early stiffening using Test Method C 451 (See Note 3).

NOTE 3—Additional characterization information may be obtained with Test Method C 359.

9.12 Determine mortar bar expansion using Test Method C 1038 using a 14-day immersion period.

9.13 Determine drying shrinkage using Test Method C 596.

10. Testing Time Requirements

10.1 The purchaser shall make necessary arrangements for shipment of samples to the testing laboratory. Add the time required for transport to the laboratory to the minimum time intervals allowed from receipt of the samples by the testing laboratory.

10.2 The minimum time allowed from receipt of samples by the testing laboratory to the report of test results shall be determined by the required age of specimen at the time of testing plus seven days.

10.3 A written report of results of applicable tests shall be available within not more than three days of the interval indicated in 10.2.

10.4 These time limits do not apply to retesting or additional testing. Such testing shall not provide the basis for initial acceptance or rejection of the cement (See Note 4).

NOTE 4—Aging effects on small samples of cement stored for long periods of time can produce test results that are not representative of the fresh cement nor of cement stored in large quantity for equal periods of time.

11. Testing by the Manufacturer

11.1 Test samples of cement for compliance with this specification, and for chemical analysis and fineness. Location and frequency of sampling are at the discretion of the manufacturer and are permitted to be changed upon agreement between the purchaser and supplier. Sampling and testing shall be either part of, or in addition to, the manufacturer's normal quality control.

11.2 *Special Testing*:

11.2.1 The following requirements for testing apply only to tests for sulfate resistance and low reactivity with alkali-silica-reactive aggregates.

11.2.1.1 For sulfate resistance of Types MS and HS and for Option R of any cement, make tests at least once every 12 months.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

1. Retest if the amount of an ingredient making up 10 % by mass or more of the cement is changed by ± 5 % or more by mass (See Note 5).

NOTE 5—For example, if the cement met the applicable requirement with a slag or fly ash content of 25 % by mass, retesting is required if the slag or fly ash content is changed beyond the range of 20 to 30 %.

2. Retest if the amount of an ingredient making up less than 10 % by mass of the cement is changed by ± 50 % or more of the amount previously shown to satisfy the applicable requirements (See Note 6).

NOTE 6—For example, if the cement met the applicable requirement with a silica fume content of 5 % by mass, retesting is required if the silica fume content is changed beyond the range of 2.5 to 7.5 %.

3. Retest if the mass % of SiO_2 or CaO in the cement, or if the mass % of CaO or SiO_2 in an ingredient making up 10 % by mass or more of the cement, is changed by ± 3 % or more by mass (See Note 7).

NOTE 7—For example, if the SiO_2 content of the cement met the requirement at 20 % by mass of the cement, retesting is required if the SiO_2 content changes beyond the range of 17 to 23 %.

12. Inspection

12.1 Inspection of the material shall be as agreed upon between the purchaser and the seller as part of the purchase contract.

13. Rejection

13.1 At the option of the purchaser, material that fails to conform to the applicable requirements of this specification for the type specified shall be rejected. Report rejection to the manufacturer or supplier promptly and in writing, stating the specific reasons for rejection.

13.2 At the option of the purchaser, packages more than 2 % below the mass marked thereon shall be rejected, and if the average mass of packages in any shipment, as shown by determining the mass of 50 packages taken at random, is less than that marked on the packages, reject the entire shipment.

13.3 At the option of the purchaser, bulk cement remaining in storage for more than six months after testing, or packaged cement remaining in the possession of a vendor for more than three months, shall be sampled and retested and rejected if it fails to meet any of the applicable requirements of this specification.

14. Certification

14.1 Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at the time of shipment stating the results of tests made on samples of the material taken during production or transfer and certifying that the cement conforms to applicable requirements of this specification.

14.2 At the request of the purchaser in the contract or order, the manufacturer shall state in writing the types and amounts of the ingredients used in manufacture of the hydraulic cement.

14.3 *Sulfate Resistance (Types MS and HS) and Low Reactivity with Aggregates (Option R)*—When specified, results from the tests demonstrating compliance with this specification shall be available for inspection and the manufacturer's report shall state that the applicable requirements of this specification for those properties have been met.

15. Package Marking

15.1 When the cement is delivered in packages, words stating the type of cement, the name and brand of manufacturer, the mass of cement contained therein, and a list of ingredients, using generic names in decreasing order of abundance (See Note 8), shall be plainly marked on each package. Provide similar information with the manufacturer's certification accompanying the shipment of packaged or bulk cement.

NOTE 8—The following list contains suggested generic names for some possible ingredients of hydraulic cements. The list is representative and is not inclusive.

Class of Ingredient	Examples of Generic Terms
Cement	Portland cement, portland cement clinker.
Calcium Ingredient	Calcium carbonate, limestone, lime, hydrated lime, cement kiln dust (CKD).
Pozzolan	Class F fly ash, Class C fly ash, uncalcined natural pozzolan, calcined natural pozzolan, silica fume.
Slag	Granulated iron blast-furnace slag.
Additions	Calcium sulfate, water reducer, accelerator, retarder, water-reducing retarder, air-entraining addition, processing addition.

16. Storage

16.1 The cement shall be stored in such a manner as to permit reasonable access for proper inspection and identification of each shipment and in a suitable weather-tight building, container, or package that will protect the cement from dampness and minimize warehouse set.

17. Uniformity of Source

17.1 Upon request of the purchaser in the contract or order, the manufacturer shall provide a report on the uniformity of strength of cement from the source.

18. Keywords

18.1 blended hydraulic cement; hydraulic cement; performance

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this performance specification since the last issue, C 1157 – 08a, that may impact the use of this performance specification. (Approved July 1, 2009)

(*1*) Revised the standard as a dual units performance specification.

(*2*) Revised the minimum strength requirements in Table 1.

Committee C01 has identified the location of selected changes to this performance specification since the last issue, C 1157 – 08, that may impact the use of this performance specification. (Approved December 15, 2008)

(*1*) Revised Table 1.

Committee C01 has identified the location of selected changes to this performance specification since the last issue, C 1157 – 03, that may impact the use of this performance specification. (Approved September 1, 2008)

(*1*) The standard was heavily revised throughout to improve readability, flexibility for manufacturers, and quality assurance.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1164 – 92 (Reapproved 2003)

Standard Practice for Evaluation of Limestone or Lime Uniformity From a Single Source[1]

This standard is issued under the fixed designation C 1164; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice is intended for use in instances where the purchaser desires information on the uniformity of limestone or lime produced at a single source. It is intended that this test method normally be used for the predominant material manufactured at a plant. Guidelines for sampling, testing and presentation of results (Table 1) are given.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime[2]

C 50 Methods of Sampling, Inspection, Packing, and Marking of Lime and Limestone Products[2]

C 51 Terminology Relating to Lime and Limestone (As Used by the Industry)[2]

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone[2]

C 141 Specification for Hydraulic Hydrated Lime for Structural Purposes[2]

3. Terminology

3.1 *Definitions:*

3.1.1 For definitions of terms relating to this practice refer to Terminology C 51.

4. Significance and Use

4.1 This practice is designed to present in a standardized format information on the variability of limestone or lime from a single source over a period of time. It can be applied to all materials covered in Test Methods C 25 and C 110, and Specification C 141.

TABLE 1 High Calcium Quicklime January 1989

5. Sampling

5.1 The sampling shall be done in accordance with Methods C 50.

5.2 All sampling shall be performed by personnel qualified by specific training for this purpose.

5.3 Data points shall be an average of three or more separate determinations relative to a specified unit of time. For example: (*1*) *n* determinations for daily average, (*2*) daily determinations for weekly average.

5.4 The samples shall be identified by the date or dates that the represented material was obtained.

6. Procedure

6.1 The minimum amount of testing (see 5.3) and the type of test(s) to be performed should be agreed upon by the purchaser and producer.

NOTE 1—A single daily analysis does not necessarily characterize a

[1] This practice is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.11 on Statistics.

Current edition approved Feb. 15, 1992. Published April 1992. Originally approved in 1990. Last previous edition approved in 1991 as C 1164 – 91.

www.technobetar.ir

product. A minimum of three analyses is more reasonable.

6.2 It is desirable that all tests used in a single evaluation be performed in the same laboratory, preferably by the same person, in order for the results to be comparable.

NOTE 2—In order to obtain comparable results when exchanging samples between laboratories, methods used in preparation, handling and storage of those samples must be uniform.

6.2.1 When separate evaluations of a single source are made by two or more laboratories, additional tests of a standard material or exchanged portions of the same sample may be necessary to determine differences in testing that are likely to be obtained in the different laboratories. Three or more batches may be necessary to obtain comparison between laboratories.

6.2.2 Where a within-laboratory testing standard deviation history has not been established, duplicate tests made from a single sample are required to determine the effect of testing variation on the uniformity of results made in a single laboratory.

7. Test Method

7.1 The chemical analysis of quicklime, hydrated lime, and limestone shall be determined in accordance with Test Methods C 25.

7.2 The physical analysis of quicklime, hydrated lime, and limestone shall be determined in accordance with Test Methods C 110.

7.3 The analysis of hydraulic hydrated lime shall be determined in accordance with Specification C 141.

8. Calculation

8.1 Average $\bar{X}$:

$$\bar{X} = \frac{(X_1 + X_2 + \ldots + X_n)}{n} \quad (1)$$

where:

$X_1, X_2, \ldots, X_n$ = the individual test results in accordance with Test Methods C 25 or C 110, or Specification C 141, and

n = the number of individual samples.

8.2 Total Standard Deviation:

$$s = \sqrt{\frac{(X_1 - \bar{X})^2 + (X_2 - \bar{X})^2 + \ldots + (X_n - \bar{X})^2}{(n - 1)}} \quad (2)$$

9. Report

9.1 Report the following information. Sufficient information shall be provided to identify the sample including:

9.1.1 Name of manufacturer and location,

9.1.2 Type of material or other identification,

9.1.3 All sampling and analytical practices used are to be noted (see Note 3), and

9.1.4 Period of time represented by the report.

9.2 The report shall not cover a period of time greater than one year.

NOTE 3—Laboratory designations are lost or are meaningless when averaging a number of determinations on individual samples. The purchaser needs to know the sampling and analytical practices used in generating a report to properly evaluate the information they receive concerning a specific product.

10. Keywords

10.1 hydrated lime; limestone; product uniformity; quicklime; sampling

Designation: C 1170/C 1170M – 08

Standard Test Method for Determining Consistency and Density of Roller-Compacted Concrete Using a Vibrating Table[1]

This standard is issued under the fixed designation C 1170/C 1170M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method is used to determine the consistency of concrete using a vibrating table and a surcharge and to determine the density of the consolidated concrete specimen. This test method is applicable to freshly mixed concrete, prepared in both the laboratory and the field, having a nominal maximum size aggregate of 50 mm [2 in.] or less. If the nominal maximum size of aggregate is larger than 50 mm [2 in.], the test method is applicable only when performed on the fraction passing the 50-mm [2-in.] sieve with the larger aggregate being removed in accordance with Practice C 172.

1.2 This test method, intended for use in testing roller-compacted concrete, may be applicable to testing other types of concrete such as cement-treated aggregate and mixtures similar to soil-cement.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*(**Warning**— Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 172 Practice for Sampling Freshly Mixed Concrete

D 1557 Test Methods for Laboratory Compaction Characteristics of Soil Using Modified Effort (56,000 ft-lbf/ft^3(2,700 kN-m/m^3))

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this test method, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *extremely dry consistency*, *n*—for the purpose of this standard, the consistency of concrete having no slump and a Vebe consistency greater than 20 s when measured with Procedure A or B.

3.2.2 *stiff consistency*, *n*—n—the consistency of concrete having a slump less than 25 mm [1 in] and a Vebe consistency ranging from 5 to 10 s when measured with Procedure A.[4]

3.2.3 *Vebe consistency*, *n*—the time required for a given mass of concrete to be consolidated by vibration in a cylindrically shaped mold under a surcharge mass.

3.2.4 *very stiff consistency*, *n*—for the purpose of this standard, the consistency of concrete having no slump and a Vebe consistency ranging from 10 to 20 s when measured with Procedure A.

4. Summary of Test Method

4.1 A vibrating table is used to measure the consistency of stiff to extremely dry concrete mixtures (See Note 1). Density of the compacted specimen is measured by determining the mass of the consolidated specimen and dividing by its volume.

NOTE 1—Further description of concrete of this consistency is given in ACI 207.5R[5] and ACI 211.3R.[4]

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and are the direct responsibility of Subcommittee C09.45 on Roller-Compacted Concrete.

Current edition approved Oct. 1, 2008. Published November 2008. Originally approved in 1991. Last previous edition approved in 2006 as C 1170 – 06.

www.technobetar.ir

4.2 Two procedures are provided:

4.2.1 *Procedure A* uses a 22.7-kg [50-lb] surcharge mass placed on top of the test specimen. Procedure A shall be used for testing concrete of very stiff to extremely dry consistency or when the Vebe consistency by Procedure B is 30 s or greater (See Note 2).

NOTE 2—Further description of the test procedure using a 22.7 kg [50 lb] surcharge can be found in the U. S. Bureau of Reclamation's Technical Memorandum No. 8.[6]

4.2.2 *Procedure B* uses a 12.5 kg [27.5 lb] surcharge mass placed on top of the test specimen. Procedure B shall be used for testing concrete of stiff to very stiff consistency or when the Vebe time by Procedure A is less than 20 s (See Note 3).

NOTE 3—Further description of the test procedure using a 12.5 kg [27.5 lb] surcharge can be found in the U. S. Army Corps of Engineer's test procedure CRD-C-53-01.[7]

4.2.3 Procedure A or B can be used for a Vebe consistency between 20 and 30 s.

5. Significance and Use

5.1 This test method is intended to be used for determining the consistency and density of stiff to extremely dry concrete mixtures common when using roller-compacted concrete construction.

5.1.1 Because of the stiff to extremely dry consistency of some roller-compacted concrete mixtures, the standard Vebe test method of rodding the specimen in a slump cone is substituted by Procedures A and B.[8]

5.2 Procedure A uses a 22.7-kg [50-lb] surcharge and is used for concrete consolidated by roller-compaction methods when the consistency of the concrete is very stiff to extremely dry.

5.3 Procedure B uses a 12.5-kg [27.5-lb] surcharge and is used for concrete consolidated by roller-compaction methods when the consistency of the concrete is stiff to very stiff consistency, but not extremely dry.

6. Apparatus

6.1 *Vibrating Table*—A vibrating table with a steel deck approximately 20-mm [¾-in.] thick with dimensions of approximately 380 mm [15 in.] in length, 250 mm [10 in.] in width, and 300 mm [12 in.] in height. The vibrating table shall be constructed in such a manner as to prevent flexing of the table during operation. The table deck shall be activated by an electromechanical vibrator. The table shall produce a sinusoidal vibratory motion with a frequency of at least 60 ± 2 Hz [3600 ± 100 vibrations per min] and a double amplitude of vibration of 0.43 ± 0.08 mm [0.0170 ± 0.0030 in.] when a 27 ± 2-kg [60.0 ± 2.5-lb] surcharge is bolted to the center of the table. The vibrator and table shall have a total mass of at least 90 kg [200 lb]. The table shall be level and clamped to a concrete floor or base slab that has sufficient mass to prevent displacement of the apparatus during performance of the test.

6.2 *Cylindrical Mold*—The cylindrical mold shall be made of steel or other hard metal resistant to corrosion by cement paste and shall have an inside diameter of 240 ± 2 mm [9 ½ ± 1/16 in.], a height of 200 ± 2 mm [7¾ ± 1/16 in.], and a wall thickness of 6 ± 2 mm [¼ ± 1/16 in.]. The mold shall be equipped with permanently affixed slotted metal brackets so it can be rigidly clamped to the vibrating table. The top rim of the mold shall be smooth, plane, and parallel to the bottom of the mold and shall be capable of providing an air and watertight seal when a glass or plastic plate is placed on the top rim.

6.3 *Swivel Arm and Guide Sleeve*—A metal guide sleeve with a clamp assembly or other suitable holding device mounted on a swivel arm (See Fig. 1). The swivel arm and guide sleeve must be capable of holding the metal shaft with the attached 22.7-kg [50-lb] or 12.5-kg [27.5-lb] cylindrical mass in a position perpendicular to the vibrating surface and allowing the shaft to slide freely when the clamp is released. The inside diameter of the guide sleeve shall be 3 ± 2 mm [⅛ ± 1/16 in.] larger than the diameter of the metal shaft of the surcharge. The swivel arm must be capable of maintaining the guide sleeve in a locked position directly over the center of the vibrating surface. The swivel arm shall be capable of being rotated away from the center of the table.

6.4 *Surcharge*—A cylindrical steel mass with a circular plastic plate attached to its base and a metal shaft at least 450 mm [18 in.] in length and 16 ± 2 mm [⅝ ± 1/16 in.] in diameter attached perpendicularly to the plate and embedded in the center of the mass. The shaft shall slide through the guide sleeve without binding. The plastic plate shall be approximately 13 mm [½ in.] in thickness and shall have a diameter of 230 ± 3 mm [9 ± ⅛ in.]. The surcharge assembly including the plastic plate and the metal shaft shall have a mass of either of the following:

Procedure A—22.7 ± 0.5 kg [50 ± 1 lb], or

Procedure B—12.5 ± 0.5 kg [27.5 lb ± 1 lb].

6.5 *Balance or Scale*—Balance or scale of sufficient capacity to determine the total mass of the concrete specimen and the mold. The balance or scale shall be readable to the nearest 5 g [0.01 lb].

6.6 *Strike-Off Plate*—A flat square metal plate at least 6 mm [¼ in.] thick, or a glass or clear plastic plate at least 13 mm [½ in.] thick, and at least 50 mm [2 in.] larger than the diameter of the cylindrical mold.

6.7 *Sieve*—A 50-mm [2-in.] sieve conforming to Specification E 11.

6.8 *Timing Device*—A stopwatch, capable of recording time intervals of at least 2 min to the nearest 1 s.

6.9 *Small Tools*—Square-ended shovel and hand scoops, wrench, tamping rod, and flashlight as required.

7. Sampling

7.1 Specimens of fresh concrete shall be obtained in accordance with Practice C 172.

7.2 Concrete samples shall have a nominal maximum size of aggregate of 50 mm [2 in.] or less. If the concrete has

www.technobetar.ir

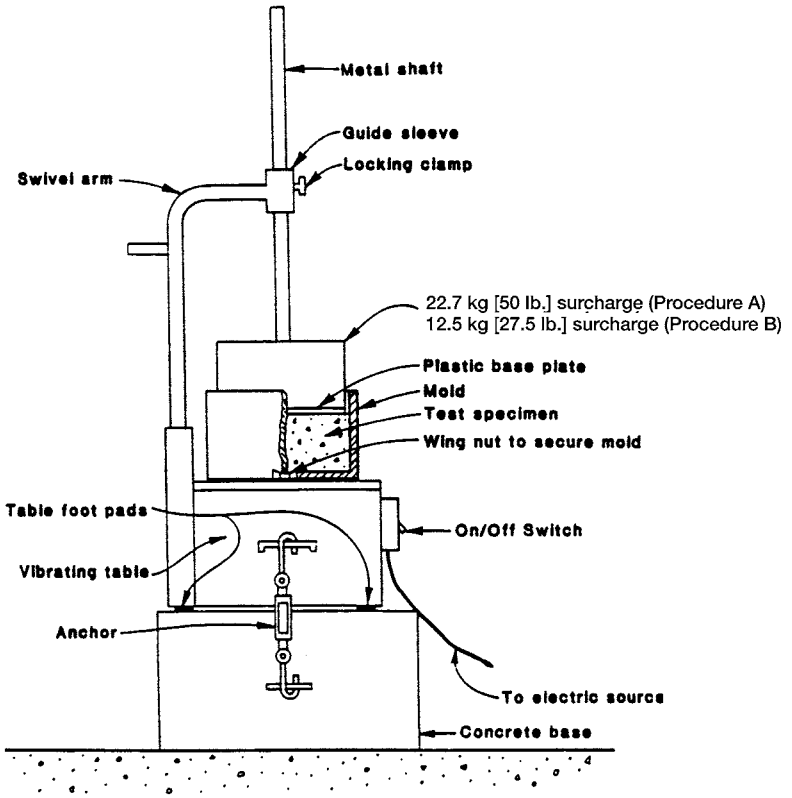

FIG. 1 Vibrating Table—Consistency Test

aggregate larger than 50 mm [2 in.], samples shall be obtained by wet sieving over a 50-mm [2-in.] sieve in accordance with Practice C 172.

7.3 Testing of concrete samples shall be completed within 45 min after the completion of mixing unless otherwise stipulated.

8. Preparation of Apparatus

8.1 *Vibrating Table*—Verify that the vibrating table meets the requirements of 6.1. Make adjustments if necessary.

8.1.1 Determine the frequency and double amplitude of the vibrating table under simulated test conditions prior to initial use and annually thereafter (See Note 4).

NOTE 4—A vibrating reed tachometer should be used to check the vibration frequency.[9]

8.2 *Cylindrical Mold*—Determine the volume of the cylindrical mold to the nearest 0.03 L [0.001 ft^3] in accordance with Test Method C 29/C 29M. Verify the volume of the mold monthly during times of regular use and annually when used infrequently. If used in density computations (that is, when a balance with tare is unavailable), determine the mass of the cylindrical mold to the nearest 5 g [0.01 lb]. For balances with tare capability, tare the balance with the mold.

8.3 In addition to the calibration schedule given in 8.1.1, calibrate the vibrating table after any event (including repairs) that might affect its operation, or whenever test results are questionable.

9. Technical Precautions

9.1 When obtaining samples, ensure that the samples are representative of the material being sampled.

9.2 Concrete with stiff to very dry consistency is highly susceptible to segregation during handling. To minimize segregation, use care in obtaining samples and during transporting, remixing, and testing of the concrete.

10. Procedure

10.1 *Vebe Consistency Time*:

10.1.1 Record the tare mass of the mold.

10.1.2 Using square-ended shovels and scoops, obtain a representative sample with a minimum mass of 25 kg [50 lb] in accordance with Practice C 172. Handle concrete in such a manner that coarse aggregate does not separate from the mortar.

10.1.3 Dampen the interior of the mold and fill with 13.5 ± 1 kg [29.5 ± 1.5 lb] of concrete. Using a square-edged scoop and tamping rod, place and distribute the concrete evenly to minimize segregation and rock pockets. Level the surface of the loose concrete.

10.1.4 Select either the 22.7 kg [50 lb] surcharge (Procedure A) or the 12.5 kg [27.5 lb] surcharge (Procedure B) (See Note 5).

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 5—The 12.5 kg [27.5 lb] surcharge is used for mixtures proportioned with a consistency of 20 s or less in accordance with Procedure A; or a paste volume in excess of the minimum volume of voids in the aggregate as determined using Test Method C 29/C 29M; or a total moisture content wet of the optimum, as determined using soil compaction test procedures in accordance with Test Methods D 1557. The 22.7 kg [50 lb] surcharge is used for mixtures proportioned with a consistency of more than 30 s in accordance with Procedure B; or with a paste volume approaching the minimum aggregate voids volume as determined using Test Method C 29/C 29M; or total moisture approaching the optimum moisture content as determined using soil compaction test procedures in accordance with Test Methods D 1557. Either procedure can be used if the consistency is between 20 and 30 s.

10.1.5 Secure the mold on the vibrating table by hand tightening the wing nuts. Slide the shaft of the surcharge mass through the guide sleeve, and rotate the surcharge to its locked position centered over the mold, ensuring that it will fit inside the mold when released. The surcharge may be lowered into the mold during this procedure to adjust the position of the mold but it shall not be placed on the specimen. Secure the wing nuts of the table with a wrench to prevent loosening during the test. Gently lower the surcharge onto the surface of the specimen.

10.1.6 If the surcharge cannot be centered in the mold without binding on the inside wall of the mold, place the surcharge directly onto the specimen in the mold without the use of the guide sleeve, and manually hold the surcharge shaft perpendicular to the top of the table. The surcharge shaft must be held manually throughout the remainder of the test. Do not apply additional hand pressure to the surcharge when manually holding the surcharge.

10.1.7 Start the vibrating table and timer. Using the flashlight, observe the concrete in the annular space between the edge of the surcharge and the inside wall of the mold. As the test progresses, mortar will fill in the annular space between the outer edge of the surcharge and the inside mold wall (See Note 6). Observe the mortar until it forms a complete ring around the total perimeter of the surcharge. When the mortar ring forms completely around the surcharge, stop the timer and vibrator; determine the elapsed time to the nearest second. Record this time as the Vebe consistency time, Procedure A or B, depending on which surcharge mass is used.

10.1.7.1 If a mortar ring forms around the total perimeter of the surcharge except at an isolated location where a rock or rock pocket impedes the complete mortar formation, the timer and vibrator shall be stopped and the elapsed time to the nearest second shall be recorded as the Vebe consistency time, Procedure A or B. Note the presence of the rock obstruction.

10.1.7.2 If the ring of mortar does not form after 90 s of vibration, stop the vibrating table and timer and record "> 90 s" as the Vebe consistency time.

NOTE 6—The time of the first appearance of mortar around the perimeter of the surcharge may be noted for information purposes only. However, this result should not be reported as a test value.

10.1.8 If the wing nuts loosen during the test, repeat the test with a fresh sample of concrete.

10.1.9 If the test result is out of the ranges specified in 4.2.1 or 4.2.2, change to the heavier or lighter surcharge mass, respectively, as needed. Once chosen, however, the same surcharge mass shall be used for the duration of the project.

10.1.10 Determine the density of the specimen in accordance with Section 10.2.

10.2 *Vebe Density of Freshly Consolidated Concrete*:

10.2.1 Following determination of the Vebe time, remove the surcharge. Add additional concrete on top of the previously compacted specimen. Overfill the mold by mounding the concrete above the top of the mold.

10.2.2 Place the surcharge on top of the loose concrete and consolidate by vibrating. If the surcharge consolidates concrete below the top level of the mold, turn off the vibrating table. Place additional concrete in the mold so that, when consolidated, the concrete will be less than 3 mm [⅛ in.] above the top of the mold. Continue vibrating; and with a sawing, screeding action, slide the surcharge across the top of the mold until the compacted concrete is level with the top of the mold. Do not allow the surcharge to remain in one position when the concrete is being finished because this can cause aggregates to be forced down and mortar to be forced out of the mold resulting in a non-representative test specimen.

10.2.3 After the surface has been screeded level with the top of the mold, stop the vibrating table. Remove the surcharge and vibrate the specimen for 5 ± 1 s to fill in minor surface tears. If the top surface of the specimen is disturbed by large amplitude oscillations, stop the vibrating table immediately

10.2.4 *Surface Strike-Off and Finishing*—After screeding the top surface even with the top of the mold, finish the surface with the strike-off plate. The strike-off is best accomplished by pressing the strike-off plate on the top surface of the cylinder mold to cover about two-thirds of the surface and withdrawing the plate with a sawing motion to finish only the area originally covered. Then place the plate on the top of the mold to cover the original two-thirds of the surface and advance it over the remaining third, with a vertical pressure and sawing motion to remove the concrete remaining above the top of the mold. Repeat section 10.2.2 and 10.2.3, if necessary, until the concrete is even with the top rim of the mold. If the finishing procedure causes surface tears that cannot be corrected with additional finishing, discontinue the surface strike-off and finishing and use the screeded surface for the density determination.

10.2.5 *Cleaning and Weighing*—After strike-off and finishing, loosen the wing nuts from the vibrating table and remove the cylinder mold. Clean all excess concrete from the exterior of the mold and determine the mass of the filled mold to the nearest 5 g [0.01 lb]. Determine the net mass of concrete by subtracting the mass of the empty mold. Alternatively, the net mass is permitted to be determined by taring the balance or scale with the empty mold.

10.2.6 Determine the density of the specimen in accordance with Section 11.

11. Calculation

11.1 Determine the density of the specimen as follows:

$$D = \frac{M_s}{V_s}$$

where:

D = density, kg/m^3 [lb/ft^3],

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:47:39 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

M_s = mass of specimen, kg [lb] = mass of specimen plus cylindrical mold – mass of cylindrical mold
V_s = volume of cylindrical mold, m^3 [ft^3].

12. Report

12.1 Report the:
12.1.1 Procedure used (Procedure A or B),
12.1.2 Vebe consistency time in seconds,
12.1.3 Density in kg/m^3 [lb/ft^3],
12.1.4 Make and model of the vibrating table, and
12.1.5 Occurrence of an incomplete ring per 10.1.7.1, if applicable.

13. Precision and Bias

13.1 The precision of this test method for measuring consistency and density is being determined.

13.2 *Bias*—The procedure in this test method for determining consistency and density of roller-compacted concrete has no bias because consistency and density can only be defined in terms of this test method.

14. Keywords

14.1 concrete; consistency; density; fresh concrete properties; roller-compacted concrete

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1170 – 06, that may impact the use of this test method. (Approved October 1, 2008)

(*1*) Revised the standard as a combined units standard with SI units listed first.
(*2*) Added three terms to the Terminology Section.
(*3*) Replaced the term "stiff plastic" with "stiff" in Sections 4 and 5.
(*4*) Revised 10.1.7, 10.1.8, and Section 12 for clarity.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1176/C 1176M – 08

Standard Practice for Making Roller-Compacted Concrete in Cylinder Molds Using a Vibrating Table[1]

This standard is issued under the fixed designation C 1176/C 1176M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers procedures for making cylindrical test specimens from concrete when the standard procedures of rodding and internal vibration, as described in Practice C 31, are not practicable. This practice is applicable to freshly mixed concrete, prepared in the laboratory and the field, having a nominal maximum size aggregate of 50 mm [2 in.] or less. If the nominal maximum size aggregate is larger than 50 mm [2 in.], the practice is applicable only when performed on the fraction passing the 50-mm [2-in.] sieve with the larger aggregate being removed in accordance with Practice C 172. This practice, intended for use in testing roller-compacted concrete, may be applicable to testing other types of concrete such as cement-treated aggregate and mixtures similar to soil-cement.

1.2 Two methods are provided for making concrete cylinders using a vibrating table:

1.2.1 Method A is a procedure for making test specimens in steel reusable molds attached to a vibrating table.

1.2.2 Method B is a procedure for making test specimens in single-use plastic molds that have been inserted into a metal sleeve attached to a vibrating table.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens

C 172 Practice for Sampling Freshly Mixed Concrete

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 470/C 470M Specification for Molds for Forming Concrete Test Cylinders Vertically

C 496/C 496M Test Method for Splitting Tensile Strength of Cylindrical Concrete Specimens

C 1170 Test Method for Determining Consistency and Density of Roller-Compacted Concrete Using a Vibrating Table

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Summary of Practice

3.1 This practice describes methods for making cylindrical concrete test specimens using a vibrating table. Test specimens are made in cylindrical molds that are attached to the vibrating table under a 9-kg [20-lb] surcharge to facilitate consolidation.

4. Significance and Use

4.1 This practice is intended to be used for stiff to extremely dry concrete mixtures commonly used in roller-compacted concrete construction. This practice is used instead of rodding or internal vibration, which cannot properly consolidate concrete of this consistency (Note 1).

NOTE 1—Further description of this concrete consistency is given in

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.45 on Roller-Compacted Concrete.

Current edition approved June 1, 2008. Published July 2008. Originally approved in 1991. Last previous edition approved in 2005 as C 1176 – 05.

ACI 207.5 Roller-Compacted Mass Concrete[3] and 211.3 Guide for Selecting Proportions for No-Slump Concrete[3]. The consistency of roller-compacted concrete may be determined in accordance with Test Method C 1170.

5. Apparatus

5.1 *Molds*:

5.1.1 *Type A Mold*—A cylindrical mold conforming to the requirements of Specification C 470 for 150-mm [6-in.] diameter by 300-mm [12-in.] high reusable molds. Molds shall be made of steel or other hard metal not readily attacked by the cement paste. Aluminum molds shall not be used. Molds shall be equipped with permanently affixed metal slotted brackets on the baseplate so the molds can be rigidly clamped to a vibrating table. The top rim of the mold shall be smooth, plane, and parallel to the bottom of the mold. The bottom of the mold shall provide a watertight seal.

5.1.2 *Type B Mold*—A single-use plastic, cylindrical mold 150 mm [6 in.] in diameter and 300 mm [12 in.] in height. The mold specifications shall conform to Specification C 470 for single-use plastic molds.

5.1.2.1 *Mold Sleeve*—A Type B cylindrical mold shall be inserted into a rigid cylindrical sleeve with a bottom baseplate that is clamped to the vibrating table. The mold sleeve shall be made of steel or other hard metal that does not react with concrete containing portland or other hydraulic cement. The sleeve shall be capable of firmly and vertically holding the plastic mold in place without deformation and shall be slotted vertically with adjustable clamps for tightening around the mold. The sleeve shall be hinged so that it can be opened to remove the mold (Fig. 1) and shall also have permanently affixed slotted metal brackets so the sleeve may be rigidly clamped to the vibrating table. The mold sleeve shall have a minimum wall thickness of 3 mm [⅛ in.], and a minimum baseplate thickness of 6 mm [¼ in.]. The inside diameter of the mold sleeve shall be 3 ± 1.5 mm [⅛ ± 1⁄16 in.] larger than the outside diameter of the Type B mold and have a height 6 to 13 mm [½ to ¼ in.] less than the height of the Type B mold.

5.2 *Vebe Vibrating Table*—A vibrating table with a 20-mm [¾-in.] thick steel deck with dimensions of approximately 380 mm [15 in.] in length, 260 mm [10 ¼ in.] in width, and 300 mm [12 in.] in height. The vibrating table shall be constructed in such a manner as to prevent flexing of the table during operation. The table deck shall be activated by an electromechanical vibrator. The total mass of the vibrator and table shall be approximately 95 kg [210 lb]. The table shall be level and clamped to a concrete floor or base slab that has sufficient mass to prevent displacement of the apparatus during specimen preparation (Note 2).

NOTE 2—The recommended vibrating table for these procedures is the Vebe vibrating table. Testing to date has been performed using this apparatus. An alternative vibrating table may be substituted for the Vebe apparatus provided it meets the specifications for the sinusoidal vibration given in 7.1.

[3] *ACI Manual of Concrete Practice, Part 1, Materials and General Properties of Concrete*, 2005, American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333.

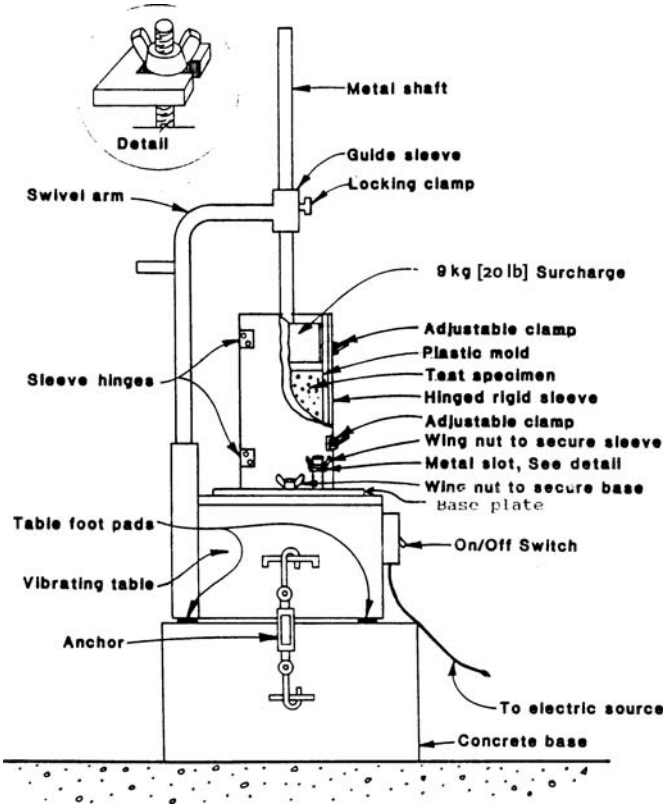

FIG. 1 Vibrating Table—Cylinder Preparation (Type B Mold)

5.3 *Swivel Arm and Guide Sleeve*—A metal guide sleeve with a clamp assembly or other suitable holding device mounted on a swivel arm. The swivel arm and guide sleeve must be capable of holding a metal shaft attached to a 9-kg [20-lb] cylindrical mass in a position perpendicular to the vibrating surface and allowing the shaft to slide freely when the clamp is released. The swivel arm must be capable of maintaining the guide sleeve in a locked position directly over the center of the specimens to be vibrated. The swivel arm shall also be capable of being rotated away from the center of the table (Note 3).

NOTE 3—The Vebe vibrating table comes equipped with the swivel arm and guide sleeve.

5.4 *Surcharge*—A cylindrical steel mass with a metal shaft at least 460 mm [18 in.] in length and 16 ± 2 mm [⅝ ± 1⁄16 in.] in diameter attached perpendicularly to and embedded in the center of the mass. The shaft shall slide through the guide sleeve without binding. The surcharge shall have a diameter of 145 ± 3 mm [5¾ ± ⅛ in.]. The surcharge assembly shall have a mass of 9.0 ± 0.25 kg [20 ± 0.5 lb] including the mass of the metal shaft (Fig. 1). If the surcharge is to be hand held, the length of the shaft may be reduced to about 300 mm [12 in.] and fabricated with a "T" or "D" handle for gripping the surcharge shaft to avoid slipping.

5.5 *Sieve*—A 50-mm [2-in.] sieve conforming to Specification E 11.

5.6 *Small Tools*—Trowels, square-ended shovel and hand scoops, steel trowel, wooden float, wrench, tamping rod, and flashlight as required.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:47:41 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6. Sampling

6.1 Samples of fresh concrete shall be obtained in accordance with Practice C 172.

6.2 Concrete samples shall have a nominal maximum size aggregate of 50 mm [2 in.] or less. If the concrete has aggregate larger than 50 mm [2 in.], samples shall be obtained by wet sieving over a 50-mm [2-in.] sieve in accordance with Practice C 172.

6.3 Concrete test specimens shall be made within 45 min after the completion of mixing concrete unless otherwise stipulated.

7. Calibration and Standardization

7.1 The vibrating table shall produce a sinusoidal vibratory motion with a frequency of at least 60 ± 2 Hz [3600 ± 100 vibrations per min] and a double amplitude of vibration of 0.45 ± 0.1 mm [0.0170 ± 0.0030 in.] when a 27.0 ± 1.0-kg [60.0 ± 2.5-lb] surcharge is rigidly bolted to the center of the table.

7.1.1 Determine the frequency and double amplitude[4] of the vibrating table under simulated test conditions prior to initial use and annually thereafter. A vibrating reed tachometer should be used to check the frequency of vibration.

7.2 Recalibrate the vibrating table after any event (including repairs) that might affect its operation, or whenever test results are questionable.

8. Technical Precautions

8.1 When obtaining samples, ensure that the samples are representative of the material being sampled.

8.2 Concrete with stiff to extremely dry consistency is highly susceptible to segregation during handling. To minimize segregation, use care in obtaining samples and during transporting, remixing, and testing of the concrete.

8.3 After at least every three months of continued use, inspect and clean the underside of the vibrating table top of any hardened concrete or cement paste which may interfere with free movement of the table top.

9. Procedure

9.1 *Method A—Type A Molds*:

9.1.1 Coat Type A molds with a suitable lubricant or bond breaker prior to casting the test specimens to facilitate removal from the mold.

9.1.2 Place the mold on the vibrating table, and center the surcharge so that the edges of the plastic plate do not touch the walls of the mold. Lower the surcharge into the mold to check for proper clearance. Attach the mold to the vibrating table, and firmly tighten the wing nuts. Move the surcharge away from the mold.

9.1.3 Place enough concrete in the mold so that the mold will be filled to one-third of its volume after consolidation (approximately 4.5 kg [9.5 lb]). A tamping rod may be used to distribute the loose concrete as it is added. During filling, use square-ended shovels and scoops to obtain representative samples, and handle the concrete in such a manner that larger sized coarse aggregate particles do not separate from the mortar.

9.1.4 Move the surcharge over the center of the mold, release the guide sleeve clamp, and place the surcharge gently on the loose concrete. The surcharge shall be able to vertically slide free without binding on the guide sleeve.

9.1.5 If the surcharge cannot be centered in the mold without binding on the inside wall of the mold, place the surcharge directly onto the specimen in the mold without use of the guide sleeve, and hold the surcharge shaft perpendicular to the top of the table. Hold the surcharge shaft manually while vibrating the specimen. Do not apply any additional hand pressure to the surcharge when manually holding the surcharge.

9.1.6 Start the vibrator table, and allow the concrete to consolidate under the surcharge. Using a flashlight, observe the concrete in the annular space between the edge of the surcharge and the inside wall of the mold. As the concrete consolidates, mortar will fill in the annular space between the outer edge of the surcharge and the inside mold wall. Observe the mortar until it forms a ring around the total perimeter of the surcharge. When the mortar ring forms completely around the surcharge, stop the vibrator. If the wing nuts loosen while casting the specimen, retighten the wing nuts, then continue vibrating to ensure complete consolidation of the specimen.

9.1.7 If a rock pocket prevents the mortar ring from forming at one small location, even though it has formed in all other locations, the vibrator can be stopped and another layer of concrete added. If a significant portion of the mortar ring does not form, this indicates the concrete may have insufficient mortar due to either improper sampling, segregation, or improper mixture proportioning. In these instances, the concrete specimen should be visually inspected after stripping from the mold, and a decision then made whether to accept or reject the specimen.

9.1.8 Repeat the procedure in 9.1.3 through 9.1.7 for the second lift of concrete, filling the mold to approximately two-thirds of its volume. For the third lift, overfill the mold by mounding the concrete above the top of the mold. Again, place the surcharge on the loose concrete and consolidate. If the surcharge consolidates concrete below the top level of the mold, turn off the vibrating table. Place additional concrete in the mold so that, when consolidated, the concrete will be about 3 mm [⅛ in.] above the top of the mold. Continue vibrating, and slide the surcharge back and forth across the top of the mold until the compacted concrete is level with the top of the mold. This replaces strikeoff with a float since stiff concrete cannot be easily floated. Do not allow the surcharge to remain in one position when the concrete is being finished because this can cause aggregates to be forced down and mortar to be forced out of the mold resulting in a nonrepresentative test specimen. After the surface has been screeded with the surcharge, vibrate the specimen for 4 ± 1 s without the surcharge to fill in minor surface tears unless damage to the specimen by large-amplitude oscillations of the vibrator is anticipated.

[4] Kaufman, L.P., Strickland, E.A., and Benavidez, A.A. "Suggested Method for the Calibration of Vibrating Tables for Maximum Index Density Testing," *Geotechnical Testing Journal*, GTJODJ, Vol 2, No. 3, September 1979, pp. 152–157.

www.technobetar.ir

9.1.8.1 When making test specimens using an alternative vibrating table, it may not be possible to vibrate the specimen without a surcharge. This is due to the disturbance of the compacted specimen when large-amplitude, low-frequency oscillations occur after the vibrator has been turned off. If this occurs, keep the surcharge in place until the vibrating table has completely stopped.

9.1.9 Remove the mold with the consolidated specimen from the vibrating table, and finish the top surface of the specimen with a steel trowel or wooden float. Avoid dislodging aggregate particles from the surface when using a wooden float.

9.2 *Method B—Type B Molds*:

Make concrete test specimens in Type B molds in accordance with 9.1. Prior to making test specimens, insert a Type B mold into the metal sleeve ensuring a close fit but not deforming the plastic mold. A sleeve assembly made from an existing steel cylindrical mold is shown in Fig. 1. Rigidly clamp the entire assembly to the vibrating table, and make the test specimen in accordance with procedures in 9.1.2 through 9.1.9.

10. Curing

10.1 Unless otherwise specified, all specimens shall be cured in accordance with the sections on curing in Practice C 192 or Practice C 31, whichever is applicable. Specimens tested for compressive strength and splitting tensile strength shall be in accordance with Test Method C 39/C 39M and Test Method C 496, respectively.

11. Keywords

11.1 concrete; cylinder preparation; roller-compacted concrete

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1176 – 05, that may impact the use of this practice. (Approved June 1, 2008)

(*1*) Revised the standard to a dual designation with SI units listed first to comply with C09's policy on units. Only the units have been revised in the text.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1177/C 1177M – 08

Standard Specification for Glass Mat Gypsum Substrate for Use as Sheathing[1]

This standard is issued under the fixed designation C 1177/C 1177M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers glass mat gypsum substrate, which is designed to be used as an exterior substrate for a weather barrier.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 473 Test Methods for Physical Testing of Gypsum Panel Products

C 645 Specification for Nonstructural Steel Framing Members

C 1264 Specification for Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage of Gypsum Panel Products

E 119 Test Methods for Fire Tests of Building Construction and Materials

3. Terminology

3.1 Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *glass mat*, *n*—a mat of glass fibers with or without a binder.

3.2.2 *edge*, *n*—the bound edge as manufactured.

3.2.3 *weather barrier*, *n*—a material that prevents the passage of rain, sleet and snow.

4. Materials and Manufacture

4.1 *Glass Mat Gypsum Substrate* shall consist of a noncombustible water-resistant core, essentially gypsum, surfaced with glass mat partially, or completely embedded in the core.

4.2 *Glass Mat Gypsum Substrate, type X (special fire-resistant)* designates glass mat gypsum substrate complying with this specification that provide not less than 1-h fire resistance rating for substrate 5⁄8 in. [15.9 mm] thick or 3⁄4-h fire resistance rating for substrate 1⁄2 in. [12.7 mm] thick, applied parallel with and on each side of load bearing 2 by 4 wood studs spaced 16 in. [406 mm] on center with 6d coated nails, 1 7⁄8 in. [48 mm] long, 0.0915 in. [2.3 mm] diameter shank, 1⁄4 in. [6.4 mm] diameter heads, spaced 7 in. [178 mm] on center with glass mat gypsum substrate joints staggered 16 in. [406 mm] on each side of the partition and tested in accordance with Test Methods E 119.

NOTE 1—Consult manufacturers for independent test data on assembly details and fire resistance ratings for other types of construction. See fire test reports or listings from recognized fire testing laboratories for assembly particulars, materials, and ratings.

5. Physical Properties

5.1 Specimens shall be taken from the samples obtained in accordance with Specification C 1264.

5.2 Specimens shall be tested in accordance with Methods C 473.

5.2.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall not be less than the following:

	Method B	
Thickness, in. [mm]	Load, lbf [N] Bearing edges perpendicular to the substrate edge	Load, lbf [N] Bearing edges parallel to the substrate edge
1⁄4 [6.4]	50 [222]	40 [178]
7⁄16 [11.1]	88 [394]	70 [314]
1⁄2 [12.7]	100 [445]	80 [356]
5⁄8 [15.9]	140 [623]	100 [445]

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Sept. 15, 2008. Published October 2008. Originally approved in 1991. Last previous edition approved in 2006 as C 1177/C 1177M–06.

5.2.2 *Humidified Deflection*—Specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Humidified deflection, eighths of an in. [mm]
¼ [6.4]	not required
7/16 [11.1]	3 [9]
½ [12.7]	2 [6]
⅝ [15.9]	1 [3]

5.2.3 *Core, End and Edge Hardness*—Specimens shall have an average hardness of not less than 15 lbf [67 N] when tested in accordance with Method B:

5.2.4 *Nail Pull Resistance*—Specimens shall have an average nail pull resistance of not less than the following when tested in accordance with Method B:

Thickness, in. [mm]	Nail pull resistance, lbf [N]
¼ [6.4]	40 [178]
7/16 [11.1]	70 [314]
½ [12.7]	80 [356]
⅝ [15.9]	90 [400]

5.2.5 *Water Resistance*—The three specimens selected shall have an average water absorption of not more than 10 weight % after a 2-h immersion.

6. Dimensions and Tolerances

6.1 Specimens shall be taken from the samples obtained in accordance with Specification C 1264.

6.2 *Thickness, width, length and end squareness* shall be determined in accordance with Test Methods C 473.

6.2.1 *Thickness*—The nominal thickness shall be ¼ , 7/16 , ½ , or ⅝ in. [6.4, 11.1, 12.7 or 15.9 mm], with tolerances in the nominal thickness of ± 1/32 in. [± 0.8 mm], and with local variations of ± 1/16 in. [± 1.6 mm] from the nominal thickness.

6.2.2 *Width*—The nominal width shall be up to 48 in. [1220 mm], with tolerance of ⅛ in. [3 mm] under the specified width.

6.2.3 *Length*—The tolerance in length shall be ± ¼ in. [± 6 mm]

6.2.4 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the substrate.

6.3 *Edges and Ends*—The edges and ends shall be straight and either square, beveled, featured, tapered, or featured and tapered.

7. Finish and Appearance

7.1 Glass mat gypsum substrate shall be free of any cracks and imperfections that would render it unfit for its designed use.

8. Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage

8.1 Shall be in accordance with Specification C 1264.

9. Keywords

9.1 core; exterior substrate; fire-resistant classification; flexural strength; glass mat; glass mat gypsum substrate; gypsum; hardness; humidified deflection; nail pull resistance; noncombustible; sheathing; substrate; type X; water resistance; weather barrier

APPENDIX

(Nonmandatory Information)

This Appendix gives general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this specification.

The definitions of type X as given in 4.2 and the alternate definition given in this appendix, are intended only as a test to define glass mat gypsum substrate for use as sheathing as meeting the requirements of type X. These tests do not indicate a preferred application nor do they limit the use of the product in other fire related assemblies.

All gypsum panel products for which type X is defined, except gypsum lath and gypsum shaftliner board, use the same test for type X products, therefore the type X designation indicates a consistent level of fire resistance.

X1. ALTERNATE DEFINITION FOR TYPE X

X1.1 Glass mat gypsum substrate, type X (special fire-resistant) designates glass mat gypsum substrate providing a greater fire resistance than regular glass mat gypsum substrate of the same thickness. Type X (special fire-resistant) glass mat gypsum substrate, when tested in accordance with Test Methods E 119, shall provide the following minimum fire resistance ratings for the assemblies described:

X1.1.1 One hour for a ⅝ in. [15.9 mm] thickness applied to a partition in a single layer application on each side of 3⅝ in. [92 mm] deep non-loadbearing galvanized steel studs complying with Specification C 645 spaced 24 in. [610 mm] on center. The ⅝ in. [15.9 mm] thick glass mat gypsum substrate 48 in. [1220 mm] wide shall be attached using 1 in. [25 mm] long drywall screws spaced 8 in. [203 mm] on center along the edges and ends, and 12 in. [305 mm] along intermediate studs. All joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly; and

www.technobetar.ir

X1.1.2 Two hours for a ½ in. [12.7 mm] thickness applied to a partition in a double layer application on each side of 2½ in. [64 mm] deep non-loadbearing galvanized steel studs complying with Specification C 645 spaced 24 in. [610 mm] on center. The base layer 48 in. [1220 mm] wide shall be attached using 1 in. [25 mm] long drywall screws spaced 12 in. [305 mm] on center along substrate edges, ends and along intermediate studs. Joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly. The face layer 48 in. [1220 mm] wide shall be attached using 1⅝ in. [41 mm] long drywall screws spaced 12 in. [305 mm] along substrate edges, ends and along intermediate studs. Joints shall be oriented parallel to and located over studs, offset 24 in. [610 mm] from the base layer joints, and staggered on opposite sides of the assembly.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1177/C 1177M – 06, that may impact the use of this specification. (Approved September 15, 2008)

(*1*) Revised 6.2.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1178/C 1178M – 08

Standard Specification for Coated Glass Mat Water-Resistant Gypsum Backing Panel[1]

This standard is issued under the fixed designation C 1178/C 1178M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers coated glass mat water-resistant gypsum backing panel designed for use on ceilings and walls in bath and shower areas as a base for the application of ceramic or plastic tile.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. Within the text, the SI units are shown in brackets.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 473 Test Methods for Physical Testing of Gypsum Panel Products

C 645 Specification for Nonstructural Steel Framing Members

C 1264 Specification for Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage of Gypsum Panel Products

E 119 Test Methods for Fire Tests of Building Construction and Materials

3. Terminology

3.1 Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *glass mat*, *n*—a mat of glass fibers with or without a binder.

3.2.2 *edge*, *n*—the bound edge as manufactured.

3.2.3 *face*, *n*—the coated surface.

3.2.4 *nominal thickness*, *n*—the manufacturer-stated fractional value of thickness of the gypsum panel product expressed in decimal value to the nearest one-thousandth (0.001) of an inch.

4. Materials and Manufacture

4.1 *Coated glass mat water-resistant gypsum backing panel* shall consist of a noncombustible water-resistant core, essentially gypsum, surfaced with glass mat, partially or completely embedded in the core, and with a water-resistant coating on one surface.

4.2 Coated glass mat water-resistant gypsum panels, type X (special fire-resistant) designates glass mat gypsum panels complying with this specification that provide not less than 1-h fire resistance rating for boards ⅝ in. [15.9 mm] thick or ¾-h fire resistance rating for panels ½ in. [12.7 mm] thick, applied parallel with and on each side of load bearing 2 by 4 wood studs spaced 16 in. [406 mm] on center with 6d coated nails, 1 ⅞ in. [48-mm] long, 0.0915 in. [2.3 mm] diameter shank, ¼ in. [6.4 mm] diameter heads, spaced 7 in. [178 mm] on center with glass mat gypsum panel joints staggered 16 in. [406 mm] on each side of the partition and tested in accordance with Test Methods E 119.

NOTE 1—Consult manufacturers for independent test data on assembly details and fire resistance ratings for other types of construction. See fire test reports or listings from recognized fire testing laboratories for assembly particulars, materials, and ratings.

5. Physical Properties

5.1 Specimens shall be taken from the samples obtained in accordance with Specification C 1264.

5.2 Specimens shall be tested in accordance with Test Methods C 473.

5.2.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall not be less than the following:

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Aug. 1, 2008. Published September 2008. Originally approved in 1991. Last previous edition approved in 2006 as C 1178/C 1178M – 06.

	Method B Load, lbf [N]	
Thickness, in. [mm]	Bearing edges perpendicular to the board edge	Bearing edges parallel to the board edge
¼ [6.4]	50 [222]	40 [178]
½ [12.7]	100 [445]	80 [356]
⅝ [15.9]	140 [623]	100 [445]

5.2.2 *Humidified Deflection*—Specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Humidified deflection, eighths of an in. [mm]
¼ [6.4]	not required
½ [12.7]	2 [6]
⅝ [15.9]	1 [3]

5.2.3 *Core, End and Edge Hardness*—Specimens shall have an average hardness of not less than 15 lbf [67 N] when tested in accordance with Method B.

5.2.4 *Nail Pull Resistance*—Specimens shall have an average nail pull resistance of not less than the following when tested in accordance with Method B:

Thickness, in. [mm]	Nail pull resistance, lbf [N]
¼ [6.4]	40 [178]
½ [12.7]	70 [311]
⅝ [15.9]	90 [400]

5.2.5 *Water Resistance*—The three specimens selected shall have an average water absorption of not more than 5 weight % after 2-h immersion.

5.2.6 *Surface Water Absorption*—Specimens shall have an average surface water absorption of the face side of the panel not more than 0.5 g after 2 h of elapsed time.

6. Dimensions and Tolerances

6.1 Specimens shall be taken from the samples obtained in accordance with Specification C 1264.

6.2 Thickness, width, and length shall be determined in accordance with Test Methods C 473.

6.2.1 *Thickness*—The thickness shall be ¼ in., ½ in. or ⅝ in. [6.4, 12.7 or 15.9 mm], with tolerances of ± 0.015 in. [± 0.40 mm] and with local variations of ± 0.030 in. [± 0.80 mm].

6.2.2 *Width*—The nominal width shall be up to 48 in. [1220 mm], with a tolerance of 3⁄32 in. [3 mm] under the specified width.

6.2.3 *Length*—The tolerance in length shall be ± ¼ in. [± 6 mm]

6.2.4 *End Squareness*—Corners shall be square with a tolerance of ± ¼ in. [±6 mm] in the full width of the panel.

6.3 *Edges and Ends*—The edges and ends shall be straight and either square or tapered.

7. Finish and Appearance

7.1 Coated glass mat water-resistant gypsum backing panel shall have surfaces true and free of imperfections that render the panel unfit for its designed use.

8. Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage

8.1 Shall be in accordance with Specification C 1264.

9. Keywords

9.1 bath; ceilings; ceramic or plastic tile; construction; core; end and edge hardness; fire-resistant; flexural strength; glass mat; gypsum; humidified deflection; immersion; nail pull resistance; shower; surface water absorption; type X; walls; water absorption; water resistance; water-resistant

APPENDIX

(Nonmandatory Information)

This Appendix gives general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this specification.

The definition of type X in 4.2 and the alternate definition given in this appendix are intended only as a test to define the coated glass mat water-resistant gypsum backing panels as meeting the requirements of type X. These tests do not indicate a preferred application nor do they limit the use of the product in other fire rated assemblies.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:48:27 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

All gypsum panel products for which type X is defined, except gypsum lath and gypsum shaftliner board, use the same test for type X products, therefore the type X definition indicates a consistent level of fire resistance.

X1. ALTERNATE DEFINITION FOR TYPE X

X1.1 Coated glass mat water-resistant gypsum panels, type X (special fire-resistant) designates glass mat gypsum panels providing a greater fire resistance than regular glass mat water-resistant gypsum panels of the same thickness. Type X (special fire-resistant) glass mat water-resistant gypsum panels, when tested in accordance with Test Methods E 119, shall provide the following minimum fire resistance ratings for the assemblies described:

X1.1.1 One hour for a ⅝ in. [15.9 mm] thickness applied to a partition in a single layer application on each side of 3 ⅝ in. [92 mm] deep non-load bearing galvanized steel studs complying with Specification C 645 spaced 24 in. [610 mm] on center. The ⅝ in. [15.9 mm] thick glass mat water-resistant gypsum panels 48 in. [1220 mm] wide shall be attached using 1 in. [25 mm] long drywall screws spaced 8 in. [203 mm] on center along the edges and ends, and 12 in. [305 mm] along intermediate studs. All joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly; and

X1.1.2 Two hours for a ½ in. [12.7 mm] thickness applied to a partition in a double layer application on each side of 2 ½ in. [64 mm] deep non-load bearing galvanized steel studs complying with Specification C 645 spaced 24 in. [610 mm] on center. The base layer 48 in. [1220 mm] wide shall be attached using 1 in. [25 mm] long drywall screws spaced 12 in. [305 mm] on center along panel edges, ends and along intermediate studs. Joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly. The face layer 48 in. [1220 mm] wide shall be attached using 1 ⅝ in. [41 mm] long drywall screws spaced 12 in. [305 mm] along panel edges, ends and along intermediate studs. Joints shall be oriented parallel to and located over studs, offset 24 in. [610 mm] from the base layer joints, and staggered on opposite sides of the assembly.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1178/C 1178M – 06, that may impact the use of this specification. (Approved August 1, 2008)

(*1*) Revised 6.2.3.

Designation: C1202 – 10

Standard Test Method for Electrical Indication of Concrete's Ability to Resist Chloride Ion Penetration[1]

This standard is issued under the fixed designation C1202; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the electrical conductance of concrete to provide a rapid indication of its resistance to the penetration of chloride ions. This test method is applicable to types of concrete where correlations have been established between this test procedure and long-term chloride ponding procedures such as those described in AASHTO T 259. Examples of such correlations are discussed in Refs **1-5**.[2]

1.2 The values stated in inch-pound units are to be regarded as the standard, except where SI units are given first followed by inch-pound units in parentheses. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C31/C31M Practice for Making and Curing Concrete Test Specimens in the Field

C42/C42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C192/C192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

2.2 *AASHTO Standard:*

T 259 Method of Test for Resistance of Concrete to Chloride Ion Penetration[4]

3. Summary of Test Method

3.1 This test method consists of monitoring the amount of electrical current passed through 2-in. (51-mm) thick slices of 4-in. (102-mm) nominal diameter cores or cylinders during a 6-h period. A potential difference of 60 V dc is maintained across the ends of the specimen, one of which is immersed in a sodium chloride solution, the other in a sodium hydroxide solution. The total charge passed, in coulombs, has been found to be related to the resistance of the specimen to chloride ion penetration.

4. Significance and Use

4.1 This test method covers the laboratory evaluation of the electrical conductance of concrete samples to provide a rapid indication of their resistance to chloride ion penetration. In most cases the electrical conductance results have shown good correlation with chloride ponding tests, such as AASHTO T 259, on companion slabs cast from the same concrete mixtures (Refs **1-5**).

4.2 This test method is suitable for evaluation of materials and material proportions for design purposes and research and development.

4.3 Sample age has significant effects on the test results, depending on the type of concrete and the curing procedure. Most concretes, if properly cured, become progressively and significantly less permeable with time.

4.4 This test method was developed originally for evaluations of alternative materials, but in practice its use has evolved to applications such as quality control and acceptance testing.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.66 on Concrete's Resistance to Fluid Penetration.

Current edition approved Feb. 1, 2010. Published March 2010. Originally approved in 1991. Last previous edition approved in 2009 as C1202 – 09. DOI: 10.1520/C1202-10.

[2] The boldface numbers in parentheses refer to the list of references at the end of this standard.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

In such cases it is imperative that the curing procedures and the age at time of testing be clearly specified.

4.5 Table 1 provides a qualitative relationship between the results of this test and the chloride ion penetrability of concrete.

4.6 Numerical results of this test (total charge passed, in coulombs) can be used as a basis for determining the acceptability of a concrete mixture. Factors such as the ingredient materials used and method and duration of curing of test specimens affect results of this test. (See Note 1)

NOTE 1—When using this test for determining acceptability of concrete mixtures, statistically-based criteria and test age for prequalification, or for acceptance based on jobsite samples, should be stated in project specifications. Acceptance criteria for this test should consider the sources of variability affecting the results and ensure balanced risk between supplier and purchaser. The anticipated exposure conditions and time before a structure will be put into service should be considered. One approach to establishing criteria is discussed in Ref **6**.

4.7 Care should be taken in interpreting results of this test when it is used on surface-treated concretes, for example, concretes treated with penetrating sealers. The results from this test on some such concretes indicate low resistance to chloride ion penetration, while 90-day chloride ponding tests on companion slabs show a higher resistance.

4.8 The details of the test method apply to 4-in. (102-mm) nominal diameter specimens. This includes specimens with actual diameters ranging from 3.75 in. (95 mm) to 4.0 in. (102 mm). Other specimen diameters may be tested with appropriate changes in the applied voltage cell design (see 7.5 and Fig. 1).

4.8.1 For specimen diameters other than 3.75 in. (95 mm), the test result value for total charge passed must be adjusted following the procedure in 11.2. For specimens with diameters less than 3.75 in. (95 mm), particular care must be taken in coating and mounting the specimens to ensure that the conductive solutions are able to contact the entire end areas during the test.

5. Interferences

5.1 This test method can produce misleading results when calcium nitrite has been admixed into a concrete. The results from this test on some such concretes indicate higher coulomb values, that is, lower resistance to chloride ion penetration, than from tests on identical concrete mixtures (controls) without calcium nitrite. However, long-term chloride ponding tests indicate the concretes with calcium nitrite were at least as resistant to chloride ion penetration as the control mixtures.

NOTE 2—Other admixtures might affect results of this test similarly. Long term ponding tests are recommended if an admixture effect is suspected.

5.2 Since the test results are a function of the electrical resistance of the specimen, the presence of reinforcing steel or other embedded electrically conductive materials may have a significant effect. The test is not valid for specimens containing reinforcing steel positioned longitudinally, that is, providing a continuous electrical path between the two ends of the specimen.

TABLE 1 Chloride Ion Penetrability Based on Charge Passed (1)

Charge Passed (coulombs)	Chloride Ion Penetrability
>4,000	High
2,000–4,000	Moderate
1,000–2,000	Low
100–1,000	Very Low
<100	Negligible

6. Apparatus

6.1 *Vacuum Saturation Apparatus* (see Fig. 2 for example):

6.1.1 *Separatory Funnel*, or other sealable, bottom-draining container with a minimum capacity of 500 mL.

6.1.2 *Beaker (1000 mL or larger) or other container*—Capable of holding concrete specimen(s) and water and of fitting into vacuum desiccator (see 6.1.3).

6.1.3 *Vacuum Desiccator*—250-mm (9.8-in.) inside diameter or larger. Desiccator must allow two hose connections through a rubber stopper and sleeve or through a rubber stopper only. Each connection must be equipped with a stopcock.

6.1.4 *Vacuum Pump or Aspirator*—Capable of maintaining a pressure of less than 50 mm Hg (6650 Pa) in desiccator.

NOTE 3—Since vacuum will be drawn over water, a vacuum pump should be protected with a water trap, or pump oil should be changed after each operation.

6.1.5 *Vacuum Gage or Manometer*—Accurate to ± 5 mm Hg (± 665 Pa) over range 0–100 mm Hg (0–13300 Pa) pressure.

6.2 *Coating Apparatus and Materials*:

6.2.1 *Coating*—Rapid setting, electrically nonconductive, capable of sealing side surface of concrete cores.

6.2.2 *Balance or Scale, Paper Cups, Wooden Spatulas, and Disposable Brushes*—For mixing and applying coating.

6.3 *Specimen Sizing Equipment* (not required if samples are cast to final specimen size).

6.3.1 *Movable Bed Water-Cooled Diamond Saw or Silicon Carbide Saw*.

7. Reagents, Materials, and Test Cell

7.1 *Specimen-Cell Sealant*—Capable of sealing concrete to poly (methyl methacrylate), for example, Plexiglas, against water and dilute sodium hydroxide and sodium chloride solutions at temperatures up to 200 °F (90 °C); examples include RTV silicone rubbers, silicone rubber caulkings, other synthetic rubber sealants, silicone greases, and rubber gaskets.

7.2 *Sodium Chloride Solution*—3.0 % by mass (reagent grade) in distilled water.

7.3 *Sodium Hydroxide Solution*—0.3 N (reagent grade) in distilled water.

7.3.1 **Warning**—Before using NaOH, review: (*1*) the safety precautions for using NaOH; (*2*) first aid for burns; and (*3*) the emergency response to spills, as described in the manufacturer's Material Safety Data Sheet or other reliable safety literature. NaOH can cause very severe burns and injury to unprotected skin and eyes. Suitable personal protective equipment should always be used. These should include full-face shields, rubber aprons, and gloves impervious to NaOH. Gloves should be checked periodically for pin holes.

symmetric poly (methyl methacrylate) chambers, each containing electrically conductive mesh and external connectors. One design in common use is shown in Fig. 1 and Fig. 3. However, other designs are acceptable, provided that overall dimensions (including dimensions of the fluid reservoir) are the same as shown in Fig. 1 and width of the screen and shims are as shown.

7.6 *Temperature Measuring Device (optional)*—30 to 250 °F (0 to 120 °C) range.

7.7 *Voltage Application and Data Readout Apparatus*—Capable of holding 60 ± 0.1 V dc across applied voltage cell over entire range of currents and of displaying voltage accurate to ± 0.1 V and current to ± 1 mA. Apparatus listed in 7.7.1-7.7.5 is a possible system meeting this requirement.

7.7.1 *Voltmeter*—Digital (DVM), 3 digit, minimum 0–99.9 V range, rated accuracy ± 0.1 %.

7.7.2 *Voltmeter*—Digital (DVM), 4½ digit, 0–200 mV range, rated accuracy ± 0.1 %.

7.7.3 *Shunt Resistor*—100 mV, 10A rating, tolerance ± 0.1 %. Alternatively, a 0.01 Ω resistor, tolerance ± 0.1 %, may be used, but care must be taken to establish very low resistance connections.

7.7.4 *Constant Voltage Power Supply*— 0–80 V dc, 0–2 A, capable of holding voltage constant at 60 ± 0.1 V over entire range of currents.

7.7.5 *Cable*—Two conductor, No. 14 (1.6 mm), insulated, 600 V.

8. Test Specimens

8.1 Sample preparation and selection depends on the purpose of the test. For evaluation of materials or their proportions, samples may be (*a*) cores from test slabs or from large diameter cylinders or (*b*) 4-in. (102-mm) diameter cast cylinders. For evaluation of structures, samples may be (*a*) cores from the structure or (*b*) 4-in. (102-mm) diameter cylinders cast and cured at the field site. Coring shall be done with a drilling rig equipped with a 4-in. (102-mm) diameter diamond-dressed core bit. Select and core samples following procedures in Test Method C42/C42M. Cylinders cast in the laboratory shall be prepared following procedures in Practice C192/C192M. When cylinders are cast in the field to evaluate a structure, care must be taken that the cylinders receive the same treatment as the structure, for example, similar degree of consolidation, curing, and temperature history during curing.

NOTE 4—The maximum allowable aggregate size has not been established for this test. Users have indicated that test repeatability is satisfactory on specimens from the same concrete batch for aggregates up to 25.0 mm (1 in.) nominal maximum size.

8.2 When results of this test method are used for evaluation of materials or mixture proportions based on cast specimens for purposes of quality control, mixture submittals, or acceptance of concrete, prepare 4-in (102-mm) diameter cylindrical specimens in accordance with Practice C192/C192M for concrete mixtures prepared in the laboratory or Practice C31/C31M from samples of fresh concrete obtained in the field. Unless otherwise specified, moist cure specimens in accordance with 8.2.1 for concrete mixtures containing only portland cement and in accordance with 8.2.2 for concrete mixtures containing supplementary cementitious materials. Use the same method and duration of curing test specimens when comparing two or more mixtures. The accelerated moist curing procedure in 8.2.3 is permitted as an alternative to the extended moist curing procedure for concrete mixtures containing supplementary cementitious materials (See Note 6).

8.2.1 *Moist Curing*—Cure test specimens for at least 28 days in accordance with Practice C192/C192M or in accordance with the standard curing procedure of Practice C31/C31M for specimens prepared in the field.

8.2.2 *Extended Moist Curing*—Cure test specimens for at least 56 days in accordance with Practice C192/C192M for specimens prepared in the laboratory or in accordance with the standard curing procedure of Practice C31/C31M for specimens prepared in the field.

8.2.3 *Accelerated Moist Curing*—Provide 7 days of moist curing in accordance with Practice C192/C192M for specimens prepared in the laboratory or in accordance with the standard curing procedure of Practice C31/C31M for specimens prepared in the field. After 7 days of moist curing, immerse the specimens for 21 days in lime-saturated water at 38.0 ± 2.0 °C (100 ± 3 °F).

NOTE 5—The 56-day moist curing period is to allow for some supplementary cementitious materials to develop potential properties because of their slower rate of hydration. Concrete containing supplementary cementitious materials may continue to show reductions in results of this test beyond 56 days, and in some cases, it may be appropriate to test at later ages, such as 3 months.

NOTE 6—The accelerated moist curing procedure has been found useful in providing an earlier indication of potential property development with slower hydrating supplementary cementitious materials (**7**). Because the two different curing methods may not provide the same results, the specifier of the test may require a correlation between results for extended moist cured and accelerated moist cured specimens and establish appropriate acceptance criteria when the accelerated moist curing procedure is used or permitted. Comparisons between results of moist cured specimens and field performance of concrete are documented in (**8**).

8.3 Transport the cores or field-cured cylinders to the laboratory in sealed (tied) plastic bags. If specimens must be shipped, they should be packed so as to be properly protected from freezing and from damage in transit or storage.

8.4 Using the water-cooled diamond saw or silicon carbide saw, cut a 2 ± ⅛ in. (51 ± 3 mm) slice from the top of the core or cylinder, with the cut parallel to the top of the core. This slice will be the test specimen. Use a belt sander to remove any burrs on the end of the specimen.

8.5 Special processing is necessary for core samples where the surface has been modified, for example, by texturing or by applying curing compounds, sealers, or other surface treatments, and where the intent of the test is not to include the effect of the modifications. In those cases, the modified portion of the core shall be removed and the adjacent 2 ± ⅛ in. (51 ± 3 mm) slice shall be used for the test.

9. Conditioning

9.1 Vigorously boil a litre or more of tapwater in a large sealable container. Remove container from heat, cap tightly, and allow water to cool to ambient temperature.

9.2 Allow specimen prepared in Section 8 to surface dry in air for at least 1 h. Prepare approximately ½ oz (10 g) of rapid

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

setting coating and brush onto the side surface of specimen. Place the sample on a suitable support while coating to ensure complete coating of sides. Allow coating to cure according to the manufacturer's instructions.

9.3 The coating should be allowed to cure until it is no longer sticky to the touch. Fill any apparent holes in the coating and allow additional curing time, as necessary. Place specimen in beaker or other container (see 6.1.2), then place container in vacuum desiccator. Alternatively, place specimen directly in vacuum desiccator. Both end faces of specimen must be exposed. Seal desiccator and start vacuum pump or aspirator. Pressure should decrease to less than 50 mm Hg (6650 Pa) within a few minutes. Maintain vacuum for 3 h.

9.4 Fill separatory funnel or other container (see 6.1.1) with the de-aerated water prepared in 9.1. With vacuum pump still running, open water stopcock and drain sufficient water into beaker or container to cover specimen (do not allow air to enter desiccator through this stopcock).

9.5 Close water stopcock and allow vacuum pump to run for one additional hour.

9.6 Close vacuum line stopcock, then turn off pump. (Change pump oil if a water trap is not being used.) Turn vacuum line stopcock to allow air to re-enter desiccator.

9.7 Soak specimen under water (the water used in steps 9.4-9.6) in the beaker for 18 ± 2 h.

10. Procedure

10.1 Remove specimen from water, blot off excess water, and transfer specimen to a sealed can or other container which will maintain the specimen in 95 % or higher relative humidity.

10.2 Specimen mounting (all sealants other than rubber gaskets; use 10.2.2 or 10.2.3, as appropriate):

10.2.1 If using two-part specimen-cell sealant, prepare approximately 0.7 to 1.4 oz (20 to 40 g).

10.2.2 *Low Viscosity Specimen-Cell Sealant*—If filter paper is necessary, center filter paper over one screen of the applied voltage cell. Trowel sealant over brass shims adjacent to applied voltage cell body. Carefully remove filter paper. Press specimen onto screen; remove or smooth excess sealant which has flowed out of specimen-cell boundary.

10.2.3 *High Viscosity Specimen-Cell Sealant*—Set specimen onto screen. Apply sealant around specimen-cell boundary.

10.2.4 Cover exposed face of specimen with an impermeable material such as rubber or plastic sheeting. Place rubber stopper in cell filling hole to restrict moisture movement. Allow sealant to cure per manufacturer's instructions.

10.2.5 Repeat steps 10.2.2 (or 10.2.3) and 10.2.4 on second half of cell. (Specimen in applied voltage cell now appears as shown in Fig. 4.)

10.3 Specimen mounting (rubber gasket alternative): Place a 4-in. outside diameter by 3-in. inside diameter by ¼-in. (100 mm outside diameter by 75 mm inside diameter by 6 mm) circular vulcanized rubber gasket in each half of the test cell. Insert sample and clamp the two halves of the test cell together to seal.

10.4 Fill the side of the cell containing the top surface of the specimen with 3.0 % NaCl solution. (That side of the cell will be connected to the negative terminal of the power supply in

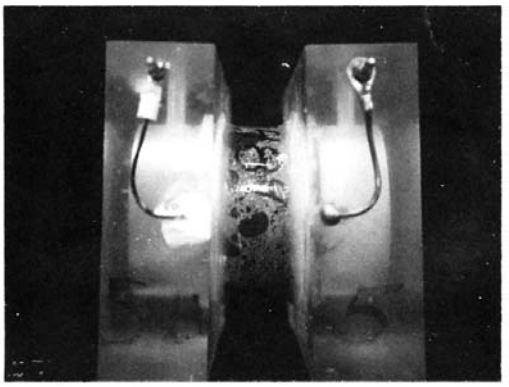

FIG. 4 Specimen Ready for Test

10.5.) Fill the other side of the cell (which will be connected to the positive terminal of the power supply) with 0.3 N NaOH solution.

10.5 Attach lead wires to cell banana posts. Make electrical connections to voltage application and data readout apparatus as appropriate; for example, for system listed in 7.7.1-7.7.5, connect as shown in Fig. 5. Turn power supply on, set to 60.0 ± 0.1 V, and record initial current reading. Temperatures of the specimen, applied voltage cell, and solutions shall be 68 to 77 °F (20 to 25 °C) at the time the test is initiated, that is, when the power supply is turned on.

10.6 During the test, the air temperature around the specimens shall be maintained in the range of 68 to 77 °F (20 to 25 °C).

10.7 Read and record current at least every 30 min. If a voltmeter is being used in combination with a shunt resistor for the current reading (see Fig. 5), use appropriate scale factors to convert voltage reading to amperes. Each half of the test cell must remain filled with the appropriate solution for the entire period of the test.

NOTE 7—During the test, the temperature of the solutions should not be allowed to exceed 190 °F (90 °C) in order to avoid damage to the cell and to avoid boiling off the solutions. Although it is not a requirement of the method, the temperature of the solutions can be monitored with thermocouples installed through the ⅛-in. (3-mm) venthole in the top of the cell. High temperatures occur only for highly penetrable concretes. If a test of a 2-in. (51-mm) thick specimen is terminated because of high temperatures, this should be noted in the report, along with the time of

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

termination, and the concrete rated as having very high chloride ion penetrability (see 12.1.9).

10.8 Terminate test after 6 h, except as discussed in Note 7.

10.9 Remove specimen. Rinse cell thoroughly in tapwater; strip out and discard residual sealant.

11. Calculation and Interpretation of Results

11.1 Plot current (in amperes) versus time (in seconds). Draw a smooth curve through the data, and integrate the area underneath the curve in order to obtain the ampere-seconds, or coulombs, of charge passed during the 6-h test period. (See Note 8) Alternatively, use automatic data processing equipment to perform the integration during or after the test and to display the coulomb value. The total charge passed is a measure of the electrical conductance of the concrete during the period of the test.

NOTE 8—*Sample Calculation*—If the current is recorded at 30 min intervals, the following formula, based on the trapezoidal rule, can be used with an electronic calculator to perform the integration:

$$Q = 900\,(I_0 + 2I_{30} + 2I_{60} + \ldots + 2I_{300} + 2I_{330} + I_{360}) \quad (1)$$

where:

Q = charge passed (coulombs),
I_o = current (amperes) immediately after voltage is applied, and
I_t = current (amperes) at t min after voltage is applied.

11.2 If the specimen diameter is other than 3.75 in. (95 mm), the value for total charge passed established in 11.1 must be adjusted. The adjustment is made by multiplying the value established in 11.1 by the ratio of the cross-sectional areas of the standard and the actual specimens. That is:

$$Q_s = Q_x \times \left(\frac{3.75}{x}\right)^2 \quad (2)$$

where:

Q_s = charge passed (coulombs) through a 3.75-in. (95-mm) diameter specimen,
Q_x = charge passed (coulombs) through x in. diameter specimen, and
x = diameter (in.) of the nonstandard specimen.

11.3 Use Table 1 to evaluate the test results. These values were developed from data on slices of cores taken from laboratory slabs prepared from various types of concretes.

11.3.1 Factors which are known to affect chloride ion penetration include: water-cement ratio, the presence of polymeric admixtures, sample age, air-void system, aggregate type, degree of consolidation, and type of curing.

12. Report

12.1 Report the following, if known:

12.1.1 Source of core or cylinder, in terms of the particular location the core or cylinder represents,

12.1.2 Identification number of core or cylinder and specimen,

12.1.3 Location of specimen within core or cylinder,

12.1.4 Type of concrete, including binder type, water-cement ratio, and other relevant data supplied with samples,

12.1.5 Description of specimen, including presence and location of reinforcing steel, presence and thickness of overlay, and presence and thickness of surface treatment,

12.1.6 Curing history of specimen; indicate moist curing, extended moist curing, or accelerated moist curing as defined in this test method, as applicable,

12.1.7 Unusual specimen preparation, for example, removal of surface treatment,

12.1.8 Test results, reported as the total charge passed over the test period (adjusted per 11.2), and

12.1.9 The qualitative chloride ion penetrability equivalent to the calculated charge passed (from Table 1).

13. Precision and Bias [5]

13.1 *Precision*:

13.1.1 *Single-Operator Precision*—The single operator coefficient of variation of a single test result has been found to be 12.3 % (Note 9). Therefore the results of two properly conducted tests by the same operator on concrete samples from the same batch and of the same diameter should not differ by more than 42 % (Note 9).

13.1.2 *Multilaboratory Precision*—The multilaboratory coefficient of variation of a single test result has been found to be 18.0 % (Note 9). Therefore results of two properly conducted tests in different laboratories on the same material should not differ by more than 51 % (Note 9). The average of three test results in two different laboratories should not differ by more than 42 % (Note 10).

NOTE 9—These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C670. The precision statements are based on the variations in tests on three different concretes, each tested in triplicate in eleven laboratories. All specimens had the same actual diameters, but lengths varied within the range 2 ± ⅛ in. (51 ± 3 mm).

NOTE 10—Although the test method does not require the reporting of more than one test result, testing of replicate specimens is usually desirable. The precision statement for the averages of three results is given since laboratories frequently will run this number of specimens. When averages of three results are established in each laboratory, the multilaboratory coefficient of variation, s_{ML} is calculated as:

$$s_{ML} = \sqrt{\frac{s_{WL}^2}{3} + s_{BL}^2} \quad (3)$$

where:

s_{WL}^2 = within-laboratory variance and
s_{BL}^2 = between-laboratory variance.

The percentage cited represents the (d2s %) limit based on the value for the multilaboratory coefficient of variation.

13.2 *Bias*—The procedure of this test method for measuring the resistance of concrete to chloride ion penetration has no bias because the value of this resistance can be defined only in terms of a test method.

14. Keywords

14.1 chloride content; corrosion; deicing chemicals; resistance-chloride penetration

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C1202 – 09, that may impact the use of this test method. (Approved February 1, 2010)

(*1*) Revised Sections 4, 8, and 12.

Committee C09 has identified the location of selected changes to this test method since the last issue, C1202 – 08, that may impact the use of this test method. (Approved May 1, 2009)

(*1*) Revised 4.4.

Committee C09 has identified the location of selected changes to this test method since the last issue, C1202 – 07, that may impact the use of this test method. (Approved December 15, 2008)

(*1*) Revised 4.4.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1214 – 02 (Reapproved 2009)

Standard Test Method for Concrete Pipe Sewerlines by Negative Air Pressure (Vacuum) Test Method[1]

This standard is issued under the fixed designation C 1214; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers procedures for testing concrete pipe sewerlines, when using the negative air pressure (vacuum) test method to demonstrate the integrity of the installed material and the construction procedures. This test method covers testing of 4 to 36-in. diameter circular concrete pipe sewerlines utilizing gasketed joints.

NOTE 1—The user of this test method is advised that methods described herein may also be used as a preliminary test to enable the manufacturer or installer to demonstrate the condition of sewer pipe prior to delivery or backfill. Minimum test times presented in Table 1 are for pipelines. Holding times for testing an individual pipe may have to be increased to allow for the accumulation of leakage when the tested pipe are incorporated into a continuous pipeline.

NOTE 2—The user of this test method is advised that the negative air pressure (vacuum) test criteria presented in this test method are similar to those in general use. The test and criteria have been used widely and successfully in testing smaller diameter pipe. Larger pipe will be accepted more conveniently by visual inspection and individual joint testing.

NOTE 3—The user of this test method is advised that no correlation has been found between loss of vacuum and water leakage.

1.2 This test method is the inch-pound companion to Test Method C 1214M; therefore, no SI equivalents are presented in the test method.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* See Section 6 for specific safety precautions.

C 822 Terminology Relating to Concrete Pipe and Related Products

C 924 Practice for Testing Concrete Pipe Sewer Lines by Low-Pressure Air Test Method

C 969 Practice for Infiltration and Exfiltration Acceptance Testing of Installed Precast Concrete Pipe Sewer Lines

TABLE 1 Minimum Test Time

Nominal Pipe Size, in.	T (Time), min/100 ft	Nominal Pipe Size, in.	T (Time), min/100 ft
4	0.3	21	3.0
6	0.7	24	3.6
8	1.2	27	4.2
10	1.5	30	4.8
12	1.8	33	5.4
15	2.1	36	6.0
18	2.4		

3. Terminology

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see Terminology C 822.

4. Summary of Test Method

4.1 The sewerline to be tested is plugged. Air is removed from the plugged line by a vacuum pump or vacuum reservoir. The amount of vacuum loss is used to determine the acceptability of the sewerline.

5. Significance and Use

5.1 This is not a routine test. The values recorded are applicable only to the sewer being tested and at the time of testing.

6. Safety Precautions

6.1 **Warning—**The user of this test method is advised that this test may be dangerous if a line is not prepared properly and proper procedures are not followed.

6.2 Access manholes or structures must be ventilated and air quality continuously monitored.

6.3 No one shall be allowed in or near the manholes during testing.

7. Preparation of the Sewerline

7.1 Where practical, clean the line prior to testing, wet the pipe surface, and eliminate debris.

[1] This test method is under the jurisdiction of ASTM Committee C13 on Concrete Pipe and is the direct responsibility of Subcommittee C13.09 on Methods of Test.

Current edition approved June 1, 2009. Published July 2009. Originally approved in 1992. Last previous edition approved in 2002 as C 1214 – 02.

NOTE 4—The user of this test method is advised that a wetted exterior pipe surface is desirable and will produce more consistent test results. Air may pass through the walls of dry pipe. This can be overcome by wetting the pipe. Usually, moisture absorbed from the backfill is sufficient to cope with this situation. If the problem persists, segmental testing of the line will establish if there is a significant leak.

7.2 Plug all pipe outlets including laterals. Review safety precautions in Section 6.

8. Procedure

8.1 Determine the test time for the sewerline to be tested by using Table 1. Table 1 has been established using the criteria specified in Table 2 and the formulas contained in the Appendixes. The test time is the time required for the vacuum to drop from 7 to 5 in. of mercury.

NOTE 5—To provide satisfactory test results, the vacuum pump shall be capable of evacuating the sewer test section in the required test time, or less, as determined by 8.1. The pump capacity required to accomplish the evacuation of the line is equal to the rate necessary to reduce the sewer to the desired pressure plus the allowable vacuum loss rate:

$$C = 0.17D^2L/T + Q \quad (1)$$

where:

C = vacuum pump capacity, ft^3/min,
T = required test time, or less, min,
D = pipe internal diameter, ft,
L = length of test section, ft, and
Q = allowable vacuum loss rate, ft^3/min.

TABLE 2 Allowable Air Loss

Nominal Pipe Size, in.	Q, ft^3/min	Nominal Pipe Size, in.	Q, ft^3/min
4	2.0	21	5.5
6	2.0	24	6.0
8	2.0	27	6.5
10	2.5	30	7.0
12	3.5	33	7.5
15	4.0	36	8.0
18	5.0		

8.2 Evacuate air until the internal air pressure of the sewerline is lowered by approximately 8 in. of mercury. Close the valve on the vacuum line and shut off the vacuum pump. Allow the air pressure to stabilize.

8.3 When the pressure has stabilized and is at or below the starting test vacuum of 7 in. of mercury, commence the test by allowing the gage pressure to drop to 7 in. of mercury, at which point the time recording is initiated. Record the drop in vacuum for the test period.

8.4 If the drop in vacuum is 2 in. of mercury or less during the test period, accept the line. If the drop in vacuum is more than 2 in. of mercury during the test period, inspect, evaluate, and retest the line to determine the cause of excessive vacuum loss.

8.5 Use or failure of this vacuum test shall not preclude acceptance by appropriate low-pressure air (see Practice C 924), water infiltration or exfiltration testing (see Practice C 969), or other means.

9. Vacuum Test Criteria

9.1 An appropriate allowable vacuum loss, Q, in cubic feet per minute has been established for each nominal pipe size. Based on field experience, the vacuum loss Qs that have been selected will enable detection of any significant leak. Table 2 lists the Q established for each pipe size.

9.2 When a main line with connected lateral is to be tested as a unit, the total volume of the main and laterals shall be considered and the allowable air loss rate shall be that listed for the main.

10. Precision and Bias

10.1 No justifiable statement is presently capable of being made either on precision or bias of this procedure since the test result merely states whether there is conformance to the criteria for success specified. Due to the sealing effects of ground water and internal flow on sewerline, the test conditions and results are not reproducible.

APPENDIXES

(Nonmandatory Information)

X1. EQUATIONS USED IN PRACTICE C 1214

X1.1 The required test time per 100 ft for a single diameter pipe using Table 2:

$$T_T = (0.00037)\,(D^2L/Q) \quad (X1.1)$$

X1.2 The required test time for a single diameter pipe using Table 1:

$$T_T = (L)\,(T/100) \quad (X1.2)$$

X1.3 For testing a sewer system involving different diameter pipe, the allowable vacuum loss rate shall be that for the main sewer. The volume of each size of lateral pipe is converted to an equivalent length of required test time as follows:

$$L_e = \Sigma\,(d^2 1/D^2) \quad (X1.3)$$

$$T_T = (L + L_e)\,(T/100) \quad (X1.4)$$

X1.4 The symbols used in the equations in this test method

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:48:51 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

are defined as follows:

where:

T = minimum test time per 100 ft of pipe vacuum to drop from 7.0 to 5.0 in. of mercury, min,
T_T = minimum test time for total system, min,
D = designated inside diameter of test section or main sewer, in.,
d = designated inside diameter of lateral, in.,
L = length of test section or main sewer, ft,
L_e = total volume of all laterals connected to the main sewer expressed as an equivalent length of the main sewer, ft,
l = total length of each diameter lateral, ft, and
Q = allowable air loss rate, ft^3/min.

X2. APPLICATION OF PRACTICE C 1214

X2.1 The following examples have been prepared to demonstrate the techniques of applying this test method.

X2.2 *Example 1*—A sewer system consists of 600 ft of 18-in. diameter concrete pipe between manholes A and B; 35 ft of 12-in. diameter pipe between manholes B and C.

X2.2.1 *Find*—The appropriate test times to demonstrate the integrity of the installed lines.

X2.2.2 *Solution*:

X2.2.2.1 For the main sewer between manholes A and B, use Eq X1.2 and from Table 1;

$$T_T = (L)\,(T/100) \quad \text{(X2.1)}$$

$$T_T = (600)\,(2.4/100) \quad \text{(X2.2)}$$

$$T_T = 14 \text{ min} \quad \text{(X2.3)}$$

X2.2.2.2 Similarly, for the main sewer between manholes B and C:

$$T_T = (35)\,(1.8/100) \quad \text{(X2.4)}$$

$$T_T = 0.6 \text{ min} \quad \text{(X2.5)}$$

X2.3 *Example 2*—The 600 ft of 18-in. diameter concrete pipe between manholes A and B in Example 1 has connected 6-in. laterals with a total length of 900 ft.

X2.3.1 *Find*—The appropriate test time to demonstrate the integrity of the installed lines.

X2.3.2 *Solution*:

X2.3.2.1 Use Eq X1.3 to convert the total volume of 6-in. laterals to an equivalent length of main sewer:

$$L_e = \Sigma\,(d^2\,1/D^2) \quad \text{(X2.6)}$$

$$L_e = 6^2 \times 900/18^2 \quad \text{(X2.7)}$$

$$L_e = 100 \text{ ft} \quad \text{(X2.8)}$$

X2.3.2.2 For the connected system, use Eq X1.4 and from Table 1, T = 2.4 min./100 ft for 18-in. pipe:

$$T_T = (L + L_e)\,(T/100) \quad \text{(X2.9)}$$

$$T_T = (600 + 100)\,(2.4/100) \quad \text{(X2.10)}$$

$$T_T = 17 \text{ min} \quad \text{(X2.11)}$$

X2.4 If a line fails the vacuum test, the following course of action shall be considered:

X2.4.1 Segmentally test the line and compare the time-vacuum loss values in each segment.

X2.4.2 If the values in each segment are comparable, the vacuum loss problem shall be distributed throughout the line, and further analysis shall be made.

X2.4.3 If the values in each segment are significantly different, each segment shall be evaluated and further analysis be made to determine the location of any significant vacuum loss.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1218/C 1218M – 99 (Reapproved 2008)

Standard Test Method for Water-Soluble Chloride in Mortar and Concrete[1]

This standard is issued under the fixed designation C 1218/C 1218M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method provides procedures for the sampling and analysis of hydraulic-cement mortar or concrete for chloride that is water soluble under the conditions of test.

1.2 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes shall not be considered as requirements of this standard.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as a standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 114 Test Methods for Chemical Analysis of Hydraulic Cement

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 823 Practice for Examination and Sampling of Hardened Concrete in Constructions

C 1084 Test Method for Portland-Cement Content of Hardened Hydraulic-Cement Concrete

D 1193 Specification for Reagent Water

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

E 832 Specification for Laboratory Filter Papers

3. Significance and Use

3.1 Water-soluble chloride, when present in sufficient amount, is capable of leading to initiation or acceleration of the corrosion of metals, such as steel, embedded in or contacting a cement system such as mortar, grout, or concrete. Thus, its determination shall be required to evaluate the potential of a cement system for undergoing such reactions or to investigate cement systems where such reaction has already occurred. However, it must be recognized that water-soluble chloride determined at some particular time in the life of a cement system is capable of being substantially different than that at another time; for example, the service environment is capable of resulting in a higher water-soluble chloride content due to changes in solubility or a lower one due to leaching.

3.1.1 Test conditions are capable of affecting water-soluble chloride determinations. Take caution when comparing results from this test method with those from other test methods.

3.2 Sulfides are known to interfere with the determination of chloride content. Blast-furnace slag aggregates and cements contain sulfide sulfur in concentrations that are capable of such interference and produce erroneously high test results. Treatment with hydrogen peroxide, as discussed in Test Methods C 114, is used to eliminate such interference.

3.3 There are aggregates that contain chloride that is not available for corrosion. Such chloride will be detected by use of this test method.[3]

4. Apparatus

4.1 *Sampling Equipment*:

4.1.1 The apparatus required for obtaining samples by coring or sawing is described in Test Method C 42/C 42M.

4.1.2 Use the following apparatus for sampling by drilling (pulverization):

4.1.2.1 Rotary impact drill and drill or pulverizing bits.

4.1.2.2 Spoon or other suitable means to collect without contamination pulverized sample material produced by drilling.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.69 on Miscellaneous Tests.

Current edition approved Jan. 1, 2008. Published January 2008. Originally approved in 1992. Last previous edition approved in 1999 as C 1218/C 1218M – 99.

www.technobetar.ir

4.1.2.3 Sample containers capable of maintaining samples in an uncontaminated state.

4.2 *Sample Processing Apparatus*—The apparatus required for processing samples shall be chosen for its suitability for the purposes of the investigation, and frequently includes a concrete saw and one or more pulverizers.

4.2.1 Samples more than 25 mm [1 in.] in maximum dimension shall be reduced in size by use of a jaw crusher or broken into smaller pieces by hammering carefully to avoid loss of smaller pieces.

4.2.2 Crush particles less than 25 mm [1 in.] in maximum dimension using a rotating-puck grinding apparatus, or by using a disc pulverizer, or mortar and pestle operated to restrict to negligible levels the loss of fine particles.

4.2.3 The 850-µm [No. 20] sieve shall comply with Specification E 11.

4.3 The apparatus required for the chloride determination step is given as the reference test method for chloride in Test Methods C 114.

4.4 Glazed paper to minimize adherence of fine particles for use as described in 7.1.

5. Reagents

5.1 The reagents required for the chloride determination are given in the reference test method for chloride of Test Methods C 114.

6. Sampling

6.1 Select the sample as required for the purpose of the investigation (Note 1).

NOTE 1—Because of the small nominal maximum size of the aggregate in a mortar, pieces of mortar having a mass of at least 10 g will be more representative of a much larger volume of mortar than would an equivalently sized sample of concrete. Practice C 823 may be used as a guide for sampling.

6.1.1 Take concrete cores in accordance with Test Method C 42/C 42M unless otherwise specified (Note 2):

NOTE 2—Concrete cores taken in accordance with Test Method C 42/C 42M may be cut longitudinally to provide a 12-mm [½-in.] thick section generally representative of the core, or cut laterally into 12-mm [½-in.] thick discs representative of the concrete core at various depths. Experience has shown that the cooling water from core cutting will not dissolve a significant amount of the chloride.

6.1.2 Powdered concrete obtained by use of a rotary impact drill is frequently useful in determining chloride concentration with depth in bridge decks and pavements. When the nominal maximum coarse aggregate size is 25 mm [1 in.] or more such samples are unrepresentative. The data must be used with care or several samples combined. Procedures for this method of sampling are as follows:

6.1.2.1 Using the rotary impact drill, drill perpendicular to the concrete surface or parallel to the axis of a cored specimen to a specified depth or a depth sufficient to obtain a representative sample of at least 20 g of powdered material. To prevent sample contamination, avoid contact of sample with hands and other sources of perspiration. Clean all sampling tools prior to each sampling operation (Note 3). Do not use lubricants during drilling.

NOTE 3—Sampling tools may be cleaned with a brush, cloth, ethyl alcohol rinse, water rinse, or other method that will not contaminate the sample.

6.1.2.2 Transfer powdered sample into the sample container using a spoon or other suitable means.

7. Sample Preparation

7.1 Pulverize the sample so that all the material will pass a 850-µm [No. 20] sieve. Thoroughly blend the material by transferring it from one glazed paper to another at least ten times.

8. Procedure

8.1 Select a sample having a mass of approximately 10 g. Weigh the sample to the nearest 0.01 g and place it into a 250-mL beaker. Add 50 ± 1 mL of reagent water meeting Specification D 1193, cover with a watch glass, bring to a boil and boil for 5 min. Allow to stand 24 h. Filter by gravity or suction through a fine-texture, Type II, Class G filter paper of Specification E 832. Transfer the filtrate to a 250-mL beaker. Add 3 ± 0.1 mL of (1:1) nitric acid and add 3 ± 0.1 mL of hydrogen peroxide (30 % solution) to the filtrate. Cover the beaker with a watch glass and allow to stand for 1 to 2 min. Heat the covered beaker rapidly to boiling. Do not allow to boil for more than a few seconds. Remove from hot plate (Note 4). Proceed in accordance with the reference test method for chloride of Test Methods C 114, starting with the procedure that follows removal of the sample from the hot plate in Test Methods C 114.

NOTE 4—It is important to keep the beaker covered during heating and digestion to prevent the loss of chloride by volatilization.

9. Calculation

9.1 Calculate percent chloride by mass of mortar or concrete, by the reference test method for chloride given in Test Methods C 114.

9.2 Other useful measures of chloride concentration can be obtained as follows:

9.2.1 For calculating kilograms of chloride per cubic meter [pounds of chloride per cubic yard] of concrete, multiply percent chloride by $D_1/100$ or $D_2/100$,

where:

D_1 = oven-dry density as determined in the section on Concrete Density in Test Method C 1084, kg/m^3[lb/yd^3].

D_2 = saturated-surface-dry density as determined in the section on Concrete Density in Test Method C 1084, kg/m^3[lb/yd^3].

The report must state which density is used in the calculation.

9.2.2 For calculating percent chloride by mass of cement, multiply percent chloride by $100/P$,

where:

P = percent cement by mass in the mortar or concrete, as known or determined in accordance with Test Method C 1084.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10. Precision and Bias

10.1 *Precision*[4]—This precision statement is based on samples passing a 600-µm [No. 30] sieve instead of an 850-µm [No. 20] sieve and on a 1 min boil instead of a 5 min boil.

NOTE 5—It is the opinion of the committee that this difference in procedure should not significantly influence the precision beyond what is presented here.

10.1.1 The single-laboratory standard deviation has been found to be 0.0013 % chloride by mass of mortar or concrete.[5] Therefore, results of two properly conducted tests in the same laboratory on the same material are not expected to differ by more than 0.0037 %.

10.1.2 The multilaboratory standard deviation has been found to be 0.0037 % chloride by mass of mortar or concrete.[5] Therefore, results of two properly conducted tests from two different laboratories on samples of the same material are not expected to differ by more than 0.0106 %.[5] (Note 6).

NOTE 6—This precision statement applies to tests of samples prepared and ground by a single laboratory. Test results of concrete construction will vary depending upon the method of obtaining the sample and the size of the sample before it is crushed and reduced to pass the 850-µm [No. 20] sieve or pulverized.

10.2 *Bias*—The procedure in this test method has no bias because the value of water-soluble chloride is defined by the procedure.

11. Keywords

11.1 chloride; chloride content; concrete; mortar; water-soluble chloride

Designation: C 1222 – 09

Standard Practice for Evaluation of Laboratories Testing Hydraulic Cement[1]

This standard is issued under the fixed designation C 1222; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers the technical training and experience of laboratory testing personnel and identifies the minimum technical requirements for laboratory equipment used in testing of hydraulic cement as prescribed by ASTM.

1.2 This practice provides minimum criteria for evaluating the capability of a laboratory to perform chemical or physical tests listed in the various specifications on hydraulic cement (see Note 1).

NOTE 1—Relevant hydraulic cement specifications are Specifications C 91, C 150, C 595, C 845, and Performance Specification C 1157.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

www.technobetar.ir

unbiased evaluation of the organization and shall have the capability to assess the technical activities of testing laboratories (see Discussion).

3.2.1.1 *Discussion*—One such evaluation authority is the Cement and Concrete Reference Laboratory (CCRL).[4] Laboratory inspection is broadened into accreditation programs by such independent authorities as the National Voluntary Laboratory Accreditation Program (NVLAP),[5] American Association for Laboratory Accreditation (A2LA)[6] AASHTO Accreditation Program (AAP),[7] and others established.

3.2.2 *laboratory technician*, *n*—an employee of the laboratory who is assigned to perform the actual testing operations primarily conducted in the laboratory.

3.2.3 *quality systems*, *n*—those internal procedures and practices that a laboratory utilizes to ensure continued compliance with applicable testing standards.

3.2.4 *subcontracting*, *n*—employing another organization to provide testing services that the laboratory contracted to provide.

3.2.5 *testing laboratory*, *n*—an organization that measures, examines, performs tests, or otherwise determines the characteristics or performance of materials or products. This may include organizations that offer commercial testing services, an in-house quality control function, an academic institution, or any other organization providing the specified testing services.

4. Significance and Use

4.1 The testing of hydraulic cement is an important element in obtaining quality construction. A testing laboratory must be selected with care.

4.2 A testing laboratory shall be deemed qualified to perform and report the results of its tests if the laboratory meets the requirements of this practice.

4.3 This practice provides guidance for evaluating the organization, personnel, facilities, and quality systems of the laboratory. This practice may be supplemented by criteria and requirements for particular projects.

5. Documentation of Organization

5.1 The following information shall be readily available for review:

5.1.1 A description of the organization, including the complete legal name and address of the main office and each laboratory location, names and positions of the principal officers and the individual in charge of the laboratory,

5.1.2 A description of the organization management structure, and

5.1.3 A listing of the range of services offered.

6. Human Resources

6.1 The manager of the laboratory shall be a chemist, materials analyst, or an engineer and a full-time employee of the organization having at least three years supervisory experience in the testing of hydraulic cement; however, a person with equivalent science-oriented education or experience having satisfactorily directed testing of hydraulic cement is acceptable.

7. Testing and Additional Requirements

7.1 *Testing Requirements*—The organization shall have the capability of performing tests associated with its range of services (see Note 2). The laboratory shall have the facilities and equipment required for preparing, storing, conditioning, and testing specimens.

NOTE 2—The range of services of a testing laboratory may involve either chemical testing or physical testing, or both. The laboratory need not perform all tests listed in the applicable ASTM specification, but rather have the required equipment and demonstrate the ability to perform the procedures within its reported range of services.

7.1.1 The laboratory shall use the latest version of each referenced ASTM standard within one year of its publication in the *Annual Book of ASTM Standards* except where an earlier version is specifically required.

7.1.2 Laboratory personnel shall have convenient access to applicable standards.

7.2 *Additional Requirements*—The following requirements apply to only those tests performed by the laboratory. They are intended to supplement certain provisions of the standard test methods.

7.2.1 Analytical balances and reference masses shall be checked at least annually and shall conform to the requirements of Test Methods C 114.

7.2.2 Flow tables shall be checked at least every 2½ years using the calibration material described in Specification C 230.

7.2.3 Compression machines shall be verified, in accordance with Practices E 4 at least annually to determine if indicated loads, with and without the maximum load indicator (when so equipped), are accurate to ±1.0 %.

7.2.4 Compression machine bearing blocks shall be checked for planeness in accordance with the requirements of Test Method C 109/C 109M at least annually using a straightedge and feeler stock and shall be refinished if found to be out of tolerance.

7.2.5 Air content measures (400 mL) shall be calibrated at least every 2½ years following the procedures described in Test Method C 185.

7.2.6 Wagner turbidimeter apparatus shall be calibrated at least every six months using the procedures described in Test Method C 115.

7.2.7 Cube molds and tampers shall be checked for conformance to the design and dimensional requirements of Test Method C 109/C 109M at least every 2½ years.

7.2.8 Vicat apparatus and vicat ring shall be inspected and checked for conformance to Test Methods C 187, C 191, and C 451 at least every 2½ years.

www.technobetar.ir

7.2.9 Gillmore test apparatus shall be inspected and checked for conformance to the requirements of Test Method C 266 at least every 2½ years.

7.2.10 Mechanical mixing apparatus shall be inspected and checked for conformance to the requirements of Practice C 305 at least every 2½ years.

7.2.11 Air-permeability apparatus and related accessory equipment shall be calibrated and checked for conformance to Test Method C 204 at least every 2½ years.

7.2.11.1 Check determinations shall be made against standard or secondary standard reference samples every six months. If the results exceed the precision of the test method, the apparatus shall be recalibrated.

7.2.12 Water-retention apparatus and related equipment shall be checked for conformance to Test Method C 1506 at least every 2½ years.

8. Subcontracting

8.1 Subcontracting for the performance of part or all of a test method is permitted. When subcontracting is used the quality of the work provided must be ensured. The requirements for evaluation differ depending on the permanence of the subcontracting.

8.2 *Permanent Subcontracting*—When all or a portion of a test method is subcontracted on a permanent basis then the subcontracted organization must be subjected to separate evaluation according to this practice for the methods subcontracted. The laboratory shall retain a copy of this evaluation for review by the evaluation authority.

8.3 *Temporary Subcontracting*—When all or a portion of a test method is subcontracted on a temporary basis then the laboratory shall ensure the quality of the subcontracted work. The level and type of assurance will depend on the extent of the subcontracting (see Note 3). The laboratory shall retain records of this assurance for review by the evaluation authority.

NOTE 3—Some examples of assurance for different levels of temporary subcontracting are: (*1*) a review of calibrations records when the use of a piece of equipment is subcontracted; and (*2*) a satisfactory rating on a proficiency sample when a method is subcontracted. Other means of assurance are test results from a standard reference material or, in the case of chemical testing records of qualification testing.

9. Quality System

9.1 *Quality System Requirements*—The laboratory shall establish a quality system for ensuring the quality of services offered.

9.1.1 The laboratory shall maintain written documentation for the following:

9.1.1.1 Procedures for sampling, handling, and testing the hydraulic cement,

9.1.1.2 Procedures for training and evaluating laboratory personnel,

9.1.1.3 Procedures for calibrating and maintaining test equipment, and

9.1.1.4 Procedures for handling technical complaints from clients about results, procedures, or methods used.

9.1.2 The laboratory shall maintain current standard test methods and other pertinent reference material.

9.1.3 The laboratory shall participate in the appropriate CCRL Cement Proficiency Sample Program (see Note 4).

NOTE 4—The CCRL offers proficiency sample programs for physical and chemical testing of portland and blended cements and physical testing of masonry cement. The laboratory should participate in the program compatible with its scope.

9.1.4 *Internal Quality System Review*—The quality system shall contain a document describing the scope of internal quality system reviews, establishing the frequency of these reviews, identifying individuals responsible for the review, describing the distribution of reports to managements, procedures for handling deficiencies, and identifying the location of resulting records.

10. Laboratory Records and Reports

10.1 *Quality System Records*—The laboratory shall maintain records indicating compliance with the procedures described in their quality system documentation. Records shall be maintained for at least five years. The records shall include at least the following:

10.1.1 Results of all calibrations and verifications performed in the laboratory,

10.1.2 Traceability or accuracy of any in-house calibration or verification equipment used,

10.1.3 An inventory and description of all required test equipment,

10.1.4 Records on laboratory personnel that document work experience, education, on-the-job training, and action taken to ensure continued competence in performing the required test methods,

10.1.5 Records of audits and inspections by outside agencies and all reports or certifications, with applicable dates, of any evaluations or accreditations issued by an evaluating authority, and

10.1.6 Records of participation in the appropriate CCRL Cement Proficiency Sample Program.

10.2 *Test Report Records*—The laboratory shall maintain a system of documentation that permits verification of any test report issued. Each test report and supporting documentation shall be retained for at least three years. Corrections or additions to reports shall clearly reference the report being amended. Include in the test report or the supporting documentation the following information:

10.2.1 Name and address of the laboratory,

10.2.2 Identification of the report and the date issued,

10.2.3 Name of the client, if applicable,

10.2.4 Project identification, if applicable,

10.2.5 Sample identification,

10.2.6 Date of receipt of test samples,

10.2.7 Date(s) of test performance,

10.2.8 Identification of the standard test method used, and a notation of all known deviations from the test method observed during the testing of the sample being reported (see Note 5).

NOTE 5—Deviation from standard test methods may adversely affect results.

10.2.9 Identification of any standard test methods subcontracted and name of the organization that provided such services,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:48:31 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.2.10 Test results and other pertinent data required by this practice,

10.2.11 Identification of the person performing the tests, and

10.2.12 Name of the person in charge of the laboratory or their designee.

11. Laboratory Evaluation

11.1 *Laboratory Evaluation*—The laboratory shall have its facilities, personnel, equipment, and procedures inspected at intervals of approximately two years by an evaluation authority (see Discussion in 3.2.1) to confirm its ability to perform the required tests.

11.2 The evaluation authority, who performs the inspection of the laboratory, shall report to the manager of the laboratory on all applicable requirements of this practice including deficiencies that existed during the inspection. The laboratory manager is responsible for the correction of any deficiencies.

11.3 The manager of the laboratory shall report corrective actions taken on all inspection deficiencies when required by the evaluating authority for accreditation.

11.4 The evaluation authority providing the accreditation shall provide to the laboratory a statement of conformance when the laboratory evaluation report, including satisfactory correction of the deficiencies, has been accepted. The statement of conformance shall be evidence of the ability of the laboratory to conduct tests on cements in accordance with relevant standards. The report and statement of conformance shall be in such form that they may be used for public disclosure at the discretion of the laboratory.

12. Keywords

12.1 hydraulic cement; laboratory evaluation

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this practice since the last issue, C 1222 – 06, that may impact the use of this practice. (Approved June 1, 2009)

(*1*) Added new 9.1.4.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1228 – 96 (Reapproved 2009)

Standard Practice for Preparing Coupons for Flexural and Washout Tests on Glass Fiber Reinforced Concrete[1]

This standard is issued under the fixed designation C 1228; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers preparation of test coupons to be used in tests of plant manufactured thin-section glass fiber reinforced concrete (GFRC).

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 947 Test Method for Flexural Properties of Thin-Section Glass-Fiber-Reinforced Concrete (Using Simple Beam With Third-Point Loading)

C 1229 Test Method for Determination of Glass Fiber Content in Glass Fiber Reinforced Concrete (GFRC) (Wash-Out Test)

3. Significance and Use

3.1 Flexural strengths, as determined by Test Method C 947, are used for quality control and design of GFRC products and may be used to verify compliance with specifications and to collect data in research and development programs. It is, therefore, important that coupons be prepared according to a standard practice. The coupons are used to make test specimens for Test Method C 947 and for Test Method C 1229 to determine the amount of glass fiber reinforcement per unit volume of GFRC for quality control purposes.

4. Apparatus

4.1 *Form*—The form shall be rectangular in shape; made from wood, fiberglass reinforced plastic (FRP), GFRC, or steel with dimensions of ½ in. (13 mm) deep by 18 in. (450 mm) wide and 48 in. (1200 mm) long.

4.2 *Steel Trowel*, at least 20 in. (500 mm) long.

4.3 *Serrated Roller*, with handle.

4.4 *Strike-Off Bar (screed)*, at least 20 in. (500 mm) long, for leveling and thickness control of specimens.

5. Sampling

5.1 Sampling shall be in accordance with governing specifications.

6. Procedure

6.1 For plant manufactured product quality control purposes, spray the glass fiber reinforced material into the test form using the same method as used in production. The methods and conditions should be the same as for production materials except no mist coat or face mix should be used.

6.2 Trim off excess material from the sides of the form using a steel trowel.

6.3 Trowel surface smooth using a steel trowel.

6.4 See Fig. 1 for cutting layout for flexural test coupons and washout test coupons.

7. Curing

7.1 Cure the sample panel using the same methods and conditions as that used for production products.

8. Coding

8.1 Identify each sample board, and coupons.

9. Retained Samples

9.1 Retain samples as prescribed by Test Method C 947.

10. Keywords

10.1 coupons; flexural tests; glass fiber content; glass fiber reinforced concrete (GFRC); strength

[1] This practice is under the jurisdiction of ASTM C27 on Precast Concrete Products and is the direct responsibility of Subcommittee C27.40 on Glass Fiber Reinforced Concrete Made by the Spray-Up Process.

Designation: C1231/C1231M – 10

Standard Practice for Use of Unbonded Caps in Determination of Compressive Strength of Hardened Concrete Cylinders[1]

This standard is issued under the fixed designation C1231/C1231M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers requirements for a capping system using unbonded caps for testing concrete cylinders molded in accordance with Practice C31/C31M or C192/C192M. *Unbonded neoprene caps of a defined hardness are permitted to be used for testing for a specified maximum number of reuses without qualification testing up to a certain concrete compressive strength level. Above that strength, level neoprene caps will require qualification testing. Qualification testing is required for all elastomeric materials other than neoprene regardless of the concrete strength.*

1.2 Unbonded caps are not to be used for acceptance testing of concrete with compressive strength below 1500 psi [10 MPa] or above 12 000 psi [85 MPa].

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Concrete cylinders tested with unbonded caps rupture more violently than comparable cylinders tested with bonded caps. The safety precautions given in the Manual of Aggregate and Concrete Testing are recommended.[2])

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C31/C31M Practice for Making and Curing Concrete Test Specimens in the Field

C39/C39M Test Method for Compressive Strength of Cylindrical Concrete Specimens

C192/C192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C617 Practice for Capping Cylindrical Concrete Specimens

D2000 Classification System for Rubber Products in Automotive Applications

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *pad*, *n*—an unbonded elastomeric pad.

3.1.2 *unbonded cap*, *n*—a metal retainer and an elastomeric pad.

4. Significance and Use

4.1 This practice provides for using an unbonded capping system in testing hardened concrete cylinders made in accordance with Practices C31/C31M or C192/C192M in lieu of the capping systems described in Practice C617.

4.2 The elastomeric pads deform in initial loading to conform to the contour of the ends of the cylinder and are restrained from excessive lateral spreading by plates and metal rings to provide a uniform distribution of load from the bearing blocks of the testing machine to the ends of the concrete or mortar cylinders.

5. Materials and Apparatus

5.1 Materials and equipment necessary to produce ends of the reference cylinders that conform to planeness requirements of Test Method C39/C39M and the requirements of Practice C617. This may include grinding equipment or capping materials and equipment to produce neat cement paste, high strength gypsum plaster, or sulfur mortar caps.

5.2 *Elastomeric Pads*:

5.2.1 Pads shall be ½ ± 1⁄16 in. [13± 2 mm] thick and the diameter shall not be more than 1⁄16 in. [2 mm] smaller than the inside diameter of the retaining ring.

5.2.2 Pads shall be made from polychloroprene (neoprene) meeting the requirements of Classification D2000 as follows:

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved Feb. 1, 2010. Published March 2010. Originally approved in 1993. Last previous edition approved in 2009 as C1231/C1231M–09. DOI: 10.1520/C1231_C1231M-10.

[2] Section on Safety Precautions, Manual of Aggregate and Concrete Testing, *Annual Book of ASTM Standards*, Vol. 04.02.

Shore A Durometer	Classification D2000 Line Call-Out
50	M2BC514
60	M2BC614
70	M2BC714

The tolerance on Shore A durometer hardness is ± 5. Table 1 provides requirements for use of caps made from material meeting the requirements of Classification D2000, above.

5.2.3 Other elastomeric materials that meet the performance requirements of qualification tests in Section 8 are permitted.

5.2.4 Elastomeric pads shall be supplied with the following information:

5.2.4.1 The manufacturer's or supplier's name,

5.2.4.2 The Shore A hardness, and

5.2.4.3 The applicable range of concrete compressive strength from Table 1 or from qualification testing.

5.2.5 The user shall maintain a record indicating the date the pads are placed in service, the pad durometer, and the number of uses to which they have been subjected.

5.3 *Retainers*, are a pair of metal fixtures used to provide support for and alignment of the neoprene pads and the cylinder ends (See Note 1 and Fig. 1). Each retainer (upper and lower) includes a (retaining) ring that is welded to or manufactured integrally with a base plate. The height of the retaining ring shall be 25 ± 3 mm [1.0 ± 0.1 in.]. The inside diameter of the retaining ring shall not be less than 102 % or greater than 107 % of the diameter of the cylinder. The thickness of the retaining ring shall be at least 12 mm [0.47 in.] for 150 mm [6 in.] diameter retainers and at least 9 mm [0.35 in.] for 100 mm [4 in.] diameter retainers. The surface of the base plate that contacts the bearing block of the testing machine shall be plane to within 0.05 mm [0.002 in.]. The thickness of the base plate shall be at least 12 mm [0.47 in.] for 150 mm [6 in.] retainers and at least 8 mm [0.3 in.] for 100 mm [4 in.] retainers. The bearing surfaces of the retainers shall not have gouges, grooves, protrusions, or indentations greater than 0.25 mm [0.010 in.] deep or greater than 32 mm^2 [0.05 $in.^2$] in surface area.

NOTE 1—Retainers made from steel and some aluminum alloys have been found acceptable.

6. Test Specimens

6.1 The specimens shall be either 6 by 12 in. [150 by 300 mm] or 4 by 8 in. [100 by 200 mm] cylinders made in accordance with Practices C31/C31M or C192/C192M. Neither end of a cylinder shall depart from perpendicularity to the axis by more than 0.5° (approximately equivalent to ⅛ in. in 12 in. [3 mm in 300 mm]). No individual diameter of a cylinder may differ from any other diameter by more than 2 %.

NOTE 2—One method of measuring the perpendicularly of ends of cylinders is to place a try square across any diameter and measure the departure of the longer blade from an element of the cylindrical surface. An alternative method is to place the end of the cylinder on a plane surface and support the try square on that surface.

6.2 Depressions under a straight edge measured with a round wire gage across any diameter shall not exceed 0.20 in. [5 mm]. If cylinder ends do not meet this tolerance, the cylinder shall not be tested unless irregularities are corrected by sawing or grinding.

TABLE 1 Requirements for Use of Polychloroprene(Neoprene) Pads

Compressive Strength,[A] psi [MPa]	Shore A Durometer Hardness	Qualification Tests Required	Maximum Reuses[B]
Less than 1500 [10]		Not permitted	
1 500 to 6 000 [10 to 40]	50	None	100
2 500 to 7 000 [17 to 50]	60	None	100
4 000 to 7 000 [28 to 50]	70	None	100
7 000 to 12 000 [50 to 80]	70	Required	50
Greater than 12,000 [80]		Not permitted	

[A] Compressive strength of concrete at age of testing as specified in Contract Documents. For acceptance testing, it is the specified compressive strength f_c'.

[B] Maximum number of reuses will be less if pads wear, crack or split. See 7.2.

7. Procedure

7.1 Unbonded caps are permitted to be used on one or both ends of a cylinder in lieu of a cap or caps meeting Practice C617, provided the caps meet the requirements of Section 5. Pad hardness shall be in accordance with Table 1. (See Note 3)

NOTE 3—The specified strength in the contract documents is for various stages of construction. This may include strength test requirements for formwork removal or release of prestress in addition to the test requirements for verification of specified compressive strength. Therefore, pad selection is based on the strength requirement for the designated stage of construction.

7.2 Examine both sides of pads for excessive wear or damage. Replace pads that have cracks or splits in their top or bottom surface that exceed ⅜ in. [10 mm] in length regardless of depth. Insert pad in the retainer before it is placed on the cylinder (Note 4).

NOTE 4—Some manufacturers recommend dusting the pads and the ends of the cylinders with corn starch or talcum powder prior to testing.

7.3 Center the unbonded cap or caps on the cylinder and place the cylinder on the lower bearing block of the testing machine. Carefully align the axis of the cylinder with the center of thrust of the testing machine by centering the upper retaining ring on the spherically seated bearing block. As the spherically seated block is brought to bear on the upper retaining ring, rotate its movable portion gently by hand so that uniform seating is obtained. After application of load, but before reaching 10 % of the anticipated specimen strength, check to see that the axis of the cylinder is vertical within a tolerance of ⅛ in. in 12 in. [3.2 mm in 300 mm] and that the ends of the cylinder are centered within the retaining rings. If the cylinder alignment does not meet these requirements, release the load, check compliance with 6.1, and carefully recenter the specimen. Reapply load and recheck specimen centering and alignment. A pause in load application to check cylinder alignment is permissible.

7.4 Complete the load application, testing, calculation, and reporting of results in accordance with Test Method C39/C39M (see Notes 5 and 6).

NOTE 5—Some users have reported damage to testing machines from the sudden release of energy stored in the elastomeric pads.

NOTE 6—Occasionally, unbonded capped cylinders may develop early cracking, but continue to carry increasing load. For this reason Test Method C39/C39M requires cylinders to be loaded until it is certain that they have been compressed beyond their ultimate capacity.

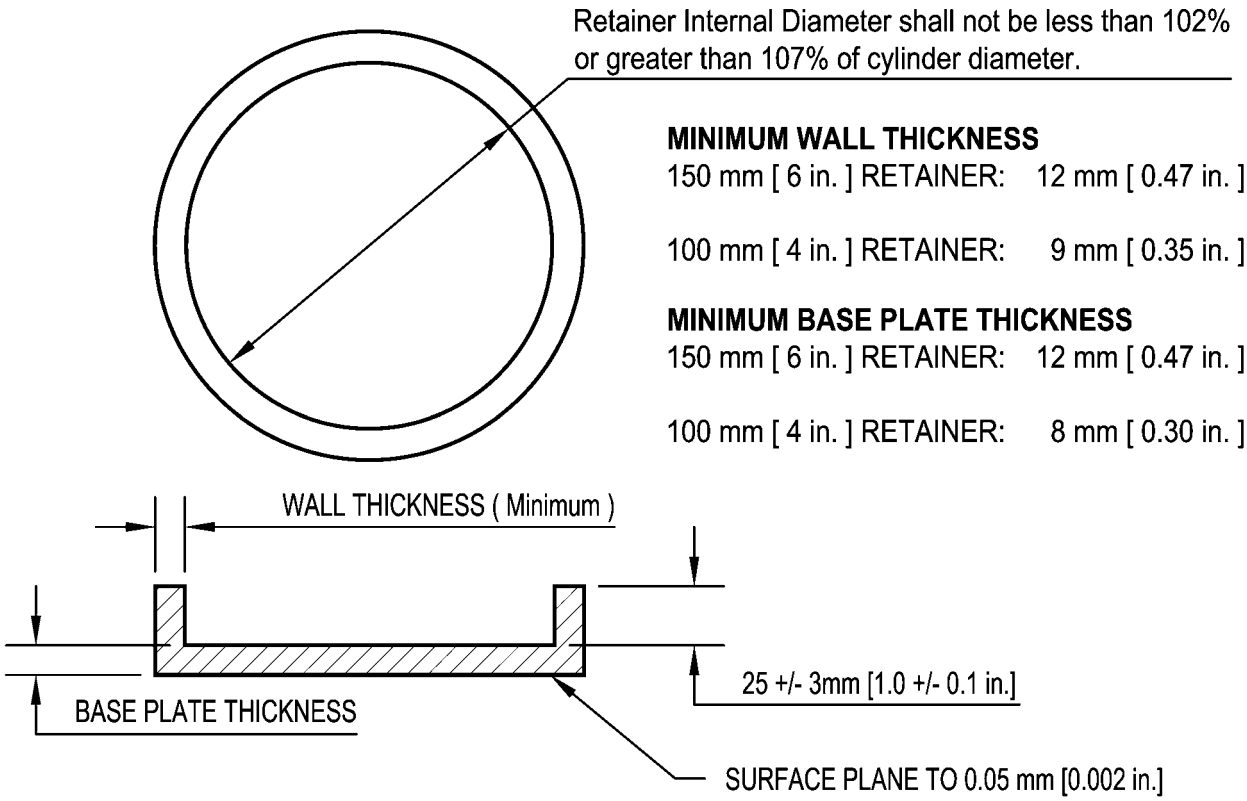

FIG. 1 Example of Retaining Ring and Base Plate

8. Qualification of Unbonded Capping Systems and Verification of Reuse of Pads

8.1 Table 1 specifies the conditions under which polychloroprene (neoprene) unbonded pads must be qualified under this section depending on the concrete strength and the Shore A hardness. Unbonded pads made of other elastomeric materials must be qualified using the procedures in this section.

8.2 When qualification tests are required they must be made by either the supplier or user of the unbonded pads. The user of the pads must retain a copy of the current qualification test report to demonstrate compliance with this practice. See X1.1.

8.3 The compressive strength of molded cylinders tested with unbonded caps shall be compared with that of companion cylinders tested with ends ground or capped to meet requirements of Test Method C39/C39M and Practice C617.

8.4 To be acceptable, tests must demonstrate that at a 95 % confidence level ($\alpha = 0.05$), the average strength obtained using unbonded caps is not less than 98 % of the average strength of companion cylinders capped or ground in accordance with 8.3.

8.4.1 When required, qualification tests in accordance with 8.5 shall be made on initial use of an unbonded cap at both the highest and lowest strength levels anticipated to establish an acceptable range of cylinder strength for use. In practice individual cylinders shall not have strengths more than 10 % greater than the high strength level or more than 10 % less than the low strength level qualified or specified in Table 1. Qualification tests shall be repeated whenever there is a change in the design or dimensions of the retaining rings, or when there is a change in pad composition or thickness, or the Shore A hardness changes by more than five units. Initial qualification tests shall include verification that after the specified maximum number of reuses the pads meet the requirements of 8.4.

8.4.2 When tests are made to establish a permissible number of reuses exceeding those in Table 1, only those tests or reuses which are within 2000 psi [14 MPa] of the highest strength level to be qualified will be included in the reuse count. Laboratories must maintain records of the number of times pads are reused.

NOTE 7—Pad life depends on the hardness and type of pad material, the strength of the concrete, the difference between the outside diameter of the cylinder and the inside diameter of the retaining ring, the unevenness and roughness of the ends of the cylinder, and other factors. Based on available information, scuffing or abrasion of the perimeter of the pad is normal, provided it does not reduce the thickness of the pad around the perimeter.

8.5 *Specimen Preparation for Qualification and Pad Reuse Testing*:

8.5.1 Pairs of individual cylinders shall be made from a sample of concrete and cured as nearly alike as possible: one cylinder per pair is to be tested after grinding or capping in accordance with 8.3 and the other is to be tested using the unbonded cap system.

8.5.2 A minimum of 10 pairs of cylinders shall be made at both the highest and lowest strength levels desired or anticipated (Note 8). The "strength level" is the average of the strengths of the 20 or more cylinders whose strengths are within a range of 1000 psi [7 MPa] (Note 9). More than one

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:48:33 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

pair of cylinders can be made from a single concrete sample, but cylinders must come from a minimum of two samples made on different days for each concrete strength level (Note 10).

NOTE 8—If the Practice C617 capped and unbonded capped specimens produce equal strengths, the number of pairs of cylinders that will be needed to demonstrate compliance will range from 9 to more than 60 depending on the variability of test results. If the two capping systems produce equal strengths, about 10 % of laboratories will require more than 60 tests and 10 % of the laboratories will require 9 tests to demonstrate statistical compliance.

NOTE 9—Note that the range of strengths permitted in qualification testing to define the strength level is 1000 psi [7 MPa], but that in counting number of reuses only cylinders within a range of 2000 psi [14 MPa] are included in the reuse count.

NOTE 10—Cylinders for qualification tests can be from pairs of cylinders tested in routine laboratory operations and, in most instances, special trial batches should not be required for qualification tests.

9. Calculation

9.1 For each strength level, compute the difference in strength for each pair of cylinders, and compute the average strength of the cylinders with reference caps and the average strength of the cylinders with unbonded caps, as follows:

$$d_i = x_{pi} - x_{si} \quad (1)$$

$$\bar{x}_s = (x_{s1} + x_{s2} + x_{s3} \ldots + x_{sn})/n$$

$$\bar{x}_p = (x_{p1} + x_{p2} + x_{p3} \ldots + x_{pn})/n$$

where:

d_i = difference in strength of a pair of cylinders computed as the strength of unbonded capped cylinder minus the strength of the cylinder prepared according to Practice C617 (may be positive or negative),

x_{pi} = cylinder strength using unbonded cap,

x_{si} = cylinder strength using Practice C617,

n = number of pairs of cylinders tested for the strength level,

$\bar{x}_s$ = average strength of Practice C617 capped cylinders for a strength level, and

$\bar{x}_p$ = average strength of unbonded cap cylinders for a strength level.

9.2 Compute the average difference, $\bar{d}$, and standard deviation of the difference, s_d, for each strength level, as follows:

$$\bar{d} = (d_1 + d_2 \ldots + d_n)/n \quad (2)$$

$$s_d = [\Sigma(d_i - \bar{d})^2/(n-1)]^{1/2}$$

9.3 To comply with this practice the following relationship must be satisfied:

$$\bar{x}_p \geq 0.98\,\bar{x}_s + (ts_d)/(n)^{1/2} \quad (3)$$

where t is the value of "students t" for $(n-1)$ pairs at $\alpha = 0.05$ from the following table:

$(n-1)$	$t(\alpha = 0.05)^A$
9	1.833
14	1.761
19	1.729
100	1.662

[A] Use linear interpolation for other values of $(n-1)$ or refer to appropriate statistical tables.

10. Keywords

10.1 cap; compressive strength; concrete; concrete test; elastomeric; neoprene; pad cap; rubber; unbonded cap

APPENDIX

(Nonmandatory Information)

X1. SAMPLE REPORT AND CALCULATION

X1.1 *Sample Report:*

X1.1.1 *Pad Material*—Lot 3742, Shore A = 52, Thickness 0.51 in.

X1.1.2 *Retaining Ring*—Set A manufactured 1-87.

X1.1.3 Concrete Cylinders: Job 1207, Nos. 1–10, January 2 to 5, 1987.

X1.1.4 *Sulfur Mortar*—Lot 3420. Compressive Strength of 6985 psi [48.2 MPa].

X1.1.5 All Tests 28 days age.

X1.2 *Summary*—

xs = 3679 psi [25.35 MPa]:
xp = 3663 psi [25.26 MPa];
sd = 46.06 psi [0.328 MPa];
n = 10:
t = 1.833.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C1231/C1231M–09, that may impact the use of this practice. (Approved February 1, 2010)

(*1*) Revised Table 1 to clarify the basis for the required hardness of the neoprene pads.

(*2*) Revised 7.1 to provide an explicit statement in the procedure on the required hardness of the pads.

(*3*) Added new Note 3 to clarify what design strength should be used for pad selection.

Committee C09 has identified the location of selected changes to this practice since the last issue, C1231/C1231M–08a, that may impact the use of this practice. (Approved January 1, 2009)

(*1*) Revised the second sentence of Note 6 by adding reference to Test Method C39/C39M for the loading requirements.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1240 – 05

Standard Specification for Silica Fume Used in Cementitious Mixtures[1]

This standard is issued under the fixed designation C 1240; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers silica fume for use in concrete and other systems containing hydraulic cement.

1.2 In the cases of slurried or densified silica fume, perform the tests on the raw silica fume from which these products have been made.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 The following safety hazards caveat pertains only to the test methods portions, Sections 10-19, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Read the material safety data sheets for materials used.

1.5 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 219 Terminology Relating to Hydraulic Cement
C 311 Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete
C 430 Test Method for Fineness of Hydraulic Cement by the 45-μm (No. 325) Sieve
C 441 Test Method for Effectiveness of Pozzolans or Ground Blast-Furnace Slag in Preventing Excessive Expansion of Concrete Due to the Alkali-Silica Reaction
C 494 Specification for Chemical Admixtures for Concrete
C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements
C 1012 Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution
C 1069 Test Method for Specific Surface Area of Alumina or Quartz by Nitrogen Adsorption
C 1157 Performance Specification for Hydraulic Cement
C 1437 Test Method for Flow of Hydraulic Cement Mortar

3. Terminology

3.1 *Definitions:*

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.24 on Supplementary and Cementitious Materials.

Current edition approved July 1, 2005. Published August 2005. Originally approved in 1993. Last previous edition approved in 2004 as C 1240-04.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

3.1.1 *silica fume*—very fine pozzolanic material, composed mostly of amorphous silica produced by electric arc furnaces as a by-product of the production of elemental silicon or ferro-silicon alloys (also known as condensed silica fume and microsilica).

3.1.2 Other terms in this specification are defined in Terminologies C 125 and C 219.

4. Ordering Information

4.1 The purchaser shall specify any optional chemical or physical requirements.

5. Chemical Composition

5.1 Silica fume shall conform to the requirements for chemical composition prescribed in Table 1.

6. Physical Requirements

6.1 Silica fume shall conform to the physical requirements prescribed in Table 2. Optional physical requirements are given in Table 3.

7. Sampling

7.1 When the purchaser desires that the silica fume be sampled and tested to verify compliance with this specification, perform the sampling and testing in accordance with Practice C 183, modified as described in 7.3.

NOTE 1—Exercise caution in the interpretation of Practice C 183, since there is a difference between the continuous manufacture of hydraulic cement and the generation and collection of silica fume. To a great extent, storage is dictated by the design of the silica-fume collection system. The design of silica-fume collection systems may not have provided for sampling points and practices.

7.2 Practice C 183, as modified, is not designed for manufacturing quality control and is not required for manufacturer's certification.

7.3 The following modification of Practice C 183 is necessary to render it applicable to silica fume.

7.3.1 Replace the words "hydraulic cement" and "cement" with the words "silica fume" every time that they appear in the text.

7.3.2 All samples, whether grab or composite, shall have a mass of at least 1 kg (2 lb).

7.3.3 When compliance verification tests of silica fume are required to be made at a laboratory other than that of the silica-fume manufacturer or marketer, coordinate the silica-fume sampling schedule, sample transportation time, and sample testing schedule among the purchaser, manufacturer, and testing laboratory so that the test results will be available when the decision to accept or reject the silica fume must be made.

7.3.4 The section entitled "Sampling" is modified as follows:

TABLE 1 Chemical Requirements

SiO_2, min, %	85.0
Moisture content, max, %	3.0
Loss on ignition, max, %	6.0

TABLE 2 Physical Requirements

Oversize:	
Percent retained on 45-μm (No. 325), max, %[A]	10
Percent retained on 45-μm (No. 325), max variation from average, percentage points[B]	5
Accelerated pozzolanic strength activity index:[C]	
With portland cement at 7 days, min percent of control	105
Specific surface, min, m^2/g	15

[A] Exercise care to avoid retaining agglomerations of extremely fine material.

[B] The average shall consist of the ten preceding tests or all of the preceding tests if the number is less than ten.

[C] Accelerated pozzolanic strength activity index is not to be considered a measure of the compressive strength of concrete containing the silica fume. This is a measure of the reactivity of a given silica fume with a given cement and may vary with the source of both the silica fume and the cement.

TABLE 3 Optional Physical Requirements[A]

Uniformity requirements:	
When air-entraining concrete is specified, the quantity of air-entraining agent required to produce air content of 18.0 vol % of mortar shall not vary from the average established by the ten preceding tests or by all preceding tests if less than ten, by more than, %	20
Reactivity with cement alkalies:[B]	
Reduction of mortar expansion at 14 days, min, %	80
Sulfate resistance expansion,[C]	
(moderate resistance) 6 months, max, %	0.10
(high resistance) 6 months, max, %	0.05
(very high resistance) 1 year, max, %	0.05

[A] Will be made only at the request of the purchaser.

[B] The indicated tests for reactivity with cement alkalies shall not be requested unless the material is to be used with an aggregate that is regarded as deleteriously reactive with alkalies in hydraulic cement. The test for reduction of mortar expansion may be made using any high-alkali cement in accordance with Test Methods C 311, if the cement to be used in the work is not known or is not available at the time of the test. The test for mortar expansion should be performed by each of the high-alkali cements to be used in the work.

[C] Only one limit shall be specified.

7.3.4.1 Take two grab samples or two composite samples for the first 100 Mg (110 tons) of silica fume. Take a grab sample or a composite sample for each subsequent 100 Mg (110 tons) of silica fume, but not less than two samples shall be taken in any sampling program.

7.3.4.2 *From Bulk Storage at Points of Discharge*—Withdraw silica fume from the discharge openings in a steady stream until sampling is completed. In sampling bulk storage at points of discharge, while the silica fume is flowing through the openings, take samples at such intervals so that, at a minimum, the sampling requirements of 7.3.4.1 are met.

7.3.5 The section entitled "Amount of Testing" is modified by deleting the first paragraph, "General."

8. Frequency of Tests

8.1 Except for the tests listed in 8.2, make all chemical determinations and physical tests on composite samples representing no more than 400 Mg (440 tons) each. Prepare each composite sample by combining portions from the samples representing each 100 Mg (110 tons), so that each 100 Mg is represented equally.

8.2 Test for specific surface, density, and accelerated pozzolanic strength activity index using composite samples that represent 3200 Mg (3520 tons) or 3 months of production, whichever gives the highest frequency. Prepare each composite sample by combining portions from the samples representing

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:48:35 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

each 400 Mg (440 tons) or 1 month, whichever gives the highest frequency, so that each sample is represented equally.

9. Preparation of Sample

9.1 Prepare composite samples for tests, as required in Section 8, by arranging all test samples in groups, with each group representing the number of megagrams required by the test or tests for which the composite sample is intended. From each of the samples in a group, take equal portions, sufficient in amount to form a composite sample large enough to permit making the required physical or chemical determinations.

9.2 Prior to testing, mix grab samples and composite samples thoroughly. A clean and dry laboratory concrete drum mixer provides adequate mixing for this purpose. Take care to limit the volume of silica fume in the drum mixer to the range of 10 to 50 % of the drum's total capacity. If necessary, secure a sheet of polyethylene film on the drum with an elastic tiedown to keep the material in the drum. Limit the mixing action to 5 ± 1 min.

9.2.1 When a small sample size precludes the use of a concrete mixer, use a heavy plastic bag, of a capacity at least five times larger than the sample volume, to mix the sample thoroughly. After placing the sample in the bag, close the bag by tying the bag opening tightly, and mix the material by rolling the bag around for 5 ± 1 min.

9.3 Take material for specific tests from a thoroughly mixed sample by using a sampling device (sampling tube, scoop, etc.) of appropriate size to make a test specimen. Make this test specimen from at least six random subsamples.

TEST METHODS—CHEMICAL ANALYSIS

10. Silicon Dioxide and Total Alkalies

10.1 *Reference Method*—Use the reference method in Test Methods C 114 for cements with insoluble residue greater than 1 %. Analysts performing sodium oxide and potassium oxide determinations shall observe the precautions outlined in the applicable section of Performance Specification C 1157 (refer to the section on Test Methods). Most pozzolans dissolve completely in lithium borate fluxes.

11. Moisture Content and Loss on Ignition

11.1 Follow the applicable provisions of Test Methods C 311.

TEST METHODS—PHYSICAL TESTS

12. Density

12.1 *Equipment*:

12.1.1 *Two 500-mL Volumetric Flasks*, Class A.

12.1.2 *Balance*, with an accuracy of at least 0.01 g.

12.1.3 *Constant Temperature Bath*, capable of being regulated within ±0.5 °C (1.0 °F).

12.2 *Deionized Water*.

12.3 *Procedure*:

12.3.1 Determine the density of the material as received, unless otherwise specified, as follows. If density determination on an ignited sample is required, first ignite the sample as described in the test for loss on ignition in the applicable section given in Test Methods C 114.

12.3.2 Determine the mass (W_f), of a 500-mL volumetric flask, to an accuracy of 0.01 g. Add 30 g of silica fume. Determine the mass of the flask and the contents (W_a) to the nearest 0.01 g. Add water to the flask to fill it one-half full, and shake it to ensure thorough wetting of the material. Fill to the mark with water. Remove air bubbles by shaking the flask at 15-min intervals until the liquid is free of air or by applying a vacuum to the flask. After all of the air bubbles are removed, place the flask in a constant temperature bath at 23 ± 0.5 °C until the flask and its contents reach a constant temperature. Remove the flask from the water bath; immediately add or remove water, at the same temperature, to the flask to get the meniscus on the mark. Wipe dry the exterior of the flask and determine the mass of the flask and its contents (W_s).

12.3.3 Empty, clean, and determine the mass of the 500-mL volumetric flask, used above, filled to the mark with water (W_t) stabilized at 23 ± 0.5 °C.

12.4 *Calculation*:

$$D_{sf} = \frac{(W_a - W_f)}{500\ \text{mL} - [(W_s - W_a)/D_w]} \quad (1)$$

where:

D_{sf} = density of silica fume, Mg/m^3,
W_f = mass of 500-mL volumetric flask, g,
W_a = mass of 500-mL volumetric flask plus approximately 30 g of silica fume, g,
W_s = mass of 500-mL volumetric flask plus silica fume plus water to the mark, g,
W_t = mass of 500-mL volumetric flask plus water to the mark, g, and
D_w = $(W_t - W_f)$/500-mL, Mg/m^3.

12.5 Report the average of two density determinations.

13. Oversize, Amount Retained When Wet-Sieved on a 45-μm (No. 325) Sieve

13.1 Use Test Method C 430. Calibrate the sieves in accordance with Test Method C 430.

NOTE 2—Oversize is used to determine the amount of contaminating material retained on the 45-μm sieve. See Appendix X2.

14. Specific Surface

14.1 Determine the specific surface by the BET, nitrogen adsorbtion method, in accordance with Test Method C 1069.[3]

15. Air Entrainment of Mortar

15.1 Follow the applicable provisions of Test Methods C 311, except use the following test mixture and equation for W_c:

	Test Mixture
Portland cement, g	300

[3] Manufacturers and examples of nitrogen adsorbtion instrumentation include Horiba Instruments, Inc., Irvine, CA, 5A-9600; Micromeritics Instrument Corporation, Norcross Georgia, FlowSorb-II 2300; Quantachrome Corporation, Boynton Beach, FL, Quantasorb Jr.; and JUWE Laborgerate Service GmbH, Korschenbroich, Germany, Stroehlein AREAmeter II. NIST SRM® 2696, Silica Fume, is available for use in comparison and evaluation of laboratory equipment and procedures.

www.technobetar.ir

Silica fume, g	30
20–30 Standard Ottawa sand, g	1170
Water, mL, sufficient to give a flow of 80 to 95 %	Y
Neutralized Vinsol resin solution, mL, sufficient to produce an air content of 18 ± 3 %	Z

$$W_c = \frac{300 + 1170 + 30 + (300 \times P \times 0.01)}{300/3.15 + 1170/2.65 + (30/D) + [(300 \times P \times 0.01)/1]} \quad (2)$$

Then calculate:

$$\text{Air content, volume \%} = 100[1 - (W_a/W_c)]W_a = W/400 \quad (3)$$

where:

W_a = actual mass per unit of volume of mortar as determined by Test Method C 185, g/mL,

W = mass of the specified 400 mL of mortar (see Test Method C 185), g,

W_c = theoretical mass per unit volume, calculated on an air-free basis and using the values for density and quantities of the materials in the mixture, g/mL,

P = percent of mixing water plus Vinsol resin solution based on mass of cement, and

D = density of silica fume used in the mixture, Mg/m^3.

15.2 Determine the flow in accordance with the applicable provisions of Test Method C 109/C 109M.

16. Accelerated Pozzolanic Strength Activity Index with Portland Cement

16.1 Use the applicable section on strength activity index with portland cement of Test Methods C 311, except change to reflect testing at constant water to cementitious materials ratio. Prepare test specimens from the batch proportions below, molding three cubes from both the control mix and the test mix.

16.1.1 *Control Mixture*:

16.1.1.1 500 g of portland cement,

16.1.1.2 1375 g of graded standard sand, and

16.1.1.3 242 mL of water.

16.1.2 *Test Mixture*:

16.1.2.1 450 g of portland cement,

16.1.2.2 50 g of silica fume,

16.1.2.3 1375 g of graded standard sand, and

16.1.2.4 242 mL of water.

16.1.2.5 *X* grams of dry high-range water reducer, meeting Specification C 494 Type F, required to produce a flow of 100 to 115 %. Add the high-range water reducer directly to the mixing water in the mixing bowl. Then add the cement or the cement-silica fume mixture and start the mixing cycle.

16.1.3 Determine the flow in accordance with the applicable provisions of Test Method C 1437.

16.1.4 *Storage of Specimens*—After 24 h of initial curing in the moist room (23 ± 2 °C and relative humidity of not less than 95 %), place the cubes in airtight glass containers and store at 65 ± 2°C for six days.

16.1.5 Determine the compressive strength, as specified in Test Method C 109/C 109M, of the three specimens of the control mixture and the three specimens of the test mixture at 7 days after molding.

17. Reactivity with Cement Alkalies

17.1 Determine the reduction of mortar expansion in accordance with Test Method C 441, except that the amount of silica fume in the test mixture shall be 10 % by mass of cementitious material.

18. Sulfate Resistance

18.1 Determine sulfate resistance according to Test Method C 1012, except that the amount of silica fume used in the test mixture is 10 % by mass of cementitious material.

19. Bulk Density

19.1 The bulk density of silica fume is defined as the mass of a unit volume of loose silica fume.

19.2 This test method covers determination of the bulk density of silica fume, as silica fume is transferred from one container to another with controlled minimum compaction. Its particular usefulness is in connection with identifying material form (as produced or densified), silo or truck storage capacity, material handling and transportation characteristics.

19.3 *Equipment*:

19.3.1 *Balance*, meeting Specification C 1005, with a sensitivity of 0.1 g.

19.3.2 *Vibrating Table*[4], Table top, electromagnetic vibrating table, with a controlled low-amplitude that does not exceed 1 mm linear vibration. Approximate deck size is 175 × 250 mm with a 5 kg capacity. The amplitude of the vibration shall be capable of being regulated to suit the characteristics of the material being handled.

19.3.3 *Stainless Steel Beaker*, of known volume, not less than 1 L calibrated to the nearest ±1 mL. Without a spout.

19.4 *Procedure*:

19.4.1 Determine the mass of the clean dry beaker to the nearest 1 g.

19.4.2 Fill the beaker with silica fume and compact by use of the vibrating table at a mid-range setting for 15 s, adding material as needed.

19.4.3 Screed or strike off the measure, with a straight edge or spatula, to produce a flat, even surface, that is level with rim or edge of the beaker. Wipe off any excess silica fume that may adhere to the sides.

19.4.4 Place the filled measure on the balance and determine the mass of the silica fume to the nearest 1 g.

19.5 *Calculation*:

19.5.1 Divide the net mass of the silica fume in grams by the volume of the container in milliliters. Multiply by 1000 to express the density in kilograms per cubic meter. To convert the value in kilograms per cubic meter to pounds per cubic foot, divide by 16.01846.

[4] The sole source of supply of the vibrating table known to the committee at this time is the Syntron Paper Jogger, Model J-1, manufactured by F.M.C. Corp., 57 Cooper Ave., Homer City, PA 15748. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

www.technobetar.ir

20. Report

20.1 Report the following information:
20.1.1 SiO_2 content, %,
20.1.2 Moisture content, %,
20.1.3 Loss on ignition, %,
20.1.4 Oversize, % retained,
20.1.5 Bulk density, kg/m^3,
20.1.6 Density, Mg/m^3,
20.1.7 Name of manufacturer and brand, if applicable,
20.1.8 Accelerated Pozzolanic Strength Activity Index,
20.1.9 Specific surface, m^2/g, and
20.1.10 Total alkalies, as equivalent Na_2O, %.

20.2 Report the following information when specifically requested by the purchaser:
20.2.1 The quantity of air-entraining agent compared to the 10 preceding tests, %,
20.2.2 Reduction of mortar expansion, %, and
20.2.3 Sulfate resistance expansion, %.

21. Precision and Bias

21.1 *Precision*:
21.1.1 *Accelerated Pozzolanic Strength Activity Index Test*:
21.1.1.1 *Single-Operator Precision*—The precision of this test will be evaluated using Practice C 670.
21.1.1.2 *Multilaboratory Precision*—The precision of this test will be evaluated using Practice C 670.
21.1.2 *Density Test*:
21.1.2.1 *Single-Operator Precision*—The single-operator standard deviation among single test results (a test result is defined in this specification as the average of two separate measurements) has been found to be 0.035 Mg/m^3.[5] Therefore, results of two properly conducted tests by the same operator should not differ by more than 0.099 Mg/m^3[5] on the same silica fume.
21.1.2.2 *Multilaboratory Precision*—The multilaboratory standard deviation among single test results (a test result is defined in this specification as the average of two separate measurements) has been found to be 0.047 Mg/m^3.[5] Therefore, results of two properly conducted tests in different laboratories on the same silica fume should not differ by more than 0.132 Mg/m^3 of their average.[5]
21.1.3 *Bulk Density*:
21.1.3.1 *Precision*—The precision of this test method will be evaluated using Practice C 670.
21.1.3.2 *Bias*—Since there is no accepted reference material suitable for determining any bias that might be associated with this test method, no statement on bias is being made.
21.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedures for measuring the accelerated pozzolanic strength activity index and the density, no statement on bias is being made.

22. Rejection and Retesting

22.1 The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the tests, the producer or supplier is not prohibited from making a claim for retesting.

23. Certification

23.1 When specified in the purchase order or contract, the purchaser shall be furnished certification that samples have been tested as directed in this specification and the specified requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

24. Packaging and Package Marking

24.1 When silica fume is delivered in packages, the name, and brand, if applicable, of the manufacturer or distributor and the mass of the silica fume contained therein shall be marked plainly on each package. Similar information shall be provided in the shipping invoices accompanying the shipment of packaged or bulk silica fume in dry or slurried forms. All packages shall be in good condition at the time of inspection.

25. Storage and Inspection

25.1 Silica fume shall be stored in such a manner as to permit easy access for the proper inspection and identification of each shipment. Facilities for inspection and sampling shall be provided at the point from which the material is to be shipped.

[5] These measurements represent, respectively, the (1s) and (d2s) limits in accordance with Practice C 670.

APPENDIXES

(Nonmandatory Information)

X1. SILICA CONTENT

X1.1 Since the quantity of amorphous silica is one of the primary characteristics that determine the pozzolanic activity of silica fume, determination of the total silicon content is important. Gravimetric ["wet method"] determinations can be accomplished using sodium carbonate (Na_2CO_3) fusion as described in Test Methods C 114 and similar procedures. Instrumental methods successfully used for determination of total silicon in high silica materials include X-ray fluorescence spectrometry, inductively coupled plasma, optical emission spectrometry, and atomic absorption spectrophotometry. Silica Fume SRM® 2696 is available from the National Institute of Standards and Technology, for use in evaluating chemical and instrumental methods of analysis of silica fume used in conjunction with product specifications. Because silica (SiO_2) is required in this specification to be at least 85 % by mass of the silica fume, additional silica reference materials, such as SRM® 1413 high alumina sand [82.77 %] and silica flour [99.9 %], may be suitable for use with instrumental methods of analysis. Analysts should note that the gravimetric method determines all chemical forms of silicon in the material as silica (SiO_2), whereas the instrumental test methods determine all chemical forms of silicon in the material as total silicon (Si), which is reported as SiO_2. Typically, it is assumed that all or nearly all of the Si that is present in silica fume is SiO_2.

X2. OVERSIZE

X2.1 The 45-μm (No. 325) sieve specification is to be used to determine the amount of foreign material present. Since silica fume is much finer than cement or fly ash, the particles will all pass through the sieve except for foreign material. Extremely fine materials tend to form agglomerations; good judgment must be exercised to differentiate between easily dispersible agglomerates and foreign materials.

X3. PROBLEM OF MIXTURE PROPORTIONING FOR VARIOUS TEST MIXTURES

X3.1 Such test methods as accelerated pozzolanic strength activity index with portland cement, reactivity with cement alkalies, and sulfate resistance require mixtures where the silica fume being tested replaces a given amount of cement. For specification purposes, 10 % by mass replacement of cement by silica fume will be used rather than that which is stated in the present methods. Water-to-cementitious materials ratio will be replaced by a flow of between 100 and 115 %. As the percent replacement with silica fume increases, the mixture becomes unworkable, and either more water is necessary or a water reducer is necessary to have a workable mixture. By limiting the mixtures to 10 % by mass replacement, the addition of water to a certain flow is a viable alternative, even though the addition of water reducer would probably produce a higher strength. Since this is a specification, the interest is in comparing material under similar conditions, rather than in maximum strength.

X4. SULFATE RESISTANCE

X4.1 Satisfactory reductions of expansion in laboratory mixtures have been obtained with silica fume replacement levels of 5 to 15 %. Each source of silica fume must be tested with high-C_3A portland cement to establish appropriate replacement levels for adequate sulfate resistance.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1240 – 04, that may impact the use of this specification. (Approved July 1, 2005)

(*1*) Revised 8.2.
(*2*) Revised X1.1.
(*3*) Revised old Note 3 and moved it to Footnote 3.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1240 – 03a, that may impact the use of this specification. (Approved June 1, 2004)

(*1*) Revised 20.1.10.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1245/C 1245M – 06

Standard Test Method for Determining Bond Strength Between Hardened Roller Compacted Concrete and Other Hardened Cementitious Mixtures (Point Load Test)[1]

This standard is issued under the fixed designation C 1245/C 1245M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method is intended for testing roller-compacted concrete specimens and covers determination of the relative bond between layers of roller-compacted concrete or other hardened concrete in multiple-lift forms of construction. It is applicable to all types of layered concrete where the total depth is sufficient to meet the minimum specimen length and diameter requirements of this test method. This test method is not intended to provide tensile strength results of the material tested.

1.2 The values stated in SI units, shown in brackets, or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other, without combining values in any way. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 1176 Practice for Making Roller-Compacted Concrete in Cylinder Molds Using a Vibrating Table

C 1435/C 1435M Practice for Molding Roller-Compacted Concrete in Cylinder Molds Using a Vibrating Hammer

D 1557 Test Methods for Laboratory Compaction Characteristics of Soil Using Modified Effort (56,000 ft-lbf/ft^3 (2,700 kN-m/m^3))

3. Terminology

3.1 Refer to Terminology C 125 for definitions of terms used in this test method.

4. Significance and Use

4.1 This test method is used to measure the effectiveness of bonding roller-compacted concrete to other roller-compacted concrete or other hardened cementitious mixtures by using a point load test at the joint. Bond strength is determined using drilled cores or cast cylindrical specimens in which the bond surface is essentially normal to the longitudinal axis at approximately the mid-length of the specimen. A splitting tensile stress normal to the bond surface is produced by applying a point load at the joint.

4.2 This test method may be used either for laboratory investigation by casting individual composite cylinders or by coring prototype structures or assemblies (Test Method C 42/C 42M).

5. Apparatus

5.1 *Testing Machine*—The testing machine shall conform to the requirements of Test Method C 39/C 39M.

5.2 *Testing Apparatus*—The testing apparatus shall be constructed of steel and allow the testing of both 4 and 6-in. [100 and 150-mm] diameter specimens. The test schematic is given in Fig. 1. The testing apparatus shall permit the positioning of a specimen such that the joint of the bonded surfaces is oriented as closely as possible parallel to the direction of loading. Figs. 2-9 provide the information necessary to construct the apparatus for 4 and 6-in. [100 and 150-mm] diameter specimens. Anvil rods (Fig. 3 and Fig. 5) shall have a hardness

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.45 on Roller Compacted Concrete.

Current edition approved July 1, 2006. Published August 2006. Originally approved in 1993. Last previous edition approved in 2003 as C 1245/C 1245M – 03.

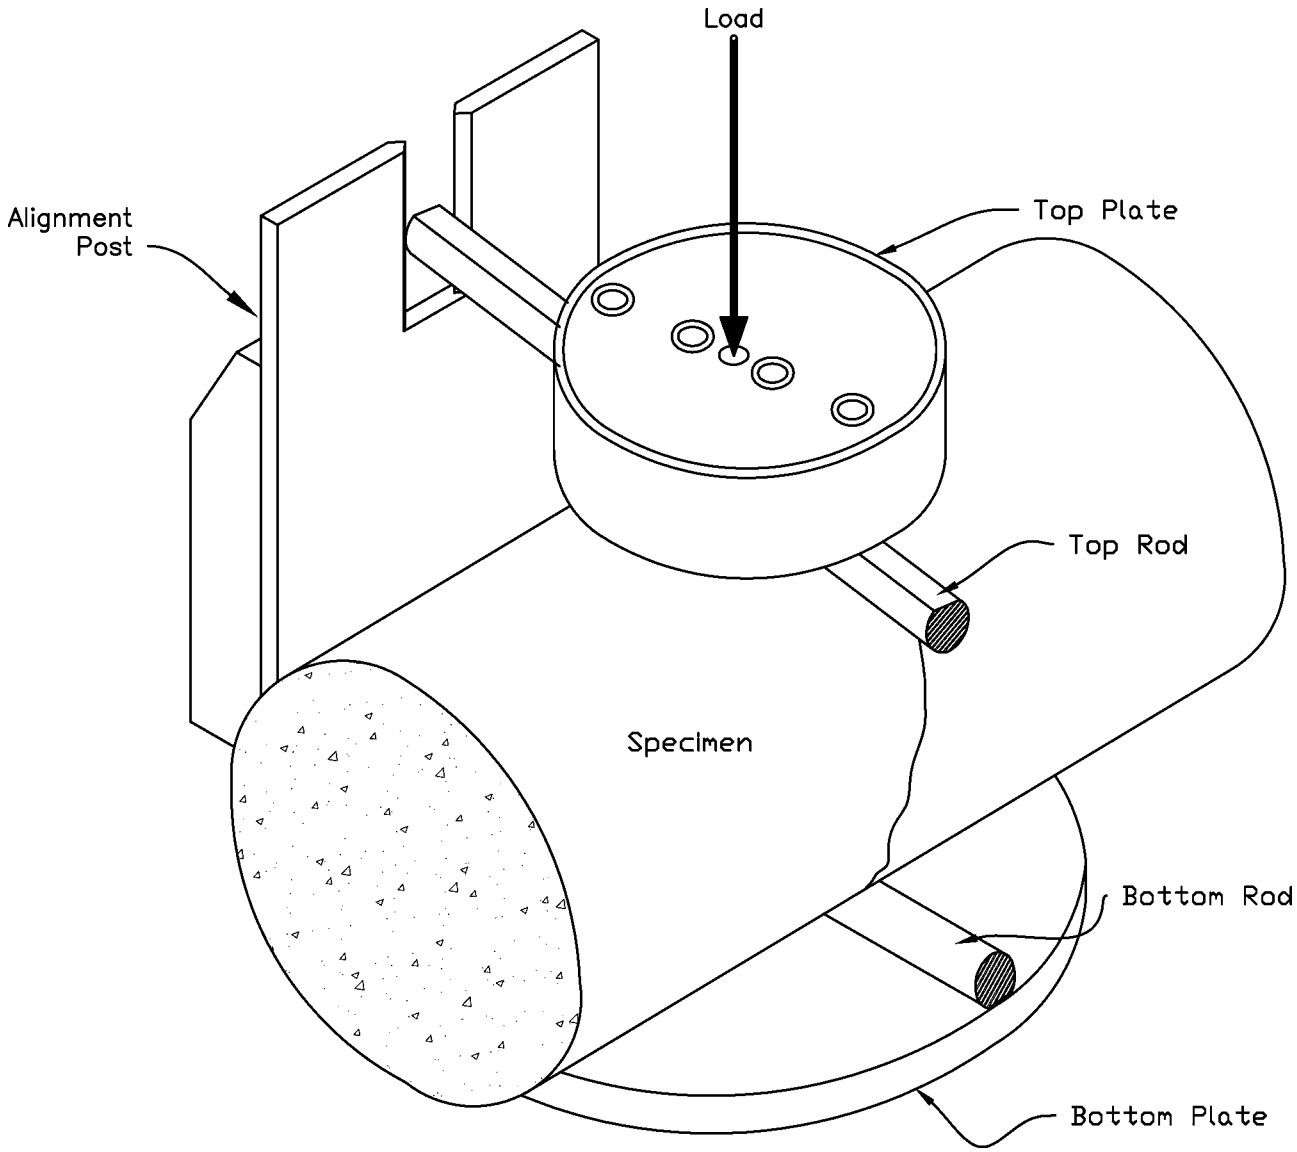

FIG. 1 Schematic of Loading Method

of not less than 55 HRC (Rockwell hardness number of 55 on the C scale) and shall be plane on the bearing surfaces to within ±0.001 in. [0.025 mm]. The alignment post shall ensure that the anvil rods are kept parallel to each other in the vertical plane. The system is easily adaptable to most testing machines.

6. Test Specimens

6.1 Test specimens shall be cores or cast cylinders 4 or 6 ± 0.25 in. [100 or 150 ± 5 mm] in diameter. Cast cylinders in accordance with Practice C 1176, Practice C 1435, or Test Method D 1557. Cut each core and cast each cylinder to ensure that the plane best describing the bond surface is oriented at 90 ± 15° to the long axes of the specimens.

6.2 Cure molded test specimens in accordance with Practice C 192/C 192M (laboratory specimens). Drilled cores shall be moisture conditioned in accordance with Test Method C 42/C 42M.

NOTE 1—Test results are not affected significantly by specimen surfaces obtained with normal coring operations. The ends of cores need not be trimmed.

NOTE 2—Where the bond surface undulates grossly, that is, the surface has a local texture exceeding 0.5 in. [13 mm] in amplitude, 6-in. [150-mm] diameter cores are preferable. No information is available on the relative results of 6-in. [150-mm] versus 4-in. [100-mm] diameter specimens.

7. Procedure

7.1 *Measurements*—Determine the diameter of the test specimens by averaging three diameters measured on the bond surface. Visually identify the bond surface by color, texture, or material contrasts. Measure diameters to the nearest 0.01 in. [0.25 mm] with calipers, whenever possible, but at least to the nearest 0.1 in. [2.5 mm]. Determine the length of each section of the bonded specimens to the nearest 0.1 in. [2.5 mm], and use these lengths to determine the section length-to-diameter ratios. Specimens must have a minimum length-to-diameter ratio of 1.2 if the bond plane is at mid-length (within ±0.25 in. [6 mm]) of the specimen. If the bond plane is not at mid-length

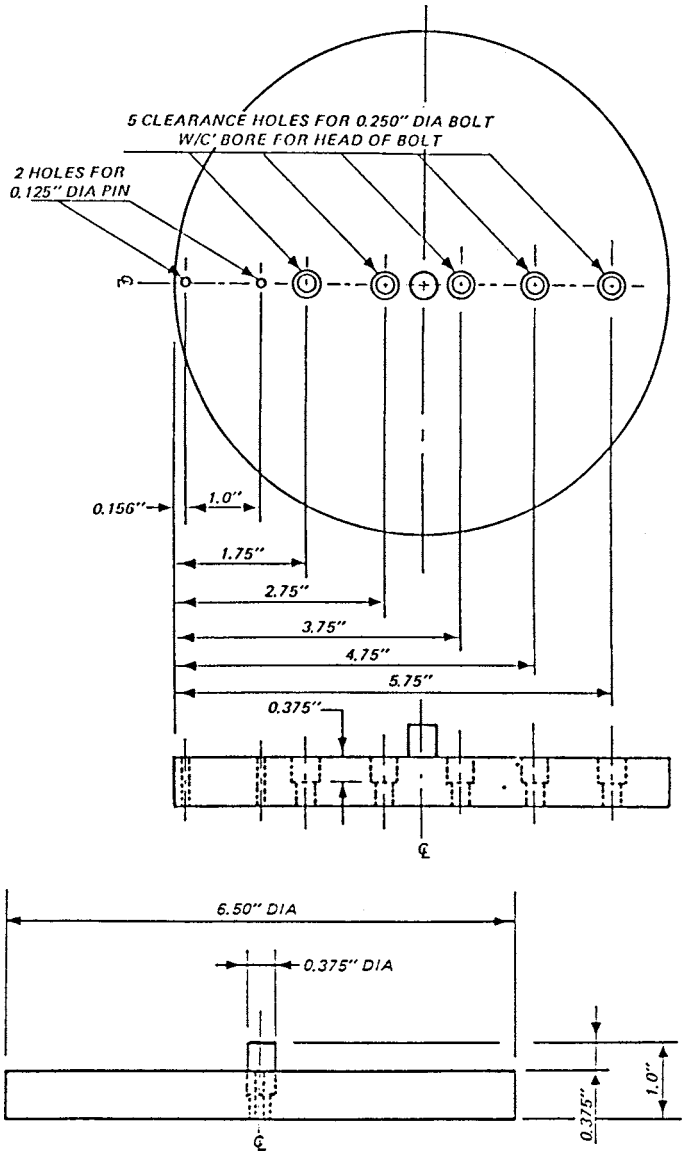

FIG. 2 Base Plate

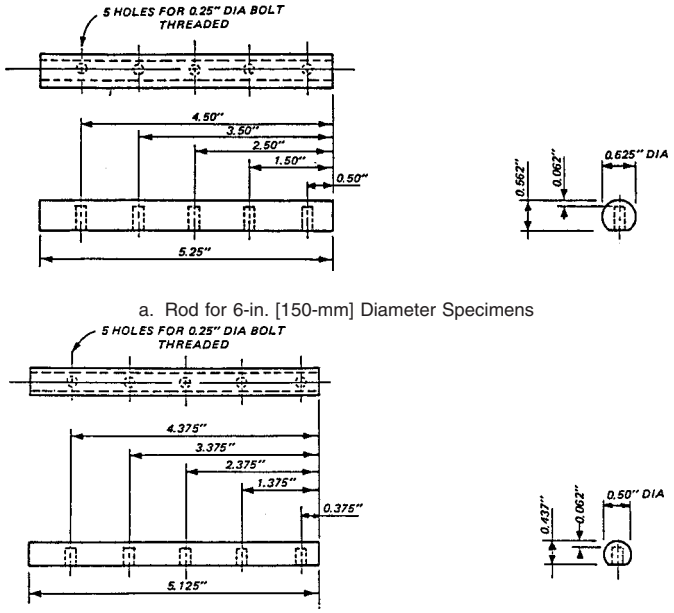

FIG. 3 Bottom Anvil Rods

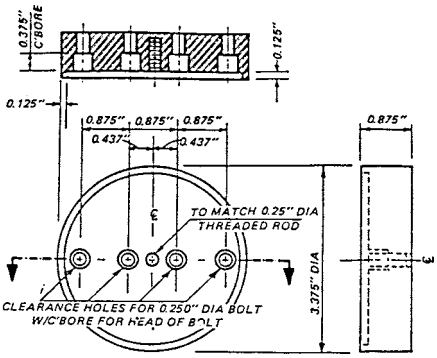

FIG. 4 Top Plate

of the specimen, the section on each side of the bond plane shall be of a length at least 0.6 the diameter. Where the bond surface is irregular or undulating, mark on the specimen a line representing a plane extending through and along the approximate average bearing of the bond surface, and measure the length from this line.

NOTE 3—Many drilled cores will not be smooth enough to justify the measurement of diameters closer than to the nearest 0.1 in. [2.5 mm].

7.2 *Positioning*—Assemble and position the apparatus in the testing machine. Place the specimen on the bottom plate with the joint in contact with the anvil rods (see Fig. 1). The longer anvil rods (Fig. 3a and Fig. 5a) and the longer alignment post (Fig. 9) are used to test 6-in. [150-mm] diameter specimens. The shorter anvil rods (Fig. 3b and Fig. 5b) and the shorter alignment post (Fig. 8) are used to test 4-in. [100-mm] diameter specimens.

7.2.1 Zero the load-indicating mechanism. Position the specimen so that the bond surface is parallel to the upper and lower anvil rods (see Fig. 1). This is best accomplished by positioning the specimen by hand while gently bringing the top anvil into contact with the specimen. Alternatively, the specimen may be supported with modeling clay or pieces of polystyrene. Where the bond surface is irregular or undulating, align the anvil rods along the approximate average bearing of the bond surface. Bring the anvil rods in contact with the bond surface at the contact point on the circumference of the specimen.

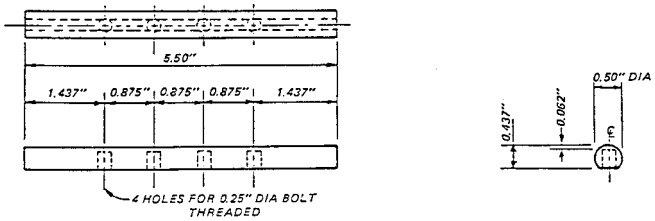
a. Rod for 6-in. [150-mm] Diameter Specimens



b. Rod for 4-in. [101-mm] Diameter Specimens

FIG. 5 Top Anvil Rods

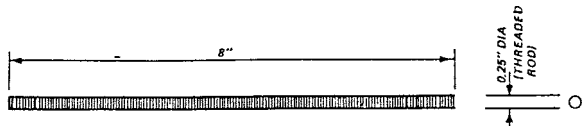


FIG. 6 Threaded Rod for Attachment of Top Plate

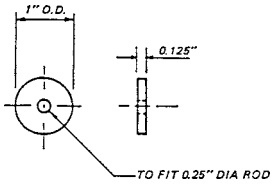

FIG. 7 Washer for Threaded Rod

7.3 *Loading*—Do not preload the specimen. Apply the load at a uniform rate within the range of 150 to 200 psi/min [1 to 1.4 MPa/min] until the specimen fails. Record the maximum load applied.

8. Calculation

8.1 Calculate the strength of the bond as follows:

$$f_{tb} = \frac{P}{D^2}$$

where:

f_{tb} = bond strength, psi [MPa],
P = maximum applied load, lbf [N], and
D = average specimen diameter at bond surface, in. [mm].

9. Report

9.1 Report the following information:

9.1.1 Date of testing.

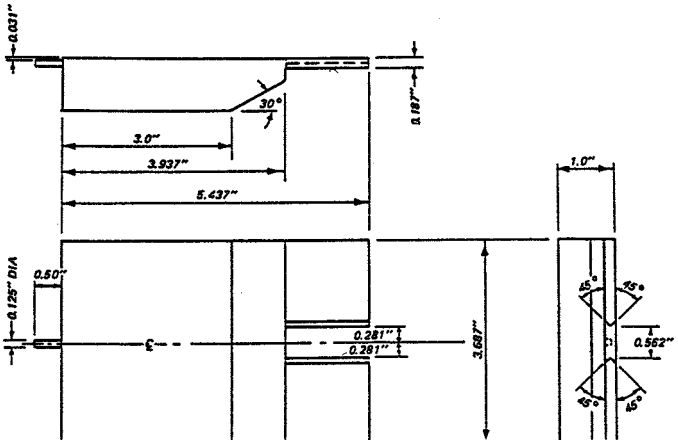

FIG. 8 Alignment Post for 4-in. [100-mm] Diameter Specimens

9.1.2 Specimen identification and if cored, the location of the core.

9.1.3 Details of the materials comprising the specimens, such as the following:

9.1.3.1 Mixture proportions of the concretes and mortars;

9.1.3.2 Details of fabrication including the practice or test method used to cast or mold cylinders;

9.1.3.3 Details of bonding techniques;

9.1.3.4 Age, when tested;

9.1.3.5 Specimen size including diameter and length of each layer material and whether a cast cylinder or drilled core was used; and

9.1.3.6 Any other information necessary to describe the production or features of the specimens.

9.1.4 Record of curing and moisture condition of the specimens at the time of test.

9.1.5 Any special treatment or prior testing performed on the specimens.

9.1.6 Strength of the bond to the nearest 10 psi [0.1 MPa].

9.1.7 Mode of failure:

9.1.7.1 Whether bond failure or aggregate failure, or both, were observed in the plane of failure;

9.1.7.2 Should the fracture occur along the original bond surface, the nature of the surface such as texture (smooth or rough), appearance (glossy or dull, undulating or flat), and detailed descriptions of discoloration, foreign objects or materials, loose or dusty material in voids, and the suspected presence and condition, or absence, of any bonding improvement agent;

9.1.7.3 Alternatively, should the plane of fracture occur partially or totally within the concrete layers adjacent to the bond surface, the percentage of the total area subjected to this type of failure versus the percentage area where failure occurred at the bond surface; and

9.1.7.4 Any unexpected features.

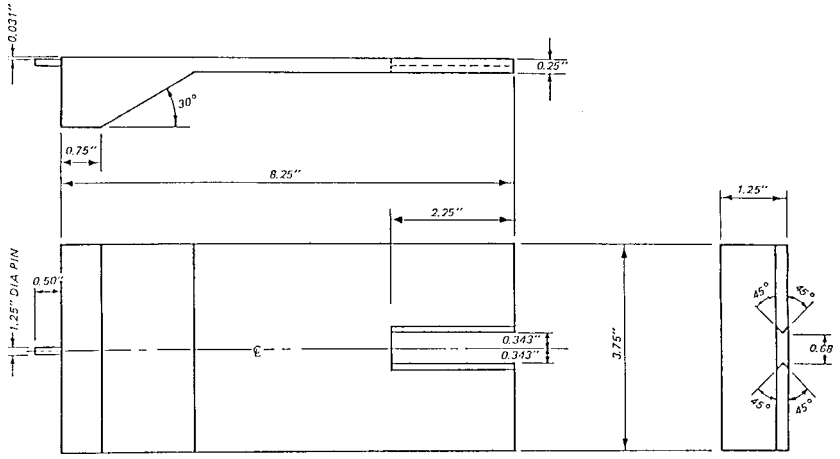

FIG. 9 Alignment Post for 6-in. [150-mm] Diameter Specimens

10. Precision and Bias

10.1 *Precision*—Precision of this test method was calculated from results published in Saucier,[3] which compared tensile strength of bonds and unbonded concrete for five mixtures of varying proportions. These data only represent within laboratory data for a single laboratory. A report of this analysis is on file at ASTM International Headquarters, as Research Report RR: C09-1025.[4]

10.1.1 The single-laboratory single-batch standard deviation for splitting tensile strength of unbonded concrete cores has been found to be 23 psi [0.16 MPa][5] in 95 % of the cases. Therefore, results of tests on two cores taken from the same batch of concrete should differ by no more than 106 psi [0.73MPa][5] in 95 % of cases.

10.1.2 The single-laboratory single-batch standard deviation for splitting tensile bond strength of cores obtained from a layered specimen has been found to be 38 psi [0.26 MPa][5] in 95 % of the cases. Therefore, results of tests on two cores taken from the same batch of concrete should differ by no more than 106 psi [07.3 MPa] in 95 % of cases.

10.2 *Bias*—This test method has no bias because there is no standard material on which to estimate this property.

11. Keywords

11.1 bond strength; bonding agents; concrete bonding; roller-compacted concretes

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1245/C 1245M – 03, that may impact the use of this test method. (Approved July 1, 2006)

(*1*) Replaced Fig. 1 with a new schematic.

(*2*) Deleted Fig. 2, a photo entitled "Test Specimen in Testing Machine" and renumbered all subsequent figures.

Designation: C 1252 – 06

Standard Test Methods for Uncompacted Void Content of Fine Aggregate (as Influenced by Particle Shape, Surface Texture, and Grading)[1]

This standard is issued under the fixed designation C 1252; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 These test methods cover the determination of the loose uncompacted void content of a sample of fine aggregate. When measured on any aggregate of a known grading, void content provides an indication of that aggregate's angularity, sphericity, and surface texture compared with other fine aggregates tested in the same grading. When void content is measured on an as-received fine-aggregate grading, it can be an indicator of the effect of the fine aggregate on the workability of a mixture in which it may be used.

1.2 Three procedures are included for the measurement of void content. Two use graded fine aggregate (standard grading or as-received grading), and the other uses several individual size fractions for void content determinations:

1.2.1 *Standard Graded Sample (Test Method A)*—This test method uses a standard fine aggregate grading that is obtained by combining individual sieve fractions from a typical fine aggregate sieve analysis. See the section on Preparation of Test Samples for the grading.

1.2.2 *Individual Size Fractions (Test Method B)*—This test method uses each of three fine aggregate size fractions: *(a)* 2.36 mm (No. 8) to 1.18 mm (No. 16); *(b)* 1.18 mm (No. 16) to 600 µm (No. 30); and *(c)* 600 µm (No. 30) to 300 µm (No. 50). For this test method, each size is tested separately.

1.2.3 *As-Received Grading (Test Method C)*—This test method uses that portion of the fine aggregate finer than a 4.75-mm (No. 4) sieve.

1.2.4 See the section on Significance and Use for guidance on the method to be used.

1.3 The values stated in SI units shall be regarded as the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 Terms used in these test methods are defined in Terminology C 125 or ACI 116R.

4. Summary of Test Method

4.1 A nominal 100-mL calibrated cylindrical measure is filled with fine aggregate of prescribed grading by allowing the sample to flow through a funnel from a fixed height into the measure. The fine aggregate is struck off and its mass is determined by weighing. Uncompacted void content is calculated as the difference between the volume of the cylindrical

[1] These test methods are under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and are the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved Nov. 1, 2006. Published November 2006. Originally approved in 1993. Last previous edition approved in 2003 as C 1252 – 03.

www.technobetar.ir

measure and the absolute volume of the fine aggregate collected in the measure. Uncompacted void content is calculated using the dry relative density (specific gravity) of the fine aggregate. Two runs are made on each sample and the results are averaged.

4.1.1 For a graded sample (Test Method A or Test Method C) the percent void content is determined directly, and the average value from two runs is reported.

4.1.2 For the individual size fractions (Test Method B), the mean percent void content is calculated using the results from tests of each of the three individual size fractions.

5. Significance and Use

5.1 Test Methods A and B provide percent void content determined under standardized conditions which depends on the particle shape and texture of a fine aggregate. An increase in void content by these procedures indicates greater angularity, less sphericity, or rougher surface texture, or combination thereof. A decrease in void content results is associated with more rounded, spherical, or smooth-surfaced fine aggregate, or a combination thereof.

5.2 Test Method C measures the uncompacted void content of the minus 4.75-mm (No. 4) portion of the as-received material. This void content depends on grading as well as particle shape and texture.

5.3 The void content determined on the standard graded sample (Test Method A) is not directly comparable with the average void content of the three individual size fractions from the same sample tested separately (Test Method B). A sample consisting of single size particles will have a higher void content than a graded sample. Therefore, use either one method or the other as a comparative measure of shape and texture, and identify which test method has been used to obtain the reported data. Test Method C does not provide an indication of shape and texture directly if the grading from sample to sample changes.

5.3.1 The standard graded sample (Test Method A) is most useful as a quick test which indicates the particle shape properties of a graded fine aggregate. Typically, the material used to make up the standard graded sample can be obtained from the remaining size fractions after performing a single sieve analysis of the fine aggregate.

5.3.2 Obtaining and testing individual size fractions (Test Method B) are more time consuming and require a larger initial sample than using the graded sample. However, Test Method B provides additional information concerning the shape and texture characteristics of individual sizes.

5.3.3 Testing samples in the as-received grading (Test Method C) may be useful in selecting proportions of components used in a variety of mixtures. In general, high void content suggests that the material could be improved by providing additional fines in the fine aggregate or more cementitious material may be needed to fill voids between particles.

5.3.4 The dry relative denstiy (specific gravity) of the fine aggregate is used in calculating the void content. The effectiveness of these test methods of determining void content and its relationship to particle shape and texture depends on the relative density (specific gravity) of the various size fractions being equal, or nearly so. The void content is actually a function of the volume of each size fraction. If the type of rock or minerals, or its porosity, in any of the size fractions varies markedly it may be necessary to determine the specific gravity of the size fractions used in the test.

5.4 Void content information from Test Methods A, B, or C will be useful as an indicator of properties such as: the mixing water demand of hydraulic cement concrete; flowability, pumpability, or workability factors when formulating grouts or mortars; or, in bituminous concrete, the effect of the fine aggregate on stability and voids in the mineral aggregate; or the stability of the fine-aggregate portion of a base course aggregate.

6. Apparatus

6.1 *Cylindrical Measure*—A right cylinder of approximately 100-mL capacity having an inside diameter of approximately 39 mm and an inside height of approximately 86 mm made of drawn copper water tube meeting the requirements of Specification B 88 , Type M or B 88M, Type C. The bottom of the measure shall be metal at least 6 mm thick, shall be firmly sealed to the tubing, and shall be provided with means for aligning the axis of the cylinder with that of the funnel. See Fig. 1.

6.2 *Funnel*—The lateral surface of the right frustum of a cone sloped 60 ± 4° from the horizontal with an opening of 12.7 ± 0.6-mm diameter. The funnel section shall be a piece of metal, smooth on the inside and at least 38 mm high. It shall have a volume of at least 200 mL or shall be provided with a supplemental glass or metal container to provide the required volume. See Fig. 2.

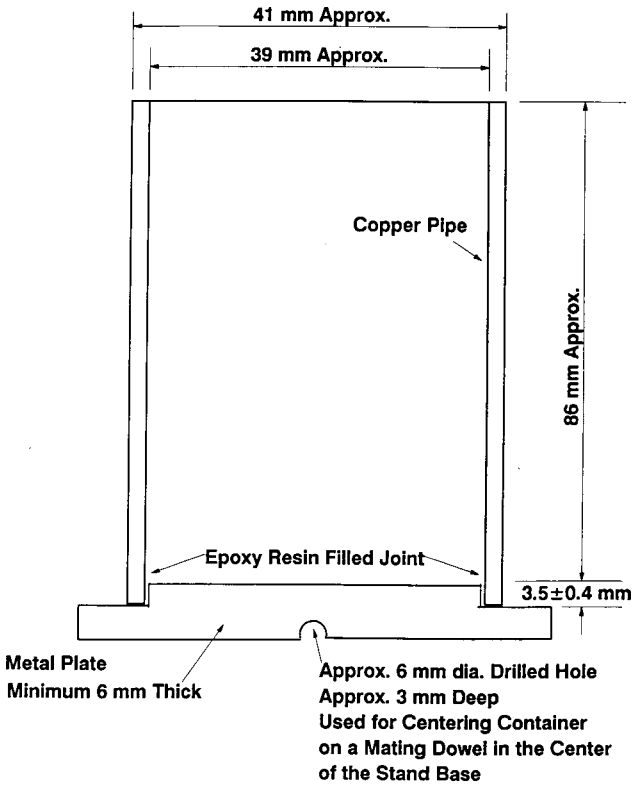

FIG. 1 Nominal 100-mL Cylindrical Measure

Section Through Center of Apparatus

FIG. 2 Suitable Funnel Stand Apparatus with Cylindrical Measure in Place

NOTE 1—Pycnometer top C9455[4] is satisfactory for the funnel section, except that the size of the opening has to be enlarged and any burrs or lips that are apparent should be removed by light filing or sanding before use. This pycnometer top must be used with a suitable glass jar with the bottom removed (Fig. 2).

6.3 *Funnel Stand*—A three- or four-legged support capable of holding the funnel firmly in position with the axis of the funnel colinear (within a 4° angle and a displacement of 2 mm) with the axis of the cylindrical measure. The funnel opening shall be 115 ± 2 mm above the top of the cylinder. A suitable arrangement is shown in Fig. 2.

6.4 *Glass Plate*—A square glass plate approximately 60 by 60 mm with a minimum 4-mm thickness used to calibrate the cylindrical measure.

6.5 *Pan*—A metal or plastic pan of sufficient size to contain the funnel stand and to prevent loss of material. The purpose of the pan is to catch and retain fine aggregate particles that overflow the measure during filling and strike off.

6.6 *Metal Spatula*, with a blade approximately 100 mm long, and at least 20 mm wide, with straight edges. The end shall be cut at a right angle to the edges. The straight edge of the spatula blade is used to strike off the fine aggregate.

6.7 *Scale or Balance*, accurate and readable to ±0.1 g within the range of use, capable of weighing the cylindrical measure and its contents.

7. Sampling

7.1 Obtain the sample(s) used for this test in accordance with Practices D 75 and Practice C 702, or from sieve analysis samples used for Test Method C 136, or from aggregate extracted from a bituminous concrete specimen. For Methods A and B, wash the sample over a 150-µm (No. 100) or 75-µm (No. 200) sieve in accordance with Test Method C 117 and then dry and sieve into separate size fractions in accordance with the procedures of Test Method C 136. Maintain the necessary size fractions obtained from one (or more) sieve analysis in a dry condition in separate containers for each size. For Method C, dry a split of the as-received sample in accordance with the drying procedure in Test Method C 136.

8. Calibration of Cylindrical Measure

8.1 Apply a light coat of grease to the top edge of the dry, empty cylindrical measure. Weigh the measure, grease, and glass plate. Fill the measure with freshly boiled, deionized water at a temperature of 18 to 24 °C. Record the temperature of the water. Place the glass plate on the measure, being sure that no air bubbles remain. Dry the outer surfaces of the measure and determine the combined mass of measure, glass plate, grease, and water by weighing. Following the final weighing, remove the grease and determine the mass of the clean, dry, empty measure for subsequent tests.

8.2 Calculate the volume of the measure as follows:

$$V = \frac{1000\,M}{D}$$

where:

V = volume of cylinder, mL,
M = net mass of water, g, and
D = density of water, kg/m^3(see table in Test Method C 29/C 29M for density at the temperature used.)

Determine the volume to the nearest 0.1 mL.

NOTE 2—If the volume of the measure is greater than 100.0 mL, it may be desirable to grind the upper edge of the cylinder until the volume is exactly 100.0 mL to simplify subsequent calculations.

9. Preparation of Test Samples

9.1 *Test Method A—Standard Graded Sample*—Weigh out and combine the following quantities of fine aggregate which have been dried and sieved in accordance with Test Method C 136.

Individual Size Fraction	Mass, g
2.36 mm (No. 8) to 1.18 mm (No. 16)	44
1.18 mm (No. 16) to 600 µm (No. 30)	57
600 µm (No. 30) to 300 µm (No. 50)	72
300 µm (No. 50) to 150 µm (No. 100)	17
	190

The tolerance on each of these amounts is ±0.2 g.

9.2 *Test Method B—Individual Size Fractions*—Prepare a separate 190-g sample of fine aggregate, dried and sieved in accordance with Test Method C 136, for each of the following size fractions:

[4] The sole source of supply of the apparatus known to the committee at this time is Hogentogler and Co., Inc., 9515 Gerwig, Columbia, MD 21045. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

www.technobetar.ir

Individual Size Fraction	Mass, g
2.36 mm (No. 8) to 1.18 mm (No. 16)	190
1.18 mm (No. 16) to 600 µm (No. 30)	190
600 µm (No. 30) to 300 µm (No. 50)	190

The tolerance on each of these amounts is ±1 g. Do not mix these samples together. Each size is tested separately.

9.3 *Test Method C—As Received Grading*—Pass the sample (dried in accordance with Test Method C 136) through a 4.75-mm (No. 4) sieve. Obtain a 190 ± 1-g sample of the material passing the 4.75-mm (No. 4) sieve for test.

9.4 *Relative Density (Specific Gravity) of Fine Aggregate*—If the dry relative density (specific gravity) of fine aggregate from the source is unknown, determine it on the minus 4.75-mm (No. 4) material in accordance with Test Method C 128. Use this value in subsequent calculations unless some size fractions differ by more than 0.05 from the relative density (specific gravity) typical of the complete sample, in which case the relative density (specific gravity) of the fraction (or fractions) being tested must be determined. An indicator of differences in relative density (specific gravity) of various particle sizes is a comparison of relative densities (specific gravities) run on the fine aggregate in different gradings. Relative density (specific gravity) can be run on gradings with and without specific size fractions of interest. If relative density (specific gravity) differences exceed 0.05, determine the relative density (specific gravity) of the individual 2.36-mm (No. 8) to 150-µm (No. 100) sizes for use with Method A or the individual size fractions for use with Test Method B either by direct measurement or by calculation using the relative density (specific gravity) data on gradings with and without the size fraction of interest. A difference in relative density (specific gravity) of 0.05 will change the calculated void content about 1 %.

10. Procedure

10.1 Mix each test sample with the spatula until it appears to be homogeneous. Position the jar and funnel section in the stand and center the cylindrical measure as shown in Fig. 2. Use a finger to block the opening of the funnel. Pour the test sample into the funnel. Level the material in the funnel with the spatula. Remove the finger and allow the sample to fall freely into the cylindrical measure.

10.2 After the funnel empties, strike off excess heaped fine aggregate from the cylindrical measure by a single rapid pass of the spatula with the width of the blade vertical keeping the straight part of its edge horizontal and in light contact with both sides of the top of the measure. Until this operation is complete, exercise care to avoid vibration or any disturbance that could cause compaction of the fine aggregate in the cylindrical measure (Note 3). Brush adhering grains from the outside of the container and determine the mass of the cylindrical measure and contents to the nearest 0.1 g. Retain all fine aggregate particles for a second test run.

NOTE 3—After strike-off, the cylindrical measure may be tapped lightly to compact the sample to make it easier to transfer the container to the scale or balance without spilling any of the sample.

10.3 Recombine the sample from the retaining pan and cylindrical measure and repeat the procedure. Average the results of two runs. See Section 11.

10.4 Record the mass of the empty measure. Also, for each run, record the mass of the measure and fine aggregate.

11. Calculation

11.1 Calculate the uncompacted voids for each determination as follows:

$$U = \frac{V - (F/G)}{V} \times 100$$

where:

V = volume of cylindrical measure, mL,
F = net mass of fine aggregate in measure, g (gross mass minus the mass of the empty measure),
G = dry relative density (specific gravity) of fine aggregate, and
U = uncompacted voids in the material, %.

11.2 For the standard graded sample (Test Method A) calculate the average uncompacted voids for the two determinations and report the results as U_s.

11.3 For the individual size fractions (Test Method B) calculate as follows:

11.3.1 First, the average uncompacted voids for the determinations made on each of the three size-fraction samples:

U_1 = uncompacted voids, 2.36 mm (No. 8) to 1.18 mm (No. 16), %,
U_2 = uncompacted voids, 1.18 mm (No. 16) to 600 µm (No. 30), %, and
U_3 = uncompacted voids, 600 µm (No. 30) to 300 µm (No. 50), %.

11.3.2 Second, the mean uncompacted voids (U_m) including the results for all three sizes:

$$U_m = (U_1 + U_2 + U_3)/3$$

11.4 For the as-received grading (Test Method C) calculate the average uncompacted voids for the two determinations and report the result as U_R.

12. Report

12.1 Report the following information for the standard graded sample (Test Method A):

12.1.1 Uncompacted voids (U_s), % to the nearest one tenth of a percent (0.1 %), and

12.1.2 Relative density (specific gravity) value used in the calculations.

12.2 Report the following percent voids to the nearest one tenth of a percent (0.1 %) for the individual size fractions (Test Method B):

12.2.1 Uncompacted voids for size fractions: *(a)* 2.36 mm (No. 8) to 1.18 mm (No. 16) (U_1); *(b)* 1.18 mm (No. 16) to 600 µm (No. 30) (U_2); and *(c)* 600 µm (No. 30) to 300 µm (No. 50) (U_3),

12.2.2 Mean uncompacted voids (U_m), and

12.2.3 Relative density (specific gravity) value(s) used in the calculations, and whether the relative density (specific gravity) value(s) were determined on a graded sample or the individual-sized fractions used in the test.

12.3 Report the following information for the as-received sample (Test Method C):

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:48:38 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

12.3.1 Uncompacted voids (U_R), % to the nearest one tenth of a percent (0.1 %).

12.3.2 Relative density (specific gravity) value used in the calculation.

13. Precision and Bias

13.1 *Precision*—Criteria for judging the acceptability of test results obtained by this test method are given as follows:

NOTE 4—The figures in Column 2 are the standard deviations that have been found to be appropriate for the materials and conditions of test described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests.

Material and Type Index	Standard Deviation[A]	Acceptable Range of Two Results[A]
Single-operator precision:		
Graded standard sand[B]	0.13 %	0.37 %
Manufactured fine aggregate[C]	0.33 %	0.94 %
Multilaboratory precision:		
Graded standard sand[B]	0.33 %	0.93 %
Manufactured fine aggregate[C]	1.1 %	3.1 %

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

[B] These estimates of precision are based on "graded standard sand" as described in Specification C 778, which is considered rounded, and is graded from 600 µm (No. 30 sieve) to 150 µm (No. 100 sieve), and may not be typical of other fine aggregates.

[C] These estimates of precision are based on results from the AASHTO Materials Reference Laboratory (AMRL) Proficiency Sample Program. The data are based on the analyses of 103 paired test results from 103 laboratories. The tests were conducted in accordance with Method C—As Received Grading on a manufactured fine aggregate.

NOTE 5—Additional precision information using multiple aggregate types, versus one material above, is available in Research Report RR: C09-1019[5], prepared by the Georgia Department of Transportation and titled *Fine Aggregate Angularity Round Robin Testing—Precision Statements*.

13.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedures in these test methods, bias has not been determined.

14. Keywords

14.1 angularity; fine aggregate; particle shape; sand; surface texture; void content

[5] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1019.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to these test methods since the last issue, C 1252 – 03, that may impact the use of these test methods. (Approved November 1, 2006)

(*1*) Revised 10.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1260 – 07

Standard Test Method for Potential Alkali Reactivity of Aggregates (Mortar-Bar Method)[1]

This standard is issued under the fixed designation C 1260; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method permits detection, within 16 days, of the potential for deleterious alkali-silica reaction of aggregate in mortar bars.

1.2 The values stated in SI units are to be regarded as standard. The values in inch-pound units are shown in parentheses, and are for informational purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* A specific precautionary statement is given in the section on Reagents.

D 1193 Specification for Reagent Water

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 *Definitions:*

3.1.1 *relative density (OD), n*—as defined in Test Methods C 127 or C 128, for coarse and fine aggregates, respectively.

3.2 For definitions of other terms relating to concrete or aggregates, see Terminology C 125.

4. Significance and Use

4.1 This test method provides a means of detecting the potential of an aggregate intended for use in concrete for undergoing alkali-silica reaction resulting in potentially deleterious internal expansion. It is based on the NBRI Accelerated Test Method (**1-4**).[3] It is especially useful for aggregates that react slowly or produce expansion late in the reaction. However, it does not evaluate combinations of aggregates with cementitious materials nor are the test conditions representative of those encountered by concrete in service.

4.2 Because the specimens are exposed to a NaOH solution, the alkali content of the cement is not a significant factor in affecting expansions.

4.3 When excessive expansions (see Appendix X1) are observed, it is recommended that supplementary information be developed to confirm that the expansion is actually due to alkali-silica reaction. Sources of such supplementary information include: (1) petrographic examination of the aggregate

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.26 on Chemical Reactions.

Current edition approved June 1, 2007. Published July 2007. Originally approved in 1989. Last previous edition approved in 2005 as C 1260 – 05a.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

[3] The boldface numbers in parentheses refer to a list of references at the end of the text.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

(Guide C 295) to determine if known reactive constituents are present; (2) examination of the specimens after tests (Practice C 856) to identify the products of alkali reaction; and (3) where available, field service records can be used in the assessment of performance.

4.4 When it has been concluded from the results of tests performed using this test method and supplementary information that a given aggregate should be considered potentially deleteriously reactive, the use of mitigative measures such as low-alkali portland cement, mineral admixtures, or ground granulated blast-furnace slag should be evaluated (see last sentence of 4.1).

5. Apparatus

5.1 The apparatus shall conform to Specification C 490, except as follows:

5.2 *Sieves*—Square hole, woven-wire cloth sieves, shall conform to Specification E 11.

5.3 *Mixer, Paddle, and Mixing Bowl*—Mixer, paddle, and mixing bowl shall conform to the requirements of Practice C 305, except that the clearance between the lower end of the paddle and the bottom of the bowl shall be 5.1 ± 0.3 mm (0.20 ± 0.01 in.).

5.4 *Tamper and Trowel*—The tamper and trowel shall conform to Test Method C 109/C 109M.

5.5 *Containers*—The containers shall be of such a nature that the bars can be totally immersed in either the water or 1N NaOH solution. The containers shall be made of material that can withstand prolonged exposure to 80 °C (176 °F) and must be resistant to a 1N NaOH solution (see Note 1). The containers must be so constructed that when used for storing specimens, the loss or gain of moisture is prevented by tight-fitting covers, by sealing, or both (see Note 2). The bars in the solution must be placed and supported so that the solution has access to the entire surface of the bar; therefore, it should be ensured that the specimens do not touch the sides of the container or each other. The specimens, if stood upright in the solution, shall not be supported by the metal gauge stud.

NOTE 1—The NaOH solution will corrode glass or metal containers.

NOTE 2—Some microwave-proof food storage containers made of polypropylene or high-density polythylene have been found to be acceptable.

5.6 *Oven, or Water Bath*—A convection oven or water bath with temperature control maintaining 80.0 ± 2.0 °C (176 ± 3.6 °F).

6. Reagents

6.1 *Sodium Hydroxide (NaOH)*—USP or technical grade may be used, provided the Na^+ and OH^- concentrations are shown by chemical analysis to lie between 0.99N and 1.01N.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type IV of Specification D 1193.

6.3 *Sodium Hydroxide Solution*—Each litre of solution shall contain 40.0 g of NaOH dissolved in 900 mL of water, and shall be diluted with additional distilled or deionized water to obtain 1.0 L of solution. The volume proportion of sodium hydroxide solution to mortar bars in a storage container shall be 4 ± 0.5 volumes of solution to 1 volume of mortar bars. The volume of a mortar bar may be taken as 184 mL. Include sufficient test solution to ensure complete immersion of the mortar bars.

6.3.1 **Warning**—Before using NaOH, review: (1) the safety precautions for using NaOH; (2) first aid for burns; and (3) the emergency response to spills, as described in the manufacturer's Material Safety Data Sheet or other reliable safety literature. NaOH can cause very severe burns and injury to unprotected skin and eyes. Suitable personal protective equipment should always be used. These should include full-face shields, rubber aprons, and gloves impervious to NaOH. Gloves should be checked periodically for pin holes.

7. Conditioning

7.1 Maintain the temperature of the molding room and dry materials at not less than 20 °C (68 °F) and not more than 27.5 °C (81.5 °F). The temperature of the mixing water, and of the moist closet or moist room, shall not vary from 23 °C (73.4 °F) by more than 1.7 °C (3 °F).

7.2 Maintain the relative humidity of the molding room at not less than 50 %. The moist closet or room shall conform to Specification C 511.

7.3 Maintain the storage oven or water bath in which the specimens are stored in the containers at a temperature of 80.0 ± 2.0 °C (176 ± 3.6 °F).

8. Sampling and Preparation of Test Specimens

8.1 *Selection of Aggregate*—Process materials proposed for use as fine aggregate in concrete as described in the section on Preparation of Aggregate with a minimum of crushing. Process materials proposed for use as coarse aggregate in concrete by crushing to produce as nearly as practical a graded product from which a sample can be obtained. Grade the sample as prescribed in Table 1. The sample shall represent the composition of the coarse aggregate as proposed for use.

8.1.1 When a given quarried material is proposed for use both as coarse and as fine aggregate, test it only by selection of an appropriate sample crushed to the fine aggregates sizes, unless there is reason to expect that the coarser size fractions have a different composition that the finer sizes and that these differences might significantly affect expansion due to reaction with the alkalies in cement or from the environment of service. In this case test the coarser size fractions in a manner similar to that employed in testing the fine aggregate sizes.

8.2 *Preparation of Aggregate*—Grade all aggregates to which this test method is applied in accordance with the requirements given in Table 1. Crush aggregates in which sufficient quantities of the sizes specified in Table 1 do not exist

TABLE 1 Grading Requirements

Sieve Size		Mass, %
Passing	Retained on	
4.75 mm (No. 4)	2.36 mm (No. 8)	10
2.36 mm (No. 8)	1.18 mm (No. 16)	25
1.18 mm (No. 16)	600 µm (No. 30)	25
600 µm (No. 30)	300 µm (No. 50)	25
300 µm (No. 50)	150 µm (No. 100)	15

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

until the required material has been produced. In the case of aggregates containing insufficient amounts of one or more of the larger sizes listed in Table 1, and if no larger material is available for crushing, the first size in which sufficient material is available shall contain the cumulative percentage of material down to that size as determined from the grading specified in Table 1. When such procedures are required, make a special note thereof in the test report. After the aggregate has been separated into the various sieve sizes, wash each size with a water spray over the sieve to remove adhering dust and fine particles from the aggregate. Dry the portions retained on the various sieves and, unless used immediately, store each such portion individually in a clean container provided with a tight-fitting cover.

8.3 *Selection and Preparation of Cement*:

8.3.1 *Reference Cement*—Use a portland cement meeting the requirements of Specification C 150 (Note 3). In addition, the autoclave expansion in Test Method C 151 shall be less than 0.20 %.

NOTE 3—The alkali content of the cement has been found to have negligible (**3**) or minor (**6**) effects on expansion in this test.

8.3.2 *Preparation of Cement*—Pass cement for use in this test through an 850-µm (No. 20) sieve to remove lumps before use.

8.4 *Preparation of Test Specimens*:

8.4.1 *Number of Specimens*—Make at least three test specimens for each cement-aggregate combination.

8.4.2 *Preparation of Molds*—Prepare the specimen molds in accordance with the requirements of Practice C 490 except, the interior surfaces of the mold shall be covered with a release agent (see Note 4). A release agent will be acceptable if it serves as a parting agent without affecting the time of setting of the cement and without leaving any residue that will inhibit the penetration of water into the specimen.

NOTE 4—TFE-fluorocarbon tape complies with the requirements for a mold release agent.

8.4.3 *Proportioning of Mortar*—Proportion the dry materials for the test mortar using 1 part of cement to 2.25 parts of graded aggregate by mass for aggregates with a relative density (OD) at or above 2.45. For aggregates with a relative density (OD) below 2.45, determine the aggregate proportion as follows:

$$\textit{Aggregate proportion} = 2.25 \times D/2.65$$

where:

D = relative density (OD) of test aggregate.

8.4.3.1 For aggregates with a relative density (OD) equal to or greater than 2.45, the quantities of dry materials to be mixed at one time in the batch of mortar for making three specimens shall be 440 g of cement and 990 g of aggregate made up by recombining the portions retained on the various sieves in the grading prescribed in Table 1 (8.2). Use a water-cement ratio equal to 0.47 by mass (see Note 5).

8.4.3.2 For aggregates with a relative density (OD) less than 2.45, the quantities of dry materials to be mixed at one time in the batch of mortar for making three specimens shall be 440 g of cement and mass of aggregate shall be 440 g multiplied by the aggregate proportion determined in 8.4.3. This aggregate mass shall be made up by recombining the portions retained on the various sieves in the grading prescribed in Table 1 (8.2). Use a water-cement ratio equal to 0.47 by mass (see Note 5).

NOTE 5—Ruggedness tests indicated that mortar bar expansions were less variable at a fixed water to cement ratio than when gaged to a constant flow (**3**).

8.4.4 *Mixing of Mortar*—Mix the mortar in accordance with the requirements of Practice C 305.

8.4.5 *Molding of Test Specimens*—Mold test specimens within a total elapsed time of not more than 2 min and 15 s after completion of the original mixing of the mortar batch. Fill the molds with two approximately equal layers, each layer being compacted with the tamper. Work the mortar into the corners, around the gauge studs, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, cut off the mortar flush with the top of the mold and smooth the surface with a few strokes of the trowel.

9. Procedure

9.1 *Initial Storage and Reading*—Place each mold in the moist cabinet or room immediately after molds have been filled. The specimens shall remain in the molds for 24 ± 2 h. Remove the specimens from the molds and, while they are being protected from loss of moisture, properly identify and make an initial comparatory reading. Make and record the initial and all subsequent readings to the nearest 0.002 mm. Place the specimens made with each aggregate sample in a storage container with sufficient tap water to totally immerse them. Seal and place the containers in an oven or water bath at 80.0 ± 2.0 °C (176 ± 3.6 °F) for a period of 24 h.

9.2 *Zero Readings*—Remove the containers from the oven or water bath one at a time. Remove other containers only after the bars in the first container have been measured and returned to the oven or water bath. The time elapsed between removal and return of the specimens to the oven or water bath shall not exceed 10.0 min. Remove the bars one at a time from the water and dry their surface with a towel paying particular attention to the two metal gauge studs. Take the zero reading (see Note 6) of each bar immediately after drying, and read as soon as the bar is in position. Complete the process of drying and reading within 15 ± 5 s of removing the specimen from the water. After readings, leave the specimen on a towel until comparatory readings have been taken on the remainder of the bars. Place all specimens made with each aggregate sample in a container with sufficient 1N NaOH, at 80.0 ± 2.0 °C (176 ± 3.6 °F) for the samples to be totally immersed. Seal the container and return it to the oven or water bath.

NOTE 6—The reference bar should be read prior to each set of specimens since the heat from the mortar bars may cause the length of the comparator to change.

9.3 *Subsequent Storage and Measurement*—Make subsequent comparator readings of the specimens periodically, with at least three intermediate readings, for 14 days after the zero reading, at approximately the same time each day. If readings are continued beyond the 14-day period, take at least one

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:48:40 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

reading per week. The procedure is identical to that described in the section on Zero Readings except that the specimens are returned to their own container after measurement.

10. Calculation

10.1 Calculate the difference between the zero comparatory reading of the specimen and the reading at each period to the nearest 0.001 % of the effective gauge length and record as the expansion of the specimen for that period. Report the average expansion of the three specimens of a given cement-aggregate combination to the nearest 0.01 % as the expansion for the combination for a given period.

11. Report

11.1 Report the following information:

11.1.1 Type and source of aggregate,

11.1.2 Type and source of portland cement,

11.1.3 Autoclave expansion and alkali content of cement as percent potassium oxide (K_2O), sodium oxide (Na_2O), and calculated sodium oxide (Na_2O) equivalent (Na_2O_{eq}= $\%Na_2O + 0.658 \times \%K_2O$),

11.1.4 Average length change in percent at each reading of the specimens,

11.1.5 Any relevant information concerning the preparation of aggregates, including the grading of the aggregate when it differs from that given in 8.2,

11.1.6 Any significant features revealed by examination of the specimens during and after test,

11.1.7 Amount of mixing water expressed as mass percent of cement,

11.1.8 A graph of the length change data from the time of the zero reading to the end of the 16 day period.

12. Precision and Bias

12.1 *Within-Laboratory Precision*—It has been found that the average within-laboratory coefficient of variation for materials with an average expansion greater than 0.1 % at 14 days is 2.94 % **(5)** (Note 7). Therefore, the results of two properly conducted tests within the same laboratory on specimens of a sample of aggregate should not differ by more than 8.3 % (Note 7) of the mean expansion.

12.2 *Multi-Laboratory Precision*—It has been found that the average multilaboratory coefficient of variation for materials with an average expansion greater than 0.1 % at 14 days is 15.2 % **(5)** (Note 7). Therefore, the results of two properly conducted tests in different laboratories on specimens of a sample of aggregate should not differ by more than 43 % (Note 7) of the mean expansion.

NOTE 7—These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

12.3 *Bias*—Since there is no accepted reference material for determining the bias of this test method, no statement on bias is being developed.

13. Keywords

13.1 aggregate; alkali-silica reactivity; length change; mortar; sodium hydroxide

APPENDIX

(Nonmandatory Information)

X1. INTERPRETATION OF TEST RESULTS

X1.1 There is good agreement in the published literature **(1,2,7-10)** for the following expansion limits:

X1.1.1 Expansions of less than 0.10 % at 16 days after casting are indicative of innocuous behavior in most cases (see Note X1.1).

X1.1.2 Expansions of more than 0.20 % at 16 days after casting are indicative of potentially deleterious expansion (see 4.3).

X1.1.3 Expansions between 0.10 and 0.20 % at 16 days after casting include both aggregates that are known to be innocuous and deleterious in field performance. For these aggregates, it is particularly important to develop supplemental information as described in 4.3. In such a situation, it may also be useful to take comparator readings until 28 days **(8,10)**.

NOTE X1.1—Some granitic gneisses and metabasalts have been found to be deleteriously expansive in field performance even though their expansion in this test was less than 0.10 % at 16 days after casting **(10)**. With such aggregate, it is recommended that prior field performance be investigated. In the absence of field performance data, mitigative measures should be taken as discussed in 4.4.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1260 – 05a, that may impact the use of this test method. (Approved June 1, 2007)

(*1*) Revised 1.1.

(*2*) Revised 8.4.3, 8.4.3.1, and 8.4.3.2.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1260 – 05, that may impact the use of this test method. (Approved December 15, 2005)

(*1*) Revised the Referenced Documents section.
(*2*) Added a Terminology section.
(*3*) Revised 8.4.3 and added new 8.4.3.1 and 8.4.3.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1264 – 05

Standard Specification for Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage of Gypsum Panel Products[1]

This standard is issued under the fixed designation C 1264; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers sampling; inspection; rejection; certification; packaging and marking; and shipping, handling, and storage of gypsum panel products.

2. Sampling

2.1 When specified by the purchase agreement, samples of gypsum panel products shall be taken at the place of manufacture or at the destination. If the samples are taken at the destination, such samples shall be taken within 24 h of the receipt of the material.

2.2 At least 0.25 % of the number of gypsum panel products in a shipment, but not less than three gypsum panel products, shall be so selected as to be representative of the shipment and shall constitute a sample for the purpose of tests by the purchaser or user.

3. Inspection

3.1 Inspection of the gypsum panel products shall be agreed upon between the purchaser and the producer or supplier as part of the purchase agreement.

4. Rejection

4.1 Rejection of gypsum panel products that fails to conform to the requirements of the specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the gypsum panel products has failed to conform to the requirements of the specification.

5. Certification

5.1 When specified in the purchase agreement, a producer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with the ASTM specification referencing this specification.

6. Packaging and Marking

6.1 Unless otherwise specified in the purchase agreement, each gypsum panel product or package shall have legibly marked thereon the following: the thickness, the name of the producer or supplier, the brand name, if any, and the ASTM specification for the product.

7. Shipping, Handling, and Storage

7.1 Gypsum panel products shall be shipped so as to be kept dry.

7.2 Gypsum panel products shall be stored so as to be kept dry, preferably inside a building. Gypsum panel products shall be neatly stacked flat with care taken to prevent sagging or damage to edges, ends, and surfaces.

7.3 Where necessary to store gypsum panel products outside, it shall be stacked flat, off the ground, supported on a level platform, and fully protected from weather and direct sunlight exposure.

8. Keywords

8.1 certification; gypsum; gypsum panel products; handling; inspection; marking; packaging; rejection; sampling; shipping; storage

Designation: C 1271 – 99 (Reapproved 2006)

Standard Test Method for X-ray Spectrometric Analysis of Lime and Limestone[1]

This standard is issued under the fixed designation C 1271; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the X-ray emission spectrometric analysis of limestone, quicklime, hydrated lime, and hydraulic lime using wavelength dispersive instruments.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific precautionary statements are given in Section 10.

2. Referenced Documents

3. Terminology

3.1 *Definitions:*

3.1.1 *emission spectroscopy*—unless otherwise specified, for definitions of terms used in this test method pertaining to emission spectroscopy, refer to Terminology E 135.

3.1.2 *lime*—unless otherwise specified, for definitions of terms used in this test method pertaining to lime, refer to Terminology C 51.

3.1.3 *statistical*—unless otherwise specified, for definitions of terms used in this test method pertaining to statistics, refer to Terminology E 456.

4. Summary of Test Method

4.1 A briquetted powder specimen or a fused-glass disk specimen is irradiated by a high-energy X-ray beam. The secondary X rays produced are dispersed by means of crystals, and the intensities are measured by suitable detectors at selected wavelengths. Data are collected based on the time required to reach a fixed number of counts, total count for a fixed time, or integration of voltage for a fixed time. Concentrations of the elements are determined by relating the measured radiation of unknown specimens to analytical curves prepared from reference materials of known composition.

5. Significance and Use

5.1 This procedure is suitable for manufacturing control and verifying that the product meets specifications. It provides rapid, multi-element determinations with sufficient accuracy to ensure product quality and minimize production delays. The analytical performance data included may be used as a benchmark to determine whether similar X-ray spectrometers provide equivalent precision and accuracy, or whether the performance of a particular X-ray spectrometer has changed.

6. Interferences

6.1 Interelement effects or matrix effects may exist for some of the elements listed. One way to compensate for these effects

[1] This test method is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.05 on Chemical Tests.

Current edition approved Feb. 15, 2006. Published March 2006. Originally approved in 1994. Last previous edition approved in 1999 as C 1271 – 99.

www.technobetar.ir

is to prepare a series of calibration curves to cover the designated concentration ranges. The composition of the specimen being analyzed must match closely the composition of the reference materials used to prepare the calibration curve. Mathematical corrections, derived from empirical relationships or fundamental parameter calculations, may be used alternatively. Any of these are acceptable, providing that the analytical accuracy required by this test method is achieved.

6.2 Calcium is the primary component of the matrix analyzed by this test method. The analyst must be aware of all possible interferences and matrix effects of this element. Orders of all wavelengths may cause interference, for example, the effect of CaKβ1 (2nd order) on PKα1.

6.3 Contamination from the grinding apparatus is an ever-present source of interference of which the analyst must always be cognizant. For example, stainless steel will impart iron, chrome, and nickel to the prepared sample.

6.4 Spectral interferences from the X-ray tube may also occur, for example, line overlap from CrKβ1 on MnKα1 caused by a chrome target tube.

7. Apparatus

7.1 *Specimen Preparation Equipment*:

7.1.1 *Jaw Crusher*, for initial crushing of lumps.

7.1.2 *Plate Grinder or Pulverizer*, with one static and one rotating disk for further grinding.

7.1.3 *Rotary Disk Mill or Shatter Box*, with hardened grinding containers and timer control for final grinding.

7.2 *Briquetting Equipment*:

7.2.1 *Briquetting Press*, capable of providing pressures up to 550 MPa (80 000 psi). The press shall be equipped with a mold assembly that provides a briquet compatible with the X-ray specimen holder.

7.3 *Fusion Equipment*:

7.3.1 *Furnace or Gas Burners*, with a timer, capable of heating the sample and flux to at least 1000 °C and homogenizing the melt.

7.3.2 *Fusion Crucibles*:

7.3.2.1 *Vitreous Carbon or Graphite*, 20 to 30-mL capacity, with a flat bottom 30 to 35 mm in diameter.

7.3.2.2 *Platinum/Gold*, 95 % platinum/5 % gold alloy, 30 to 35-mL capacity.

7.3.2.3 *Platinum/Gold Casting Dish*, 95 % platinum/5 % gold alloy, 30 to 35-mL capacity, with a flat bottom 30 to 35 mm in diameter.

7.3.3 *Polishing Wheel*, suitable for polishing the fusion disk to obtain a uniform surface for irradiation. The analyst should be aware at all times of possible contamination from the polishing media used for surfacing the disk (6.3).

7.4 *Excitation Source*:

7.4.1 *X-Ray Tube Power Supply*, providing constant potential or rectified power of sufficient energy to produce secondary radiation of the specimen for the elements specified. The generator may be equipped with a line voltage regulator and current stabilizer.

7.4.2 *X-Ray Tubes*, with targets of various high-purity elements, capable of continuous operation at required potentials and currents, and that will excite the elements to be determined.

7.5 *Spectrometer*, designed for X-ray emission analysis and equipped with specimen holders and a specimen chamber. The chamber may contain a specimen spinner, and it must be equipped for vacuum operation.

7.5.1 *Analyzing Crystals*—Flat or curved crystals with optimized capability for diffraction of the wavelengths of interest.

7.5.2 *Collimator*, for limiting the characteristic X rays to a parallel bundle when flat crystals are used in the instrument. A collimator is not necessary for curved crystal optics.

7.5.3 *Detectors*, sealed or gas flow, proportional type, Geiger counters, scintillation counters or equivalent.

7.5.4 *Vacuum System*, providing for the determination of elements whose radiation is absorbed by air (atomic number below 20). The system shall consist of at least one vacuum pump, gage, and electrical controls to provide automatic pumpdown of the optical path and maintain a controlled pressure, usually 13 Pa or less.

7.6 *Measuring System*, consisting of electronic circuits capable of counting or integrating pulses received from the detectors. The counts, count rate, or integrated voltages may be displayed on meters, recorders, digital counters, or voltmeters. The counts, count rates, or integrated voltages can also be presented to a computer or programmable calculator for conversion to percent concentration. Pulse height analyzers may be required to provide more accurate measurements for some measurements.

8. Reagents and Materials

8.1 *Purity and Concentration of Reagents*—The purity and concentration of chemical reagents shall conform to the requirements prescribed in Practices E 50.

8.2 *Binders*—Various binders have been used successfully to prepare briquettes suitable for presentation to the instrument. As a general rule, the binder should not contain an element that will be determined. In addition, the sample to binder ratio must be present in the analytical sample as in the reference materials that were used to establish the calibration.

8.3 *Fluxes*—Various fluxes have been used successfully to prepare fusion disks. The flux must be capable of dissolving or dispersing the analyzed elements in an homogeneous and reproducible fashion in the melt. The prepared disks must then be suitable for presentation to the instrument.

8.4 *Detector Gas (P-10)*, consisting of a mixture of 90 % argon and 10 % methane for use with gas flow proportional counters only.

9. Reference Materials

9.1 Certified reference materials are available from the National Institute for Standards and Technology (NIST) and other international certification agencies. Refer to Test Methods C 25 for a current listing.

9.2 Reference materials with matrixes similar to that of the test specimen and containing varying amounts of the elements to be determined may be used provided that they have been analyzed in accordance with ASTM standard test methods.

9.3 Standard additions method or spiked samples may also be used to create standards for which appropriate reference

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

materials are not available for an element desired to be analyzed. The matrix material must match that of the test specimen.

10. Safety Precautions

10.1 Occupational health and safety standards for ionizing radiation shall be observed at all X-ray emission spectrometer installations. It is also recommended that operating and maintenance personnel follow the guidelines of safe operating procedures given in current handbooks and publications from the original equipment manufacturer, NIST, U.S. Government Printing Office, or similar handbooks on radiation safety. See NIST Standards Catalog and ANSI-NIST Handbook 114.

10.2 *Personnel*—X-ray equipment shall be used only under the guidance and supervision of a responsible, qualified person.

10.3 *Monitoring Devices*—Either film badges or dosimeters shall be worn by all operating and maintenance personnel. Periodic radiation surveys of the equipment for leaks and excessive scattered radiation shall be made by a qualified person using an ionization chamber detector to meet local, state, and federal radiation standards. The personal film badge survey record, the radiation survey record, and an equipment maintenance record shall be available upon request.

10.4 Special precautions for operators and maintenance personnel shall be posted at the equipment site.

10.5 Radiation caution signs shall be posted near the X-ray equipment and at all entrances to the radiation area.

10.6 Fail-Safe "X-ray on" warning lights shall be used on the equipment.

11. Sampling

11.1 Gross sample is to be taken in accordance with Methods C 50.

11.2 Sample preparation is to be performed in accordance with Methods C 50 and Test Methods C 25.

11.3 Special preparation may be required to grind the analytical sample finer than is required in 11.2.

12. Preparation of Reference Materials and Test Specimens

12.1 Treat reference materials and specimens exactly the same way throughout the procedure. Either briquetted powder or fused disk specimens may be used.

13. Preparation of Apparatus

13.1 Prepare and operate the spectrometer in accordance with the manufacturer's instructions, using the parameters given in Table 1. Once established, control all instrument parameters closely to ensure repeatable analyses.

14. Calibration and Standardization

14.1 *Calibration (Preparation of Analytical Curves)*—Select a sufficient number of reference materials to cover the concentration ranges of the elements sought. Average duplicate intensity measurements of each reference material, and establish a calibration curve for each element in accordance with Practice E 305. Establish the curve by a least squares or multiple regression fit of the X-ray intensity measurements versus the corresponding weight percent concentrations of the element in the reference materials.

TABLE 1 Analytical Lines and Crystals

Element	Wavelength, A	Crystals
Sodium	11.91	TLAP, multilayer
Magnesium	9.889	ADP, TLAP, RAP, multilayer
Aluminum	8.338	PET, EDdT, RAP
Silicon	7.126	PET, EDdT, RAP, InSb
Phosphorus	6.155	Ge, PET
Sulfur	5.373	Ge, PET, NaCl
Chlorine	4.729	PET, Ge
Potassium	3.742	LiF 200, PET
Calcium	3.359	LiF 200, PET
Titanium	2.750	LiF 200, LiF 220
Manganese	2.103	LiF 200, LiF 220
Iron	1.937	LiF 200, LiF 220
Strontium	0.8766	LiF 200, LiF 220
Barium	2.775	LiF 200, LiF 220
Lead	1.175	LiF 200, LiF 220

14.2 *Standardization (Analytical Curve Adjustment)*—Verify that the calibration curve for each element has not drifted using a control reference material. Drift is indicated by a change in counts that exceeds the normal variation of counts for that element. A change of 1 % or greater usually signifies that the calibration curve for that element has drifted and should thus be adjusted. Re-measure the reference materials to verify that acceptable analyses are obtained after the adjustments are made.

15. Procedure

15.1 *Excitation*—Introduce the specimen into the specimen chamber, using care not to contaminate the surface to be excited. Produce the secondary fluorescence using the equipment used in 7.4.

15.2 *Radiation Measurements*—Obtain and record the counting rate measurement for each element. Either fixed count or fixed time modes may be used. A predetermined minimum count rate is obtainable only after unacceptable long counting times for lime materials, with the exception of the major oxides (Si, Fe, Al, Ca, and Mg). A minimum counting time of 60 s is acceptable.

15.3 *Spectral Interferences*—Some X-ray spectrometers will not resolve radiation completely from several line overlaps. Care must therefore be exercised in these cases. Alternate wavelengths without interference may be used. Otherwise, mathematical calculations must be used to correct for the interferences.

NOTE 1—If a goniometer is used, the setting for the 2 θ peak must be determined experimentally within each laboratory. Periodic checks to verify the setting are advisable.

15.4 *Replicate Measurements*—Make a minimum of two measurements on each test specimen. The performance of an X-ray spectrometer is not improved significantly by making multiple measurements on the same surface of the same specimen; however, for those elements not having sufficient counts in the predetermined time, the statistics near the detection limit will improve with multiple exposures. Confidence in the accuracy of analysis will also improve by analyzing more than one specimen.

16. Calculation of Results

16.1 Determine the concentration of the various elements using the radiation measurements for the test specimen and the appropriate analytical curves.

16.2 If mathematical corrections must be made to correct the concentrations for interelement effects, any one of a number of correction procedures may be used. Refer to the equipment manufacturer's manual for the instrument being used. Computers are normally interfaced to the X-ray spectrometers in laboratories using such correction systems. Refer to Guide E 1361 for a guide to interelement corrections.

NOTE 2—With computer-controlled X-ray spectrometers that convert output signals automatically to percent concentrations and make interelement corrections, calculated results are usually printed without operator involvement.

17. Precision and Bias

17.1 *Precision*—An acceptable number of laboratories tested this test method in accordance with Practice E 1060. Precision data are provided in the annex.

17.1.1 *Repeatability (R1)*—Calculations for within-laboratory precision are listed in the annex.

17.1.2 *Reproducibility (R2)*—Calculations for between-laboratory precision are listed in the annex.

17.2 *Bias (Accuracy)*—Bias data calculated in accordance with Practice E 1060 are included in the annex.

18. Keywords

18.1 chemical analysis; hydrated lime; hydraulic lime; limestone; quicklime; wavelength dispersive; X-ray spectrometric

ANNEX

(Mandatory Information)

A1. HIGH CALCIUM LIMESTONE BY THE BRIQUETTE METHOD

A1.1 *Summary of Test Method*:

A1.1.1 A briquetted powder specimen of high calcium limestone is prepared and irradiated as directed in Test Method C 1271.

A1.2 *Provisions*:

A1.2.1 There are no special provisions in the test method that are not referred to in Test Method C 1271.

A1.3 *Precision and Bias*:

A1.3.1 *Round Robin*—An interlaboratory study, consistent with the guidelines of Practice E 691, was conducted in 1997. Five high calcium limestone materials were analyzed by eight laboratories performing replicate measurements on four briquettes.

A1.3.2 *Precision*—The relative precision of this test method, characterized by repeatability (S_r and r) and reproducibility (S_R and R) has been determined for the materials and elements to be:

A1.3.2.1 Silicon as % Silicon Dioxide (% SiO_2):

Material	Average	S_r	S_R	r	R
S-1143	0.054	0.012	0.022	0.034	0.062
S-1145	0.156	0.009	0.048	0.026	0.133
S-1142	0.627	0.011	0.070	0.032	0.197
S-1141	0.875	0.026	0.084	0.071	0.234
S-1144	1.866	0.062	0.091	0.174	0.254

A1.3.2.2 Iron as % Ferric Oxide (% Fe_2O_3):

Material	Average	S_r	S_R	r	R
S-1143	0.0244	0.0013	0.0156	0.0038	0.0436
S-1145	0.0359	0.0018	0.0067	0.0050	0.0188
S-1141	0.1357	0.0023	0.0062	0.0064	0.0173
S-1142	0.1917	0.0021	0.0168	0.0058	0.0469
S-1144	0.8792	0.0137	0.0388	0.0383	0.1087

A1.3.2.3 Aluminum as % Aluminum Oxide (% $A1_2O_3$):

Material	Average	S_r	S_R	r	R
S-1143	0.0463	0.0015	0.0259	0.0042	0.0724
S-1145	0.0736	0.0040	0.0330	0.0111	0.0924
S-1142	0.1142	0.0030	0.0321	0.0083	0.0899
S-1141	0.1159	0.0036	0.0330	0.0102	0.0924
S-1144	0.4404	0.0163	0.0444	0.0457	0.1244

A1.3.2.4 Calcium as % Calcium Oxide (% CaO):

Material	Average	S_r	S_R	r	R
S-1144	53.347	0.150	0.295	0.421	0.826
S-1141	53.683	0.159	0.428	0.446	1.199
S-1142	54.304	0.127	0.359	0.356	1.006
S-1145	55.599	0.110	0.371	0.307	1.039
S-1143	55.837	0.143	0.284	0.401	0.794

A1.3.2.5 Magnesium as % Magnesium Oxide (% MgO):

Material	Average	S_r	S_R	r	R
S-1143	0.176	0.015	0.085	0.042	0.238
S-1145	0.216	0.006	0.085	0.017	0.237
S-1144	0.637	0.007	0.024	0.021	0.067
S-1142	0.919	0.010	0.039	0.028	0.109
S-1141	1.406	0.049	0.106	0.138	0.298

A1.3.2.6 Manganese as % Manganese (% Mn):

Material	Average	S_r	S_R	r	R
S-1145	0.0024	0.0003	0.0016	0.0009	0.0044
S-1143	0.0035	0.0003	0.0015	0.0009	0.0041
S-1142	0.0170	0.0036	0.0046	0.0101	0.0128
S-1141	0.0248	0.0003	0.0021	0.0007	0.0059
S-1144	0.0900	0.0004	0.0196	0.0011	0.0550

www.technobetar.ir

A1.3.3 *Repeatability*—The difference in absolute value between test results of the averages of two briquettes of the same sample, carried out separately and consecutively, in the same laboratory by the same operator using the same apparatus, may be expected to occur with a probability of approximately 0.95 (95 % confidence level). The repeatability limit for this test method is the following:

Silicon as % Silicon Dioxide (% SiO_2)	0.009 + 0.081 *x*
Iron as % Ferric Oxide (% Fe_2O_3)	0.0015 + 0.0411 *x*
Aluminum as % Aluminum Oxide (% Al_2O_3)	0.1038 *x*
Calcium as % Calcium Oxide (% CaO)	0.386
Magnesium as % Magnesium Oxide (% MgO)	0.0751 *x*
Manganese as % Manganese (% Mn)	0.0027

where: *x* is the average of test results from two briquettes.

A1.3.4 *Reproducibility*—The difference in absolute value of replicate determinations, carried out in different laboratories using samples taken at random from a single sample prepared from the same bulk sample after the last stage of reduction, may be expected to occur with a probability of approximately 0.95 (95 % confidence level). The reproducibility limit for this test method is the following:

Silicon as % Silicon Dioxide (% SiO_2)	0.109 + 0.093 *x*
Iron as % Ferric Oxide (% Fe_2O_3)	0.0227 + 0.0963 *x*
Aluminum as % Aluminum Oxide (% Al_2O_3)	0.0768 + 0.1104 *x*
Calcium as % Calcium Oxide (% CaO)	0.973
Magnesium as % Magnesium Oxide (% MgO)	0.1781 + 0.0174 *x*
Manganese as % Manganese (% Mn)	0.588 *x*

where: *x* is the average of test results.

A1.3.5 *Bias*—Certified reference materials are used for the calibration of this test method. No bias is expected for the method.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1278/C 1278M – 07a

Standard Specification for Fiber-Reinforced Gypsum Panel[1]

This standard is issued under the fixed designation C 1278/C 1278M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers fiber-reinforced gypsum panels described in 1.1.1-1.1.4.

1.1.1 *Interior Fiber-Reinforced Gypsum Panels* are designed to be used for walls, ceilings, or partitions and affords a suitable surface to receive decoration.

1.1.2 *Water-Resistant Fiber-Reinforced Gypsum Backing Panels* are designed primarily to be used as a base for the application of ceramic or plastic tile on walls or ceilings. This product is also suitable for decoration.

1.1.3 *Exterior Fiber-Reinforced Gypsum Soffit Panels* are designed for use on exterior soffits and carport ceilings that are completely protected from contact with liquid water.

1.1.4 *Water-Resistant Exterior Fiber-Reinforced Gypsum Sheathing Panels* are designed for use as sheathing on buildings.

1.1.5 *Interior Fiber-Reinforced Gypsum Underlayment Panels* are designed for use as a base for application of finished flooring materials.

1.1.6 *Fiber-Reinforced Gypsum Board Panels* are designed for use in roofing systems.

1.2 Specifications applicable to all fiber-reinforced gypsum panels are located in Sections 1-4 and 11-13 except as modified by applicable product sections. Specifications applicable to specific panels are located in the following sections:

Interior Fiber-Reinforced Gypsum Panels	5
Water-Resistant Fiber-Reinforced Gypsum Backing Panels	6
Exterior Fiber-Reinforced Gypsum Soffit Panels	7
Water-Resistant Exterior Fiber-Reinforced Gypsum Sheathing Panels	8
Interior Fiber-Reinforced Gypsum Underlayment Panels	9
Fiber-Reinforced Gypsum Roof Board Panels	10

1.3 The values stated in either inch-pound units or SI (metric) are to be regarded separately as the standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be used independently of the other. Values from the two systems shall not be combined.

1.4 The text of this specification references notes and footnotes that provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

2. Referenced Documents
