Designation: C 5 – 03

Standard Specification for Quicklime for Structural Purposes[1]

This standard is issued under the fixed designation C 5; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers all classes of quicklime such as crushed lime, granular lime, ground lime, lump lime, pebble lime, and pulverized lime, used for structural purposes.

2. Referenced Documents

2.1 *ASTM Standards:*

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime[2]

C 50 Practice for Sampling, Inspection, Packing, and Marking of Lime and Limestone Products[2]

C 51 Terminology Relating to Lime and Limestone (As Used by the Industry)[2]

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone[2]

C 1489 Specification of Lime Putty for Structural Purposes[2]

E 11 Specification for Wire-Cloth Sieves for Testing Purposes[3]

3. Terminology

3.1 *Definitions*—Unless otherwise specified, for definitions of terms used in this standard, refer to Terminology C 51.

4. Chemical Composition

4.1 The quicklime shall conform to the following requirements as to chemical composition, calculated on a nonvolatile basis:

	Calcium Lime	Magnesium Lime
Calcium oxide, min, %	75	
Magnesium oxide, min, %		20
Calcium and magnesium oxide, min, %	95	95
Silica, alumina, and oxide of iron, max, %	5	5
Carbon dioxide, max, %:		
If sample is taken at place of manufacture	3	3
If sample is taken at any other place	10	10

5. Residue

5.1 The quicklime shall contain no more than 15 weight % of residue.

6. General Requirements

6.1 Quicklime shall be slaked and aged in accordance with the printed directions of the manufacturer. The resulting lime putty shall be stored until cool.

6.2 Lime putty prepared in accordance with Appendix X1.4.2 must conform to the requirements of Specification C 1489.

7. Sampling, Inspection, etc.

7.1 The sampling, inspection, rejection, retesting, packaging, and marking shall be conducted in accordance with Methods C 50.

8. Test Methods

8.1 Conformance to chemical requirements shall be determined in accordance with Test Methods C 25.

8.2 Conformance to plasticity and residue requirements shall be determined in accordance with Test Methods C 110.

9. Keywords

9.1 building (structural); calcium oxide; dolomitic lime; high calcium lime; lime putty; magnesium oxide; plasticity; quicklime; residue; slaking

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Structural Lime.

Current edition approved May 10, 2003. Published July 2003. Originally approved in 1913. Last previous edition approved in 1997 as C 5 – 79 (1997).

APPENDIX

(Nonmandatory Information)

X1. SLAKING AND PREPARATION OF LIME PUTTY

X1.1 *Introduction*

X1.1.1 Quicklime can never be used as such for structural purposes; it must always be slaked first. Since the method of slaking is an important factor in determining the quality of the finished product, the following directions for the preparation of lime putty are given, not as a part of the specification, but as information for the further protection of the purchaser.

X1.1.2 Different kinds of lime vary considerably in the way in which they behave with water. A little supervision over the operation of slaking will amply pay for itself by ensuring the production of the greatest possible quantity and the best possible quality of putty. To find out how to slake a new lot of lime, it is safest to try a little of it and see how it works. Since different lots of the same brand of lime vary somewhat, and since the weather conditions at the time have a decided influence, it is wise to try a sample from each lot used, whether familiar with the brand or not.

X1.2 Classification of Limes

X1.2.1 In a bucket, put two or three lumps of lime about the size of one's fist, or, in the case of granular lime, an equivalent amount. Add sufficient water to just barely cover the lime, and note how long it takes for slaking to begin. Slaking has begun when pieces split off from the lumps or when the lumps crumble. Water of the same temperature should be used for test and field practice.

X1.2.2 If slaking begins in less than 5 min, the lime is quick slaking; from 5 to 30 min, medium slaking; over 30 min, slow slaking.

X1.3 Directions for Slaking

X1.3.1 Slake quicklime in accordance with the printed directions of the manufacturer. When such directions are not provided, proceed as follows:

X1.3.2 For quick-slaking lime, always add the lime to the water, not the water to the lime. Have sufficient water at first to cover all the lime completely. Have a plentiful supply of water available for immediate use—a hose throwing a good stream, if possible. Watch the lime constantly. At the slightest appearance of escaping steam, hoe thoroughly and quickly, and add enough water to stop the steaming. Do not be afraid of using too much water with this kind of lime.

X1.3.3 For medium–slaking lime, add the water to the lime. Add enough water so that the lime is about half submerged. Hoe occasionally if steam starts to escape. Add a little water now and then if necessary to prevent the putty from becoming dry and crumbly. Be careful not to add any more water than required, and not too much at a time.

X1.3.4 For slow–slaking lime, add enough water to the lime to moisten it thoroughly. Let it stand until the reaction has started. Cautiously add more water, a little at a time, taking care that the mass is not cooled by the fresh water. Do not hoe until the slaking is practically complete. If the weather is very cold, it is preferable to use hot water, but if this is not available, the mortar box may be covered in some way to retain the heat.

X1.4 Preparation of Putty for Use

X1.4.1 After slaking, prepare putty for use as follows:

X1.4.2 *White Coat*—After slaking and aging finishing quicklime in accordance with the printed directions of the manufacturer, store the putty until cool. If no printed directions are provided by the manufacturer, prepare the putty for use as follows: After the action has ceased, run off the putty through a No. 10 (2.00-mm) sieve conforming to Specification E 11, and store for a minimum of 2 weeks.

X1.4.3 *Base Coats*—After the action has ceased, run off the putty through a No. 8 (2.36-mm) sieve conforming to Specification E 11. Add sand up to equal parts by weight, all of the hair or other fibers required, and store for a minimum of 2 weeks.

X1.4.4 *Masons' Mortar*—After the action has ceased, add part or all of the sand required, and store for a minimum of 24 h.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 10/C 10M – 09

Standard Specification for Natural Cement[1]

This standard is issued under the fixed designation C 10/C 10M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers natural cement.

NOTE 1—Examples of typical past uses of natural cement include unit masonry mortar, cement plaster, grout, whitewash, and concrete.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. Values in SI units [or inch-pound units] shall be obtained by measurement in SI units [or inch-pound units] or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units [or SI units]. Values are stated in only SI units when inch-pound units are not used in practice.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)
C 114 Test Methods for Chemical Analysis of Hydraulic Cement
C 150 Specification for Portland Cement
C 151 Test Method for Autoclave Expansion of Hydraulic Cement
C 183 Practice for Sampling and the Amount of Testing of Hydraulic Cement
C 185 Test Method for Air Content of Hydraulic Cement Mortar
C 187 Test Method for Normal Consistency of Hydraulic Cement
C 188 Test Method for Density of Hydraulic Cement
C 191 Test Methods for Time of Setting of Hydraulic Cement by Vicat Needle
C 204 Test Methods for Fineness of Hydraulic Cement by Air-Permeability Apparatus
C 219 Terminology Relating to Hydraulic Cement
C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency
C 465 Specification for Processing Additions for Use in the Manufacture of Hydraulic Cements
C 778 Specification for Standard Sand
C 786 Test Method for Fineness of Hydraulic Cement and Raw Materials by the 300-μm (No. 50), 150-μm (No. 100), and 75-μm (No. 200) Sieves by Wet Methods
IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Terminology

3.1 For definitions of terms related to this specification, see Terminology C 219.

4. Ordering Information

4.1 Orders for material under this specification shall include the following:

4.1.1 This specification number and date, and

4.1.2 Optional physical requirements as given in 7.2.

5. Additions

5.1 The cement covered by this specification shall contain no addition except as follows:

5.1.1 Water, or calcium sulfate, or both.

5.1.2 Processing additions used in the manufacture of the cement shall have been shown to meet the requirements of Specification C 465 in the amounts used or greater.

6. Chemical Requirements

6.1 Natural cements shall conform to the standard chemical requirements in Table 1.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.10 on Hydraulic Cements for General Concrete Construction.

Current edition approved June 1, 2009. Published July 2009. Originally approved in 1904. Last previous edition approved in 2007 as C 10 – 07.

TABLE 1 Standard Requirements

	Applicable Test Methods	Requirements
Chemical Requirements		
Loss on ignition, max, %:	C 114	12
Insoluble residue, min, %:	C 114	2
Sulfur trioxide (SO_3), max, %:	C 114	3.0
Physical Requirements		
Autoclave length change, max, %:	C 151, as modified in 10.1.4	0.80
Fineness, m^2/kg or % retained:	C 204 or C 786	[A]
Time of setting, Vicat test[B]:	C 191	
Time in minutes, not less than		30
Air content of mortar[C], volume %:	C 185	
max		12
Compressive strength, min, MPa [psi]:	C 109/C 109M, as modified in 10.1.7	
7 days		3.5 [510]
28 days		7.0 [1020]

[A]The fineness shall be chosen at the option of the purchaser as per 7.2.
[B]The time of setting is that described as initial setting time in Test Method C 191.
[C]Compliance with the requirements of this specification does not necessarily ensure that the desired air content will be obtained in concrete.

7. Physical Requirements

7.1 Natural cements shall conform to the respective standard physical requirements prescribed in Table 1.

7.2 In order to match historic cements, at the option of the purchaser, the required values for % retention on the 300-µm (N0. 50), 150-µm (No. 100), and 75-µm (No. 200) sieves, or of air permeability fineness shall be agreed at time of placing the order.

NOTE 2—If no data on historic cement fineness are available, the purchaser may wish to consider that previous editions of this specification from 1904 to 1976 required minimum values as follows:

1954-1976: Minimum 550 m^2/kg fineness (air-permeability method)

1937-1954: Maximum 15% retained on a 75-µm (No. 200) sieve

1904-1937: Maximum 10% retained on a 150-µm (No. 100) sieve, maximum 30 % retained on a 75-µm (No. 200) sieve

8. Acceptance and Rejection

8.1 Natural cement meets the strength requirements of this standard if the 7-day strength exceeds the minimum in Table 1. The cement also meets the strength requirements of this standard if the cement fails the 7-day strength minimum, but exceeds the 28-day strength minimum in Table 1.

8.2 If the cement fails an initial test for autoclave expansion, it meets the requirements of this standard if it passes on a second and third series of test specimens.

8.3 The cement shall be rejected if it fails to meet any of the requirements of this specification, subject to the provisions of 8.1 and 8.2.

8.4 Re-test cement remaining in storage for a period longer than six months after initial test. Reject it if it fails to meet any of the requirements of this specification at that time.

8.5 Tentative or provisional acceptance of the cement shall not deprive the purchaser of the right of rejection in the event final tests or retests fail to meet applicable requirements.

8.6 At the option of the purchaser, packages more than 2 % below the mass marked thereon shall be rejected and if the average mass of packages in any shipment, as shown by determining the mass of 50 packages selected at random, is less than that marked on the packages, the entire shipment shall be rejected.

9. Packaging and Package Marking

9.1 When the cement is delivered in packages, the words "Natural Cement," the name and brand of the manufacturer, and the mass of the cement contained therein, shall be plainly indicated on each package. Similar information shall be provided in the shipping documents accompanying the shipment of packaged or bulk cement. All packages shall be in good condition at the time of inspection.

10. Test Methods

10.1 Sample the cement and determine the properties enumerated in this specification in accordance with the following ASTM methods:

10.1.1 *Sampling*—Practice C 183.

10.1.2 *Chemical Analysis*—Test Methods C 114.

10.1.3 *Fineness*—One of the following test methods shall be used:

10.1.3.1 Test Method C 204. In this fineness determination, the specific gravity of natural cement shall be considered to be 2.90. Tests shall be made at a porosity of 0.530 ± 0.005. In case of dispute, the true specific gravity used shall be as determined in accordance with Test Method C 188.

10.1.3.2 Test Method C 786.

10.1.4 *Autoclave Expansion*—Test Method C 151 with the following modification:

10.1.4.1 The cement used in preparing the test specimens shall be a blend of 75 weight percent of the natural cement to be tested with 25 weight percent of portland cement conforming to the requirements of Type II cement in Specification C 150.

10.1.4.2 The natural cement and the portland cement shall be dry mixed to a uniform blend before water is added.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.1.5 *Time of Setting*—Test Method C 191.

10.1.6 *Air Content of Mortar*—Test Method C 185. In this air content determination, the specific gravity of natural cement shall be considered to be 2.90. In case of dispute, the true specific gravity used shall be as determined in accordance with Test Method C 188.

10.1.7 *Compressive Strength*—The compressive strength shall be determined for mortar cubes prepared as follows:

10.1.7.1 The proportions shall be one part of cement to one part of standard sand by mass. The amount of mixing water is based on the amount of water required to produce a neat cement paste of normal consistency from the same sample of cement according to Test Method C 187. Calculate the percentage of water required as follows:

$$y = \frac{P}{3} + 6.5$$

where:

y = water required for the mortar as a percentage of the combined mass of cement and sand, and

P = water needed for normal consistency, percent by mass of cement.

10.1.7.2 The standard sand shall be 20-30 sand conforming to Specification C 778.

10.1.7.3 The mortar shall be mixed in accordance with Practice C 305. The quantities of materials to be mixed at one time in the batch of mortar for making six and nine test specimens shall be as follows:

	Number of Specimens	
	6	9
Cement, g	900	1335
Sand, g	900	1335
Water, mL	18y	26.7y

10.1.7.4 The 2-in. [50-mm] cube specimens shall be molded and tested in accordance with Test Method C 109/C 109M.

11. Keywords

11.1 hydraulic cement; natural cement; specification

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C 10 – 07, that may impact the use of this specification. (Approved June 1, 2009)

(*1*) Revised the standard as a dual unit specification.

Committee C01 has identified the location of selected changes to this specification since the last issue, C 10 – 06, that may impact the use of this specification. (Approved December 1, 2007)

(*1*) Revised Note 1.

Designation: C11 – 10

Standard Terminology Relating to Gypsum and Related Building Materials and Systems[1]

This standard is issued under the fixed designation C11; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This standard covers terminology relating to gypsum and related building materials and systems. The terms are generically defined. More specific and expanded definitions may appear in appropriate standards.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C22/C22M Specification for Gypsum
C28/C28M Specification for Gypsum Plasters
C35 Specification for Inorganic Aggregates for Use in Gypsum Plaster
C36/C36M Specification for Gypsum Wallboard[3]
C37/C37M Specification for Gypsum Lath[3]
C52 Specification for Gypsum Partition Tile or Block[3]
C59/C59M Specification for Gypsum Casting Plaster and Gypsum Molding Plaster
C61/C61M Specification for Gypsum Keene's Cement
C317/C317M Specification for Gypsum Concrete
C318/C318M Specification for Gypsum Formboard
C472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete
C473 Test Methods for Physical Testing of Gypsum Panel Products
C475/C475M Specification for Joint Compound and Joint Tape for Finishing Gypsum Board
C843 Specification for Application of Gypsum Veneer Plaster
C557 Specification for Adhesives for Fastening Gypsum Wallboard to Wood Framing
C587 Specification for Gypsum Veneer Plaster
C588/C588M Specification for Gypsum Base for Veneer Plasters[3]
C954 Specification for Steel Drill Screws for the Application of Gypsum Panel Products or Metal Plaster Bases to Steel Studs from 0.033 in. (0.84 mm) to 0.112 in. (2.84 mm) in Thickness
C1007 Specification for Installation of Load Bearing (Transverse and Axial) Steel Studs and Related Accessories
C1396/C1396M Specification for Gypsum Board
E84 Test Method for Surface Burning Characteristics of Building Materials
E96/E96M Test Methods for Water Vapor Transmission of Materials
E119 Test Methods for Fire Tests of Building Construction and Materials
E337 Test Method for Measuring Humidity with a Psychrometer (the Measurement of Wet- and Dry-Bulb Temperatures)

3. Terminology

accelerator, *n*—a material that reduces setting time.

accessories, *n*—products fabricated for the purpose of forming corners, edges, control joints, or decorative effects.

adhesive, *n*—a substance capable of holding materials together by surface attachment.

admixture, *n*—a material other than water, aggregates, hydraulic cementitious material, and fiber reinforcement that is used as an ingredient to modify properties and is added to the batch before or during its mixture.

aggregate, *n*—an inert granular material which may be added to gypsum plasters. **(C35)**

all purpose compound, *n*—a compound formulated and manufactured to serve as a taping or finishing compound, or both.

anhydrite, *n*—the mineral consisting primarily of anhydrous calcium sulfate, $CaSO_4$.

[1] This terminology is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.91 on Terminology and Editorial.

Current edition approved Jan. 1, 2010. Published February 2010. Originally approved in 1916. Last previous edition approved in 2008 as C11–08c. DOI: 10.1520/C0011-10.

www.technobetar.ir

arris (of an arch), *n*—the outside corner or angle formed by the meeting of a wall surface with the curved surface of an arch (see Fig. 1).

base coat, *n*—any or all layers of plaster in place prior to application of finish coats.

DISCUSSION—The first application is normally called a scratch coat and the second application is referred to as a brown coat.

bedding coat, *n*—that coat of plaster to receive aggregate or other decorative material of any size, impinged or embedded into its surface, before it sets.

bond plaster, *n*—a calcined gypsum plaster specially formulated for application over rough monolithic concrete as a bonding coat for a subsequent gypsum plaster layer. **(C28/C28M)**

bridging, *n*—*in framing*, sections of wood or metal pieces used between framing members to stiffen, give lateral support, and minimize rotation.

brown coat, *n*—the second layer in three-coat plaster application.

building construction joint, *n*—a designed division of a building that allows movement of all component parts of the building, in any plane, which may be caused by thermal, seismic, wind loading, or any other force. The construction of the separation is accomplished by one of the following methods: (*1*) manufactured devices suitable for this application, or (*2*) by field fabrication of suitable materials.

calcined gypsum, *n*—a dry powder; primarily calcium sulfate hemihydrate, resulting from calcination of gypsum; cementitious base for production of most gypsum plasters: also called plaster of paris, sometimes called stucco.

calcium sulfate, *n*—the chemical compound $CaSO_4$.

cementitious material, *n*—a material that, when mixed with water, with or without aggregate, provides the plasticity and the cohesive and adhesive properties necessary for placement, and the formation of a rigid mass.

check cracking (in joint systems), *n*—short, narrow cracks randomly oriented in the surface of the dried joint compound.

coat, *n*—a layer of plaster applied in a single operation.

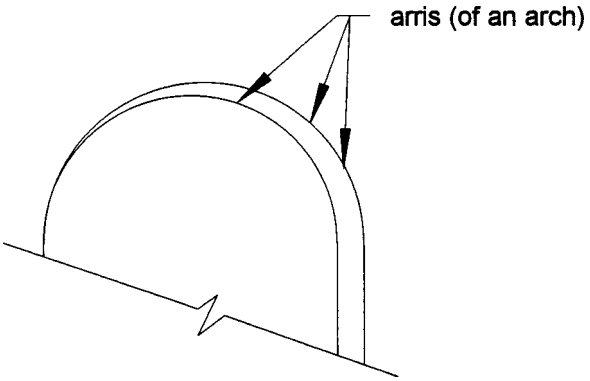

FIG. 1 Arris (of an Arch)

combined water, *n*—the water chemically held, as water of crystallization, by the calcium sulfate dihydrate or hemihydrate crystal.

compressive strength, *n*—the maximum load sustained by a standard specimen of a material when subjected to a crushing force.

consistency, *n*—a property of a material determined by the complete flow force relation. **(C557)**

consistency (normal), *n*—the number of millilitres of water per 100 g of gypsum plaster or gypsum concrete required to produce a mortar or a slurry of specified fluidity. **(C472)**

control (expansion-contraction) joint, *n*—a designed separation in the system materials that allows for movement caused by expansion or contraction of the system. The construction of the separation is accomplished by one of the following methods: *(1)* manufactured devices suitable for this application, or *(2)* by field fabrication of suitable materials.

core (of gypsum board), *n*—the hardened material filling the space between the face and back papers consisting substantially of rehydrated gypsum with additives.

cored tile or block, *n*—see **gypsum tile or block**. **(C52)**

cornerbead, *n*—an accessory for outside corners.

corner reinforcement, exterior, *n*—a preformed section of wire or expanded sheet steel, for the reinforcement of exterior stucco external corners (arrises).

cure (portland cement plaster or stucco), *v*—(*1*) to provide conditions conducive to the hydration process of portland cement plaster or stucco, or (*2*) to maintain proper temperature and a sufficient quantity of water within the plaster to ensure cement hydration.

density, *n*—the weight per unit volume of a material. **(C472)**

dried sample, *n*—a sample devoid of free water.

edge (of glass mat gypsum panels), *n*—the bound edge as manufactured.

edge (of gypsum board), *n*—the paper-bound edge as manufactured.

edge trim, *n*—an accessory to cover exposed ends or edges of gypsum board.

embedding compound—see **taping compound.**

end (of glass mat gypsum panels), *n*—the end perpendicular to the bound edge. The gypsum core is always exposed.

end (of gypsum board), *n*—the end perpendicular to the paper-bound edge. The gypsum core is always exposed.

expansion joint, *n*—see **control (expansion-contraction) joint**.

face, *n*—the surface designed to be left exposed to view or to receive decoration or additional finishes.

featured edge, *n*—an edge configuration of the paper bound edge of gypsum board that provides special design or performance.

fineness modulus, *n*—an empirical factor obtained by adding total percentages of a sample of aggregate retained on each of a specified series of sieves and dividing by 100. The sieve sizes used are: No. 100 (150 μm), No. 50 (300 μm), No. 30

www.technobetar.ir

(600 µm), No. 16 (1.18 mm), No. 8 (2.36 mm), No. 4 (4.75 mm), ⅜ in. (9.5 mm), ¾ in. (19.0 mm), 1½ in. (38.1 mm) and larger, increasing in the ratio of 2 to 1.

finish coat, *n*—the final layer of plaster applied over a basecoat or other substrate.

finishing compound, *n*—(*sometimes called topping compound*) a compound specifically formulated and manufactured for use over taping or all purpose compounds to provide a smooth and level surface for the application of decoration.

fire-resistance classification, *n*—a standard rating of fire-resistance and protective characteristics of a building construction or assembly. **(E119)**

flame spread classification, *n*—a standard rating of relative surface burning characteristics of a building material as compared to a standard material. **(E84)**

flexural strength, *n*—the maximum load sustained by a standard specimen of a sheet material when subjected to a bending force.

floating, *v*—the act of spreading, compacting, or consolidating to achieve a specified uniform appearance.

framing member, *n*—stud, plate, track, joist, furring, and other support to which a gypsum panel product, or metal plaster base is attached.

free water, *n*—all water contained by gypsum board or plaster in excess of that chemically held as water of crystallization.

gauging plaster, *n*—a calcined gypsum plaster designed to be mixed with lime putty. **(C28/C28M)**

glass mat, *n*—a woven or non-woven fabric of glass fibers with or without a binder.

grout, *n*—gypsum or portland cement plaster used to fill crevices or to fill hollow metal frames.

gypsum, *n*—the mineral consisting primarily of fully hydrated calcium sulfate, $CaSO_4 \cdot 2H_2O$ or calcium sulfate dihydrate. **(C22/C22M)**

gypsum backing board, *n*—a ¼ in. to ⅝ in. gypsum board for use as a backing for gypsum wallboard, acoustical tile, or other dry cladding.

water resistant gypsum backing board—a gypsum board designed for use on walls primarily as a base for the application of ceramic, or plastic tile.

gypsum base for veneer plasters, *n*—a gypsum board used as the base for application of a gypsum veneer plaster. **(C588/C588M)**

gypsum board, *n*—the generic name for a family of sheet products consisting of a noncombustible core primarily of gypsum with paper surfacing.

gypsum casting plaster, *n*—a calcined gypsum plaster used primarily to form objects, such as lamp bases, art ware, and novelties, etc. **(C59/C59M)**

gypsum concrete, *n*—a calcined gypsum mixed with wood chips or aggregate, or both. **(C317/C317M)**

gypsum core board, *n*—a ¾ in. (19.0 mm) to 1 in. (25.4 mm) gypsum board consisting of a single board or factory laminated multiple boards, used as a gypsum stud or core in semisolid or solid gypsum board partitions.

gypsum formboard, *n*—a gypsum panel product used as the permanent form for poured gypsum roof decks. **(C318/C318M)**

gypsum lath, *n*—a gypsum board used as the base for application of gypsum plaster. **(C37/C37M)**

perforated gypsum lath—a gypsum lath having perforations to provide mechanical keying of the basecoat plaster.

foil-backed gypsum lath—the same as plain gypsum lath except that in addition, the back surface shall be covered with a continuous sheet of pure bright finished aluminum foil.

type X lath—a gypsum lath specially manufactured to provide specific fire-resistant characteristics.

gypsum molding plaster, *n*—a calcined gypsum plaster used primarily for plaster casts or molds, sometimes used as a gauging plaster. **(C59/C59M, C28/C28M)**

gypsum neat plaster, *n*—a calcined gypsum mixed at the mill with ingredients to control working quality and setting time. **(C28/C28M)**

DISCUSSION—Neat plaster is either fibered or unfibered. The addition of aggregate is required on the job.

gypsum panel products, *n*—the general name for a family of sheet products consisting essentially of gypsum.

gypsum plaster, *n*—the generic name for a family of powdered cementitious products consisting primarily of calcined gypsum with additives to modify physical characteristics, and having the ability, when mixed with water, to produce a plastic mortar or slurry which can be formed to the desired shape by various methods and will subsequently set to a hard, rigid mass. **(C28/C28M)**

gypsum sheathing, *n*—a gypsum board used as a backing for exterior surface materials, manufactured with water-repellant paper and may be manufactured with a water-resistant core. **(C1396/C1396M)**

gypsum tile or block, *n*—a cast gypsum building unit. **(C52)**

gypsum veneer plaster systems, *n*—veneer plaster applied in accordance with Specification C843 to gypsum base for veneer plasters.

gypsum wallboard, *n*—a gypsum board used primarily as an interior surfacing for building structures. **(C36/C36M)**

foil-backed gypsum wallboard—a gypsum wallboard with the back surface covered with a continuous sheet of pure bright finished aluminum foil. **(C36/C36M)**

type X gypsum wallboard—a gypsum wallboard specially manufactured to provide specific fire-resistant characteristics **(C36/C36M).**

gypsum wood-fibered plaster, *n*—a calcined gypsum plaster containing shredded or ground wood fiber added during manufacture.

hemihydrate, *n*—the dry powder, calcium sulfate hemihydrate, resulting from calcination of $CaSO_4 \cdot 2H_2O$, calcium sulfate dihydrate. See **calcined gypsum**.

joining, *n*—the juncture of two separate plaster applications of the same coat, usually within a single surface plane.

joint compound, *n*—a compound used for taping or finishing gypsum board, or both.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:11 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

joint tape, *n*—a type of paper, metal, fabric, glass mesh, or other material, commonly used with a cementitious compound, to reinforce the joints between adjacent gypsum boards. **(C475/C475M)**

joint tape, self-adhering, *n*—a joint tape manufactured to adhere directly to the substrate.

DISCUSSION—Tapes having this quality do not require mechanical or embedment means of attachment to the substrate.

Keene's cement, *n*—an anhydrous gypsum plaster characterized by a low mixing water requirement and special setting properties, primarily used with lime to produce hard, dense finish coats. **(C61/C61M)**

key, *n*—the grip or mechanical bond of one coat of plaster to another coat, or to a substrate.

DISCUSSION—It may be accomplished physically by the penetration of wet mortar or crystals into paper fibers, perforations, scoring irregularities, or by the embedment of the lath.

lath—see **gypsum lath**.

load-bearing partition, *n*—a partition designed to support a portion of the building structure.

machine direction, *n*—the direction parallel to the paper-bound edge of the gypsum board.

manufactured sand, *n*—the fine material resulting from the crushing and classification by screening, or otherwise, of rock, gravel, or blast furnace slag. **(C35)**

masonry cement, *n*—a hydraulic cement for use in mortars for masonry construction, containing one or more of the following materials: portland cement, portland blast furnace slag cement, portland-pozzolan cement, natural cement, slag cement, or hydraulic lime; and in addition usually containing one or more materials such as hydrated lime, limestone, chalk, calcareous shell, talc, slag, or clay as prepared for this purpose.

mechanical bonds, *n*—the attachment created when plaster penetrates, into or through, the substrate, or envelops irregularities in the surface of the substrate.

members (in application of gypsum panel products), *n*—framing to which gypsum panel products are attached.

mill-mixed plaster (ready-mixed plaster), *n*—material formulated and dry-blended by the manufacturer, requiring only the addition of and mixing with water.

mortar, *n*—a mixture of gypsum plaster with aggregate or hydrate lime, or both, and water to produce a trowelable fluidity.

natural sand, *n*—the fine granular material resulting from the natural disintegration of rock or from the crushing of friable sandstone. **(C35)**

neat gypsum plaster—see **gypsum neat plaster**.

nominal thickness (of gypsum panel products), *n*—the manufacturer-stated thickness of the gypsum panel product.

paper joint tape, *n*—a strip of paper reinforcing material designed to be embedded in the joint compound and to reinforce the joint between two gypsum boards.

perlite aggregate, *n*—a siliceous volcanic glass expanded by heat. **(C35)**

perm, *n*—a unit of measurement of water vapor permeance; a metric perm, or 1 g/24 h·m^2·mm Hg. U.S. unit, 1 grain/h·ft^2·in. Hg. **(E96/E96M)**

permeability, *n*—the property of a porous material that permits a fluid (or gas) to pass through it; in construction, commonly refers to water vapor permeability of a sheet material or assembly and is defined as water vapor permeance per unit thickness. Metric unit of measurement, metric perms per centimetre of thickness. See **water vapor transmission, perm, permeance**. **(E96/E96M)**

permeance (water vapor), *n*—the ratio of the rate of water vapor transmission (WVT) through a material or assembly between its two parallel surfaces to the vapor pressure differential between the surfaces. Metric unit of measurement is the metric perm, 1 g/24 h·m^2·mm Hg; U.S. unit, 1 grain/h·ft^2·in. Hg. See **water vapor transmission**, **permeability**, **perm**. **(E96/E96M)**

plaster—see **gypsum plaster, gypsum neat plaster**.

plaster bond, *n*—the adhesion between plaster coats or between plaster and substrate.

plastic cement, *n*—a hydraulic cement to which one or more plasticizing agents (but not more than 12 % by volume) have been added during intergrinding or blending to increase the workability and molding qualities of the resultant cement paste, mortar, or plaster.

plasticity, *n*—the property of freshly mixed cement paste, mortar, or plaster which determines its workability and molding qualities.

portland cement, *n*—a hydraulic cement produced by pulverizing clinker consisting essentially of hydraulic calcium silicates, and usually containing one or more forms of calcium sulfate as an interground addition.

portland cement plaster, *n*—a plaster mix in which portland cement or combinations of portland and masonry cements or portland cement and lime are the principal cementitious materials mixed with aggregate.

purity, *n*—the percentage of $CaSO_4 \cdot ½\ H_2O$ in the calcined gypsum portion of a gypsum plaster or gypsum concrete, as defined by Specification C28/C28M, for Gypsum Plasters. The percentage of $CaSO_4 \cdot 2H_2O$ in the gypsum or the gypsum portion of fully hydrated, dry, set gypsum plaster. **(C472, C28/C28M)**

ready-mixed plaster, *n*—a calcined gypsum plaster with aggregate added during manufacture. **(C28/C28M)**

recessed edge, *n*—see **tapered edge**

relative humidity, *n*—the ratio of actual water vapor pressure to the saturation water vapor pressure at the same temperature, expressed as a percentage. **(E337)**

retarder, *n*—a material that extends setting time.

round edge, *n*—a rounded, paper-bound edge formation on gypsum board, commonly used for gypsum lath. **(C37/C37M, C473)**

saddle-tie, *for furring*, *n*—a single or double strand of wire used to attach furring members to framing members of wall or ceiling assemblies. See Fig. 2.

saddle-tie, *for furring*, *v*—to attach furring members to framing members of wall or ceiling assemblies using a single or double strand of wire. See Fig. 2.

saddle-tie, *for wire hangers*, *v*—to attach wire hangers to main runners. See Fig. 3.

www.technobetar.ir

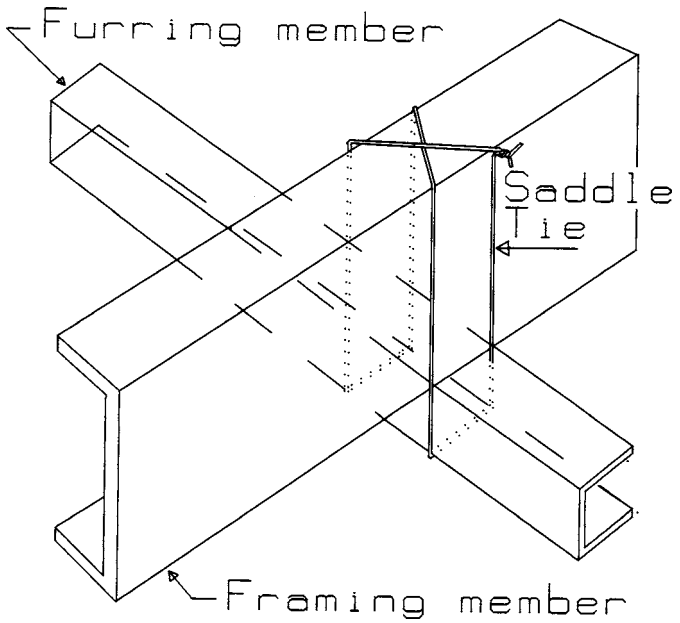

FIG. 2 Saddle-Tie

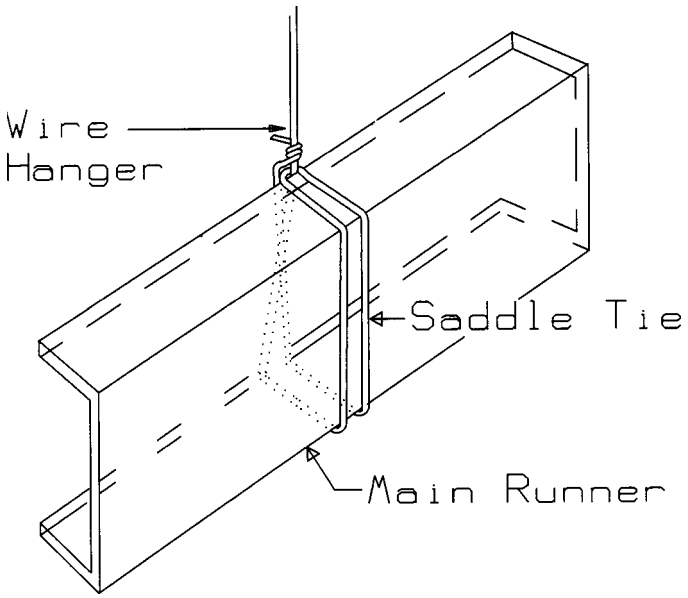

FIG. 3 Saddle-Tie

sample as received, *n*—a representative portion of product or material in the state received by the testing laboratory.

scratch coat, *n*—the first layer of plaster applied over lath or other substrate.

set, *n*—the chemical and physical change in plaster as it goes from a plastic, workable state to a rigid state. See **setting time**. **(C472)**

setting time, *n*—the elapsed time required for a gypsum plaster to attain a specified hardness and strength after mixing with water. **(C472)**

shipment (of gypsum panel products), *n*—the quantity of gypsum panel products shipped by a manufacturer and included on a single invoice.

smooth-trowel finish, *n*—a uniform finish free of grainy or coarse areas, trowel marks, or other avoidable imperfections.

steel drill screw, *n*—self-drilling screw with the ability to drill its own hole and form or cut mating threads without deforming its threads or breaking. **(C954, C1007)**

stucco, *n*—a portland cement-aggregate plaster mix designed for use on exterior surfaces. See **portland cement plaster**.

synthetic gypsum, *n*—a chemical product, consisting primarily of calcium sulfate dihydrate ($CaSO_4 \cdot 2H_2O$) resulting primarily from an industrial process.

tapered edge, *n*—an edge formation of gypsum board which provides a shallow depression at the paper-bound edge to receive joint reinforcement. Also known as a **recessed edge**. **(C473, C36/C36M)**

taping compound, *n*—(*sometimes called embedding compound*) a compound specifically formulated and manufactured for use in embedding of joint reinforcing tape at gypsum board joints.

temper, *v*—to mix or restore to a workable consistency.

texture finish, *n*—any applied decorative finish other than smooth.

three-coat work, *n*—plaster applied in three successive coats with time between coats for setting or drying, or both.

topping compound—see **finishing compound**.

veneer plaster, *n*—a calcined gypsum plaster formulated to be applied in thin coats. **(C587)**

vermiculite aggregate, *n*—a micaceous mineral that expands with heat. **(C35)**

wallboard—see **gypsum wallboard**. **(C36/C36M)**

water absorption, *n*—the amount of water absorbed by a material under specified test conditions commonly expressed as weight percent of the test specimen.

water-repellent paper, *n*—gypsum board paper surfacing which has been formulated or treated to resist water penetration.

water-resistant core, *n*—a gypsum board specially formulated to resist water penetration.

water vapor transmission (WVT), *n*—the rate of water vapor flow, under steady specified conditions, through a unit area of a material, between its two parallel surfaces and normal to the surfaces. Metric unit of measurement is 1 g/24 h·m^2. See **permeability**,**permeance**, **perm**. **(E96/E96M)**

wood-fibered plaster, *n*—a calcined gypsum plaster containing shredded or ground wood fiber added during manufacture. **(C28/C28M)**

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this terminology since the last issue, C11–08c, that may impact the use of this terminology. (Approved January 1, 2010)

(*1*) Revised the definition of **nominal thickness (of gypsum panel products)**.

Committee C11 has identified the location of selected changes to this terminology since the last issue, C11–08b, that may impact the use of this terminology. (Approved August 1, 2008)

(*1*) Added the new term **steel drill screw**.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 22/C 22M – 00 (Reapproved 2005)ε1

Standard Specification for Gypsum[1]

This standard is issued under the fixed designation C 22/C 22M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—Paragraph 1.3 was added editorially October 2005.

1. Scope

1.1 This specification covers gypsum, calcium sulfate combined with two molecules of water in crystalline form and having the approximate chemical formula $CaSO_4 \cdot 2H_2O$.

1.2 The values stated in either inch-pound units or SI (metric) are to be regarded separately as the standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be used independently of the other. Values from the two systems shall not be combined.

1.3 The text of this specification references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 471M Test Methods for Chemical Analysis of Gypsum and Gypsum Products [Metric]

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete

3. Terminology

3.1 *Definitions*—Definitions shall be in accordance with Terminology C 11.

4. Chemical Composition

4.1 Gypsum shall contain not less than 70.0 weight percent $CaSO_4 \cdot 2H_2O$.

4.2 The chemical composition, within the limits prescribed by 4.1, shall be specified in the purchase order or contract.

5. Physical Properties

5.1 *Size*—If necessary, gypsum shall be crushed or ground, or both, to the size specified in the purchase order.

6. Sampling

6.1 *Bulk*—When gypsum is shipped in bulk, samples of approximately 5 lb [2 kg] each shall be taken at regular intervals during the complete loading or unloading of the carrier, in such a way as to accumulate not less than 200 lb [90 kg] of material and to represent correctly the percentages of both the coarse particles and the fines in the shipment. This material shall be broken to pass a 1-in. [25.0-mm] sieve, thoroughly mixed, and reduced by quartering to provide not less than a 1-lb [0.5-kg] sample for the laboratory.

6.2 *Packages*—When gypsum is shipped in packages, not less than 1 % of the packages shall be sampled. Samples shall be taken from both the surface and the center of the packages. These samples shall then be broken, mixed, and quartered in accordance with 6.1.

6.3 *Laboratory Samples*—Each laboratory sample shall be placed immediately in an airtight container and shipped to the laboratory for testing.

7. Test Methods

7.1 The chemical composition of gypsum shall be determined in accordance with Test Methods C 471M.

7.2 The physical properties of gypsum shall be determined in accordance with Test Methods C 472.

8. Inspection

8.1 Inspection of the gypsum shall be agreed upon between the purchaser and the supplier as part of the purchase agreement.

9. Rejection

9.1 Rejection of gypsum that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the gypsum has failed to conform to the requirements of this specification.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved October 1, 2005. Published November 2005. Originally approved in 1919. Last previous edition approved in 2000 as C 22/C 22M – 00.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

10. Certification

10.1 When specified in the purchase agreement, a manufacturer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

11. Packaging and Package Marking

11.1 Gypsum shall be shipped either in packages or in bulk.

11.2 When shipped in packages for resale, the following information (See Note 1) shall be legibly marked on each package or on a tag of suitable size attached thereto:

11.2.1 Name of manufacturer,

11.2.2 Description of material, and

11.2.3 Net or gross weights, or both, of the package.

11.3 When shipped in bulk, a card containing the required information in accordance with 11.2 shall be conspicuously placed in the carrier.

NOTE 1—State law may require additional information.

12. Keywords

12.1 calcium sulfate; gypsum

Designation: C 25 – 06

Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime[1]

This standard is issued under the fixed designation C 25; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 These test methods cover the chemical analysis of high-calcium and dolomitic limestone, quicklime, and hydrated lime. These test methods are classified as either standard (preferred) or alternative (optional).

1.2 The standard test methods are those that employ classical gravimetric or volumetric analytical procedures and are typically those required for referee analyses where chemical specification requirements are an essential part of contractual agreement between buyer and seller.

1.3 Alternative or optional test methods are provided for those who wish to use procedures shorter or more convenient than the standard methods for the routine determinations of certain constituents. Optional test methods may sometimes be preferred to the standard test methods, but frequently the use of modern and expensive instrumentation is indicated which may not be accessible to everyone. Therefore, the use of these test methods must be left to the discretion of each laboratory.

1.4 The analytical procedures appear in the following order:

	Section
Aluminum Oxide	15
Available Lime Index	28
Calcium and Magnesium Oxide:	
Alternative EDTA Titration Method	31
Calcium Carbonate Equivalent	33
Calcium Oxide:	
Gravimetric Method	16
Volumetric Method	17
Carbon Dioxide by Standard Method	22
Combined Oxides of Iron and Aluminum	12
Ferrous Iron	Appendix X5
Free Calcium Oxide	Appendix X6
Free Moisture in Hydrated Lime	21
Free Moisture in Limestone	20
Free Silica	29
Insoluble Matter Including Silicon Dioxide:	
Standard Method	8
Optional Perchloric Acid Method	9
Insoluble Matter Other Than Silicon Dioxide	11
Loss on Ignition	19
Magnesium Oxide	18
Manganese:	
Bismuthate Method	Appendix X4
Periodate (Photometric) Method	27
pH Determination of Alkaline Earth Solutions	34
Phosphorus:	
Titrimetric Method	Appendix X3
Molybdovanadate Method	26
Silicon Dioxide	10
Strontium Oxide	Appendix X2
Sulfur Trioxide	23
Total Carbon:	
Direct Combustion-Thermal Conductivity Cell Method	32
Total Carbon and Sulfur:	
Combustion/Infrared Detection Method	35
Total Iron:	
Standard Method, Potassium Dichromate Titration	13
Potassium Permanganate Titration Method	Appendix X1
Ortho-Phenanthroline, Photometric Method	14
Total Sulfur:	
Sodium Carbonate Fusion	24
Combustion-Iodate Titration Method	25
Unhydrated Oxides	30

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific precautionary statements, see 9.3, 10.2.1, 18.4.3, 31.6.4.2, X2.3.1, and X5.4.1.1.

2. Referenced Documents

3. Terminology

3.1 Definitions—Unless otherwise specified, for definitions of terms used in these test methods refer to Terminology C 51.

4. Significance and Use

4.1 These test methods provide accurate and reliable analytical procedures to determine the chemical constituents of limestone, quicklime, and hydrated lime (See Note 1). The percentages of specific constituents which determine a material's quality or fitness for use are of significance depending upon the purpose or end use of the material. Results obtained may be used in relation to specification requirements.

4.2 Because quicklime and hydrated lime quickly absorb water and carbon dioxide from the air, precision and bias are extremely dependent upon precautions taken during sample preparation and analysis to minimize excessive exposure to ambient conditions.

NOTE 1—These test methods can be applied to other calcareous materials if provisions are made to compensate for known interferences.

5. General Apparatus and Materials and Reagents

5.1 *General Apparatus and Materials*:

5.1.1 *Balance*—The balance shall be of an analytical type with a capacity not to exceed 200 g. It may be of conventional design or it may be a constant-load, direct-reading type. It shall be capable of reproducing weighings within 0.0002 g with an accuracy of ± 0.0002 g. Rapid weighing devices that may be provided such as a chain, damper, or heavy riders shall not increase the basic inaccuracy by more than 0.0001 g at any reading and with any load within the rated capacity of the balance.

5.1.2 *Weights*—Weights used for analysis shall conform to Class S-1 requirements of the National Institute of Standards and Technology as described in NIST Circular 547.[4] They shall be checked at least once a year or when questioned, and adjusted to within allowable tolerances for Class S-1 weights. All new sets of weights purchased shall have the weights of 1 g and larger made of stainless steel or other corrosion-resistant alloy not requiring protective coating and shall meet the density requirements for Class S.

5.1.3 *Glassware and Laboratory Containers*—Standard volumetric flasks, burets, pipets, dispensers, etc., shall be carefully selected precision grade or better and shall be calibrated, if necessary, to meet the requirements of each operation. Standard-type interchangeable ground glass or TFE-fluorocarbon joints are recommended for all volumetric glassware. Polyethylene containers are recommended for all aqueous solutions of alkalies and for standard solutions where the presence of dissolved silica or alkali from the glass would be objectionable.

5.1.4 *Desiccators*—Desiccators shall be provided with a good desiccant such as anhydrous magnesium perchlorate, activated alumina, sulfuric acid, or phosphoric anhydride. Anhydrous calcium sulfate may also be used provided it has been treated with a color-changing indicator to show when the desiccant has lost its effectiveness. Calcium chloride and silica gel are not satisfactory desiccants for this type of analysis.

5.1.5 *Filter Paper*—Filter paper shall conform to the requirements of Specification E 832, Type II (quantitative). Class E shall be used for coarse and gelatinous precipitates. When medium-textured paper is required, Class F filter paper shall be used. When a retentive paper is needed, Class G shall be used.

Recommendations: Class	Filter Pore Size (microns)	Filter Speed
E	20 to 25	fast speed
F	8	medium speed
G	2.5	slow speed

5.1.6 *Crucibles*—Platinum crucibles and tight fitting lids should preferably be made of pure unalloyed platinum and be of 25 to 35-mL capacity. Where alloyed platinum is used for greater stiffness or to obviate sticking of fused material to crucible or lid, the alloyed platinum should not decrease in weight by more than 0.2 mg when heated at 1200 °C for 1 h.

5.1.7 *Muffle Furnace*—The electric muffle furnace should be capable of continuous operation up to 1000 °C and be capable of intermittent operation at higher temperatures if required. It should have an indicating pyrometer accurate to ± 25 °C.

5.2 *Reagents*:

5.2.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society[5] where such specifications are available. Other grades may be used provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination. In addition to this, it is desirable in many cases for the analyst to ensure the accuracy of his results by running blanks or checking against a comparable sample of known composition.

www.technobetar.ir

5.2.2 *Purity of Water*—Unless otherwise indicated, references to water are understood to mean distilled water or other water of equivalent purity. Water conforming to Specification D 1193 meets these requirements.

5.2.3 *Concentration of Reagents*:

5.2.3.1 *Concentrated Acids and Ammonium Hydroxide*—When acids and ammonium hydroxide are specified by name or chemical formula only, it shall be understood that concentrated reagents approximating the following specific gravities or concentrations are intended:

Acetic acid ($HC_2H_3O_2$)	99.5 %
Hydrochloric acid (HCl)	sp gr 1.19
Hydrofluoric acid (HF)	48 %
Nitric acid (HNO_3)	sp gr 1.42
Perchloric acid ($HClO_4$)	70 %
Phosphoric acid (H_3PO_4)	85 %
Sulfuric acid (H_2SO_4)	sp gr 1.84
Ammonium hydroxide (NH_4OH)	sp gr 0.90

5.2.3.2 *Dilute Reagents*—The concentration of dilute acids and NH_4OH except when standardized, are specified as a ratio stating the number of measured volumes of the concentrated reagent to be diluted with a given number of measured volumes of water. In conformance with international practice, new and revised methods will use the "plus" designation instead of the ratio (:) symbol as the specified designation of dilution; for example, $H_2SO_4(5 + 95)$ means 5 volumes of concentrated H_2SO_4(sp gr 1.84) diluted with 95 volumes of water.

5.2.3.3 *Standard Solutions*—Concentrations of standard solutions shall be expressed as normalities (*N*) or as equivalents in grams per millilitre of the component to be determined, for example: 0.1 *N* $K_2Cr_2O_7$ solution (1 mL = 0.004 g Fe_2O_3). The average of at least three determinations shall be used for all standardizations. The standardization used to determine the strength of the standard solutions is described in the text under each of the appropriate procedures.

6. General Procedures

6.1 *Sampling*—Samples of lime and limestone for chemical analysis shall be taken and prepared in accordance with the requirements of Practice C 50 applicable to the material to be tested.

6.2 *Tared or Weighed Crucibles*—The tare weight of crucibles shall be determined by preheating the empty crucible to constant weight at the same temperature and under the same conditions as shall be used for the final ignition of a residue and cooling in a desiccator for the same period of time used for the crucible containing the residue.

6.3 *Constancy of Weight of Ignited Residue*—To definitely establish the constancy of weight of the ignited residue, the residue and container shall be ignited at the specified temperature and time, cooled to room temperature in a desiccator, and weighed. The residue and container shall then be reheated for at least 30 min at the same temperature, cooled in a desiccator for the same period of time, and reweighed. Additional ignition periods may be required until two consecutive weights do not differ by more than 0.2 mg, at which time it shall be considered that constant weight has been attained. For ignition loss, each reheating period shall be 5 min.

6.4 *Calculation*:

6.4.1 The calculations included in the individual procedures sometimes assume that the exact weight specified has been used. Accurately weighed samples which are approximately but not exactly equal to the weight specified may be used provided appropriate corrections are made in the calculation. Unless otherwise stated, weights of all samples and residues should be recorded to the nearest 0.0001 g.

6.4.2 In all mathematical operations on a set of observed values, the equivalent of two more places of figures than in the single observed values shall be retained. For example, if observed values are read or determined to the nearest 0.1 mg, carry numbers to the nearest 0.001 mg in calculation.

6.5 *Rounding Figures*—Rounding figures to the nearest significant place required in the report should be done after the calculations are completed, in order to keep the final results free from calculation errors. The rounding procedure should follow the principle outlined in Practice E 29.

7. Performance Requirements for Test Methods

7.1 *Referee Analyses*—The reference test methods that appear in Sections 8 through 32, or any other test methods qualified in accordance with 7.3, are required for referee analysis in those cases where conformance to the requirements of a chemical specification are questioned. In these cases a limestone, quicklime, or hydrated lime shall not be rejected for failure to conform to chemical requirements unless all sample preparation and analysis of any one constituent is made entirely by reference test methods prescribed in the appropriate sections of this test method or by other qualified test methods. Exception can be made when specific test methods are prescribed in the standard specification for the limestone, quicklime, or hydrated lime in question. The test methods actually used for the analysis shall be designated.

7.1.1 When there is a question regarding acceptance, referee analyses shall be made in duplicate. If the two results do not agree within the permissible variation given in Table 1, the determination including sample preparation shall be repeated

TABLE 1 Maximum Permissible Variations in Results[A]

(Column 1) Constituent	(Column 2) Maximum Difference Between Duplicates	(Column 3) Maximum Difference of the Average of Duplicates from SRM Certificate Values[B]
Al as Al_2O_3	0.20	± 0.30
Ca as CaO	0.20	± 0.30
Mg as MgO	0.20	± 0.30
C (lime and hydrated lime)	0.20	± 0.30
C (limestone)	0.60	± 0.60
Fe as Fe_2O_3	0.10	± 0.15
Si as SiO_2	0.15	± 0.30
Mn	0.05	± 0.10
P	0.02	± 0.05
Sr as SrO	0.05	[C]
S	0.03	± 0.05

[A] For demonstrating the performance of rapid test methods the SRM closest in overall composition to the limestone shall be used (See Table 2). In the case of quicklime or hydrated lime, the SRM closest in overall composition, after heating at 1000 °C for 1 h, to the product composition shall be used, except for C and S determinations (See Note 3).

[B] Interelement corrections may be used for any standardization provided improved accuracy can be demonstrated.

[C] No SRM currently available.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

in duplicate until the results agree within the permissible variation. When the results agree within the permissible variation, their average shall be accepted as the correct value. For the purpose of comparing results, the percentages shall be calculated to one more significant figure than reported as indicated in the test methods. When a blank determination is specified, one shall be made with each individual analysis or with each group of two or more samples analyzed on the same day for a given constituent.

7.1.2 Test results from Referee methods intended for use as a basis for product acceptance or rejection, or for manufacturer's certification, can be used only after demonstration of precise and accurate analyses by meeting the requirements of 7.1.3, or except when demonstrated under 7.3.2.1. Such demonstrations may be made concurrently with analysis of the limestone, quicklime, or hydrated lime product being tested. The demonstration is required only for those constituents being used as a basis for acceptance, rejection, or certification of a limestone, quicklime, or hydrated lime, but may be made for any constituent of limestone, quicklime, or hydrated lime product for which a standard exists. Such demonstrations must be made annually.

7.1.3 Demonstrations shall be made by analysis of each constituent of concern in a SRM limestone, quicklime, or hydrated lime (See Notes 2 and 3). Duplicate samples shall be run on different days. The same test methods to be used for analysis of the limestone, quicklime, or hydrated lime being tested shall be used for analysis of the SRM. If the duplicate results do not agree within the permissible variation given in Table 1, the determinations shall be repeated, following identification and correction of problems or errors, until a set of duplicate results do agree within the permissible variation.

NOTE 2—The term SRM refers to approved Standard Reference Materials listed in Table 2.

NOTE 3—There are no SRMs that are quicklime or hydrated lime as supplied. When analyzing a quicklime or hydrated lime the SRM in carbonate form needs to be converted to closely resemble the matrix of the product being tested. To accomplish this conversion, heat the chosen SRM for 1 h at 1000 °C, immediately prior to analysis and protect it from hydration or carbonation with sealed containers and desiccation during cooling. Carbon and sulfur may be driven off during heating, rendering the converted SRM unsuitable as a standard for carbon and sulfur determinations. For carbon and sulfur determinations use the appropriate SRM in its normal matrix.

7.1.4 The average of the results of acceptable duplicate determinations for each constituent may differ from the SRM certificate value by no more than the value shown in Column 3 of Table 1. When no SRM certificate value is given, a generally accepted accuracy standard for that constituent has not been identified. In such cases, only the differences between duplicate values as specified in 7.1.3 shall apply and notification of this exception shall be reported.

7.1.5 In questions concerning the acceptance or rejection of a limestone, quicklime, or hydrated lime product, upon request data shall be made available to all parties involved demonstrating that precise and accurate results were obtained with SRM samples by the same analyst making the acceptance determination.

7.2 *Optional Analyses*—The alternative test methods, as opposed to reference methods, provide procedures that are, in some cases, shorter or more convenient to use for routine determination of some constituents (See Note 4). In some instances longer, more complex procedures have been retained as alternative test methods to permit comparison of results by different procedures or for use when unusual materials are being examined, or when unusual preparation for analysis is required. Results from alternative test methods may be used as a basis for acceptance or rejection.

NOTE 4—It is not intended that the use of reference test methods be confined to referee analysis. A reference test method may be used in preference to an alternative test method when so desired. A reference test method must be used where an alternative test method is not provided.

7.2.1 Duplicate analyses and blank determinations are left to the discretion of the analyst when using the alternative test methods. The final results should include the number of determinations performed and whether or not they were corrected for blank values.

TABLE 2 Approved SRM List

7.3 *Performance Requirements for Alternative Test Methods*:

7.3.1 *Definition and Scope*—When analytical data obtained in accordance with this section is required, any test method may be used that meets the requirements of 7.3.2. A test method is considered to consist of the specific procedures, reagents, supplies, equipment, instrument, etc. selected and used in a consistent manner by a specific laboratory.

7.3.1.1 If more than one instrument is used for the same analysis, use of each instrument shall constitute a separate test method and each must be qualified separately.

7.3.2 *Qualification of a Test Method*—Prior to use each test method (See 7.3.1) must be qualified for each material that will be tested. Qualification data or, if applicable, requalification data shall be made available.

7.3.2.1 Using the test method chosen, make single determinations for each constituent under consideration on the SRM which in overall composition most closely resembles the limestone, quicklime, or hydrated lime to be tested (See Note 2). Complete two rounds of tests on nonconsecutive days repeating all steps of sample preparations. Calculate the differences between values and the averages of values from the two rounds of tests. Blank determinations are not required, if it has been determined that blank values do not affect the validity of the data. Blank or interference-corrected data must be so designated.

7.3.2.2 The differences between duplicates obtained for any single constituent shall not exceed the limits shown in Column 2 of Table 1.

7.3.2.3 For each constituent the average of the duplicates obtained shall be compared to the SRM Certificate value and shall not differ from the certified value by more than the value in Column 3 of Table 1. The qualification testing shall be conducted with newly prepared specimens.

7.3.2.4 The standardization, if applicable, used for qualification and analysis of each constituent shall be determined by valid curve-fitting procedures (See Note 5). Restandardization shall be performed as frequently as required to ensure that the accuracy and precision in Table 1 are maintained.

NOTE 5—An actual drawing of a curve is not required, if such a curve is not needed for the method in use. A point-to-point, saw-tooth curve that is artificially made to fit a set of data points does not constitute a valid curve-fitting procedure.

7.3.3 *Partial Results*—Test methods that provide acceptable results for some constituents, but not for others, may be used only for those components for which acceptable results are obtained.

7.3.4 *Report of Results*—Chemical analyses obtained by qualified alternative test methods shall be indicated as having been obtained by alternative methods and the type of test method used shall be designated.

7.3.5 *Rejection of Material*—See 7.1 and 7.2.

7.3.6 *Requalification of a Test Method*:

7.3.6.1 Requalification of a test method, as defined in 7.3.2, shall be required annually.

7.3.6.2 Requalification also shall be required upon receipt of substantial evidence that the test method may not be providing data in accordance with Table 1. Such requalification may be limited to those constituents indicated to be in error and shall be carried out prior to further use of the method for analysis of those constituents.

7.3.6.3 Substantial evidence that a test method may not be providing data in accordance with Table 1 shall be considered to have been received when a laboratory is informed that analysis of the same material by Reference Test Methods run in accordance with 7.1.1, a certified value of an approved SRM, or an accepted value of a known secondary standard differs from the value obtained by the test method in question by more than twice the value of Column 2 of Table 1 for one or more constituents. When indirect test methods are involved, as when a value is obtained by difference, corrections shall be made for minor constituents in order to put the analyses on a comparable basis prior to determining the differences (See Note 6). For any constituents affected, a test method also shall be requalified after any substantial repair or replacement of one or more critical components of an instrument essential to the test method.

NOTE 6—Instrumental analyses can usually detect only the element sought. Therefore, to avoid controversy, the actual procedure used for the elemental analysis should be noted when differences with reference procedures exist. For example, Combined Oxides of Iron and Aluminum by Wet Test should be compared to the sum of Fe_2O_3 and Al_2O_3 obtained instrumentally.

7.3.6.4 If an instrument or piece of equipment is replaced even by one of identical make and model, or is significantly modified, a previously qualified test method using such new or modified instrument or equipment shall be considered a new method and must be qualified in accordance with 7.3.2.

7.4 *Precision and Bias*—Different analytical test methods are subject to individual limits of precision and bias. It is the responsibility of the user to demonstrate that the test methods used at least meet the requirements shown in Table 1.

8. Insoluble Matter Including Silicon Dioxide (Standard Method)

8.1 *Scope*—This test method is based on a double evaporation to dryness of the hydrochloric acid solution of the limestone or lime sample to convert silicon dioxide (SiO_2) to the insoluble form. The acid-insoluble residue of a typical limestone consists of free silica and a mixture of minerals such as clay, mica, feldspar, tourmaline, barytes, garnet, zircon, rutile, etc.

8.2 *Summary of Test Method*—After dissolution in hydrochloric acid, the silica is dehydrated by a double evaporation to dryness. After each dehydration, the dry salts are redissolved with dilute hydrochloric acid, the solution is filtered, and the siliceous residue and other insoluble matter separated. The two papers containing the residues are combined, ignited, and weighed.

8.3 *Procedure*:

8.3.1 Weigh 0.5 g of quicklime or hydrated lime, or 1.0 g of limestone ground to pass a No. 50 (250-μm) sieve (See Note 7). If the sample is a limestone or hydrated lime, ignite in a covered platinum crucible in an electric muffle (See Note 8) at 950 °C for 15 min or longer to effect complete decomposition. Transfer to an evaporating dish, preferably of platinum (See Note 9), containing about 10 mL of water, mix to a thin slurry,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

add 5 to 10 mL of HCl, and digest with the aid of gentle heat and agitation until solution is complete (See Note 10).

NOTE 7—Due to the rapidity with which quicklime and hydrated lime absorb water and carbon dioxide from the air, samples must be protected in tightly stoppered containers at all times. Samples for analysis are to be weighed quickly and the sample container re-stoppered immediately after the sample has been removed.

NOTE 8—Ignition of the sample in an electric muffle is far superior to flame ignition. However, if an electric muffle is not available, flame ignition and the blast lamp may be used.

NOTE 9—If a platinum dish is not available, porcelain may be used. A glass container positively must *not* be used.

NOTE 10—Alternatively, the loss on ignition (LOI) can be determined first, using 0.5 g of sample. The insoluble matter including silicon dioxide can then be assayed using the ignited product that remains in the LOI crucible.

8.3.2 Evaporate the solution to dryness on a steam bath. When dry or nearly so, cover the dish and place it in an air bath or drying oven or on a metal triangle resting on a hot plate. Heat for 1 h at 100 °C, remove the dish from the heat, and allow the dish and contents to cool slightly.

8.3.3 Drench the cooled mass with 20 mL (1 + 1) HCl and place on the water bath for 10 min. Filter the mixture containing the insoluble residue through a retentive filter of suitable size. Wash filter thoroughly with warm, diluted (5 + 95) HCl and then twice with hot water. Reserve the paper and residue.

8.3.4 Evaporate the filtrate to dryness, dehydrate and extract the residue with HCl as before, but this time heat the acidified solution for 1 to 2 min. Filter through a second and smaller piece of retentive filter paper and wash as before. Retain the filtrate for iron, aluminum, calcium, and magnesium determinations; combine the two wet papers containing the separated residues and transfer to a weighed platinum crucible.

8.3.5 Char carefully without allowing the paper to inflame, and then ignite at 1000 °C for 30 min in an electric muffle furnace (See Note 8). Cool in a desiccator and weigh. The increase in weight represents the insoluble matter including SiO_2.

8.4 *Calculation*—Calculate the percentage of insoluble matter including silicon dioxide to the nearest 0.01 % as follows:

$$\text{Insoluble matter including } SiO_2 = (A/B) \times 100 \quad (1)$$

where:

A = mass of ignited residue, g, and
B = original mass of sample, g.

8.5 *Precision and Bias*—This test method was originally approved for publication before the inclusion of precision and bias statements within standards was mandated. The user is cautioned to verify by the use of reference materials, if available, that the precision and bias of this test method are adequate for the contemplated use.

9. Insoluble Matter Including Silicon Dioxide (Optional Perchloric Acid Method)

9.1 *Scope*—In this test method the insoluble matter including silicon dioxide is determined gravimetrically as in the standard method except that perchloric acid is used to dehydrate the silica. The procedure is more rapid than in the standard method because only a single dehydration is necessary. Fuming perchloric acid is a very powerful dehydrating agent, and silicic acid can usually be completely converted to the insoluble silicon dioxide in less than 20 min. This test method has been determined by other agencies such as the Association of Official Agricultural Chemists (AOAC) to be comparable to the standard hydrochloric acid method.

9.2 *Summary of Test Method*—The sample is decomposed without prior ignition by a mixture of nitric (HNO_3) and perchloric ($HClO_4$) acids and evaporated to fumes of $HClO_4$. The fuming perchloric acid is refluxed at this temperature for a short period of time to completely dehydrate the silica. The residue of silica and insoluble matter is filtered and washed free of acids and salts. The filter paper containing the residue is burned off, the resultant ash is ignited at high temperature until the ash is white, and then is weighed.

9.3 *Procedure*:

Warning—Perchloric acid ($HClO_4$) is an extremely reactive liquid. When using $HClO_4$, there are precautions to be followed which, if unheeded, may lead to serious explosions. Contact of the hot concentrated acid with organic matter must be absolutely avoided. Any organic matter in the sample must first be destroyed by the addition of nitric acid (HNO_3) to the sample prior to fuming with $HClO_4$. All evaporations involving $HClO_4$ must be done in a well-ventilated hood made of nonporous and inorganic material, preferably Type 316L stainless steel. Facilities should be provided for washdown procedures that should be performed regularly and thoroughly. These precautions on perchloric acid use are fully discussed in Practices E 50.

9.3.1 Weigh 0.5 g of quicklime or hydrated lime, or 1 g of limestone ground to pass a No. 50 (250-µm) sieve. Transfer the sample to a 250-mL beaker, wet carefully with a few millilitres of water, and dissolve cautiously with 10 mL of concentrated nitric acid. Add 20 mL of perchloric acid and boil until dense white fumes appear. If the solution darkens at this point, add several millilitres of HNO_3 until the solution clears. Heat again to fumes.

9.3.2 With the beaker covered, boil gently for 15 min to completely dehydrate the silica. Never allow contents to become solid or go to dryness, otherwise the separation of silica will be incomplete. If this happens, add more $HClO_4$ and repeat the dehydration.

9.3.3 Cool, add 50 mL of water, heat to boiling, and filter immediately using medium textured paper. Wash paper and residue thoroughly (at least 15 times) with hot water. Test with pH paper until washings are free of acid (See Note 11). Reserve the filtrate for iron, aluminum, calcium, and magnesium determinations.

NOTE 11—The filter paper and silica residue must be washed free of perchlorate salts to prevent small explosions from occurring in the crucible when the filter paper is charred and ignited.

9.3.4 Place the filter paper and contents in a weighed platinum or porcelain crucible and heat gently with a low flame until paper chars without inflaming, or alternatively char in an electric muffle at 300 to 400 °C. Slowly raise the temperature until the carbon has been burned and the ash is white. Finally, ignite at 1000 °C for 30 min. Cool in a desiccator and weigh as insoluble matter including SiO_2.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.4 *Calculation*—Calculate the percentage of insoluble matter including silicon dioxide to the nearest 0.01 % as follows:

$$\text{Insoluble matter including } SiO_2,\ \% = (A/B) \times 100 \quad (2)$$

where:

A = mass of ignited residue, g, and
B = original mass of sample, g.

9.5 *Precision and Bias*:

9.5.1 Four laboratories cooperated in testing on four limestone samples and three laboratories cooperated in testing on an additional eight limestone samples thereby obtaining the precision data summarized in Table 3.

9.5.2 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

10. Silicon Dioxide

10.1 *Scope*—For control purposes or routine determinations, a separate analysis of SiO_2 may not be necessary. However, for certain applications in process industries, the amount of silica derived from the lime or limestone could be important. To satisfy situations such as this, silicon dioxide may be determined by volatilizing the SiO_2 from the insoluble residue with hydrofluoric acid and the percent SiO_2 determined by the difference in mass obtained.

10.2 *Procedure*:

10.2.1 To the ignited residue in the platinum crucible (See 8.3.5 or 9.3.4), add 5 mL of water, 5 mL of hydrofluoric acid (HF), and 1 or 2 drops of H_2SO_4.

Warning—All acids should be handled with care, but extra precaution is required with hydrofluoric acid. This is a very dangerous acid, harmful to eyes and skin; rubber gloves and goggles should be worn when using this acid. It does its work silently and leaves a festering sore that is slow to heal. Any acid that touches the skin should be immediately washed off with copious quantities of water. A physician should be notified immediately if any acid is sprayed into the eyes or if prolonged contact with the skin occurs.

10.2.2 Evaporate to dryness on a hot plate and heat in an electric muffle at 1000 °C (See Note 8) for 2 or 3 min. Cool in a desiccator and weigh. The difference between this mass and the mass of insoluble matter including silicon dioxide is the mass of SiO_2.

10.3 *Calculation*—Calculate the percent of silicon dioxide to the nearest 0.01 % as follows:

$$SiO_2,\ \% = ([A-B]/C) \times 100 \quad (3)$$

where:

A = mass of ignited residue, g (insoluble matter including SiO_2),
B = mass of ignited residue less SiO_2, g, and
C = original mass of sample, g.

10.4 *Precision and Bias*:

10.4.1 Three laboratories cooperated in testing on four limestone samples and two laboratories cooperated in testing on an additional eight limestone samples thereby obtaining the precision data summarized in Table 3.

10.4.2 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

11. Insoluble Matter

11.1 *Scope*—The difference between the mass of insoluble matter (including silicon dioxide) and silicon dioxide represents the mass of insoluble matter other than silicon dioxide. The insoluble matter contains the remnants of any clay, siliceous minerals, or other refractory material present in limestone. The elemental components are mainly iron and aluminum which should be removed and added to the main filtrate from the SiO_2 separation. If the insoluble matter including silica is reported as such and no hydrofluoric acid treatment is indicated, then there is no need to make a recovery of the metals and the insoluble residue may be discarded.

11.2 *Procedure*—The insoluble matter left in the crucible after the silica is volatilized with HF may be dissolved by fusing the residue with 2 to 3 g of sodium carbonate (Na_2CO_3) (See Note 12). Cool the melt and dissolve it in diluted HCl. Add the solution to the filtrate from the dehydration and separation of insoluble matter including silicon dioxide (See 8.3.4 or 9.3.3).

NOTE 12—Fusion with pyrosulfate is to be avoided because this will introduce undesirable sulfates into the solution.

11.3 An alternative fusion can also be made using either lithium metaborate or lithium tetraborate as opposed to using sodium carbonate.

TABLE 3 Precision Summary of Classical Test Methods

Section	Test Method	Average,[A] % Found	Range,[A] % Found	Repeatability (R_1, E 173)	Reproducibility (R_2, E 173)
8	Insol + SiO_2 (Standard)	. . .	. . .	. . .	. . .
9	Insol + SiO_2 (Optional)	1.405	0.09–6.40	0.184	0.351
10	SiO_2	1.177	0.03–5.36	0.128	0.146
11	Insoluble Matter	0.242	0.02–0.93	0.169	0.204
12	Combined Oxides	0.459	0.22–1.21	0.181	0.282
13	Fe_2O_3	0.180	0.05–0.36	0.064	0.183
15	Al_2O_3	0.268	0.10–0.88	0.165	0.223

www.technobetar.ir

11.4 *Calculation*—Calculate the percentage of insoluble matter other than silicon dioxide to the nearest 0.01 % as follows:

$$\text{Insoluble matter other than } SiO_2,\ \% = A - B \quad (4)$$

where:
A = insoluble matter including SiO_2, %, and
B = SiO_2, %.

11.5 *Precision and Bias*:

11.5.1 Three laboratories cooperated in testing on four limestone samples and two laboratories cooperated in testing on an additional eight limestone samples thereby obtaining the precision data summarized in Table 3.

11.5.2 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

12. Combined Oxides (Iron, Aluminum, Phosphorus, Titanium, Manganese)

12.1 *Scope*—The combined oxides describe a group of metals that form precipitates with ammonium hydroxide which may then be ignited to their respective oxides. Historically, it has been the practice to report the combined oxides present in limestone samples as a group because it was not always easy or desirable to determine each metal oxide separately. The group of metal oxides consists primarily of the oxides of iron and aluminum, with minor amounts of titanium dioxide (TiO_2), phosphorus pentoxide (P_2O_5), and manganese oxide (Mn_3O_4) also present. Where separate determinations are preferred, the combined oxides are usually weighed first, iron oxide is then assayed separately, and aluminum oxide is finally determined by calculating the difference between the percent combined oxides and the percent Fe_2O_3. The other metal oxides are generally assumed to be present in trace amounts and are often disregarded. When necessary, these metals may be analyzed separately and appropriate corrections made in the Al_2O_3 analysis.

12.2 *Summary of Test Method*—In this test method, aluminum, iron, titanium, and phosphorus are precipitated from the filtrate after SiO_2 removal, by means of ammonium hydroxide. With care, little if any manganese will be precipitated. The precipitate is ignited and weighed as the combined metal oxides.

12.3 *Special Solution*:

12.3.1 *Methyl Red Solution (0.2 %)*—Dissolve 2 g of methyl red indicator with 1 L of 95 % ethyl alcohol.

12.4 *Procedure*:

12.4.1 To the acid solution from the determination of SiO_2(See 8.3.4 or 9.3.3), add hydrochloric acid (HCl) if necessary to ensure a total of 10 to 15 mL of HCl.

NOTE 13—Sufficient hydrochloric acid must be present before the solution is rendered ammoniacal to prevent the precipitation of magnesium.

12.4.2 If a platinum evaporating dish has been used for the dehydration of SiO_2, or a fusion made in the platinum crucible containing the HF-insoluble residue, iron may have been partially reduced. The iron must then be oxidized by adding 1 mL of saturated bromine water to the filtrate. Boil the filtrate to eliminate the excess bromine completely before adding methyl red indicator.

12.4.3 Dilute with water to a volume of 200 to 250 mL, add a few drops of methyl red solution, and heat just to boiling. Add NH_4OH (1 + 1) (See Note 14) until the color of the solution becomes distinctly yellow, then add 1 drop in excess (See Note 15). Heat the solution containing the precipitate to boiling and boil for 50 to 60 s. Remove from heat and allow the precipitate to settle (not more than 5 min). Filter using medium-textured paper and wash the precipitate two or three times without delay with a hot, 2 % solution of ammonium chloride (NH_4Cl) (See Note 16).

NOTE 14—The NH_4OH used to precipitate the hydroxides must be free of any dissolved carbon dioxide (CO_2).

NOTE 15—At the neutral point, it usually takes 1 drop of NH_4OH (1 + 1) to change the color of the solution from red to orange and another drop to change the color from orange to yellow. If the color fades during the precipitation or while heating, add more of the indicator. The boiling should not be prolonged as the precipitate may peptize and be difficult to retain on the filter. The solution should be distinctly yellow when it is ready to filter. If it is not, restore the yellow color with more NH_4OH (1 + 1).

NOTE 16—Two drops of methyl red indicator solution should be added to the NH_4Cl solution in the wash bottle followed by NH_4OH (1 + 1) added dropwise until the color just changes to yellow. If the color reverts to red at any time due to heating, it should be brought back to yellow by the addition of a drop of NH_4OH (1 + 1).

12.4.4 Set aside the filtrate and dissolve any precipitate from the paper with 40 mL hot (1 + 3) HCl, pouring the hot acid through the paper into the beaker in which the precipitation was made. Wash the filter paper thoroughly with hot HCl (1 + 19) followed by hot water and reserve the paper. Boil the solution and precipitate the hydroxides with NH_4OH as before. The precipitate is filtered through a fresh piece of medium textured filter paper and washed four or five times (See Note 17) with a hot 2 % solution of NH_4Cl. Combine filtrates for Ca and calcium magnesium analysis.

NOTE 17—If perchloric acid has been used, the final precipitate should be washed at least eight times to remove all traces of perchlorate salts (See 9.3).

12.4.5 Place the moist precipitate and the two filter papers in a weighed platinum crucible (See Note 9), heat slowly until the papers are charred, and finally ignite to constant weight at 1050 to 1100 °C. Cool in a desiccator and weigh.

12.5 *Calculation*—Calculate the percentage of ammonium hydroxide group (combined oxides) to the nearest 0.01 % as follows:

$$\text{Combined oxides},\ \% = (A/C) \times 100 \quad (5)$$

where:
A = mass of the combined oxides, g, and
C = original mass of sample, g.

12.6 *Precision and Bias*:

12.6.1 Four laboratories cooperated in testing on four limestone samples and three laboratories cooperated in testing on an additional seven limestone samples thereby obtaining the precision data summarized in Table 3.

www.technobetar.ir

12.6.2 The user is cautioned to verify by the use of test reference materials, if available, that the bias of this test method is adequate for the contemplated use.

13. Total Iron, Standard Method

13.1 *Scope*—Iron in limestone is usually present as pyrite (FeS_2) with occasional occurrences of other discrete iron minerals. The amount present varies according to the location and geological history of the deposit. During lime calcination, most if not all of the iron minerals present in the limestone ore will be converted to iron oxide or sulfate.

13.2 *Summary of Test Method*—In this test method, the total Fe_2O_3 content of the sample is determined from the ignited combined oxides by fusing the oxides with potassium pyrosulfate and leaching the melt with sulfuric acid. The iron is reduced to the ferrous state with stannous chloride and titrated with a standard solution of potassium dichromate ($K_2Cr_2O_7$).

13.3 *Special Solutions*:

13.3.1 *Stannous Chloride Solution* (50 g/L)—Dissolve 5 g of $SnCl_2 \cdot 2H_2O$ in 10 mL of HCl and dilute to 100 mL with water. Add several pieces of mossy tin metal to the bottle to preserve the $SnCl_2$ solution.

13.3.2 *Sodium Diphenylamine Sulfonic Acid Indicator* (2 g/L)—Dissolve 0.20 g sodium diphenylamine sulfonate in 100 mL of water. Store in a dark-colored bottle.

13.3.3 *Mercuric Chloride Solution* (5 %)—Dissolve 5 g of $HgCl_2$ in 100 mL of water.

13.3.4 *Potassium Dichromate, Standard Solution* (0.05 *N*)—Dry pure crystals of $K_2Cr_2O_7$ at 110 °C, then pulverize and dry at 180 °C to constant weight. Dissolve 2.4518 g of pulverized $K_2Cr_2O_7$ in water and dilute to 1 L. This is a primary standard, 1 mL = 0.0040 g Fe_2O_3.

13.4 *Procedure*:

13.4.1 To the combined oxides of iron and aluminum (See Note 18) in the platinum crucible, add 3 to 4 g of potassium pyrosulfate ($K_2S_2O_7$). Fuse at low heat until the oxides form a clear melt in the crucible. Cool, break up the button by gently tapping the crucible on the bench, and wash fragments into a small beaker with hot H_2SO_4(5 + 95). Add 5 mL of H_2SO_4(sp gr 1.82) to the contents in the beaker, and heat to dissolve the fused mass. Evaporate the solution to fumes of sulfuric acid and fume strongly for about 10 min. Cool, add 20 mL of water, and warm to dissolve the salts. There may be traces of silica appearing at this point, which for most routine work can be ignored. If the analyst prefers to determine it, however, the precipitate can be filtered, washed, and ignited. The recovered SiO_2 can then be added to the mass of SiO_2 previously found and its mass deducted from the gross mass of iron and aluminum reported (See Note 18).

NOTE 18—When the iron is present in small quantities, it is not always desirable to determine it in the ignited oxides from the 0.5-g sample. Under these conditions, the alternative procedure should be used with a larger sample weight.

NOTE 19—The recovered SiO_2 is usually small, but could be as much as 1 to 2 mg, even after two evaporations.

13.4.2 To the sulfuric acid solution, add 10 mL HCl (1 + 1) and heat to near boiling. Add dropwise stannous chloride solution (See Note 20) until the yellow color of the ferric iron just disappears. Add 2 or 3 drops of $SnCl_2$ in excess.

NOTE 20—If the stannous chloride has little effect and more than 5 to 10 mL are required, it has probably become oxidized to stannic chloride and a fresh supply should be obtained.

13.4.3 Cool the mixture and add approximately 100 mL of cold water. Add 10 mL of mercuric chloride solution, stir, and allow to stand for 3 to 5 min.

NOTE 21—A slight, white, silky precipitate should form. If the precipitate appears gray or black, it indicates too much $SnCl_2$ was added and the analysis must be repeated.

13.4.4 Add 5 mL of H_3PO_4 and 3 drops of sodium diphenylamine sulfonate indicator.

13.4.5 Titrate with standard 0.05 *N* $K_2Cr_2O_7$ solution adding the solution slowly while stirring constantly. The end point is indicated by a change in color from green to deep blue-violet.

13.5 *Calculation*:

$$Fe_2O_3, \% = (A/C) \times B \times 100 \quad (6)$$

where:

A = $K_2Cr_2O_7$ used in titration, mL,
B = 0.004 (Fe_2O_3 equivalent of $K_2Cr_2O_7$), and
C = sample, g.

13.6 *Precision and Bias*:

13.6.1 Four laboratories cooperated in testing on four limestone samples and three laboratories cooperated in testing on an additional seven limestone samples thereby obtaining the precision data summarized in Table 3.

13.6.2 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

14. Total Iron by Ortho-Phenanthroline Photometric Method

14.1 *Scope*—When the iron oxide content is very low, less than 0.1 %, and an accurate analysis at this low level is required, it is preferable to determine iron using procedures that have better sensitivity than the titrimetric methods. For an accurate determination of minute amounts of iron, the ortho phenanthroline method has proved invaluable.[6] In general, the method consists of reducing the iron to the ferrous state and then adding a slight excess of 1, 10 phenanthroline, which forms a complex with ferrous iron, giving an orange-pink color. The color intensity is proportional to the iron content of the solution.

14.2 *Summary of Test Method*—The bulk of the iron in the sample is dissolved with HCl, the silica dehydrated and separated by filtration, and the insoluble matter including SiO_2, ignited in a platinum crucible and treated with HF and H_2SO_4 to expel the SiO_2 and recover the small amount of iron that may not have dissolved with HCl. The acidified solution is transferred to a volumetric flask and diluted to volume. The iron is reduced with hydroxylamine hydrochloride and the

[6] Sandel, E. B., *Colorimetric Determination of Traces of Metals,* 3rd Ed., Interscience Publications, 1959.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

color of the ferrous complex is developed with 1,10 phenanthroline and compared against a set of iron standards similarly treated.

14.3 *Special Solutions*:

14.3.1 *Hydroxylamine Hydrochloride* (10 g/100)—Dissolve 10 g of hydroxylamine hydrochloride in 100 mL of water. Prepare fresh every week.

14.3.2 *Ammonium Acetate* (20 g/100)—Dissolve 200 g in 1 L of water.

14.3.3 *1,10 (Ortho) Phenanthroline* (0.1 g/100)—Dissolve 1.0 g in 1 L of hot water.

14.3.4 *Iron Standard Solution* (1 mL = 1.0 mg Fe_2O_3)—Dissolve 0.7000 g of pure iron wire by heating gently in 20 mL of HCl (1 + 1) and dilute to 1 L in a volumetric flask.

14.3.4.1 *Iron Work Standard Solution* (1 mL = 0.01 mg Fe_2O_3)—Transfer 10 mL of the iron standard solution to a 1 L volumetric flask and dilute to volume with water.

14.3.5 *Preparation of Calibration Curve*—To each of six 50 mL volumetric flasks, add, respectively, 1, 2, 4, 6, 8, and 10 mL of working iron standard solution. When diluted to volume, each mL of the prepared standard solutions will contain, respectively 0.2, 0.4, 0.8, 1.2, 1.6, and 2.0 micrograms Fe_2O_3.

14.3.5.1 Add to each flask in the following sequence, mixing after each addition, 1 mL of hydroxylamine hydrochloride solution, 5 mL of ammonium acetate, and 5 mL of 1,10 phenanthroline. Roll a small piece of congo red paper into a ball and insert it into the volumetric flask. Add NH_4OH (1 + 1) until the congo red indicator turns bright red, then add 1 drop of NH_4OH (1 + 1) in excess. Dilute to 50 mL, mix, and let stand for 15 to 20 min. Determine the absorbance of the solution in a spectrophotometer at a wavelength setting of 510 nm using water in the reference cell. Prepare a calibration curve by plotting the absorbance versus the concentration of Fe_2O_3 in µg/mL of solution.

14.4 *Procedure*:

14.4.1 Weigh 1 g of the properly prepared sample in 10 mL HCl (1 + 1) and evaporate rapidly to dryness. Add 50 mL of HCl (1 + 4) and heat to dissolve the salts. Filter the insoluble matter including SiO_2 through a retentive paper and wash several times with hot water. Reserve the residue. Heat the filtrate to boiling.

14.4.2 Place the paper containing the insoluble matter from the evaporated HCl solution in a platinum crucible. Char the paper at low heat without inflaming, then ignite at higher heat until the carbon has been completely burned off. Cool, add 1 mL H_2SO_4 and 10 to 15 mL HF and evaporate to fumes of sulfuric acid. Cool, dilute the contents of the crucible with water, and warm to dissolve salts. Transfer the acidified solution to the main solution containing the bulk of the iron.

14.4.3 Transfer the combined solutions to a 100 mL volumetric flask and dilute to volume. Pipet the aliquot containing 0.02 to 0.10 mg Fe_2O_3 into a 50 mL volumetric flask. Dilute to about 25 mL and add in the following sequence, mixing well after each addition: 1 mL hydroxylamine hydrochloride, 5 mL ammonium acetate, and 5 mL of 1,10 phenanthroline. Roll a small piece of congo red paper into a ball and insert into the volumetric flask. Add NH_4OH (1 + 1) until the congo red indicator turns a bright red, then add one drop of NH_4OH (1 + 1) in excess. Dilute to 50 mL, mix and let stand for 15 to 20 min. Determine the absorbance of the solution in a spectrophotometer at a wavelength setting of 510 nm using water in the reference cell. Compare against a set of standards similarly treated.

14.5 *Calculation*:

14.5.1 Calculate the % Fe_2O_3 as follows:

$$\% Fe_2O_3 = \frac{C \times D}{W \times 10^4} \quad (7)$$

where:

C = concentration of Fe_2O_3 in sample solution, µg/mL (determined from calibration curve),
D = dilution factor, and
W = sample mass, g.

14.6 *Precision and Bias*:

14.6.1 The number of laboratories, materials, and determinations in this study does not meet the minimum requirements for determining precision prescribed in Practice E 691:

	Test Methods C 25	Practice E 691 Minimum
Laboratories	2	6
Materials	5	4
Determinations	4	2

14.6.2 The following precision statements are provisional. Within five years, additional data will be obtained and processed which does meet the requirements of Practice E 691.

14.6.2.1 Precision, characterized by repeatability, *Sr* and *r*, and reproducibility, *SR* and *R*, has been determined for the following test method and materials to be:

Precision Statement for Test Method:	% Fe_2O_3			Color	
Material	Average	*Sr*	*SR*	*r*	*R*
S-1143	0.0358	0.0058	0.0201	0.0163	0.0564
S-1145	0.0480	0.0053	0.0214	0.0148	0.0599
S-1141	0.1688	0.0466	0.0640	0.1306	0.1792
S-1142	0.2025	0.0141	0.0631	0.0396	0.1767
S-1144	0.9252	0.0562	0.2096	0.1574	0.5870

15. Aluminum Oxide

15.1 *Scope*—Aluminum oxide, for the purpose of this test method, is considered to be the difference between the combined oxides and Fe_2O_3. When phosphorus or titanium are determined, their oxides must also be deducted.

15.2 *Procedure*—Subtract the percent Fe_2O_3 obtained in accordance with Sections 5.1.1 and 5.1.2 from the percent combined oxides (See Section 5.1). Report the remainder as percent Al_2O_3. In special cases where P_2O_5 and TiO_2 need to be reported, a correction for these oxides must be made.

15.3 *Calculation*—Calculate the percent Al_2O_3 as follows:

$$Al_2O_3, \% = A - B \quad (8)$$

where:

A = combined oxides ($Al_2O_3 + Fe_2O_3$), %, and
B = Fe_2O_3, %.

15.4 *Precision and Bias*:

15.4.1 Four laboratories cooperated in testing on four limestone samples and three laboratories cooperated in testing on an additional seven limestone samples thereby obtaining the precision data summarized in Table 3.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

15.4.2 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

16. Calcium Oxide by Gravimetric Method

16.1 *Scope*—Calcium is separated from magnesium by means of a double precipitation as the oxalate after the determination of the ammonium hydroxide group. The precipitate is converted to CaO by ignition and weighed. The gravimetric method should be used when a recovery of aluminum is indicated or when a determination of strontium by gravimetric analysis is required.

16.2 *Summary of Test Method*—Calcium is precipitated with ammonium oxalate $(NH_4)_2C_2O_4$, filtered, ignited to the oxide, and redissolved with HCl. Any of the NH_4OH group of metals that escaped precipitation before may be recovered at this point by the addition of a small amount of NH_4OH and boiling. Any precipitate that separates out is assumed to be $Al(OH)_3$ and after ignition to Al_2O_3 this amount is added to the mass of Al_2O_3 calculated in 16.2. Calcium is precipitated a second time as the oxalate, filtered, washed, ignited, and weighed as CaO.

16.3 *Special Solutions*:

16.3.1 *Ammonium Oxalate Solution* (saturated)—Dissolve 45 g of ammonium oxalate $(NH_4C_2O_4)$ in 1 L of hot water. When cooled to room temperature the supersaturated solution will partially crystallize out and the supernatant solution will then be saturated with ammonium oxalate.

16.3.2 *Ammonium Oxalate Wash Solution* (1 g/L)—Dissolve 1 g of $(NH_4)_2C_2O_4$ in 1 L of water.

16.4 *Procedure*:

16.4.1 Add 30 mL of HCl (1 + 1) and 20 mL of 10 % oxalic acid to the combined filtrates from the iron and aluminum hydroxide precipitation and heat the solution to boiling. To the boiling solution, add ammonium hydroxide (1 + 3) slowly until a precipitate begins to form. At this point, add the ammonium hydroxide still more slowly (dropwise, with a pipet) while stirring continuously until the methyl red just turns yellow. Add 25 mL of hot saturated ammonium oxalate solution while stirring. Remove from the heat and let stand until the precipitate has settled and the supernatant liquid is clear. Allow to cool for a minimum of 1 h, and filter using a retentive paper. Wash the paper and precipitate with five 10-mL portions of cold, neutral 0.1 % solution of $(NH_4)_2C_2O_4$(See Note 22). Reserve filtrate for the magnesium determination.

NOTE 22—Hot solutions should be avoided when washing the CaC_2O_4 precipitate. One litre of hot water will dissolve 5 mg of CaO. One litre of cold 0.1 % $(NH_4)_2C_2O_4$ solution will dissolve only 0.1 mg of CaO.

16.4.2 Place the wet filter and precipitate in a platinum crucible, and char the paper without inflaming at low heat. Increase the heat to burn off all the carbon and ignite at 1000 °C for about 10 min. Cool, dissolve the ignited oxide in 50 mL of dilute HCl (1 + 4), and dilute to about 100 mL with water. Add a few drops of methyl red indicator and neutralize with NH_4OH till the color of indicator changes to yellow. Heat just to boiling. If a small amount of $Al(OH)_3$ separates, filter it, wash with a hot 2 % solution of NH_4Cl, ignite, weigh, and add this to the mass of Al_2O_3 determined in 15.2.

16.4.3 Heat the filtrate to boiling and add slowly, while stirring, 35 mL of saturated $(NH_4)_2C_2O_4$ solution. Digest, filter, and wash as in 16.4.1. Combine the filtrate and washing with the ones reserved from the first precipitation, and retain for the determination of MgO. Place the filter in a tared platinum crucible with cover and carefully char the paper without inflaming. Increase the heat to burn off the carbon and ignite the calcium oxide in the covered platinum crucible at 1000 °C. Cool in a desiccator and weigh as CaO. Repeat the ignition to constant weight avoiding any hydration or carbonation of the lime.

16.5 *Calculation*—Calculate the percent calcium oxide (CaO) as follows:

$$\text{CaO, \%} = (M/W) \times 100 \quad (9)$$

where:

M = mass of CaO, g, and
W = mass of sample, g.

16.6 *Precision and Bias*:

16.6.1 Two laboratories cooperated in testing on four limestone samples and obtained the precision data summarized in Table 3.

16.6.2 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

17. Calcium Oxide by Volumetric Method

17.1 *Scope*—This volumetric test method is used mostly for ordinary control work in the plant laboratory, but it is capable of giving exact results, especially with those products that are free of interfering elements. Traces of strontium, barium, magnesium, or oxalate that may be present will also be titrated and calculated as calcium on an equivalence, not weight, basis.

17.2 *Summary of Test Method*—In this test method, the calcium oxalate precipitate is dissolved with dilute sulfuric acid and the liberated oxalic acid is titrated with standard potassium permanganate. The calcium equivalent of the oxalic acid is determined and the grams of CaO calculated.

17.3 *Special Solutions*:

17.3.1 *Potassium Permanganate, Standard Solution* (0.175 *N*):

17.3.1.1 Dissolve 5.64 g of potassium permanganate $(KMnO_4)$ in 1 L of water and boil gently for 20 to 30 min. Dilute again to 1 L, cover and allow to age for several days. Filter through purified asbestos or a wad of glass wool, and standardize against the National Institute of Standards and Technology's standard sample 40C of sodium oxalate $(Na_2C_2O_4)$ or equivalent as follows:

17.3.1.2 Transfer 0.5 g of the standard sodium oxalate dried at 105 °C to a 400-mL beaker. Add 250 mL of diluted H_2SO_4(5 + 95) freshly boiled for 10 to 15 min and cooled to 27 ± 3 °C. Stir until the oxalate has dissolved. Add 40 to 42 mL of the standard $KMnO_4$ solution at the rate of 25 to 35 mL/min, while stirring slowly. Let stand until the pink color disappears (about 60 s) (See Note X1.2).

17.3.1.3 Heat the contents of the beaker to 60 °C and complete the titration at this temperature by adding $KMnO_4$ solution until a slight pink color persists for 30 s. Add the last

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

0.5 to 1 mL dropwise, allowing each drop to become decolorized before the next one is added.

17.3.1.4 Determine the exact normality of the $KMnO_4$ solution from the following:

$$N = W/V \times 0.06701 \quad (10)$$

where:

N	=	normality of $KMnO_4$ solution,
W	=	mass of standard sodium oxalate,
V	=	$KMnO_4$ used to titrate sodium oxalate, mL, and
0.06701	=	sodium oxalate equivalent to 1 mL of 1 *N* $KMnO_4$ solution, g.

17.3.1.5 Determine the CaO equivalent of the $KMnO_4$ solution as follows:

$$F = N \times 0.02804 \quad (11)$$

where:

F	=	CaO equivalent of the $KMnO_4$ solution in grams CaO/mL,
N	=	normality of $KMnO_4$ solution, and
0.02804	=	CaO equivalent to 1 mL of 1 *N* $KMnO_4$ solution, g.

17.4 *Procedure*:

17.4.1 Add 30 mL of HCl (1 + 1) and 20 mL of 10 % oxalic acid to the combined filtrates from the iron and aluminum hydroxide precipitation and heat the solution to boiling. To the boiling solution, add ammonium hydroxide (1 + 3) slowly until a precipitate begins to form. At this point, add the ammonium hydroxide still more slowly (dropwise, with a pipet) while stirring continuously until the methyl red just turns yellow. Add 25 mL of hot saturated ammonium oxalate while stirring. Remove from the heat and let stand until the precipitate has settled and the supernatant liquid is clear. Allow to cool and filter at the end of 1 h. Wash the paper with cold water, limiting the total washings to 125 mL (See Note 23). Retain the filtrate for magnesium.

NOTE 23—A Gooch crucible may be used instead of filter paper to filter the CaC_2O_4 precipitate.

17.4.2 With a jet of hot water, wash the precipitate from the paper into the beaker in which the precipitation was made. Fold the paper and leave it adhering to the upper portion of the beaker. Add to the contents of the beaker 250 mL of hot, diluted H_2SO_4(1 + 19) and heat to 80 to 90 °C.

17.4.3 Titrate with 0.175 *N* $KMnO_4$ solution until the pink end point is obtained. Drop the folded filter paper that contained the original precipitate into the liquid and macerate it with a stirring rod; the pink color of the solution will be discharged (See Note 24). Finish the titration by adding the $KMnO_4$ standard solution dropwise until the end point is again obtained.

NOTE 24—There will always be some fine particles of precipitate imbedded in the pores of the filter paper which are dissolved by the acid in solution. The filter paper is not introduced at the beginning of the titration to avoid introduction of traces of organic matter due to the action of the hot sulfuric acid on the paper; these would consume $KMnO_4$ and give high results for CaO.

17.5 *Calculation*—Calculate the percentage of CaO in the sample using the CaO equivalent from 17.3.1.5 as follows:

$$\text{CaO, \%} = (V \times F)/W \times 100 \quad (12)$$

where:

V	=	$KMnO_4$ solution used in titration, mL,
F	=	CaO equivalent of $KMnO_4$, and
W	=	original mass of sample, g.

17.6 *Precision and Bias*:

17.6.1 Two laboratories cooperated in testing on twelve limestone samples and obtained the precision data summarized in Table 3.

17.6.2 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

18. Magnesium Oxide

18.1 *Scope*—Magnesium oxide in lime and limestone may vary from a few tenths to 2 % for high-calcium limestone to as much as 22 % for dolomitic limestone. The pyrophosphate gravimetric method has been used successfully throughout the industry to determine magnesium within this wide range.

18.2 *Summary of Test Method*—In this test method, magnesium is doubly precipitated as magnesium ammonium phosphate from the filtrate after removal of calcium. The precipitate is ignited and weighed as magnesium pyrophosphate ($Mg_2P_2O_7$). The MgO equivalent is then calculated.

18.3 *Special Solutions*:

18.3.1 *Ammonium Phosphate, Dibasic Solution* (250 g/L)—Dissolve 250 g of dibasic ammonium phosphate ($(NH_4)_2HPO_4$) in 1 L of water.

18.3.2 *Ammonium Hydroxide Wash Solution* (5 + 95)—Dilute 50 mL of NH_4OH with 950 mL of water and add 1 or 2 mL of HNO_3.

18.4 *Procedure*:

18.4.1 Add 2 drops of methyl red indicator to the combined filtrates from the determination of calcium, acidify with HCl, and concentrate to about 250 mL. Add to this solution about 10 mL of the $(NH_4)_2HPO_4$ solution, 250 g/L, and cool the solution to room temperature. Add NH_4OH slowly while stirring constantly until the solution is alkaline or the crystalline magnesium ammonium phosphate begins to form; then add about 15 to 20 mL of NH_4OH in excess and continue stirring for several more minutes. Allow the beaker and precipitate to stand in a cool place overnight. Filter and wash with cold dilute ammonium hydroxide wash solution (5 + 95).

18.4.2 Dissolve the precipitate with hot diluted HCl (1 + 9) and wash the filter paper well with hot diluted HCl (1 + 99). Dilute the solution to 100 mL, cool to room temperature, and add 1 mL of the 20 % solution of $(NH_4)_2HPO_4$. Precipitate the magnesium ammonium phosphate as before and allow to stand for about 2 h in a cool place.

18.4.3 Filter the precipitate on paper or in a tared Gooch crucible, washing with diluted NH_4OH (5 + 95). If filtered through a Gooch, place directly in a muffle at 400 °C and raise heat to 1100 °C. If filtration was through paper, place paper and precipitate in a weighed platinum or porcelain crucible. Slowly char the paper without inflaming and carefully burn off the

www.technobetar.ir

resulting carbon (**Warning**—Extreme caution should be exercised during this ignition. Reduction of the phosphate precipitate can result if carbon is in contact with it at high temperatures. There is also a danger of occluding carbon in the precipitate if ignition is too rapid.). Ignite at 1100 °C for ½ h, cool in desiccator, and weigh as $Mg_2P_2O_7$ (See Note 25).

NOTE 25—For research purposes or in the most exacting types of work, the manganese content of the pyrophosphate residue should be determined and deducted as $Mn_2P_2O_7$.

18.5 *Calculation*—Calculate the percentage of MgO to the nearest 0.01 % as follows:

$$\text{MgO, \%} = A \times 36.2/B \quad (13)$$

where:

A = $Mg_2P_2O_7$, g,
B = sample, g, and
36.2 = molecular ratio of 2MgO to $Mg_2P_2O_7 \times 100$.

18.6 *Precision and Bias*:

18.6.1 Four laboratories cooperated in testing on three limestone samples and three laboratories cooperated in testing on an additional nine limestone samples thereby obtaining the precision data summarized in Table 3.

18.6.2 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

19. Loss on Ignition

19.1 *Scope*—Loss on ignition (LOI) is the loss in weight expressed as percent of the initial "as received" sample weight obtained after ignition of the sample at 1000 °C to constant weight. The loss in weight is due to a release of free moisture, chemically combined "lattice" or "hydroxy" water, CO_2, SO_2, and volatile pyrolytic products of any organic material that may be present.

19.2 *Summary of Test Method*—The tared crucible containing the weighed sample is ignited to constant weight. The loss in weight is the LOI of the sample.

19.3 *Procedure*—Transfer approximately 1 g of the sample prepared to pass a 100-mesh (149-µm) U.S. standard sieve to a tare-weighed porcelain or platinum crucible. Cover with a lid and weigh accurately to within 0.1 mg. When testing quicklime, the crucible cover is not required. Also, quicklime may be placed directly into a muffle at 1000 °C avoiding preignition. Pre-ignite in a muffle furnace at approximately 400 °C for 30 min. Then increase muffle temperature to 1000 °C ± 20 °C, and maintain at this temperature for a minimum of 20 min or until constant mass is obtained. The difference between the original mass of the sample and the final mass represents the loss on ignition.

19.4 *Calculation*—Calculate LOI as follows:

$$\text{LOI, \%} = (A - B)/C \times 100 \quad (14)$$

where:

A = mass of crucible + sample, g,
B = mass of crucible plus sample after ignition, g, and
C = mass of sample, g.

19.5 *Precision and Bias*:

19.5.1 Fifteen laboratories cooperated in testing on three samples of high calcium limestone to obtain the precision data for percent LOI given in 19.5.2 and 19.5.3.

19.5.2 The repeatability (Practice E 691 [r]) was found to be 0.158 % LOI.

19.5.3 The reproducibility (Practice E 691 [R]) was found to be 0.463 % LOI.

19.5.4 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

20. Free Moisture in Limestone

20.1 *Scope*—For the purpose of this test method, the conventional definition of "hygroscopic moisture" or "free water" (also known as "free-moisture") is accepted; that is, the amount of water and any other volatile matter than can be expelled from a sample of the material by drying to constant weight at a temperature slightly above the boiling point of water.

20.2 *Summary of Test Method*—The sample in a container is heated in a drying oven at 115 to 120 °C constant weight. The loss in weight represents the free moisture.

20.3 *Special Apparatus*:

20.3.1 *Bottle,* weighing, low-form, glass-stoppered, or wide-form, large porcelain crucible.

20.4 *Procedure*—Weigh 1 g of the prepared sample in the stoppered weighing bottle. Remove the stopper and heat in a drying oven at 115 to 120 °C for 2 h. Quickly stopper, cool in a desiccator, and weigh, lifting the stopper momentarily just before weighing. The use of a similar weighing bottle as a counterpoise carried through all the operations is a desirable procedure unless a single pan balance is used. The loss in weight represents "free moisture" loss at 120 °C.

20.5 *Calculation*—Calculate the percent "free moisture" as follows:

$$\text{Free-moisture, \%} = (A - B)/C \times 100 \quad (15)$$

where:

A = mass of crucible and sample before heating, g,
B = mass of crucible and sample after heating at 120 °C, g, and
C = original mass of sample, g.

20.6 *Precision and Bias*—The precision and bias of this test method have not been determined.

21. Free Moisture in Hydrated Lime

21.1 *Scope*—The free moisture in hydrated lime is that water that is released from the sample at a temperature of 115 to 120 °C. This distinguishes it from the hydroxyl water that is chemically bound to the lime and which cannot be liberated except at higher temperatures.

21.2 *Summary of Test Method*—Free moisture in hydrated lime is determined by aspirating a slow stream of CO_2-free air over the sample in a container placed inside a 115 to 120 °C oven. The loss in weight of the sample is equal to the free moisture of the hydrated lime.

21.3 *Special Apparatus*:

21.3.1 *Sample Flask E,* illustrated in Fig. 1, consists of a 50-mL flat-bottom, glass-stoppered flask, supplied with a ground glass joint and solid ground glass stopper.

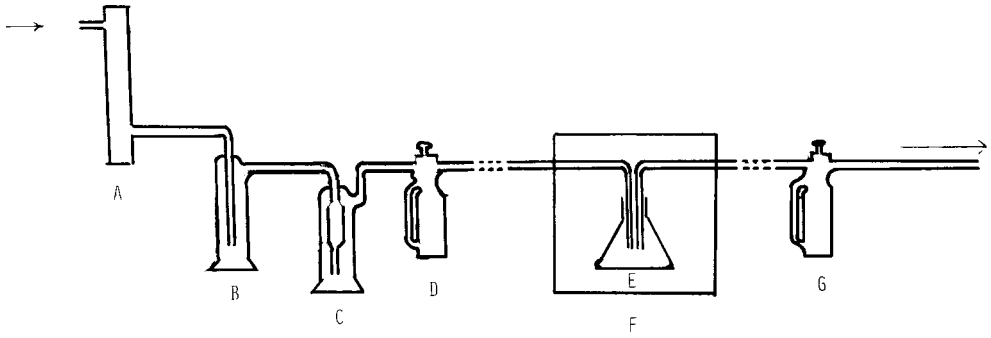
www.technobetar.ir



A Soda-Lime Tower at inlet to remove CO_2.
B Bottle containing lime water to show when soda lime tower is exhausted.
C Fleming jar containing sulfuric acid to remove water from air.
D Absorption bulb filled with Anhydrone (Magnesium Perchlorate) to complete drying of air.
E 50-mL sample flask.
F Drying oven operating at 110 °C.
G Absorption bulb filled with Anhydrone to prevent moisture backup into sample.

FIG. 1 Apparatus for Free Moisture in Hydrated Lime

21.3.1.1 The flask shall be fitted with an interchangeable hollow ground-glass stopper, equipped with two glass entry tubes for conducting the dry air over the sample.

21.3.2 *Purifying Train* (See Fig. 1), located outside the oven *F* for conducting the dry air over the samples, shall consist of a series of scrubbers and absorption bulbs to remove CO_2 and moisture from the air. The apparatus are arranged in the following order starting from the air source:

21.3.2.1 *Soda-Lime Tower A,* at the air inlet to remove CO_2 from the air.

21.3.2.2 *Bottle B,* containing lime water to show when the soda lime is exhausted.

21.3.2.3 *Fleming Jar C,* containing sulfuric acid to remove water from the air.

21.3.2.4 *Absorption Bulb D,* filled with Anhydrone (magnesium perchlorate) to complete the drying of the air.

21.3.2.5 *Sample Flask E.*

21.3.2.6 *Drying Oven F.*

21.3.2.7 *Absorption Bulb G,* also filled with Anhydrone and located on the exit side of the sample bulb as a protective barrier against atmospheric moisture.

21.4 *Procedure*—Weigh 2.5 to 3 g of the prepared sample, and using glazed paper folded in the shape of a funnel, transfer it rapidly into the previously weighed bottle and immediately restopper it. Insert the bottle into the 120 °C oven and quickly exchange stoppers. Connect the sample bottle to the purifying train by means of flexible tubing and pass a slow current of dry CO_2-free air through the apparatus for 2 h. Disconnect the sample bottle from the train, remove it from the oven with another quick exchange of stoppers, and place it in a desiccator to cool. When cool, remove it to the balance case for several minutes before weighing it, and just before weighing, lift the stopper slightly for an instant to relieve any vacuum that may exist in the bottle. The loss in weight of the sample represents "free moisture" loss as 120 °C. Use a bottle similar to the one containing the sample as a counterpoise in all weighings unless a single-pan balance is used.

21.5 *Calculation*—Calculate the percent "free moisture" in the sample as follows:

$$\text{Free moisture, } \% = (A - B)/C \times 100 \quad (16)$$

where:

A = mass of sample flask + sample, g,
B = mass of sample flask after drying, g, and
C = mass of sample, g.

21.6 *Precision and Bias*—The precision and bias of this test method have not been determined.

22. Carbon Dioxide by Standard Method

22.1 *Scope*—Carbon dioxide in limestone is sometimes determined to verify the presence of carbonates other than calcium or magnesium. These may include carbonates of iron, manganese, and occasionally traces of other substances. Samples of lime and hydrated lime are analyzed for CO_2 to check for the presence of carbonates, most of which are there as uncalcined limestone.

22.2 *Summary of Test Method*—The sample is decomposed with HCl and the liberated CO_2 is passed through a series of scrubbers to remove water and sulfides. The CO_2 is absorbed with Ascarite, a special sodium hydroxide absorbent, and the gain in weight of the absorbtion tube is determined and calculated as percent CO_2.

22.3 *Special Apparatus*:

22.3.1 The apparatus illustrated in Fig. 2 consists of the following:

22.3.1.1 *Purifying Jar A,* Fleming, containing sulfuric acid.

22.3.1.2 *Drying Tube B,* U-shaped with side arms and glass stoppers. Side arms are shaped to hold rubber tubing. Contains Anhydrone on left side and Ascarite on right side.

22.3.1.3 *Erlenmeyer Flask C,* 250-mL, 24/40 ground-glass joint.

22.3.1.4 *Separatory Funnel D,* with ground-glass stopper and interchangeable hollow ground-glass joint. A delivery tube bent at the end extends into the sample flask about ½ in. from the bottom. Used to introduce acid into flask.

22.3.1.5 *Condenser E.*

22.3.1.6 *Gas-Washing Bottle F,* 250-mL, with fritted disk containing distilled water to retain most of the acid volatilized from the alkalimeter.

22.3.1.7 *U-Tube G,* containing mossy zinc to remove the last traces of HCl.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

A Purifying jar, Fleming, containing concentrated H_2SO_4.
B Drying tube, U-shaped, Ascarite in right side, Anhydrone in left side.
C Erlenmeyer flask, 250-mL, 24/40 glass joint.
D Separatory funnel.
E Condenser.
F Gas-washing bottle, 250-mL with fritted disk, containing water to retain most of the acid volatilized from the alkalimeter.
G U-tube containing mossy zinc to remove the last traces of HCl.
H Gas-washing bottle, 250-mL with fritted disk, containing concentrated H_2SO_4.
I Trap.
J Absorption bulb containing Anydrone.
K CO_2 absorption bulb containing Ascarite.
L U-guard tube with Anhydrone in left side and Ascarite in right side.
M Purifying jar, Fleming, containing concentrated H_2SO_4.

FIG. 2 Apparatus for Carbon Dioxide by Standard Method

22.3.1.8 *Gas-Washing Bottle H,* 250-mL, with fritted disk, containing concentrated H_2SO_4 and trap *I,* to remove any SO_3 mist that may have been carried over.

22.3.1.9 *Absorption Bulb J,* containing Anhydrone to remove last traces of water vapor.

22.3.1.10 *CO_2 Absorption Bulb,* containing Ascarite filled as follows: On the bottom of the bulb, place a layer of glass wool extending above the bottom outlet and on top of this a layer of Anhydrone about ⅜ in. thick; immediately above this is placed another layer of glass wool, and Ascarite is then added to almost fill the bulb. A top layer of Anhydrone about ⅜ in. thick is placed on top of the Ascarite and topped off with a covering of glass wool.

22.3.1.11 *U-Guard Tube L,* filled with Anhydrone in left side and Ascarite in right side.

22.3.1.12 *Purifying Jar M,* Fleming, containing H_2SO_4.

22.4 *Procedure*:

22.4.1 Weigh an indicated amount of prepared sample, 0.5 g for limestone and 5 g for lime or hydrated lime, and transfer to the 250-mL Erlenmeyer flask. Connect the sample flask to apparatus as shown in the diagram (See Fig. 2). Purge the system free of carbon dioxide by passing a current of CO_2-free air through the apparatus for 10 to 15 min.

22.4.2 Weigh the absorption bulb and attach it to the train. Remove the glass stopper from separatory funnel, place 50 mL of dilute HCl (1 + 1) in the separatory funnel (*D*) and replace the stopper with the interchangeable hollow ground-glass joint through which passes a tube for admitting purified air. Open the stopcock of the separatory funnel and admit air through the top of the funnel to force the hydrochloric acid into the Erlenmeyer flask (*C*).

22.4.3 Start cold water circulating through the condenser (*E*) and, with CO_2-free air passing at a moderate rate through the absorption train, place a small hot plate or gas burner under the sample flask and boil for about 2 min. Remove the hot plate and continue the flow of purified air at about three bubbles per second for 30 min to sweep the apparatus free of CO_2. Close the absorption bulb, disconnect it from the train and weigh, opening the stopper momentarily to equalize the pressure. Use a second absorption bulb as counterpoise in all weighings unless a single pan balance is used.

22.5 *Calculation*—Calculate the percent CO_2 as follows:

$$CO_2, \% = (A - B)/C \times 100 \quad (17)$$

where:
A = mass of absorption bulb + CO_2, g,
B = mass of absorption bulb before the run, g, and
C = mass of sample, g.

22.6 *Precision and Bias*—The precision and bias of this test method have not been determined.

23. Sulfur Trioxide

23.1 *Scope*—This test method will determine sulfur compounds, mostly present as sulfates in lime and limestone, that are soluble in dilute HCl. Iron pyrites and other sulfides will not be included because they will either be volatilized as H_2S or not react at all with the acid.

23.2 *Summary of Test Method*—In this test method, sulfate is precipitated from an acid solution of the lime or limestone with barium chloride ($BaCl_2$) and the SO_3 equivalent is calculated.

23.3 *Special Solution*:

23.3.1 *Barium Chloride Solution* (100 g/L)—Dissolve 100 g of barium chloride ($BaCl_2 \cdot 2H_2O$) in 1 L of water.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

23.4 *Procedure*—Select and weigh the prepared sample into a 250-mL beaker containing 50 mL of cold water in accordance with the following:

Expected SO_3 Range, %	Sample Weight, g
0.001 to 0.500	10.00
0.500 to 2.50	5.00
2.50 to 12.5	2.00

Stir until all lumps are broken and the lighter particles are in suspension. Add 50 mL of diluted HCl (1 + 1) and heat until the reaction has stopped and decomposition is complete. Digest for several minutes at a temperature just below boiling. Add a few drops of methyl red indicator and render the solution alkaline (yellow color) with NH_4OH (1 + 1). Heat the solution to boiling. Filter through a medium-textured paper and wash the residue thoroughly with hot water. Dilute the filtrate to 250 mL, add 5 mL of HCl (1 + 1), heat to boiling, and add slowly 10 mL of hot $BaCl_2$ solution. Continue the boiling until the precipitate is well formed, stir well, and allow to stand overnight at room temperature. Take care to keep the volume of solution between 225 and 250 mL, and add water for this purpose if necessary. Filter through a retentive paper and wash the precipitate with hot water. Place the paper and contents in a weighed platinum crucible, and slowly char the paper without flaming. Burn off all the carbon, ignite in a muffle at 1000 °C, cool in a desiccator, and weigh.

23.5 *Calculation*—Calculate the percentage of SO_3 to the nearest 0.001 as follows:

$$SO_3, \% = A \times 0.343/W \times 100 \quad (18)$$

where:

A = mass of $BaSO_4$, g,
W = mass of sample, g, and
0.343 = molecular ratio of SO_3 to $BaSO_4$.

23.6 *Precision and Bias*:

23.6.1 Six laboratories cooperated in testing on four samples of limestone and lime materials covering the range from 0.04 to 5.15 % SO_3 to obtain the precision data given in 23.6.2 and 23.6.3.

23.6.2 The repeatability (Practice E 173 R_1) was found to be (0.135 % SO_3 per weight in grams of sample analyzed).

23.6.3 The reproducibility (Practice E 173 R_2) was found to be (0.271 % SO_3 per weight in grams of sample analyzed).

23.6.4 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

24. Total Sulfur by Sodium Carbonate Fusion

24.1 *Scope*—Sulfur in limestone is chiefly, if not wholly, present as sulfide, usually as pyrite. If the total sulfur obtained in the following test method is in excess of that present as soluble sulfate, the difference can be assumed to be present as iron disulfide.

24.2 *Summary of Test Method*—The sample is fused with sodium carbonate and the ignited mass is leached in water and dissolved with HCl. The solution is made ammoniacal and the hydroxide precipitate is filtered. The sulfur in the filtrate is precipitated with a 10 % solution of barium chloride. The precipitate is ignited and weighed as barium sulfate ($BaSO_4$) and the SO_3 equivalent is calculated.

24.3 *Procedure*:

24.3.1 Select and weigh the prepared sample into a porcelain crucible in accordance with the following:

Expected S Range, %	Sample Weight, g	Na_2CO_3 Weight, g
0.001 to 0.20	10.00	5.00
0.200 to 1.00	5.00	2.50
1.00 to 5.00	2.00	1.00

Add the indicated amount of Na_2CO_3 and mix well. Heat in a muffle at 600 °C for 15 min. Increase the heat 50 °C every 15 min until 1000 °C is reached and maintain at this temperature for 15 min. (See Note 26). Cool, place the crucible and cover in a 400-mL beaker, and cover with hot water. Add 10 mL bromine water (See Note 27) and then add sufficient HCl (1 + 1) to make the solution slightly acid to methyl red. Boil until solution is complete and all bromine has been expelled. Remove the crucible and wash with hot water.

NOTE 26—Since not enough flux is used to produce more than a sintering, the air entering the crucible after the bulk of the carbon dioxide has been released effects very speedy oxidation in the porous mass.

NOTE 27—It has been found that 10 mL of 30 % hydrogen peroxide (H_2O_2) may be substituted for the bromine water to accomplish oxidation without affecting the analytical result.

24.3.2 Add a few drops of methyl red indicator and render the solution alkaline with NH_4OH (1 + 1). Heat the solution to boiling, filter using a retentive paper and wash with hot water. To the filtrate add 5 mL of HCl (1 + 1), adjust the volume to about 250 mL, and bring the solution to boiling. To the boiling solution, add 10 mL of hot $BaCl_2$ solution, slowly and with stirring. Allow to stand overnight. Filter through a retentive paper and wash the precipitate with hot water. Place paper and contents in a weighed platinum crucible and slowly char the paper without flaming. Burn off the carbon and ignite in a muffle at 1000 °C for 1 h. Cool in a desiccator and weigh as $BaSO_4$.

24.4 *Calculation*—Calculate the percentage of sulfur to the nearest 0.001 as follows:

$$S, \% = A \times 13.73/W \quad (19)$$

where:

A = mass of $BaSO_4$, g,
W = sample, g, and
13.73 = mass of molecular ratio of S to $BaSO_4 \times 100$.

24.5 *Precision and Bias*:

24.5.1 Six laboratories cooperated in testing on four samples of limestone and lime materials covering the range from 0.021 to 2.15 % sulfur to obtain the precision data given in 24.5.2 and 24.5.3.

24.5.2 The repeatability (Practice E 173 R_1) was found to be (0.065 % S per weight in grams of sample analyzed).

24.5.3 The reproducibility (Practice E 173 R_2) was found to be (0.094 % S per weight in grams of sample analyzed).

24.5.4 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

25. Total Sulfur by the Combustion-Iodate Titration Method

25.1 *Scope*—This test method covers the determination of sulfur in concentration from 0.005 to 1 %. At the combustion

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

temperature of approximately 1650 °C, complete combustion of the sulfur in the sample will take place regardless of sulfur form or sample matrix.

25.2 *Summary of Test Method*—A major portion of the sulfur in various types of lime and limestone samples is converted to oxides of sulfur, primarily sulfur dioxide (SO_2), by combustion in a stream of oxygen at the elevated temperature of a high-frequency induction furnace. During the combustion, the SO_2 is absorbed in an acidified starch-iodine solution and titrated with potassium iodate. The latter is standardized against limestone standard samples of known sulfur content to compensate for characteristics of a given apparatus and for day-to-day variation in the percentage of sulfur recovered as SO_2. Compensation is also made for the blank due to accelerators and crucibles.

25.3 *Apparatus:*

25.3.1 *Induction Furnace*—The induction furnace shall be supplied with a rheostat used to control the power input to the reduction coil that will avoid heating some types of samples too rapidly during the early stages of combustion. The train of the induction furnace shall include an oxygen purifier, described in 25.3.3.

25.3.2 *Automatic Titrator*—This apparatus shall consist of an absorption and titration vessel of appropriate volume and contain an inlet bubbler tube for the sulfur gases with a float valve to prevent backflow of liquid when the sample is starting to consume oxygen. The vessel must be shaped to effect complete absorption of SO_2 in a small volume of solution. The titrator comes equipped with a buret that should be approximately 10 mL in capacity marked with 200 divisions. The automatic titrator utilizes a photoelectric cell to activate a titrator inlet valve that allows the titration to proceed without the presence of an operator.

25.3.3 *Oxygen Purifiers*—Reagent-grade oxygen from a commercial tank is passed through a suitable two-stage reduction valve to provide an even and adequate flow of oxygen through a purifying train consisting of a sulfuric acid tower, an absorption bulb containing 20 to 30-mesh inert base impregnated with NaOH, and another absorption bulb containing anhydrous magnesium perchlorate Mg (ClO_4). A flowmeter precedes the induction furnace assembly.

25.3.4 *Combustion Crucibles*—The crucibles for use with the induction furnace must be of adequate thickness to retain the molten slag and have a sulfur blank as low and consistent as possible. The crucibles for use in the induction furnace must have adequate capacity and may be provided with suitable covers.

25.3.5 *Glass Accelerator Scoop.*

25.3.6 *Starch Dispenser*—A plastic bottle with a device for dispensing a few millilitres of starch solution at a time.

25.3.7 *Timer,* having a 0 to 15-min range in ¼-min intervals. Turns off the furnace at end of preset time and automatically resets.

25.3.8 *Loading Funnel*—Three-legged funnel that fits over the crucible and simplifies addition of sample.

25.4 *Reagents:*

25.4.1 *Copper (Low-Sulfur) Ring Accelerator.*

25.4.2 *Iron (Low-Sulfur) Accelerator*—Iron chips. (For samples containing very low percentages of sulfur, the use of iron powder is recommended because of its low blank.)

25.4.3 *Tin Metal (Low-Sulfur) Accelerator,* granular.

25.4.4 *Potassium Iodate* (KIO_3) *Crystal.*

25.4.5 *Potassium Iodide* (KI) *Crystal.*

25.4.6 *Starch,* soluble.

25.5 *Special Solutions*:

25.5.1 *Potassium Iodate,* standard solutions.

25.5.1.1 KIO_3*Standard Solution A*—Dissolve 0.2227 g KIO_3 in 900 mL of water containing 1 g sodium hydroxide (NaOH) and dilute to 1 L. For a 0.500-g sample, the buret reads directly in percent sulfur.

25.5.1.2 *Starch-Iodide Solution*—Transfer 2 g of soluble starch (for example, Arrowroot) to a 50-mL beaker, add a few millilitres of water, and stir into a smooth paste. Slowly add starch to 500 mL of distilled water while stirring. Add 4 g of NaOH and continue stirring the solution until the appearance changes from cloudy to translucent. Add 6 g of potassium iodide (KI), stir until the KI is dissolved, and dilute to 1 L.

NOTE 28—Discard any starch solution that imparts a red tinge to the blue color when titrating.

25.6 *Calibration*—This test method and instrument should be standardized by using a limestone sample of known sulfur content as determined by the Total Sulfur Method by Sodium Carbonate Fusion, Section 24. The Leco instrument, in addition, may be standardized daily by running limestone reference materials whose sulfur content, as determined by the Total Sulfur Method, ranges from 0.02 to 0.05 %. The limestone standards are run to determine the day-to-day variations in the test method and to verify that the electronics in the Leco are working properly.

25.6.1 It has been found through round robin studies that the practice of pre-igniting samples at 1000 °C causes erratic recovery of sulfur. This practice should not be used.

25.7 *Procedure*:

25.7.1 Allow 15 min for the electronics in the furnace assembly and titrator to warm up.

25.7.2 Set the grid-current tap switch to low, medium, or high position. Determine the position on a test run, with the sample and accelerators that will give a complete combustion at approximately 400 mA as indicated on the plate current ammeter.

25.7.3 Set the automatic timer to the estimated time required to evolve the sulfur in the sample completely, as follows:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Sample	Time, Min
Quicklime	8
Hydrated Lime	10
Limestone	12

25.7.4 Weigh the sample and brush carefully into the combustion crucible using the loading funnel. The correct sample weight is determined by the estimated sulfur content of the sample as follows:

Sulfur %	Sample Weight (g)
0.001	0.500

25.7.5 The choice of accelerators is left to the discretion of the user, as each furnace will burn differently in accordance with type and amount used. Generally, the more accelerator used, the greater the furnace temperature. Tin metal, iron chip, iron powder, and copper ring have been found to be suitable materials. Porous covers should be used to prevent splattering of the hot flux and damage to the combustion tube. Do not re-use crucibles or covers.

25.7.6 Run a blank determination before each series (of sulfur determinations) using a crucible that contains all the accelerators but no sample.

25.7.7 Place the crucible and sample on the pedestal and lift into position in the combustion tube.

25.7.8 With the oxygen flow at 1 L/min, close stopcock on bottom of titration vessel, and add the HCl to the middle of the bell-shaped portion of the titration vessel. Always fill to the same level.

25.7.8.1 Add one measure of starch solution to the titration vessel. Fill the iodate buret.

25.7.9 Turn the double throw switch on the titrator to the end-point position (down). Slowly rotate the end-point control in a clockwise direction until it has added KIO_3 in the amount to give a solid medium blue color. After the indicator light (for solenoid valve) has stopped blinking, place the switch in the neutral position and fill the KIO_3 buret again. Turn the switch to the titrate position.

25.7.10 Turn on the power of the high-frequency furnace. The temperature will rise in the crucible as indicated by the plate current ammeter on the induction furnace that must indicate a reading of at least 400 mA before complete combustion of sulfur can take place.

25.7.11 As sulfur dioxide is given off, the unit will begin titrating automatically. The titration is finished when the indicator light stops blinking for a period of time, or the iodate in the buret stops falling over a period of time.

25.7.12 Inspect the crucible for a proper burn. A rough, bumpy surface or appearance of non-combustion indicates that the furnace temperature was too low. Sticking of the porous cover to the crucible indicates that the furnace temperature may have been too hot. Both conditions indicate poor sulfur recovery and may be helped by a slight change in accelerator amounts.

25.8 *Calculation*:

25.8.1 Calculation of Furnace Factor *(F)*

$$F=\frac{R}{(A-B)/(W\times 2)} \tag{20}$$

where:

A = buret reading as % Sulfur (S),
B = buret reading for Blank determination,
R = % Sulfur (by Sodium Carbonate Fusion Method) of the reference material, and
W = weight of sample, g.

25.8.2 Calculate the percentage of sulfur in the sample by using furnace factor *F*.

$$\%\ S=F\times\frac{A-B}{W\times 2} \tag{21}$$

where:

A = buret reading as % Sulfur (S),
B = buret reading for Blank determination,
F = furnace factor, and
W = weight of sample, g.

25.9 *Precision and Bias*:

25.9.1 Nine laboratories cooperated in testing on three samples of high-calcium limestone to obtain the precision data for % sulfur given in 25.9.2 and 25.9.3.

25.9.2 The repeatability (Practice E 691 [r]) was found to be 0.0070 % sulfur.

25.9.3 The reproducibility (Practice E 691 [R]) was found to be 0.0120 % sulfur.

25.9.4 The user is cautioned to verify by the use of reference materials, if available, that the bias of this test method is adequate for the contemplated use.

26. Phosphorus by Molybdovanadate Method

26.1 *Scope*—This method is suitable for the determination of small amounts of phosphorous in lime and limestone samples. The procedure is based on the fact that phosphorous in its ortho form will combine with ammonium molybdovanadate to yield a yellow color that can be measured spectrophotometrically. Total phosphate is determined after a strong oxidation decomposition with perchloric acid.

26.2 *Summary of Test Method*—The sample is decomposed with perchloric acid, the solution filtered, SiO_2 expelled, and the insoluble residue fused with Na_2CO_3. Ammonium molybdovanadate which is then added reacts with the phosphorous in solution to form the heteropoly phosphomolybdovanadate complex. The absorbance of the solution is measured with a photometer at 430 nm and compared against standards similarly treated.

26.3 *Special Solutions*:

26.3.1 *Phosphorous Standard Stock Solution* (0.5 mg P/mL)—Weigh 1.0983 g of potassium dihyrogen phosphate, KH_2PO_4, into a 250-mL beaker and dampen with about 5 to 10 mL of water. Add 10 mL HNO_3 and 25 mL $HClO_4$(See Note 29), heat on a hot plate, and evaporate to heavy fumes of $HClO_4$. Cover and boil until the solution is colorless or slightly yellow (10 to 15 min). Cool the solution, transfer to a 500-mL volumetric flask, dilute to volume, and mix. Store in a borosilicate or plastic bottle with a screw cap.

26.3.2 *Phosphorous Working Standard* (0.05 mg P/mL)—Dilute 50 mL of stock solution 26.3.1 to 500 mL with distilled water. Store in a Pyrex or plastic bottle with screw cap.

26.3.3 *Ammonium Molybdovanadate Solution*:

26.3.3.1 Dissolve 1.25 g of ammonium metavanadate in 400 mL of 1 + 1 nitric acid in a 1 L volumetric flask.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

26.3.3.2 Dissolve 50 g of ammonium molybdate in 400 mL of distilled water.

26.3.3.3 Pour solution from 26.3.4.2 into solution 26.3.4.1, mix, and dilute to volume with distilled water.

26.4 *Preparation of Standard Curve*:

26.4.1 To each of seven individual 50 mL volumetric flasks, add with a buret 0, 1, 2, 4, 6, 10, and 14 mL of phosphorous working standard solution corresponding to 0, 0.05, 0.10, 0.20, 0.30, 0.50, and 0.70 mg of phosphorous, respectively.

26.4.2 Add 1 mL of perchloric acid and dilute to about 20 mL with water. Add 10 mL of the molybdovanadate solution, swirling the contents of the flask during the addition. Dilute to volume with distilled water, mix well, and allow to stand for 10 min. The prepared standard solutions will contain 0 (blank), 1.0, 2.0, 4.0, 6.0, 10.0, and 14.0 micrograms (µg) P/mL.

26.4.3 Determine the absorbance of each standard solution in the spectrophotometer at a wavelength of 430 nm using the blank standard as the reference solution. Prepare a calibration curve by plotting absorbance versus concentration of phosphorous in µg/mL.

26.5 *Procedure*:

26.5.1 Weigh 5.0 g of prepared sample into a 250-mL beaker and dampen with about 5 to 10 mL of water. Add 10 mL HNO_3 and 25 mL $HClO_4$(See Note 29), heat on hot plate, and evaporate to heavy fumes of $HClO_4$. Cover and boil until solution is colorless or slightly yellow (10 to 15 min). Cool slightly and add 50 mL H_2O. Filter through retentive filter paper and wash thoroughly with hot H_2O (See Note 30). Reserve filtrate.

NOTE 29—If a special perchloric acid hood is not available, the use of perchloric may be omitted. Instead, add 10 mL HNO_3 and evaporate to dryness. Take up salts with 5 mL HCl, break up residue, and again evaporate to dryness. Boil up with 1 mL of HNO_3 and 20 mL of water, and filter, etc.

NOTE 30—The filter paper and silica residue must be washed free of perchlorate salts to prevent small explosions from occurring in the crucible when the filter paper is charred and ignited.

26.5.2 Place paper and contents in a platinum crucible and heat gently with a low flame until paper chars. Ignite at a higher temperature until ash is white. Cool, add 2 drops of H_2SO_4(1 + 1) and 10 to 15 mL HF. Evaporate cautiously to dryness and heat in a muffle at 1000 °C for 2 min (See Note 31). Fuse residue with 0.5 g of Na_2CO_3, cool, add 5 mL H_2O and 1 mL $HClO_4$ and warm to dissolve. Combine the filtrates and transfer to a 100 mL volumetric flask. Dilute to volume and mix.

NOTE 31—The treatment of the residue with HF and H_2SO_4 may be omitted if the SiO_2 in the sample is low, <3 %.

26.5.3 Pipet 25 mL of solution into a 50 mL-volumetric flask and add 10 mL ammonium molydovanadate solution, dilute to volume and mix well. Allow to stand 30 min and measure the absorbance at 430 nm using the blank standard solution in the reference cell. Compare against a set of standards similarly treated.

26.6 *Calculation*:

26.6.1 Calculate % P_2O_5 as follows:

$$\%\ P_2O_5 = \frac{C \times D \times 2.2913}{W \times 10^4} \qquad (22)$$

where:

C = concentration of P in sample solution, µg/mL determined from calibration curve,
D = dilution factor, and
W = g of sample.

26.7 *Precision and Bias*:

26.7.1 The number of laboratories, materials, and determinations in this study does not meet the minimum requirements for determining precision prescribed in Practice E 691:

	Test Methods C 25	Practice E 691 Minimum
Laboratories	3	6
Materials	5	4
Determinations	4	2

26.7.2 The following precision statements are provisional. Within five years, additional data will be obtained and processed which does meet the requirements of Practice E 691.

26.7.2.1 Precision, characterized by repeatability, *Sr* and *r*, and reproducibility, *SR* and *R*, has been determined for the following test method and materials to be:

Precision Statement for Test Method:	% P_2O_5			Color	
Material	Average	*Sr*	*SR*	*r*	*R*
S-1145	0.0031	0.0010	0.0017	0.0029	0.0046
S-1142	0.0091	0.0019	0.0031	0.0053	0.0087
S-1141	0.0221	0.0014	0.0043	0.0040	0.0122
S-1144	0.0657	0.0063	0.0144	0.0175	0.0404
S-1143	0.1353	0.0077	0.0147	0.0215	0.0413

27. Manganese by the Periodate (Photometric) Method

27.1 *Scope*—In this method, periodate is the oxidizing agent used to convert manganous into permanganate ion whose color can then be read in a photometer at a wavelength of 545 nm. This method is capable of determining small amounts of Mn as low as 10 ppm.

27.2 *Summary of Test Method*—The same sample solution prepared in the determinations of phosphorous by molybdovanadate (See 26.5.1 to 26.5.2) can be used for the determination of manganese by periodate. The acid solution is oxidized to permanganate by potassium periodate. Photometric measurement is made at 545 nm.

27.3 *Special Solutions*:

27.3.1 *Manganese Standard Solution* (1 mL to 50 µg Mn)—Dissolve 0.0500 g pure manganese (Mn) metal in 20 mL H_2SO_4(1 + 9) and dilute to 1 L with water.

27.3.2 *Nitric-Phosphoric Acid Mixture*—Add 800 mL HNO_3 and 200 mL H_3PO_4 to 400 mL of H_2O and dilute to 2 L.

27.4 *Preparation of Calibration Curve*:

27.4.1 Transfer 0, 1, 2, 3, 5 and 10 mL of manganese standard solution to six 150 mL beakers, respectively. Add 25 mL of acid mixture to each and heat but do not boil. While heating, add potassium periodate (KIO_3) crystals, a few milligrams at a time (about 0.3 g total), until the permanganic color is fully developed. Keep solution near boiling for 10 min after color develops; the total heating period should last about 30 min.

27.4.2 Allow to cool, transfer to a 50-mL volumetric flask, dilute to volume and mix. Read absorbance at 545 nm using the "0" standard (blank) in the reference cell and construct a calibration curve by plotting absorbance versus concentration of Mn in µg/mL.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

27.5 *Procedure*:

27.5.1 Weigh 2.0 g of prepared sample into a 250-mL beaker and dampen with about 5 to 10 mL of water. Add 10 mL HNO_3 and 20 mL $HClO_4$(See Note 32), heat on hot plate, and evaporate to heavy fumes of $HClO_4$. Cover and boil until solution is colorless or slightly yellow (10 to 15 min). Cool slightly and add 50 mL H_2O. Filter through retentive filter paper and wash thoroughly with hot H_2O (See Note 30). Reserve filtrate.

NOTE 32—If a special perchloric hood is not available, omit the use of $HClO_4$. Instead, evaporate to dryness twice with nitric acid and finally boil with 10 mL HNO_3 and 50 mL H_2O.

27.5.2 Transfer paper and contents to a platinum crucible and heat until paper chars. Ignite at a higher temperature until ash is white. Cool, expel SiO_2 with HF and H_2SO_4, evaporate to dryness (See Note 31) and fuse residue with Na_2CO_3. Cool, add 10 mL H_2O and 2 mL HNO_3 and warm to dissolve. Combine solution with filtrate reserved in 27.5.1 and transfer to a 100 mL volumetric flask. Dilute to volume and mix.

27.5.3 Transfer an aliquot containing <500 µg Mn to a 150 mL beaker. Add 25 mL of acid mixture, heat to near boiling and develop the permanganate color by small additions of KIO_3 as directed in 27.4.1. Cool the solution, transfer to a 50 mL volumetric flask, dilute to volume and mix.

27.5.4 Record the absorbance at 545 nm using the blank standard solution in reference cell as in preparation of standard curve, and compare against a set of standards similarly treated.

27.6 *Calculation*:

27.6.1 Calculate the percent Mn as follows:

$$\% \text{ Mn} = \frac{C \times D}{W \times 10^4} \quad (23)$$

where:

C = concentration of Mn in sample solution µg/mL determined from calibration curve,
D = dilution factor, and
W = g of sample.

27.7 *Precision and Bias*:

27.7.1 The number of laboratories, materials, and determinations in this study does not meet the minimum requirements for determining precision prescribed in Practice E 691:

	Test Methods C 25	Practice E 691 Minimum
Laboratories	4	6
Materials	5	4
Determinations	4	2

27.7.2 The following precision statements are provisional. Within five years, additional data will be obtained and processed which does meet the requirements of Practice E 691.

27.7.2.1 Precision, characterized by repeatability, *Sr* and *r,* and reproducibility, *SR* and *R,* has been determined for the following test method and materials to be:

Precision Statement for Test Method:		% Mn		Color	
Material	Average	*Sr*	*SR*	*r*	*R*
S-1145	0.0011	0.0004	0.0005	0.0011	0.0014
S-1143	0.0025	0.0005	0.0007	0.0014	0.0020
S-1142	0.0147	0.0010	0.0010	0.0028	0.0028
S-1141	0.0271	0.0012	0.0024	0.0034	0.0066
S-1144	0.1096	0.0072	0.0108	0.0200	0.0304

28. Available Lime Index

28.1 *Scope*—The available lime index of high-calcium quicklime and hydrated lime designates those constituents that enter into the reaction under the conditions of this specified test method, otherwise known as the "rapid sugar test method." The interpretation of results obtained by this test method shall be restricted by this definition.

28.2 *Summary of Test Method*—The sample is slaked and dispersed with water. The lime is solubilized by reaction with sugar to form calcium sucrate which is then determined by titration against standard acid using phenolphthalein as the indicator.

28.3 *Special Solutions*:

28.3.1 *Hydrochloric Acid, Standard* (1.000 *N*)—Prepare a solution by diluting 83 mL of HCl to 1 L with CO_2-free water. Standardization of sock solution should be performed on a regular basis at a minimum of once per month. For precision and bias information on standardization with Na_2CO_3 or Tris-(Hydroxymethyl) Amino-Methane see Practice E 200.

28.3.2 *Standardization of HCl with Na_2CO_3*:

28.3.2.1 Transfer approximately 20 g of primary standard anhydrous sodium carbonate (Na_2CO_3) to a platinum dish or crucible, and dry at 250 °C for 4 h. Cool in a desiccator.

28.3.2.2 Weigh accurately 4.4 g to the nearest 0.1 mg of the dried Na_2CO_3 and transfer to a 500-mL flask. Add 50 mL of CO_2-free water, swirl to dissolve the carbonate, and add two drops of a 0.1 % solution of methyl red in alcohol. Titrate with the HCl solution to the first appearance of a red color, and boil the solution carefully, until the color is discharged (See Note 29). Cool to room temperature, and continue the titration, alternating the addition of HCl solution and the boiling and cooling to the first appearance of a faint red color that is not discharged on further heating.

28.3.2.3 *Calculation*—Calculate normality as follows:

$$A = (B \times 18.87)/C \quad (24)$$

where:

A = normality of the HCl solution,
B = Na_2CO_3 used, g, and
C = HCl solution consumed, mL.

NOTE 33—This titration can also be performed potentiometrically with the aid of a glass electrode and a calomel electrode.

28.3.3 *Standardization of HCl with TRIS (THAM)—[Tris-(Hydroxymethyl) Amino-Methane]*:

28.3.3.1 Transfer an appropriate amount of primary standard tris-(hydroxymethyl) amino-methane to suitable dish or crucible and dry in a vacuum at 70 °C for 24 h (refer to Practice E 200). As an alternative, Tris can also be dried at 105 °C (± 5 °C) for 2 h in a regular laboratory drying oven. Cool in a desiccator to room temperature.

28.3.3.2 *Preparation of Mixed Indicator*—Mix 100 mg of Bromocresol Green with 2 mL 0.1 *N* NaOH and dilute with CO_2-free water to 100 mL. Dissolve 100 mg of Alizarin Red S in 100 mL CO_2-free H_2O. Mix equal portions of Bromocresol Green and Alizarin Red S solutions to form mixed indicator.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

28.3.3.3 Weigh approximately 8 g of TRIS to the nearest 0.1 mg and dissolve in 50 mL of CO_2-free water. Add 6 drops of mixed indicator (See Note 30) and titrate to a bright yellow end-point with acid.

NOTE 34—This titration can also be performed potentiometrically using a suitable pH meter to a pH of 4.70.

28.3.3.4 *Calculation*—Calculate normality as follows:

$$A = B/(0.121136 \times C) \quad (25)$$

where:

A = normality of the HCl solution,
B = Tris-(Hydroxymethyl) Amino-Methane used, g,
C = HCl solution consumed, mL.

28.3.4 *Phenolphthalein Indicator (4 %)*—Dissolve 4 g of dry phenolphthalein in 100 mL of 95 % alcohol.

28.3.5 *Sucrose Solution*—(40 g of pure cane sugar in solid form may be used per sample in place of a sugar solution.) Prepare a 40 % solution (w/v) using pure cane sugar and CO_2-free water in a large beaker and stir until dissolved. Add several drops of phenolphthalein indicator solution. Add 0.1 *N* NaOH solution dropwise with stirring until a faint pink color persists. Stock solution of sugar may be made for convenience; however, it should not be stored for more than two days. As an alternative the acidity of each lot of sugar can be determined, and a correction applied to the titration.

28.4 *Procedure*:

28.4.1 *Procedure for Quicklime*:

28.4.1.1 The sample as received at the laboratory shall be thoroughly mixed and a representative sample with minimum weight of 100 g shall be taken and pulverized to pass a No. 50 sieve for analysis. Weigh rapidly 2.804 g of the finely pulverized sample, brush carefully into a 500-mL Erlenmeyer flask containing about 40 mL of CO_2-free water (See Note 35), and immediately stopper the flask.

NOTE 35—Water should not be added to the sample because, especially with quicklime, there is a tendency for the material to cake and form lumps difficult to completely dissolve in the sugar solution later. On the other hand, if the lime is added to a little water, a better dispersion of the fine particles occurs, leading to a more rapid dissolution of the sample. It is possible that in the case of quicklime, some slaking action occurs to facilitate the dispersion and solution.

28.4.1.2 Remove the stopper. Place the flask on a hot plate and immediately add 50 mL of boiling CO_2-free water to the flask. Swirl the flask and boil actively 1 min for complete slaking. Remove from the hot plate, stopper the flask loosely, and place in a cold-water bath to cool to room temperature.

28.4.1.3 Add 100 mL of the neutralized sugar solution (or approximately 40 g of pure cane sugar). Stopper the flask, swirl, and let stand for 15 min to react. (Reaction time should not be less than 10 min nor more than 20 min.) Swirl at 5-min intervals during reaction. Remove stopper, add 4 to 5 drops of 4 % phenolphthalein indicator solution and wash down the stopper and sides of the flask with CO_2-free water.

28.4.1.4 When titrating (See Note 36), first add about 90 % of the acid requirement from a 100-mL buret. Finish the titration, more carefully at approximately one drop per second, to the first disappearance of the pink color, which persists for 3 s. Note the endpoint and ignore any further return of color.

NOTE 36—A mechanical stirrer may be used during the titration if desired. Put a clean magnetic stirrer bar into the flask and place the flask on the magnetic stirrer. Adjust to stir as rapidly as possible without incurring any loss by spattering. Unless the operator is familiar with previous analyses of the lime under test, and in cases where the available lime content varies to extremes, it is good practice to run a preliminary test by slow titration to determine the proper amount of acid required to neutralize the sample.

28.4.2 *Procedure for Hydrated Lime*—The procedure for determining $Ca(OH)_2$ is the same as for CaO with the exception that cold CO_2-free water is used and the boiling and cooling steps are omitted.

28.5 *Calculation*:

28.5.1 Calculate for CaO as follows:

$$\text{Available lime (CaO), } \% = N \times V \times 2.804/W \quad (26)$$

where:

N = normality of acid solution,
V = standard HCl used (1.000 *N*), mL,
W = weight of sample, g, and
2.804 = CaO, g, equivalent to 1 mL of standard acid × 100, or 1 mL of standard HCl = 1 % CaO if exactly 2.804 g of sample is used.

28.5.2 Calculate for $Ca(OH)_2$ as follows:

$$\text{Available lime } [Ca(OH)_2], \% = N \times V \times 3.704/W \quad (27)$$

where:

N = normality of acid solution,
V = standard HCl (1.000 *N*), mL,
W = weight of sample, g, and
,mdit> 3.704 = $Ca(OH)_2$, g, equivalent to 1 mL of standard acid × 100 or 1 mL of standard HCl = 1.32 % $Ca(OH)_2$ when exactly 2.804 g of sample is used.

28.6 *Precision and Bias*:

28.6.1 Twenty-four laboratories cooperated in the testing of three high calcium quicklimes and one high calcium hydrated lime thereby obtaining the repeatability (*r*) and reproducibility (*R*) (Practice E 691) data contained in Table 4.

28.6.2 The user is cautioned that the repeatability and reproducibility are considered adequate for the purposes of the test method. However, higher levels of MgO and nonreactive CaO increase the value of the repeatability (within lab) slightly and the reproducibility value (between labs) noticeably.

28.6.3 Due to the lack of a recognized industry standard, the bias of this test method has not been determined.

29. Free Silica

29.1 *Scope*—Free silica is usually present in the acid-insoluble residue of lime and limestone samples. This method is applicable to the determination of free silica when it exceeds 0.05 %.

TABLE 4 Precision Data (Results in % Available CaO)

Material	Average	*r*	*R*
Hydrated lime	71.967	0.367	0.963
Magnesian quicklime	88.495	0.479	1.784
Shaft kiln quicklime	94.393	0.398	1.405
Rotary kiln quicklime	94.438	0.337	1.092

www.technobetar.ir

29.2 *Summary of Test Method*—After dissolution of a large sample of lime or limestone, the insoluble matter including SiO_2 is separated, ashed, and the oxides fused with pyrosulfate. The silicic acid liberated from the clay minerals in the insoluble matter is dissolved in a hot solution of sodium hydroxide but the free silica is unaffected.

29.3 *Procedure*:

29.3.1 Weigh 5.0 g of the prepared sample in a 400-mL beaker, add 25 mL of HCl (1 + 1), and heat to a boil. Using a retentive paper, filter the insoluble matter including SiO_2 and wash several times with hot water. Discard the filtrate.

29.3.2 Place the paper containing the insoluble matter in a platinum crucible and char the paper without inflaming at low heat. Increase the heat to burn off the carbon, but do not exceed 600 ± 50 °C. Cool, add approximately 10 g of fused and powdered $KHSO_4$ or $K_2S_2O_7$ in the platinum crucible, and blend thoroughly with a small spatula. Fuse thoroughly over a gas burner, first by gradual heating to prevent loss of SO_3. When the fusion becomes quietly molten, finish the fusion at a dull red heat not over 800 °C.

NOTE 37—Do not continue heating to a point where salts begin to freeze on top of the melt and on the sides of the crucible because of the difficulty of subsequent solution.

29.3.3 Cool the crucible and its contents and dissolve the melt by heating with 150 to 200 mL of water in a 400-mL beaker. To the warm solution, cautiously add approximately 12 g of NaOH pellets a few at a time to dissolve the precipitated silicic acid (See Note 37). Digest on a hot plate for 30 min at 80 to 90 °C.

NOTE 38—Free silica is not transformed to silicic acid by the fusion and is not affected by the caustic treatment.

29.3.4 Filter quickly, using a retentive paper; thoroughly scrub and wash the beaker with hot water. Wash the filter paper and its contents ten times with hot water; five times with hot dilute HCl (1 + 1) to dissolve iron and other contaminants of the free silica, and finally five times with hot water or until free of acid. Transfer the paper and residue to a tared platinum crucible, ignite at 1000 °C to constant weight, cool in a dessicator, and weigh as free silica.

29.3.5 To the ignited and weighed residue add 2 drops of H_2SO_4(1 + 1) and approximately 10 mL of HF, evaporate to dryness, ignite and weigh (See Note 34). If the mass of the residue exceeds 0.001 g, the determination may have been improperly accomplished. Replicate determinations should then be made to verify the validity of the results, or the residue examined by X-ray diffraction to determine whether refractory or highly insoluble minerals are present.

NOTE 39—Occasionally the free silica is contaminated by compounds not decomposed during fusion or dissolved in the subsequent treatments. The residue then is treated with HF and sulfuric and SiO_2 expelled.

29.4 *Calculation*—Calculate the percent free silica as follows:

$$\text{Free silica, } \% = (A - B)/W \times 100 \quad (28)$$

where:

A = crucible + insoluble residue, g,
B = crucible minus SiO_2, g, and
W = sample, g.

29.5 *Precision and Bias*—The precision and bias of this test method have not been determined.

30. Unhydrated Oxides Calculated on As-Received Basis

30.1 *Scope*—From the analytical determinations made in accordance with the preceding sections, it is possible to calculate combined water, $CaCO_3$, and $CaSO_4$ in samples of lime and hydrated lime. Unhydrated oxides of MgO in hydrated lime can also be calculated.

30.2 *Summary of Test Method*—Determine the percent of free water, LOI, CO_2, SO_3, CaO, and MgO in accordance with the preceding sections. Calculate combined H_2O, calcium carbonate, calcium sulfate, and unhydrated magnesium oxide using the following procedures.

30.3 *Procedure*:

30.3.1 Calculate percentage of combined water in quicklime from the loss on ignition and CO_2 determinations, as follows:

$$\text{Combined } H_2O, \% = \% \text{ LOI} - \%(CO_2 + \text{FM}) \quad (29)$$

30.3.2 Calculate the percentage of combined water in hydrated lime from the LOI, CO_2, and free moisture (FM) determinations as follows:

$$\text{Combined } H_2O, \% = \% \text{ LOI} - \%(CO_2 + \text{FM}) \quad (30)$$

30.3.3 Calculate the percent unhydrated oxides on the as-received basis as follows (See Notes 40-42):

NOTE 40—The calculations involved in determining the percentage of unhydrated oxides on the as-received basis are illustrated in Table 5.

NOTE 41—This method for calculating the percentage of hydrated oxides is intended primarily for use with Type S hydrated lime.

NOTE 42—It is recognized that the results from this method of calculation may not be in strict accord with the actual composition of the material. Experience indicates, however, that these results provide an index to the performance of the material in practice. The value obtained by this calculation shall be reported to the nearest 0.5 %.

30.3.3.1 Calculate the CaO equivalents of the CO_2 and SO_3 as follows:

$$CO_2 \times 1.275 = \text{equivalent CaO } (A) \text{ as } CaCO_3 \quad (31)$$

$$SO_3 \times 0.700 = \text{equivalent CaO}(B) \text{ as } CaSO_4 \quad (32)$$

TABLE 5 Example of Calculation, Unhydrated Oxides

Compound	Values Determined From Chemical Analysis, %	Residual Values	Factors	Calculated Values, %
CO_2	0.40		× 1.275	= equivalent CaO = 0.51
SO_3	0.48		× 0.700	= equivalent CaO = 0.34
CaO	42.79 – (0.51 + 0.34 = 0.85)	= 41.94	× 0.3213	= equivalent H_2O = 13.48
H_2O	25.09 – 13.48	= 11.61	× 2.238	= equivalent MgO = 25.98
MgO	30.68 – 25.98			= unhydrated MgO = 4.70

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

30.3.3.2 Subtract the sum of these CaO equivalents from the total CaO:

$$\text{Total CaO} - (A + B) = \text{hydrated CaO}(C) \quad (33)$$

30.3.3.3 Calculate the H_2O equivalent of the remaining CaO as follows:

$$\text{Hydrated CaO } (C) \times 0.3213 = \text{equivalent } H_2O \ (D) \text{ as } Ca(OH)_2 \quad (34)$$

30.3.3.4 Subtract this value for H_2O (D) from the combined water as calculated in 30.3.1 and 30.3.2.

$$\text{Combined water} - H_2O \ (D) = \text{equivalent } H_2O \ (E) \text{ as } Mg(OH)_2 \quad (35)$$

30.3.3.5 Calculate the MgO equivalent of the remaining water (E) as follows:

$$H_2O \ (E) \times 2.238 = \text{equivalent MgO } (F) \text{ as } Mg(OH)_2 \quad (36)$$

30.3.3.6 Subtract this MgO equivalent (F) from the total MgO as determined from preceding sections to obtain the percentage of unhydrated MgO on the as-received basis.

$$\text{Total MgO} - \text{MgO equivalent } (F) = \textit{unhydrated MgO} \quad (37)$$

31. Calcium and Magnesium Oxide (Alternative EDTA Titration Method)

31.1 *Scope*—This test method is a rapid EDTA complexometric method for determining calcium and magnesium in lime and limestone products. Ordinarily the EDTA procedure is designed to follow routine separations, that is, single dehydration of silica and a single precipitation with NH_4OH of the combined oxides of iron and aluminum. For expediency, the assays can be run directly without prior separation of the combined oxides of iron and aluminum by using the complexing action of EDTA at appropriate pH levels.

31.2 *Summary of Test Method*:

31.2.1 In this test method, calcium and magnesium are determined by EDTA titration after separation of silica and the NH_4OH group during a routine analysis of lime and limestone. The assays may also be made after a direct HCl decomposition followed by removal of the silica and insoluble.

31.2.2 If interfering elements are present in large enough quantities to cause problems, the interferences may be suppressed by the addition of complexing or masking agents such as triethanolamine or cyanide.

31.2.3 For the determination of calcium, the solution is adjusted to a pH of 12 to 12.5 with KOH solution and titrated with EDTA to a blue end point using hydroxy naphthol blue as the indicator. Both CaO and MgO are then titrated from a solution buffered to pH 10 with $NH_3 \cdot NH_4Cl$ using Calmagite as the indicator. MgO is calculated by subtracting the EDTA equivalent to CaO present from the EDTA equivalent to CaO + MgO.

31.3 *Reagents*:

31.3.1 *EDTA Solution* (0.4 %)—Dissolve 4 g of disodium dihydrogen ethylenediamine tetraacetic acid in water and dilute to 1 L.

31.3.2 *Potassium Hydroxide, Standard Solution* (1 *N*)—Dissolve 56 g of KOH in 1 L of distilled water.

31.3.3 *Ammonia Buffer* (pH 10.5)—Dissolve 67.5 g of NH_4Cl in 300 mL of distilled water, add 570 mL of NH_4OH, and dilute to 1 L.

31.3.4 *Hydroxy Naphthol Blue* (calcium indicator)—Disodium salt of 1-(2-naphthol azo-3,6 disulfonic acid)2 naphthol-4-sulfonic acid on suitable carrier.

31.3.5 *Calmagite* (magnesium + calcium indicator)—1-(hydroxyl-4-methyl-2 phenylazo)-2 naphthol-4 sulfonic acid on a suitable carrier.

NOTE 43—Both the hydroxy naphthol blue and Calmagite indicators are manufactured by Mallinckrodt Chemical Works, St. Louis, MO. Each indicator is a diluted mixture of dye plus an inert carrier.

31.3.6 *Hydrochloric Acid* (1 + 1).

31.3.7 *Hydrochloric Acid* (1 + 9).

31.3.8 *Triethanolamine* (1 + 2).

31.3.9 *Potassium Cyanide Solution* (20 g/L)—Dissolve 2 g of KCN in 100 mL of water.

31.3.10 *Calcium Standard Solution* (1.00 mg CaO/mL)—Weigh 1.785 g of $CaCO_3$, primary standard grade. Dissolve in HCl (1 + 9) and dilute to 1 L with distilled water.

31.3.11 *Magnesium Standard Solution* (1.00 mg MgO/mL)—Dissolve 0.603 g of magnesium metal turnings in HCl and dilute to 1 L with distilled water.

31.4 *Apparatus*:

31.4.1 *Magnetic Stirrer* with light.

31.4.2 *Stirring Bar,* TFE-fluorocarbon-covered.

31.5 *Standardization*:

31.5.1 *Calcium*—Pipet 10 mL of standard CaO solution into an Erlenmeyer flask and add 100 mL of distilled water. To prevent precipitation of calcium, add about 10 mL of EDTA titrating solution. Adjust to pH 12 to 12.5 with about 15 mL of 1 *N* KOH solution and stir. Add 0.2 to 0.3 g of hydroxy naphthol blue indicator (See Note 44) and complete titration to a clear blue end point (See Note 45). Titrate three or more aliquots and use the average to calculate the titer of the CaO solution.

$$\text{CaO titer, mg/mL} = 10 \text{ mg CaO standard/mL EDTA titration} \quad (38)$$

NOTE 44—The amount of indicator is usually a matter of individual preference, but if Mallinckrodt reagents are used, the recommended dosages are considered the proper amounts to add for easy end point detection.

NOTE 45—The use of a magnetic stirrer with light may be very helpful in detecting the color change. The end point is the first definite blue color that remains stable for at least 30 s.

31.5.2 *Magnesium*—Pipet 10 mL of the 1.00-mg/mL standard MgO solution into an Erlenmeyer flask and add 100 mL of distilled water. Adjust to pH 10 with 10 mL of the ammonium chloride-ammonium hydroxide buffer solution, and add 0.3 to 0.4 g of Calmagite indicator (See Note 44). Titrate with disodium EDTA, noting the color change from a red to deep blue end point (See Note 45). Titrate three or more aliquots and use the average to calculate the magnesium titer.

$$\text{MgO titer, mg/mL} = 10 \text{ mg MgO standard/mL EDTA titration} \quad (39)$$

31.6 *Procedure*:

31.6.1 If using limestone, dry the sample at 110 °C to constant weight and cool to room temperature.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

31.6.2 Weigh 0.5 g of the dry sample into a 250-mL beaker, add 10 mL of HCl (1 + 1), and carefully evaporate to dryness on hot plate. Dissolve residue in 25 mL of HCl (1 + 9), dilute to about 100 mL with water, and digest at low heat for 15 min. Cool, transfer to a 250-mL volumetric flask, dilute to volume, mix, and let settle or filter using a medium textured paper.

31.6.3 Alternatively, if the standard procedure has been used to determine the silica and insoluble and iron and aluminum, the filtrate remaining after the precipitation of the iron and aluminum with ammonia can be used for the Ca and Mg EDTA determination. Continue the analysis as follows: Acidify the filtrate with HCl, transfer to a 250-mL volumetric flask, dilute to volume with distilled water, and mix.

31.6.4 *Calcium Oxide*:

31.6.4.1 Pipet a 20-mL aliquot from the 250-mL volumetric flask and transfer to an Erlenmeyer flask. Dilute to 150 mL with water, adjust the pH to 12 with about 30 mL of 1 *N* KOH solution, and stir.

NOTE 46—Precipitation of calcium hydroxide can be prevented, if necessary, by adding one half to one third of the estimated volume of disodium EDTA solution before the addition of the potassium hydroxide. Presence of a large precipitate can cause loss of sharpness in the end point.

31.6.4.2 If the sample is known to contain significant quantities (>1 %) of iron, manganese, and heavy metals (See Note 47), add 2 to 3 drops of 2 % potassium cyanide solution, or 10 mL of triethanolamine.

NOTE 47—If silica and phosphate or excessive amounts (>5 %) of iron and aluminum are present, they should first be removed by a double ammonia precipitation as in the standard procedure.

Warning—Cyanides should be used with utmost care because they can be very toxic compounds. They should be kept basic and prescribed disposal procedures used. Waste cyanide solutions must not be poured down laboratory sinks. Such solutions can be rendered relatively harmless by making them strongly basic, pH 12 or higher, with sodium hydroxide, adding calcium hypochlorite, and letting the solution stand for 24 h.

31.6.4.3 Add 0.2 to 0.3 g of hydroxy naphthol blue indicator (See Note 39) and titrate as in 36.5.1 to a clear blue end point (See Note 45).

31.6.4.4 *Calculation*:

$$\text{CaO, \%} = \text{CaO titer} \times \text{mL EDTA} \times 1.25/\text{weight of sample, g} \quad (40)$$

31.6.5 *Magnesium Oxide*:

31.6.5.1 Pipet a 20-mL aliquot of the acid solution from the 250-mL volumetric flask and transfer to an Erlenmeyer flask. Dilute with 100 mL of water, add about 20 mL of ammonia buffer to pH 10, and stir.

31.6.5.2 Add 2 to 3 drops of 2 % potassium cyanide solution, or 10 mL of triethanolamine and 1 drop of triethanolamine (**Warning**—See 31.6.4.2) (See Note 47). Add EDTA standard solution equivalent to calcium titration; then add approximately 0.4 g of Calmagite indicator (See Note 39).

31.6.5.3 Titrate to a blue end point with the 0.4 % EDTA solution (See Note 45).

31.6.5.4 The titration determines both the calcium and magnesium present in solution. Subtraction of the EDTA titration obtained for calcium from the total titration gives the titration value for magnesium.

31.6.5.5 *Calculation*:

$$\text{mL EDTA solution equivalent to MgO} = (\text{mL EDTA solution used in CaO + MgO titration}) - \text{mL} - \text{mLEDTA solution used in CaO titration}) \quad (41)$$

$$\text{MgO, \%} = \text{mL EDTA equivalent to MgO} \times \text{MgO EDTA titer} \times 1.25/\text{weight of sample, g} \quad (42)$$

TABLE 6 Precision of Calcium Oxide

Sample Tested	CaO Found	Repeatability 1 sigma	Reproducibility 1 sigma
A-1a	53.48	0.31	0.27
A-2b	30.98	0.28	0.41
L-1	53.92	0.29	0.26
P-1a	53.88	0.31	0.28
Pooled	. . .	0.30	0.31

TABLE 7 Precision of Magnesium Oxide

Sample Tested	MgO Found	Repeatability Within Laboratories	Reproducibility Between Laboratories
A-1a	1.58	0.19	0.18
A-2b	21.58	0.24	0.41
L-1	0.58	0.21	0.22
P-1a	1.45	0.23	0.24
Pooled	. . .	0.22	0.28

31.7 *Precision and Bias:*[7]

31.7.1 The precision of this test method was tested by ten laboratories using three limestone and one dolomite reference samples. The results shown in Tables 6 and 7 are summarized as follows:

31.7.1.1 The overall precision (1 sigma) between laboratories (reproducibility) for CaO is ± 0.31 absolute units.

31.7.1.2 The overall precision (1 sigma) between laboratories for MgO is ± 0.28 absolute units.

31.7.1.3 The overall precision (1 sigma) within laboratories (repeatability) for CaO is ± 0.24 absolute units.

31.7.1.4 The overall precision (1 sigma) within laboratories for MgO is ± 0.22 absolute units.

32. Total Carbon by the Direct Combustion-Thermal Conductivity Cell Method

32.1 This test method covers the determination of carbon in lime and hydrated lime samples having a carbon concentration in the range from 0.005 to 5 %.

32.2 *Summary of Test Method*—All the carbon in the sample is converted to CO_2 by combustion in a stream of purified oxygen using an induction furnace. Under some conditions, CO is formed and a catalyst furnace is used to convert it to CO_2. The products of combustion are swept into the carbon analyzer where the CO_2 is selectively absorbed by a molecular sieve. The CO_2 is later released and swept by a fresh stream of oxygen past a thermal conductivity cell which senses the amount of CO_2 present. The signal from the sensor is amplified and electronically converted to % C which is displayed on a digital readout panel.

[7] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C07-1000.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

32.3 *Apparatus*:

32.3.1 *Combustion Furnace and Carbon Determinator*—This unit is commercially available.

32.3.2 *Crucibles*—Use crucibles recommended by the manufacturer of the instrument.

32.3.3 *Oxygen Cylinder with Two-Stage Regulator.*

32.3.4 *Purifying Train,* consisting of a sulfuric acid tower, an absorption bulb containing Ascarite and another absorption bulb containing Anhydrone. A flowmeter precedes the induction furnace assembly.

32.3.5 *Catalyst Furnace,* to convert CO to CO_2.

32.3.6 *Combustion Tube with Built-In Jet.*

32.4 *Reagents*:

32.4.1 *Iron Chip Accelerator,* low-carbon.

32.4.2 *Copper-Tin Accelerator.*

32.5 *Preparation of Apparatus*:

32.5.1 Assemble the apparatus. Start the flow of oxygen at 1500 mL/min and the carrier gas flow at the rate recommended by the manufacturer of the apparatus.

32.5.2 Test the furnace and the analyzer to ensure the absence of leaks and make the required electrical power connections. Prepare the induction furnace and analyzer for calibration and sample analysis according to the manufacturer's manual of instructions.

32.5.3 After the instrument has been prepared for calibration, check the CO_2 collection time which should have an 80 to 90-s time duration. The collection time can be checked by operating without a sample. If it is outside of this range, make the necessary adjustment of the collect relay as provided for in the manual of instructions.

32.6 *Calibration*:

32.6.1 Select NIST steel calibration standards containing approximately 0.02 to 1 % carbon (See Note 48).

NOTE 48—The accuracy of this test method is dependent to a large extent on the accuracy of the methods used to certify the carbon concentration in the calibration standards as well as upon their homogeneity. Tests made on NIST steel standards have shown that they are sufficiently homogeneous to permit the use of samples as small as 20 mg.

32.6.2 Condition the analyzer if more than 2 h have elapsed since the last sample was run and determine the blank reading as follows:

32.6.2.1 Load into a crucible 1.5 g of iron chip accelerator and 1 g of tin-coated copper.

32.6.2.2 Proceed as directed in 32.7.1 to 32.7.4.

32.6.2.3 Repeat 32.6.2.1 and 32.6.2.2 a sufficient number of times to establish that low and consistent blank readings are obtained.

32.6.2.4 The normal blank reading should be 0.007 to 0.009. If it is out of this range, determine the cause, correct it, and repeat the steps as directed in 32.6.2.1 through 32.6.2.2.

32.6.3 *Calibration Curve*:

32.6.3.1 The calibration of the analyzer should be done using carbon standards that bracket the percent carbon in the samples estimated from previous tests, using the following guidelines:

% Carbon in Sample	High-Carbon Standard, %	Low-Carbon Standard, %
0.5–1	1.0	0.4
0.2–0.5	0.6	0.2
0.1–0.2	0.2	0.1
0.02–0.1	0.1	0.01

32.6.3.2 Treat each standard as directed in 32.7.1 to 32.7.4.

32.6.3.3 Select two standards, one slightly higher and the other slightly lower than the carbon concentration of the sample.

32.6.3.4 Run the high standard first and observe the reading. The carbon reading should be within ± 1 % of the standard carbon value plus the blank (See Note 49). If it is within this range, proceed to 32.6.3.7.

NOTE 49—For example, with a blank reading of 0.009, a carbon standard which has a standardized value of 0.428 % should read 0.433 to 0.441.

32.6.3.5 If the reading is out of this range, run a duplicate sample.

32.6.3.6 If the second sample has approximately the same value as the first sample, adjust the slope control (See Note 50) to bring the reading to within the tolerance of the standard.

NOTE 50—Not all manufacturers may have this particular feature in their instrument, in which case the manual of instructions supplied with each instrument should be adhered to very closely and the instructions followed.

32.6.3.7 Run a carbon standard that has a carbon value lower than the sample as directed in 32.6.3.1 to 32.6.3.3.

32.6.3.8 The reading should be within +1 % of the carbon value plus the blank (See Note 50).

32.6.3.9 If the reading is within tolerance range, proceed to sample analysis, 32.7.1 to 32.7.4.

32.6.3.10 If the reading is out of the tolerance range, run a duplicate sample. If the second sample has the same out of tolerance value as the first sample, repeat 32.6.3.4 to 32.6.3.9, readjusting the slope control to bring the high standard within the tolerance of the standard.

32.6.3.11 If the standards are still out of line, refer to the manufacturer's manual for instruction, determine the cause, correct it, and repeat the standardization procedure, 32.6.3.2 to 32.6.3.8.

32.7 *Procedure*:

32.7.1 Stabilize the furnace and analyzer as directed in 32.5.1 to 32.5.3.

32.7.2 Weigh duplicate samples to the nearest 1 mg, using the following guidelines:

Carbon Content, %	Sample Weight, g
0 to 0.1	1.000
0.1 to 2	0.500
2 to 5	0.250

32.7.3 Transfer the sample to a combustion crucible, add 1.5 g of iron chip accelerator and 1 g of the tin-coated copper accelerator. Place the crucible on the furnace pedestal, raise the pedestal into position, and lock the system. Start the flow of oxygen at 1500 mL/min, and flush the system for 30 s.

32.7.4 Start the cycle timer which energizes the furnace and starts the programmer, after having set it to provide a combustion cycle of 1 min. Using the variable transformer, manually control the plate current within the range from 350 to 450 mA. When the cycle is complete, remove and discard the crucible. Record the reading.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

32.8 *Calculation*—Subtract the value found for the blank in 32.6.2.3 from the reading found in 32.7.4 and record the net reading. Calculate the percentage of carbon as follows:

$$\text{Carbon, } \% = A/B \quad (43)$$

where:
A = net carbon content, %, and
B = sample mass, g.

32.9 *Precision and Bias*—The precision and bias of this test method have not yet been determined.

33. Calcium Carbonate Equivalent

33.1 *Scope*—The calcium carbonate equivalence (CCE) test is used to determine the neutralizing capability of a calcareous material and to report this value in terms of percent calcium carbonate equivalents (% $CaCO_3$).

33.2 *Significance and Use*—Calcareous materials such as crushed limestone, hydrated lime and pulverized slags (from the production of steel) have been used extensively as soil modifiers or agricultural liming materials. A measure of their neutralizing capability can be determined through the use of this method of test. Not all neutralizing components of acalcareous material may be beneficial, therefore, the chemical analysis is suggested.

33.3 *Apparatus*:

33.3.1 *pH Metre,* conforming to Sections 4 and 5 of Test Method E 70.

33.3.2 *Mechanical Stirrer.*

33.3.3 *Sieve,* No. 60 (250-µm).

33.4 *Reagents*:

33.4.1 *Preparation of Mixed Indicator*—Mix 100 mg of Bromocresol Green with 2 mL of 0.1 *N* NaOH and dilute with CO_2-free water to 100 mL. Dissolve 100 mg of Alizarin Red S in 100 mL CO_2-free H_2O. Mix equal portions of Bromocresol Green and Alizarin Red S solutions to form mixed indicator.

33.4.2 *Hydrochloric Acid,* Standard (1.0 *N*)—Prepare a 1.0 *N* solution of hydrochloric acid (HCl) and standardize. Refer to available lime index test method for procedure on standardization of hydrochloric acid. For further information on preparation and standardization of solutions see Practice E 200.

33.4.3 *Phenolphthalein Indicator Solution* (1 g/100 mL)—Dissolve 1.0 g phenolphthalein in 100 mL of alcohol.

33.4.4 *Sodium Hydroxide Standard Solution* (0.5V AN)—Dissolve 20 g of sodium hydroxide (NaOH) in 150 mL of carbon dioxide—free water. Cool the solution to 25 °C and dilute to 1 L. Prepare free from carbonates and store in a polyethylene bottle provided with a siphon tube and with guard tubes containing soda-lime, or other suitable device, to prevent absorption of carbon dioxide (CO_2) from the air:

33.4.4.1 Standardize against 1.0 *N* hydrochloric acid with three 50 mL aliquots using phenolphthalein solution as indicator. Take the average of the three results as the normality of the Sodium Hydroxide Standard Solution.

$$\text{Normality (NaOH)} = \frac{V_2 N_2}{V_1} \quad (44)$$

where:
V_1 = volume of NaOH Standard Solution,
V_2 = volume of HCl used to neutralize NaOH, and
N_2 = normality of HCl Standard Solution.

33.5 *Preparation of Sample*:

33.5.1 Weigh and dry the limestone and slag samples to constant weight at a temperature of 110 ± 5 °C. Record the as-received and dry weights in order to calculate moisture content. Use lime samples as received. Grind the sample to pass a No. 60 (250-µm) sieve, mix thoroughly, and store in airtight containers.

33.6 *Procedure*:

33.6.1 *Indicator Titration Method*—Using Table 8 as a guide (See Note 51), weigh the material, to the nearest 0.1 mg, and place into a 500-mL Erlenmeyer flask; add 100 mL of 1.0 *N* HCl and boil gently for 5 min. Cool, and titrate the excess acid with 0.5 *N* NaOH solution using phenolphthalein as indicator. Calculate CCE as described in 33.6.3.

33.6.2 *Potentiometric Titration Method* (applicable to agricultural liming materials containing large amounts of ferrous iron or coloring matter, but not to silicate materials)—Proceed as in 33.6.1 through "Cool. . .". Transfer to a 400-mL beaker and insert glass and calomel electrodes of a pH metre and a

TABLE 8 Recommended Sample Weight[A]

Sample Type	Formula	Purity, %	Theoretical C.C.E.	Sample Weight, g
Magnesium oxide	MgO	97	248.33	1.9
Dolomitic lime	CaO MgO	97	207.69	2.3
Calcium oxide	CaO	97	178.48	2.6
Dolomitic Type N hydrate	Ca(OH)2 MgO	98	175.01	2.6
Dolomitic Type S hydrate	Ca(OH)2 Mg(OH)2	98	151.21	3.0
Calcium hydroxide	Ca(OH)2	98	135.11	3.4
Dolomitic limestone	CaCO3 MgCO3	97	108.56	4.3
Calcium carbonate	CaCO3	97	100.00	4.6

[A] For those materials not listed in Table 8: To determine the amount of 1.0 *N* HCl required for neutralization, a preliminary titration using 2 g of sample (weighed to the nearest 0.1 mg) should be performed to a yellow end point using mixed indicator. Using the following formula, determine the sample weight need for testing and proceed to 33.6.1.

$$Wr, \text{ grams (g)} = \frac{Wu * 100}{Vu + 10}$$

where:
Wr = sample weight required for testing, g,
Wu = sample weight used in preliminary titration, g, and
Vu = volume of 1.0*N* HCl used in preliminary titration, mL.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

mechanical stirrer. Stir at a moderate speed to avoid splash. Deliver from a buret the 0.5 *N* NaOH solution rapidly to pH 5, then dropwise until the solution attains pH 7 and remains constant for 1 min while stirring. Report as $CaCO_3$ equivalent as described in 33.6.3.

33.6.3 Calculation of Percent Calcium Carbonate Equivalence:

33.6.3.1 *Dry Basis*:

$$\% \ CaCO_{3(dry)} = \frac{5.0045\ (V_1N_1 - V_2N_2}{W} \quad (45)$$

where:

V_1 = HCl solution used, mL,
N_1 = normality of HCl solution,
V_2 = NaOH solution required for titration of excess acid, mL,
N_2 = normality of NaOH solution, and
W = sample weight, g.

33.6.3.2 *As-received basis (limestone only)*:

$$\% \ CaCO_{3(as\ received)} = [1 - (A - B/A)] \times \% \ CaCO_{3(dry)} \quad (46)$$

where:

A = as received sample weight from 33.5.1, and
B = dry sample weight from 33.5.1.

34. pH of Alkaline Earth Solutions

34.1 *Scope*—This method covers the electrometric pH analysis of solutions made from a variety of lime, hydrate, and limestone-bearing materials.

34.2 *Summary of Test Method*—In this test method a sample of material is mixed with CO_2-free deionized water so that the pH of the solution is determined electrometrically. To ensure that an accurate measurement of pH is obtained for samples with a pH greater than 11.5, it is critical that all samples and buffer solutions be at 25.0 °C when measured.

34.3 *Special Apparatus*:

34.3.1 *pH Metre*—A commercially available pH metre capable of calibration with a minimum of two different buffers (See Note 51).

NOTE 51—It is necessary that the pH metre be equipped with a combination pH electrode as well as a temperature compensation probe. It is strongly recommended that a combination pH and temperature compensation probe be used.

34.3.2 *Constant Temperature Water Bath*—The water bath should be large enough to hold all samples and buffer solutions necessary to perform this method.

34.4 *Special Solutions*:

34.4.1 *Potassium Chloride Solution (0.2 M)*—Dry reagent grade KCl crystals at 110 °C for 1 h. Dissolve 14.91 g of the dry KCl in CO_2-free deionized water and dilute to 1 L.

34.4.2 *Sodium Hydroxide Solution (0.2 M)*—Dissolve 8.00 g of NaOH in CO_2-free deionized water and dilute to 1 L. Standardize this solution with potassium acid phthalate using phenolphthalein as the indicator.

34.4.3 *Hydroxide-Chloride Buffer Solution (pH 13.0 at 25.0 °C)*—Dilute 25.0 mL of the KCl solution and 66.0 mL of the NaOH solution to 100 mL with CO_2-free deionized water.

34.4.4 *Phenolphthalein Indicator*—Dissolve 4 g of dry phenolphthalein in 100 mL of 95 % alcohol.

34.4.5 Commercially available pH buffer solutions, pH 7 and pH 10.

34.5 *Standardization of Sodium Hydroxide Solution*:

34.5.1 *Initial Standardization*—Transfer 50.0 mL of the sodium hydroxide solution to be standardized to a well rinsed 50-mL Class A buret by means of a pipette. Accurately weigh out 8.0 ± 0.1 g of reagent grade potassium hydrogen phthalate which has been dried in an oven at 110 °C for 1 h. Record the weight to the nearest 0.1 mg, then quantitatively transfer the weighed material into a 400-mL beaker. Add 185 mL of CO_2-free deionized water which is at a temperature of 26.0 ± 2.0 °C. Stir this mixture gently until all of the crystals dissolve. Add five drops of the phenolphthalein indicator solution and proceed to titrate the prepared standard with the sodium hydroxide solution to be standardized. Titrate to an endpoint of light pink which will persist for at least 6 s.

34.5.2 *Calculation of Sodium Hydroxide Normality*—The normality of the sodium hydroxide solution can be calculated from the following equation:

$$\text{Normality of NaOH} = \frac{\text{Wt. of potassium hydrogen phthalate}}{\text{mL of NaOH} \times \text{factor of } 0.204228} \quad (47)$$

This preliminary standardization may reveal the necessity for either dilution with CO_2-free deionized water or the 0.2 molarity specified.

34.5.3 *Correction if Base is "too weak"*—If the molarity (normality) is determined to be too weak, it can be adjusted by the addition of additional sodium hydroxide. An example of this calculation follows. If 1.0 L of 0.1979 N solution needs to be strengthened to 0.2000 N, calculate how many grams of sodium hydroxide need to be added as follows:

$$\begin{aligned} &1.0\ L \times 0.1979\ M = 0.1979\ \text{mole} \\ &0.2\ M - 0.1979\ M = 0.0021\ M \\ &NaOH = 39.997\ \text{g/mole} \\ &39.997\ \text{g/mole} \times 0.0021\ \text{mole} = 0.0830\ \text{g needed} \end{aligned} \quad (48)$$

After the addition of additional sodium hydroxide is completed, recheck the standardization as specified in section 34.4.

34.5.4 *Correction if Base is "too strong"*—If the molarity (normality) is determined to be too strong, it can be adjusted by the addition of CO_2-free deionized water. An example of this calculation follows. If 1.0 L of 0.2019 N solution needs to be weakened to 0.2000 N, calculate how many millilitres of CO_2-free deionized water need to be added as follows:

$$\begin{aligned} &1.0\ L \times 0.2019\ M = 0.2019\ \text{mole} \\ &0.2019 - 0.200 = 0.0019\ L \text{ or } 1.9\ mL \text{ of } CO_2 - \\ &\text{free deionized water needed} \end{aligned} \quad (49)$$

After the addition of additional CO_2-free deionized water is completed, recheck the standardization as specified in section 34.5.

34.6 *Calibration of pH Metre*—Due to the wide variety of commercially available pH equipment, a detailed calibration procedure cannot be incorporated into this test method. Follow the manufacturer's instructions for calibration of your particular equipment.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

34.6.1 Using the appropriate combination of the commercially available pH 7 and pH 10.0 buffers, and the Hydroxide-Chloride buffer (pH 13.0), choose the pair of buffers which best brackets the pH of the sample being tested. Standardize your pH metre in accordance with the manufacturer's instructions. For samples with pH less than 11.5, the temperature of the samples and buffers should be kept at 25.0 ± 3.0 °C (See Note 53).

NOTE 52—For alkaline solutions in this pH range the temperature does not cause errors to the extent that it does with samples with a pH in excess of 11.5, therefore the temperature is not as critical.

For samples with a pH greater than 11.5, it is imperative that all solutions be at 25.0 ± 0.1 °C while they are being measured. If all buffers and test solutions are not within this range, due to the high pH being measured, large errors in the measured pH will occur. This can easily be accomplished by the use of a constant temperature water bath (See Note 54).

NOTE 53—In strongly alkaline solutions, especially above pH 12, the concentration of hydroxide ions is so high that the small amount of hydrogen ions produced by the ionization of water is sufficient to change the pH appreciably with temperature.

34.7 *Procedure—Materials with pH Less than 11.5*:

34.7.1 Weigh 10.0 g of the prepared sample and record the weight to the nearest 0.1 mg. Quantitatively transfer the weighed material into a 250-mL Erlenmeyer flask containing 200 mL of CO_2-free deionized water. Add a magnetic stir bar, immediately stopper the flask with a rubber stopper, and stir for 30 min.

34.7.2 Let the solution stand for at least 30 min to allow the suspended material to settle out from the suspension, as well as to allow the sample temperature to stabilize at 25.0 ± 3.0 °C. A constant temperature water bath may be necessary to obtain the desired temperature range.

34.7.3 Once the temperature of the sample is stabilized at 25.0 ± 3.0 °C, using a 50-mL transfer pipette, transfer 50 mL of the settle solution to a 100-mL beaker containing a magnetic stir bar.

34.7.4 Slowly stir the sample solution using a magnetic stirrer. Using a previously standardized pH metre, standardized in accordance with section 34.6, quickly measure the pH of the sample. Report the pH to four significant figures.

34.8 *Procedure—Materials with pH of 11.5 and greater*:

34.8.1 Weigh 10.0 g of the prepared sample and record the weight to the nearest 0.1 mg. Quantitatively transfer the weighed material into a 250-mL Erlenmeyer flask containing 200 mL of CO_2-free deionized water. Add a magnetic stir bar, immediately stopper the flask with a rubber stopper, and stir for 30 min.

34.8.2 Place the sample solution into a constant temperature water bath set at 25.0 °C. Let the solution stand for at least 30 min to allow the suspended material to settle out from the suspension as well as to allow the sample temperature to stabilize at 25.0 ± 0.1 °C.

34.8.3 Once the temperature of the sample is stabilized at 25.0 ± 0.1 °C, using a 50-mL transfer pipette, transfer 50 mL of the settled solution to a 100-mL beaker containing a magnetic stir bar.

34.8.4 Slowly stir the sample solution using a magnetic stirrer. Using a previously standardized pH metre, standardized in accordance with section 34.6, quickly measure the pH of the sample solution (See Note 53). It is imperative that the temperature of the test solution remain at 25.0 ± 0.1 °C during the pH measurement. If needed, the pH measurement should be carried out in a constant temperature water bath. Report the pH to four significant figures.

34.9 *Precision and Bias*:

34.9.1 The number of laboratories, materials, and determinations in this study does meet the minimum requirements for determinating precision prescribed in Practice E 691:

	Test Methods C 25	Practice E 691 Minimum
Laboratories	7	6
Materials	12	4
Determinations:	3	2

34.9.2 *Precision Statement for Test Method: pH*—Precision, characterized by repeatability, *Sr* and *r,* and reproducibility, *SR* and *R,* has been determined for the following materials to be:

Materials	Average	*Sr*	*SR*	*r*	*R*
Sample A kiln dust	12.3817	0.0069	0.2791	0.0194	0.7814
Sample B waste lime	12.2998	0.0297	0.4004	0.0831	1.1210
Sample C dolo hydrate	12.4073	0.0123	0.2408	0.0345	0.6741
Sample D dolo lime	12.3942	0.0177	0.2785	0.0495	0.7799
Sample E –325 stone	11.2199	0.0274	0.3355	0.0766	0.9393
Sample F cyclone dust	12.4090	0.0164	0.2336	0.0459	0.6541
Sample G bottom ash	12.1948	0.0120	0.4049	0.0336	1.1338
Sample H fly ash	9.6776	0.0557	0.3821	0.1559	1.0699
Sample I fly ash	11.3193	0.0143	0.2191	0.0402	0.6136
Sample J hydrate	12.4111	0.0244	0.2994	0.0684	0.8384
Sample K h. hyd. lime	12.5477	0.0069	0.1875	0.0193	0.5249
Sample L quicklime	12.4331	0.0260	0.1767	0.0728	0.4949

35. Total Carbon and Sulfur by the Combustion/Infrared Detection Method

35.1 *Scope*:

35.1.1 This test method is for the determination of carbon or sulfur, or both, in lime and limestone. This test method has also been adapted for use with kiln flue dusts. This test method covers the determination of carbon and sulfur in an acceptable concentration range from 0.01 to 13 % carbon and from 0.005 to 3 % sulfur.

35.1.2 Hydrated lime, hydroxides, and samples with high moisture cannot be suitably analyzed for sulfur using an induction furnace unit. Significant portions of SO_2 will be trapped in the dust filter which will be moist due to the water released or produced from the combustion. These samples must be analyzed on a resistance-furnace-type unit. Carbon results will not be similarly effected. Because of the high moisture content in the post-combustion gases, moisture filters must be checked often, and when needed, changed.

35.1.3 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

35.2 *Summary of Test Method*:

35.2.1 A sample of lime, limestone, or kiln flue dust is weighed into a ceramic crucible, accelerators are added, and the crucible is placed in the furnace. In a pure oxygen environment at the high temperatures generated by the furnace,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the sample is fluxed and oxidized converting carbon into CO/CO_2 and sulfur into SO_2. The combustion gases are swept through a drying tube to remove the combustion moisture and then swept toward the analyzer. In the analyzer, the gas stream passes through the carbon and sulfur infrared detection cells where measurement occurs.

35.2.2 Both carbon and sulfur are calibrated against a reference material or standard with known carbon and sulfur concentrations. This is to compensate for characteristics of a given apparatus, and for the blank due to accelerators and crucibles.

35.3 *Apparatus*:

35.3.1 *Furnace*:

35.3.1.1 *Induction*—The induction furnace works by supplying power to an inductor coil, which interacts with the sample and accelerators in a ceramic crucible. The power can be controlled by the voltage to the coil and the accelerators used in combusting the sample. Some instruments are supplied with a rheostat used to control the power input to the induction coil. This is used to avoid heating some types of samples too rapidly during the early stages of combustion. Combustion takes place in an oxygen stream, which carries the combustion products through various dust and moisture traps to a detector.

35.3.1.2 *Resistance*—The resistance furnace is an open-ended combustion system that provides an oxygen environment in two separate areas. A purge flow of oxygen around the front of the combustion area provides an oxygen blanket to keep the atmosphere out while acting as a primary source for combustion. The second oxygen flow is delayed to start after the majority of the sample has been combusted and provides a direct lance flow of oxygen onto the sample to combust the remaining sample material.

35.3.2 *Detector*—The detector shall consist of one or more infrared solid-state absorption detectors for carbon or sulfur, or both. The detector may be packaged with the furnace unit as long as interference does not occur during analysis.

NOTE 54—Halogens can be a source of problems. If they are, or are suspected to be, present, it is suggested that a halogen trap be used.

35.3.3 *Combustion Crucibles*—The crucibles must be of adequate thickness and capacity to retain the molten slag and have a sulfur blank as low and consistent as possible.

Warning—There is an explosion hazard associated with the analysis of coal and coke in an induction furnace. Flammable gasses may collect in the IR cell within the closed system. These types of materials should be analyzed in a resistance furnace. See the manufacturer's instructions and cautions before analyzing any samples.

Warning—It is extremely dangerous to change the oscillator tube in the induction furnace electrical cabinet. This should only be done by trained personnel. Serious injury or death can result. See manufacturer's instructions and cautions before attempting to change the oscillator tube.

35.4 *Reagents*—Use reagents recommended by the instrument manufacturer or their equivalent.

35.5 *Calibration*:

35.5.1 *Calibration Standard*—This test method and instrument must be calibrated daily or as indicated by check standards by using a standard of known carbon and sulfur content.

35.5.2 *Check Standard*—The instrument calibration must be validated on a regular basis (See 35.6.3.6) using a check standard. The check standard is used to determine the shift-to-shift variations in the test method and to verify that the electronics are working properly. The check and calibration standard cannot be the same standard. The standards must have a known carbon or sulfur content, or both, either as determined by a reference method, such as the Total Gravimetric Sulfur Method (See Section 24), or certified upon purchase traceable to a nationally recognized standard.

35.6 *Procedure*:

35.6.1 *Instrumental Setup*—Clean and perform routine maintenance on furnace and detector units in accordance with recommended procedures in the manufacturer's operating manual. It is recommended that a minimum of three conditioning samples be analyzed before instrument calibration.

35.6.2 *Calibration Procedure*:

35.6.2.1 Prepare blanks, analyze, reset instrument blank values, and record results. Check with previous blank values and if necessary repeat. Prepare calibration samples, analyze, reset instrument values, and record results.

35.6.2.2 It is recommended that a check standard be prepared and analyzed on a routine basis (See 35.6.3.6). This is to verify that routine samples tested during a specific interval are accurate according to the last instrument calibration.

35.6.2.3 Run laboratory samples as specified in 35.6.3.

35.6.3 *Sample Procedure*:

35.6.3.1 Weigh samples to the nearest 0.1 mg in accordance with the manufacturer's instructions for a specific instrument.

NOTE 55—It has been found through round-robin studies that the practice of pre-igniting samples at 1000 °C causes erratic recovery of sulfur. This practice should not be used.

35.6.3.2 Place the sample in the instrument and perform the analysis.

35.6.3.3 Analysis time is generally 65 s. This can be determined by watching the integration time of materials, and finding out what is a normal time for the type of sample you are running. If analysis time for sulfur exceeds the normal expected time, then changing of the Anhydrone tube is recommended as moisture absorption/desorption of SO_2 may be occurring. Be cautious about the variability of instruments and materials. It is possible to have bimodal curves that indicate a late release of sulfur. When in doubt, check the instrument with a material of known concentration.

NOTE 56—An anhydrone tube that has collected moisture or particulates may "cake" and cause your analysis time to increase. When operating the instrument, you can also expect the analysis time to increase due to dust and moisture from combustion of the sample. The tube should be cleaned, or replaced, at regular intervals.

35.6.3.4 Inspect the crucible for a proper burn. A rough, bumpy surface or appearance of noncombustion indicates that the furnace temperature was too low.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

35.6.3.5 After each analysis, record results and continue. It is recommended that samples be saved until results can be verified by a check standard.

35.6.3.6 Analyze the check standard after a minimum of every 10 samples to verify instrument performance. If the analysis of the check standard is not within tolerance (See Note 57), then find the cause and recalibrate.

NOTE 57—For purposes of this procedure, tolerance can be defined as results which meet the published certified value of the standard within the published standard deviation of the standard's certified value. The use of NIST traceable standards or comparable is recommended.

35.7 *Precision and Bias*—The precision and bias of this test method have not yet been determined.

HISTORICAL ASTM METHODS

X1. TOTAL IRON BY THE POTASSIUM PERMANGANATE TITRATION METHOD

INTRODUCTION

The following test methods have been published as information only and are a collection of classical methods that had historically been widely used by the industry. Because they are presently of limited use, they have been deleted from the main body of reference test methods. Since some laboratories may still wish to perform these analyses, they have been placed in these appendixes. The precision and bias testing has not been performed for these methods. Therefore, users are advised to develop their own laboratory precision and to check against standard reference materials. Subcommittee C07.05 encourages comments and evaluation of these methods.

X1.1 *Scope*—This test method permits a more accurate analysis of the trace amounts of iron that may be present because a larger sample is used.

X1.2 *Summary of Test Method*—The sample is dissolved in HCl and the SiO_2 is dehydrated and separated from the soluble salts by filtration. The small amount of iron left in the insoluble residue is dissolved with sulfuric acid after SiO_2 is expelled with HF, and the recovered iron is combined with the bulk of the iron in the main filtrate. Iron is reduced with $SnCl_2$ and titrated with $KMnO_4$ solution.

X1.3 *Special Solutions:*

X1.3.1 *Manganese Sulfate Solution* (70 g/L)—Dissolve 70 g of crystalline manganese sulfate ($MnSO_4$) in 500 mL of water. Add 140 mL H_3PO_4 and 130 mL H_2SO_4. Dilute to 1 L.

X1.3.2 *Potassium Permanganate, Standard Solution* (0.05 *N*):

X1.3.2.1 Dissolve 1.60 g of potassium permanganate ($KMnO_4$) in 1 L of water and boil gently in a flask for 20 to 30 min. Cool, dilute again to 1 L, stopper, and allow to stand for several days in the dark. Filter through purified asbestos or a wad of glass fiber and standardize against the National Institute of Standards and Technology's standard sample 40C, sodium oxalate ($Na_2C_2O_4$), or equivalent in accordance with X1.3.2.2 through X1.3.2.4.

NOTE X1.1—Alternatively, potassium dichromate may be used in place of potassium permanganate as in the procedure of 13.4.

X1.3.2.2 Transfer 0.15 g of the standard sodium oxalate, dried at 105 °C, to a 400-mL beaker. Add 250 mL of diluted H_2SO_4(5 + 95), which has been previously boiled for 10 min and cooled to 27 ± 3 °C. Stir until the oxalate has dissolved. Add 40 to 42 mL of the standard $KMnO_4$ solution at the rate of 25 to 30 mL/min, while stirring slowly. Let stand until the pink color disappears (about 60 s).

NOTE X1.2—If the pink color should persist because of the addition of too much $KMnO_4$ solution, discard and begin again, adding a few millilitres less of the $KMnO_4$ solution initially.

X1.3.2.3 Heat the contents of the beaker to 60 °C and complete the titration at this temperature by adding $KMnO_4$ solution until a slight pink color persists for 30 s. Add the last 0.5 to 1 mL dropwise, allowing each drop to become decolorized before the next one is added.

X1.3.2.4 One millilitre of standard $KMnO_4$ solution will be approximately equivalent to 0.004 g of ferric oxide (Fe_2O_3). Determine the exact Fe_2O_3 equivalent of the solution from the following:

$$N=(W/V)\times 14.925 \quad \text{(X1.1)}$$

where:

N = normality of $KMnO_4$ solution,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

W = sodium oxalate, g,
V = $KMnO_4$ solution used to titrate the sodium oxalate solution, mL, and
14.925 = sodium oxalate equivalent to 1 mL of 1 *N* $KMnO_4$ solution, g.

Fe_2O_3 equivalent of $KMnO_4 = N \times 0.07984$, where 0.07984 = g Fe_2O_3 equivalent to 1 mL of 1 *N* $KMnO_4$ solution.

X1.4 *Procedure:*

X1.4.1 Weigh 2 to 5 g (depending upon the amount of iron present) of the properly prepared sample into a beaker and add 25 mL of HCl (1 + 1). After the reaction ceases, evaporate the solution to dryness. Add 50 mL of HCl (1 + 4), heat to dissolve the salts, filter the insoluble matter including SiO_2 using a medium-textured paper, then wash the paper and contents several times with hot water. Retain the filter paper. Heat the solution to boiling, add a few drops of methyl red indicator, and precipitate the iron by adding enough NH_4OH to change the color of the indicator from red to distinct yellow. Allow the precipitate to settle slightly, filter, and wash using hot water. Dissolve contents of the paper by placing paper and contents in 50 mL of hot HCl (1 + 3). Filter into a clean beaker and wash. Reserve filtrate.

X1.4.2 Place the paper containing the insoluble matter from the evaporated HCl solution in a platinum crucible. Char the paper without inflaming, at low heat, increase the heat to ash the paper, and ignite at 1000 °C for 15 min. Cool, add 1 mL of H_2SO_4 and 10 to 15 mL of HF, and evaporate to fumes of sulfur trioxide. Cool, dilute the contents of the crucible with water, and warm to dissolve salts. Transfer the acidified solution to the main solution containing the bulk of the iron.

X1.4.3 Heat the solution to near boiling. Reduce the iron by adding $SnCl_2$ dropwise from a pipet, while swirling the beaker constantly, until the yellow color of the ferric iron just disappears (See Note 21). Add 2 or 3 drops of $SnCl_2$ in excess, but no more. Cool the beaker quickly in running water, then add all at once 10 mL of $HgCl_2$ solution. Stir and allow to stand for 3 to 5 min (See Note 22). Transfer with washing to a 600-mL of 1-L beaker containing 300 mL of cold water and 25 mL of the $MnSO_4$ solution. Titrate with standard 0.05 *N* $KMnO_4$ solution, added very slowly while stirring constantly, until a permanent pink end point is obtained. A blank should also be determined.

X1.5 *Calculation*—Calculate the percent iron oxide (Fe_2O_3) to the nearest 0.01 % as follows:

$$Fe_2O_3, \% = (A \times B)/C \times 100 \quad \text{(X1.2)}$$

where:
A = 0.05 *N* $KMnO_4$ solution used in titration, mL,
B = Fe_2O_3 equivalent of $KMnO_4$, and
C = sample weighed, g.

X1.6 *Precision and Bias*—The precision and bias of this test method have not been determined.

X2. STRONTIUM OXIDE BY THE GRAVIMETRIC SULFATE (ETHER) METHOD

X2.1 *Scope*—There may be certain applications that require a separate determination of strontium content or an exact determination of calcium. This test method is designed to determine the SrO present which will allow a correction for the percent CaO as obtained in previous sections.

X2.2 *Summary of Test Method*—The alkaline earth oxides are converted to nitrates. The different solubilities of calcium and strontium nitrate in absolute alcohol and ether are used to separate the two metals from each other. After filtration, the strontium nitrate precipitate is dissolved with water and the strontium precipitated with H_2SO_4 filtered, ignited, and weighed as strontium sulfate ($SrSO_4$).

X2.3 *Procedure:*

X2.3.1 Transfer the weighed oxides obtained in the gravimetric determination of calcium oxide (See Section 5.1.4) to a small flask of 20-mL capacity and dissolve in HNO_3. Evaporate to dryness and heat at 150 to 160 °C. Treat the thoroughly dried nitrates with as little (rarely over 2 mL) of a mixture of equal parts of absolute alcohol and ether as may be needed to dissolve the calcium salt, hastening solution by occasional, gentle agitation. After standing overnight in the stoppered flask, collect the insoluble matter on the smallest possible filter and wash with more of the above mixture of alcohol and ether.

Warning—Ethers tend to form peroxides by air oxidation on standing which are highly explosive. Peroxide containing ethers should not be distilled unless the peroxide is first destroyed by a suitable agent such as sodium sulfate or ferrous sulfate and should not be allowed to stand indefinitely in the laboratory.

X2.3.2 Let the filter air dry, then pass a few millilitres of hot water through the filter to dissolve the strontium nitrate. A few tenths of a milligram of residue may remain, consisting of material other than lime or alkaline earth, whose mass should therefore be deducted from the mass of the lime determined by the gravimetric method (See Section 16).

NOTE X2.1—This correction is unnecessary if it can be shown that the impurities are derived from the glass of the small flask in which the nitrates of calcium and strontium were evaporated.

X2.3.3 To the solution of strontium nitrate, in a small beaker add a few drops of H_2SO_4 and a quantity of alcohol equal to the volume of the nitrate solution. The precipitate of strontium sulfate is allowed to develop and settle at room temperature for a period of 12 h.

X2.3.4 Filter the $SrSO_4$ on a small filter paper, and wash with 50 % alcohol. Ignite at low temperature, cool, moisten with dilute H_2SO_4(1 + 1), evaporate to dryness, again ignite, and weigh as strontium sulfate ($SrSO_4$). The sulfate may be tested spectroscopically for traces of calcium and barium if it is considered necessary.

X2.4 *Calculation:*

X2.4.1 Calculate the mass of strontium oxide as follows:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$$SrO, \% = (A/B) \times 56.41 \quad (X2.1)$$

where:

A = mass of $SrSO_4$,
B = original mass of sample, g, and
56.41 = molecular ratio of SrO to $SrSO_4$ × 100.

X2.4.2 Deduct the percent SrO from the percent CaO determined in Section 17.

X2.5 *Precision and Bias*—This test method was originally approved for publication before the inclusion of precision and bias statements within standards was mandated. The user is cautioned to verify by the use of reference materials, if available, that the precision and bias of this test method are adequate for the contemplated use.

X3. PHOSPHORUS BY THE TITRIMETRIC METHOD

X3.1 *Scope*—This is a titrimetric test method for determining phosphorus in samples of limestone, quicklime, or lime hydrate. A fairly large sample weight is required because this test method is not sensitive enough for an accurate analysis at the low levels of phosphorus frequently encountered in limestone rock.

X3.2 *Summary of Test Method*—The sample is dissolved in dilute nitric acid, the solution filtered, the residue fused with a little sodium carbonate and its nitric acid solution added to the other. An HF-HNO_3 treatment is included if the rock contains more than 3 % SiO_2. Ammonium molybdate is added to the nitric acid solution to precipitate phosphorus as ammonium phosphomolybdate. The phosphomolybdate is dissolved in an excess of a standard solution of sodium hydroxide which is then back-titrated with standard acid in the presence of phenolphthalein indicator.

X3.3 *Special Solutions:*

X3.3.1 *Ammonium Molybdate Solution:*

X3.3.1.1 *Solution A*—Add 400 mL of nitric acid to 600 mL of water. Mix and cool.

X3.3.1.2 *Solution B*—Dissolve 118 g of 85 % molybdic acid with 400 mL of water and add 80 mL of NH_4OH. Cool.

X3.3.1.3 Add Solution B to Solution A slowly with constant stirring, let solution stand for 24 h. Filter immediately before using.

X3.3.2 *Potassium Nitrate Solution* (10 g/L)—Dissolve 10 g of potassium nitrate (KNO_3) in water freshly boiled to expel CO_2 and cooled. Dilute to 1 L.

X3.3.3 *Sodium Hydroxide, Standard Solution* (0.3 *N*)—Dissolve 12 g of sodium hydroxide (NaOH) in 1 L of water that has been freshly boiled to expel CO_2, and cooled. Add 10 mL of a freshly filtered, saturated solution of barium hydroxide $Ba(OH)_2$ (See Note X3.1). Shake the solution frequently for several hours and filter it. Store in a stoppered flask protected from the CO_2 of the air by means of a guard tube packed with Ascarite. Standardize against standard acid phthalate such as NIST Standard Sample No. 84 or benzoic acid, NIST Standard Sample No. 39 furnished by the National Institute of Standards and Technology[4] , as follows:

NOTE X3.1—$Ba(OH)_2$ precipitates the carbonate as insoluble $BaCO_3$.

X3.3.3.1 Lightly crush 5 to 6 g of standard acid potassium phthalate to a fineness of approximately 10 mesh and dry for 2 h at 100 °C. Place in a small glass-stoppered container and cool in a desiccator.

X3.3.3.2 Accurately weigh about 1 g of the dried standard and transfer it to a 500-mL Erlenmeyer flask.

X3.3.3.3 Add 50 mL of CO_2-free distilled water and swirl gently to dissolve. Add 3 drops of phenolphthalein indicator and titrate with the sodium hydroxide to the first pink color.

X3.3.3.4 Calculate the normality of NaOH as follows:

$$N = W/V \times 204.228 \quad (X3.1)$$

where:

N = normality of NaOH solution,
W = grams of potassium acid phthalate,
V = millilitres of NaOH used, and
204.228 = gram equivalent weight of potassium acid phthalate.

X3.3.3.5 Calculate the phosphorus pentoxide (P_2O_5) equivalent (See Note X3.2) of the NaOH solution in grams per millilitre as follows:

$$E = N \times 0.003086 \quad (X3.2)$$

where:

E = P_2O_5 equivalent of the NaOH solution, g/mL,
N = normality of the NaOH solution, and
0.003086 = P_2O_5 equivalent of 1 *N* NaOH solution, g/mL.

NOTE X3.2—Phosphorus reacts to form ammonium phosphomolybdate $2(NH_4)_3PO_4 \cdot 12MoO_3$. The precipitate reacts with the NaOH solution thus:

2(NH4)3PO4 · 12MoO3 + 46NaOH = 2(NH4)2HPO4
+ (NH4)2MoO4 + 23Na2MoO4 + 22H2O

The equivalent weight of P_2O_5(0.003086) is obtained by dividing the molecular weight of P_2O_5(141.96) by 46 (for 46 moles of NaOH in the equation) and by 1000 (number of millilitres in 1 L). As the actual composition of the precipitate is influenced by the conditions under which the precipitation is made, it is essential that all the details of the procedure be followed closely as prescribed.

X3.3.4 *Sulfuric Acid, Standard* (0.15 *N*)—Dilute 4.0 mL of H_2SO_4 to 1 L with water that has been freshly boiled and cooled. Standardize against the standard NaOH solution. Determine the ratio in strength of the standard H_2SO_4 solution to the standard NaOH solution by dividing the volume of NaOH solution by the volume of H_2SO_4 solution used in titration.

X3.4 *Procedure:*

X3.4.1 Dissolve 10 g of the prepared sample by adding 80 mL of dilute HNO_3(1 + 1) and heating on hot plate. Add 350 mg of ferric nitrate salt ($Fe(NO_3)3 \cdot 9\ H_2O$) (See Note X3.3) and 15 g of ammonium chloride (NH_4Cl), make ammoniacal,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

then add 5 mL of NH_4OH (1 + 1) in excess. Heat to boiling, filter on medium-textured paper and wash with diluted NH_4OH (5 + 95). Discard the filtrate.

NOTE X3.3—Small amounts of phosphorus in the sample can be concentrated very easily this way. The iron combines with the phosphate to form $FePO_4$ that is very insoluble in NH_4OH and affords the analyst the opportunity to separate it from major matrix elements.

X3.4.2 Place the precipitating beaker under the funnel and punch a small hole in the tip of the filter cone by pushing a platinum wire through it. Pour 25 mL of hot HNO_3(1 + 4) through the paper and wash free of iron with hot 5 % HNO_3. Discard the paper.

X3.4.3 Evaporate the nitric acid of solution to dryness and to the dry salts add 30 mL of aqua regia mix (160 mL of HNO_3 + 40 mL HCl (1 + 1). Boil on hot plate until reddish-brown fumes cease to come off and for several minutes thereafter. Add 100 mL of water and boil.

X3.4.4 Filter into a 500-mL Erlenmeyer flask and wash with hot water. Ignite the residue, cool, add 1 mL of HNO_3 and 10 mL of HF and evaporate to dryness (See Note X3.4). Evaporate twice with nitric acid to expel all the HF. Fuse residue with a pinch of Na_2CO_3(0.5 g), dissolve in dilute nitric acid, and add to the filtrate in the Erlenmeyer flask.

NOTE X3.4—The treatment of the residue with HF and HNO_3 may be omitted if the SiO_2 in the sample is low, <3 %.

X3.4.5 Neutralize the nitric acid solution with NH_4OH until iron hydroxide just begins to form. Reacidify with nitric acid slowly until precipitate just dissolves, then add 1 mL of HNO_3 for every 100 mL of solution. Heat the solution to 40 °C and add 40 mL of ammonium molybdate ($(NH_4)_2MoO_4$) (filtered). Stopper the flask, shake for several minutes, and allow to settle overnight (12 h).

X3.4.6 Filter through a retentive paper. Wash the flask and precipitate five times with 15-mL portions of a 1 % solution of KNO_3 and then wash the paper ten times with 10-mL portions of the same solution. The paper should be carefully washed each time from the rim downward and then allowed to drain completely before washing with the next portion of wash solution. (The wash solution must be free of CO_2.)

X3.4.7 Return the paper and precipitate to the flask, add about 75 mL of CO_2-free water, and add enough standard sodium hydroxide solution to decompose the precipitate and leave approximately 2 mL in excess. Record the millilitres of NaOH solution added.

X3.4.8 Stopper the flask and shake to disintegrate the paper. Wash the stopper and sides of the flask with CO_2-free water, add 6 drops of phenolphthalein indicator solution, and titrate the excess sodium hydroxide with standard H_2SO_4 until the pink color of indicator just disappears. Record the millilitres of standard acid.

X3.5 *Calculation:*

NOTE X3.5—Titanium and vanadium interfere in this determination but should not be encountered in significant amounts in this class of material.

X3.5.1 Calculate the percent P_2O_5 as follows:

$$P_2O_5,\ \% = \{E(V_1 - V_2R)\}/W \times 100 \qquad \text{(X3.3)}$$

where:

E = P_2O_5 equivalent of the NaOH solution, g/mL,
V_1 = NaOH solution used, mL,
V_2 = H_2SO_4 solution used, mL,
R = ratio in strength of the NaOH solution to the H_2SO_4 solution, and
W = mass of sample, g.

X3.6 *Precision and Bias*—The precision and bias of this method have not been determined.

X4. MANGANESE BY THE BISMUTHATE METHOD

X4.1 *Scope*—This is the standard titrimetric method that may be used to determine manganese in lime and limestone samples when the concentration of manganese is at least 0.05 %.

X4.2 *Summary of Test Method*—After dissolution of the sample, bivalent manganese is oxidized to permanganic acid by the use of sodium bismuthate ($NaBiO_3$) in nitric acid solution, filtering, washing with nitric acid, adding a measured excess of ferrous sulfate and then determining this excess by titration with a standard solution of permanganate.

X4.3 *Apparatus:*

X4.3.1 *Filtering Crucible*—An asbestos Gooch crucible or a fritted glass crucible of fine porosity.

X4.4 *Reagents:*

X4.4.1 *Sodium Bismuthate*—The sodium bismuthate shall contain enough active oxygen to correspond to at least 75 % $NaBiO_3$.

X4.4.2 *Ferrous Ammonium Sulfate Solution* (12 g/L)—Dissolve 12 g of $Fe(NH_4)_2(SO_4)_2 \cdot 6H_2O$ in 1 L of cool H_2SO_4(5 + 95).

X4.4.3 *Standardization of Ferrous Ammonium Sulfate Solution*—Measure into a 250-mL Erlenmeyer flask, 50 mL of cold nitric acid (3 + 97). Add about 0.5 g of sodium bismuthate ($NaBiO_3$), agitate, dilute with 50 mL of HNO_3(3 + 97) and filter through asbestos or a fritted glass crucible. To the filtrate add 50 mL of the ferrous ammonium sulfate solution and titrate with standard $KMnO_4$ solution to pink color. Determine the ratio (R) of the standard $KMnO_4$ solution to the standard ferrous ammonium sulfate solution by dividing the volume of $KMnO_4$ solution by the volume of $Fe(NH_4)_2(SO_4)_2$ solution used in the titration.

X4.4.4 *Nitric Acid* (3 + 97).

X4.4.5 *Potassium Permanganate Standard Solution* (0.05 *N*)—The same solution as prepared in the Total Iron, Standard Method, Section 13.

X4.5 *Procedure:*

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X4.5.1 Dissolve 10 g of the sample in 100 mL of diluted HNO_3(1 + 1), filter, and wash the residue with hot water. Ignite the residue in platinum, fuse with a little Na_2CO_3, and add the nitric acid solution of the melt to the main filtrate.

X4.5.2 Dilute the solution to 150 mL and add 0.5 g of sodium bismuthate. Heat for a few minutes or until the pink color has disappeared and MnO_2 has precipitated. If MnO_2 does not precipitate, add more bismuthate.

X4.5.3 Clear the solution by slowly adding ferrous ammonium sulfate solution (12 g/L) until the MnO_2 dissolves. Boil to expel brown fumes, cool to 10 to 15 °C, add 0.5 to 1.5 g of $NaBiO_3$(or an amount equal to at least 26 times the weight of manganese present), and agitate vigorously for 1 min. Add 50 mL of cold HNO_3(3 + 97) and filter through a Gooch crucible or fritted glass crucible of fine porosity. Wash with 50 mL of cold HNO_3(3 + 97) or until the washings run colorless.

X4.5.4 Add enough ferrous ammonium sulfate solution (12 g/L) from a buret to discharge completely the permanganate color and then add 1.0 to 2.0 mL in excess. Record the buret reading. Titrate the excess ferrous with 0.05 *N* $KMnO_4$ solution to a faint pink end point.

X4.6 *Calculation*—Calculate the percentage of manganese as follows:

$$\text{Mn, } \% = (V_1 R - V_2)\text{N/W} \times 1.0988 \quad \text{(X4.1)}$$

where:

V_1 = $Fe(NH_4)_2(SO_4)_2$ solution used, mL,
R = ratio in strength of $KMnO_4$ solution to the $Fe(NH_4)_2(SO_4)_2$ solution,
V_2 = $KMnO_4$ solution used, mL,
N = normality of $KMnO_4$ solution,
W = mass of sample, g, and
1.0988 = manganese equivalent of $KMnO_4 \times 100$.

X4.7 *Precision and Bias*—The precision and bias of this test method have not been determined.

X5. FERROUS IRON BY TITRATION WITH POTASSIUM PERMANGANATE

X5.1 *Scope*—The determination of ferrous iron in carbonate rocks is difficult if not impossible in the presence of carbonaceous matter. Nevertheless, acceptable results are sometimes obtainable if there is not much of such matter, and if it does not give a colored solution with acid. But even then, it is only the soluble iron, existing chiefly if not wholly as carbonate, that is determinable.

X5.2 *Summary of Test Method*—The limestone sample is decomposed with dilute sulfuric acid in a steam or CO_2 atmosphere and the soluble ferrous iron is titrated with $KMnO_4$. In the absence of carbonaceous matter, it is possible to determine ferrous iron in the insoluble residue. Metallic iron, if introduced by grinding media, will also be determined as ferrous iron, and precautions should be taken to avoid this contaminate.

X5.3 *Special Solutions:*

X5.3.1 Potassium Permanganate, *Standard Solution* (0.05 *N*)—Prepare as in Total Iron, Standard Method (See Section 13).

X5.3.2 *Diphenylamine Sulfonate Indicator Solution*—Dissolve 0.2 g of sodium diphenylamine sulfonate in 100 mL of water.

X5.3.3 *Potassium Dichromate, Standard Solution* (0.028 *N*)—Weigh 2.728 g of dry National Institute of Standards and Technology potassium dichromate ($K_2Cr_2O_7$) or other pure, dry $K_2Cr_2O_7$ and dilute to 2 L in a volumetric flask. The solution contains the equivalent of 0.002 g FeO/mL.

X5.4 *Procedure:*

X5.4.1 *In Absence of Carbonaceous Matter:*

X5.4.1.1 Weigh several grams of prepared sample into a flask of about 250-mL capacity, add 25 mL of water, and boil water until air is expelled. While still boiling, add diluted H_2SO_4(1 + 1) a little at a time until effervescence ceases, then add a few millilitres in excess (See Note X5.1). Calcium sulfate precipitates, but the iron will remain in solution. Remove the flame and tightly insert a stopper through which passes a small stopcock funnel. When the flask is cool, or nearly so, pour cold water into the funnel and cautiously open the cock so the water may be drawn into the flask. Keep filling the funnel as fast as it empties until the solution in the flask amounts to 100 to 150 mL (See Note X5.2). Immediately titrate the iron solution in the flask with 0.05 *N* $KMnO_4$ solution (See Note X5.3). The ferrous iron thus found is mostly, if not altogether, that existing as carbonate.

Warning—The contents of the flask may erupt violently unless this addition is made with care.

NOTE X5.1—With a carbonate that is wholly decomposable without the aid of heat, solution may be accomplished in a flask filled with CO_2, using cold acid. This mode of acid decomposition lessens the danger of attacking silicates if these are present.

NOTE X5.2—Such precaution to exclude air is hardly necessary, in most cases; however, since in the presence of H_2SO_4 the oxidation of ferrous iron is exceedingly slow. It is ordinarily quite sufficient to equalize the internal and external pressures by opening the cock, removing the stopper, and pouring in cold water.

NOTE X5.3—If MnO_2 is absent, the potassium dichromate method of titration may be substituted and HCl used instead of H_2SO_4. In this case, there is no separation of an insoluble calcium salt which renders easier the subsequent determination of iron in the insoluble residue.

X5.4.2 *Ferrous Iron in the Insoluble Residue in Absence of Carbonaceous Matter:*

X5.4.2.1 Filter the titrated solution (See X5.4.1.1) through a medium-sized, hardened filter. Transfer the residue completely to the paper and wash with hot water. Rinse the contents of the paper into a large platinum crucible (80 to 100-mL capacity) with a snugly fitting cover of transparent polypropylene and having a plastic tube for the introduction of CO_2 and a small plastic funnel for the addition of acid and the escape of vapors and steam.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X5.4.2.2 Add 18 mL of $H_2SO_4(1 + 1)$ and air-free water until the crucible is at least half full. Drop in a small coil of platinum wire to prevent bumping, fit the cover tightly, and pass CO_2 through for at least 10 min as the mixture is gradually brought to boiling. Stop the stream of gas as soon as steam escapes, immediately add 7 mL of HF through the funnel, and boil gently for 10 to 15 min, or until decomposition is complete.

X5.4.2.3 Prepare an 800-mL beaker containing 500 mL of air-free water, 12 g of boric acid, and 20 mL of $H_2SO_4(1 + 3)$. Quickly transfer the crucible cover and contents to the 800-mL beaker. With the aid of a stirring rod, remove the crucible and cover from the beaker and rinse it off with water. Add 3 to 5 drops of sodium diphenylamine sulfonate indicator and titrate with the $K_2Cr_2O_7$ standard solution to a purple color that persists for 20 to 30 s.

NOTE X5.4—Potassium dichromate is preferred because it reacts much less rapidly on organic matter than permanganate.

X5.4.3 *Ferrous Iron in Presence of Insoluble Carbonaceous Matter:*

X5.4.3.1 Weigh 2 to 5 g of prepared sample into a flask of about 250-mL capacity, pass in a stream of CO_2 through a delivery tube and introduce dilute $H_2SO_4(1 + 1)$ till effervescence ceases, then add a few more millilitres in excess. Heat if necessary to decompose the limestone (See Note X5.5) and filter quickly (See Note X5.6) through asbestos or sintered glass fiber (in an atmosphere of carbon dioxide if much iron is present). Wash the filter and the residue a few times with water and titrate the filtrate at once with 0.05 *N* $KMnO_4$ solutions. Discard the residue (See Note X5.7).

NOTE X5.5—Heat is not needed with limestone if active agitation is used; but with dolomites, heat is necessary.

NOTE X5.6—It is important to allow the acid to act no longer than is necessary and to filter quickly.

NOTE X5.7—A determination of the ferrous iron in the insoluble matter is usually not worth attempting because of the admixed organic matter.

X5.5 *Calculation*—Calculate the percent FeO as follows:

$$\text{FeO, } \% = V \times N \times 7.184/W \quad \text{(X5.1)}$$

where:

V = titrant ($KMnO_4$ or $K_2Cr_2O_7$), mL,
N = normality of $KMnO_4$ or $K_2Cr_2O_7$ solution,
W = weight of sample, g, and
7.184 = equivalent weight of FeO × 100.

X5.6 *Precision and Bias*—The precision and bias of this test method have not been determined.

X6. TEST METHOD FOR FREE CALCIUM OXIDE IN HIGH-CALCIUM HYDRATED LIME[8]

X6.1 Scope

X6.1.1 This test method covers the determination of the amount of free calcium oxide (CaO) in high-calcium hydrated lime capable of being hydrated by steam at atmospheric pressure.

X6.2 Summary of Test Method

X6.2.1 This test method is based on the principle of gain in weight of CaO when it is hydrated to form calcium hydroxide ($Ca(OH)_2$).

X6.2.2 The sample is dried, subjected to steam at atmospheric pressure, again dried, and the gain in weight calculated to CaO.

X6.3 Apparatus

X6.3.1 *Drying Oven,* thermostatically controlled, CO_2-free atmosphere.

X6.3.2 *Analytical Balance.*

X6.3.3 *Steam Bath,* as shown in Fig. X6.1.

X6.4 Procedure

X6.4.1 Weigh a clean, dry, 10-mL Erlenmeyer flask on an analytical balance.

NOTE X6.1—Once started, complete the test without interruption.

X6.4.2 Add to the flask, by means of a widestem funnel, 3 to 5 g of the lime to be tested. Reweigh to get the exact sample weight.

NOTE X6.2—The flask should be kept stoppered at all times, except when weighing, drying, or steaming.

X6.4.3 Place the flask in the drying oven that has been previously heated to 120 °C, and maintain at this temperature for 30 min. Remove, stopper, cool in a desiccator, and weigh.

NOTE X6.3—Oven atmosphere can be kept CO_2 free by placing therein a container of soda lime, quicklime, or other suitable CO_2-absorbing medium.

X6.4.4 Place the flask and the sample in a vigorously boiling steam bath and steam for 30 min. Protect the flask in the steam bath by a drip shield during the steaming period. Remove the flask to the oven, dry for 30 min at 120 °C, stopper, cool in a desiccator, and weigh.

X6.4.5 Record all weighings to the fourth decimal place.

X6.5 Calculation

X6.5.1 Calculate the percentage of water and CaO as follows:

$$\text{Free water, } \% = [(W_1 - W_2)/S] \times 100 \quad \text{(X6.1)}$$

$$\text{Free CaO, } \% = \frac{(W_3 - W_2) \times 3.114}{S} \times 100$$

where:

W_1 = weight of sample and flask before drying,
W_2 = weight of sample and flask after drying,
W_3 = weight of sample and flask after steaming and drying, and
S = weight of sample.

[8] This test method was taken from the Appendix of Specification C 911.

Designation: C 28/C 28M – 00 (Reapproved 2005)

Standard Specification for Gypsum Plasters[1]

This standard is issued under the fixed designation C 28/C 28M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers four gypsum plasters; gypsum mill-mixed plaster, gypsum neat plaster, gypsum wood fibered plaster and gypsum gauging plaster.

NOTE 1—Specification C 842 contains application procedures for interior gypsum plaster.

1.2 The values stated in either inch-pound or SI (metric) units are to be regarded separately as the standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be used independently of the other. Values from the two systems shall not be combined. This paragraph does not apply to the appendix.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 The following safety hazards caveat pertains only to the test methods described in the appendix to this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 22 Specification for Gypsum

C 35 Specification for Inorganic Aggregates for Use in Gypsum Plaster

C 471M Test Methods for Chemical Analysis of Gypsum and Gypsum Products

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters, and Gypsum Concrete

C 778 Specification for Standard Sand

C 842 Specification for Application of Interior Gypsum Plaster

E 11 Specification for Wire-Cloth and Sieves for Testing Purposes

3. Terminology

3.1 *Definitions*—Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *gypsum gauging plaster for finish coat*, *n*—a calcined gypsum plaster designed to be mixed with lime putty for the finish coat.

3.2.2 *gypsum neat plaster*, *n*—calcined gypsum mixed at the mill with other ingredients to control working quality and setting time.

3.2.2.1 *Discussion*—Neat plaster is either fibered or unfibered. The addition of aggregate is required on the job.

3.2.3 *gypsum mill-mixed plaster*, *n*—calcined gypsum plaster, mixed at the mill with a mineral aggregate, designed to function as a base coat to receive various finish coats.

3.2.3.1 *Discussion*—Other materials are not prohibited from being added to control setting time and other desirable working properties.

3.2.4 *gypsum wood-fibered plaster*, *n*—A calcined gypsum plaster in which wood fiber is used as an aggregate.

4. Materials

4.1 *Calcined Gypsum*—Calcined gypsum shall be manufactured from gypsum meeting the requirements of Specification C 22.

4.2 *Vermiculite Aggregate*, Specification C 35.

4.3 *Perlite Aggregate*, Specification C 35.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Oct. 1, 2005. Published October 2005. Originally approved in 1920. Last previous edition approved in 2000 as C 28/C 28M – 00[ε1].

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

4.4 *Sand Aggregate*, Specification C 35.
4.5 *Ottawa Sand*, Specification C 778 for 20–30 sand.
4.6 *Wood Fiber*, non staining wood fiber.

TABLE 1 Composition and Physical Properties

Product	Aggregate Type	Composition, Aggregate per 100 lb of Plaster, not more than		Setting Time[A]	Compressive Strength[B] not less than	
		ft³	m³	hours	psi	MPa
Mill-Mixed Plaster over Lath Base	Vermiculite	2	0.057	1½ to 8	450	3.1
	Perlite	2	0.057	1½ to 8	600	4.1
	Sand	2.5	0.071	1½ to 8	700	4.8
Mill-Mixed Plaster over Masonry	Vermiculite	3	0.085	1½ to 8	325	2.2
	Perlite	3	0.085	1½ to 8	400	2.8
	Sand	3	0.085	1½ to 8	400	2.8
Neat Plaster	none	...	...	2 to 16[C]	750[D]	5.2
Wood Fibered Plaster	none	...	...	1½ to 8	1200	8.3
Gauging Plaster	none	...	...	[E]	1200	8.3

[A] Setting time shall be not less than the shorter time shown nor more than the longer time shown.
[B] Compressive strengths are as tested at the setting times specified in Test Methods C 472.
[C] When mixed with 3 parts by weight of Ottawa sand.
[D] When mixed with 2 parts by weight of Ottawa sand.
[E] When not retarded, the setting time shall be not less than 20 nor more than 40 minutes and, when retarded, not less than 40 minutes.

5. Composition

5.1 When tested in accordance with Test Methods C 471M, calcined gypsum shall contain no less than 66.0 weight % $CaSO_4 \cdot ½ H_2O$.

5.2 *Aggregate*—plasters shall contain a volume of aggregate not more than that shown in Table 1.

NOTE 2—An approximation of the aggregate content may be made by using the test methods in the appendix. A more accurate method for determining sand in plaster is described in Test Methods C 471M. Test Methods C 471M requires that the original sand and plaster components be available separately.

6. Mechanical Properties

6.1 *Compressive Strength*—When tested in accordance with Test Methods C 472 the compressive strength shall be as specified in Table 1.

6.2 *Setting Time*—When tested in accordance with Test Methods C 472 using the Vicat method, the setting time shall be as specified in Table 1.

NOTE 3—*Setting Time*—Attention is directed to conditions affecting job set of gypsum plasters that are usually beyond the control of the producer. Materials added at the site of application such as water and aggregates affect job sets. In addition, the various bases with different absorptive values may affect job performance. The plaster may be retarded to provide a setting time of not more than 4 h. Setting times more than 2 h may result in lower compressive strengths.

6.3 *Fineness of Gauging Plaster for Finish Coat*—When tested in accordance with Test Method C 472 all shall pass a No. 14 [1.4 mm] sieve and not less than 60 % shall pass a No. 100 [150 µm] sieve.[3]

7. Sampling

7.1 At least 1 % of the packages, but not less than 5 packages, shall be sampled. Packages to be sampled shall be selected at random. Samples shall be taken both from the outer portion and the center of each package. The materials so obtained shall be thoroughly mixed to provide a composite sample of not less than 7 lb [3.2 kg]. This composite sample shall be placed immediately in a clean, dry, airtight container for delivery to the laboratory.

8. Packaging and Package Marking

8.1 Gypsum plasters shall be dry and free of lumps, and shall be shipped in packages.

8.2 When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached to the package:

8.2.1 Name of manufacturer or seller,
8.2.2 Brand, and
8.2.3 Net weight of the package.

9. Inspection

9.1 Inspection of the gypsum plaster shall be agreed upon between the purchaser and the supplier as part of the purchase agreement.

10. Rejection

10.1 Rejection of gypsum plaster that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting requirements of this specification.

11. Certification

11.1 When specified in the purchase agreement, a manufacturer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

12. Keywords

12.1 aggregate; gauging plaster; gypsum plaster; mill-mixed plaster; neat plaster; plaster; wood fibered plaster

[3] Detailed requirements for these sieves are given in Specification E 11.

APPENDIX

(Nonmandatory Information)

X1. DETERMINATION OF AGGREGATE CONTENT OF MILL-MIXED PLASTER

INTRODUCTION

The determination of the aggregate content of mill-mixed plaster is normally not precise. Most gypsum plasters contain natural impurities that cannot be separated from the aggregate by either mechanical or chemical means. A better estimate can be made by obtaining the approximate purity of the gypsum plaster used in the product from the manufacturer.

An accurate method for determining sand in set plaster is contained in Test Methods C 471M. Separate specimens of the sand and gypsum plaster used in the mill-mixed plaster are required for Test Methods C 471M.

X1.1 Scope

X1.1.1 This appendix covers mechanical and chemical test methods for separating the aggregate from gypsum plaster.

X1.2 Mechanical Separation

X1.2.1 *Significance and Use*:

X1.2.1.1 This test method is used to estimate the weight or volume of aggregate contained in mill-mixed gypsum plasters by mechanical separation.

X1.2.2 *Interferences*:

X1.2.2.1 It is assumed by this test method that the aggregate meets Specification C 35 and that only a minor portion of the aggregate passes through a 100-mesh (150 μm) sieve. To the extent that a greater portion passes the 100 mesh sieve, the results will show lower values for volume of the aggregate, and higher values for the weight of the gypsum plaster, than actually in the sample.

X1.2.3 *Apparatus*:

X1.2.3.1 *Sieve*—Specification E 11, 100 mesh (150 μm).

X1.2.3.2 *Balance*—with a capacity of not less than 100 g and a precision of at least 0.1 g.

X1.2.4 *Procedure*:

X1.2.4.1 Weigh 100 g of the sample to ±0.1 g.

X1.2.4.2 Sieve the 100 g specimen through the 100 mesh (150 μm) sieve. Examine the material on the sieve to be sure small lumps or agglomerates of plaster are not retained. The retained portion is assumed to be aggregate. If the weight ratio of the aggregate and plaster is to be determined, weigh each portion to the nearest 0.1 g. If the volume ratio of aggregate to the weight of plaster is to be determined, measure the volume of aggregate retained on the sieve to the nearest mL and weigh the material passing through the sieve to the nearest 0.1 g.

X1.2.5 *Calculation and Report*:

X1.2.5.1 *Weight Ratio*— Calculate and report the weight ratio as pounds of aggregate/100 lb (45 kg) of plaster per Eq X1.1.

$$W_R = \frac{w_a}{w_p} \times 100 \quad \text{(X1.1)}$$

where:

W_R = weight ratio, lbs of aggregate/100 lbs (45 kg) of plaster,
w_a = weight of aggregate, g, and,
w_p = weight of plaster, g.

X1.2.5.2 *Volume Ratio*— Calculate and report the volume ratio as cubic feet of aggregate/100 lbs (45 kg) of plaster per Eq X1.2.

$$V_R = \frac{v_a}{w_p} \times 1.60 \quad \text{(X1.2)}$$

where:

V_R = Volume ratio, cubic feet of aggregate per 100 lbs of plaster,
v_a = volume of aggregate, mL, and
w_p = weight of plaster, g.

X1.2.6 *Precision and Bias*:

X1.2.6.1 It is not practical to specify the precision or the bias of this test method because of the unknown variabilities in the particle sizes of the aggregates.

X1.3 Chemical Separation

X1.3.1 *Significance and Use*:

X1.3.1.1 This test method is used to estimate the weight or volume of aggregate contained in mill-mixed gypsum plasters by chemical separation.

X1.3.2 *Interferences*:

X1.3.2.1 It is assumed in this test method that all of the material insoluble in ammonium acetate is aggregate and the soluble material is plaster. In many cases there is a significant amount of insoluble material in the plaster. To the extent that this is true it will produce erroneous calculated amounts of aggregate and plaster. If possible, obtain the approximate purity of the plaster from the manufacturer. This information will greatly increase the accuracy of the results.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:39 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X1.3.2.2 In the volume calculation it is assumed that the volume of the insoluble material in the plaster is insignificant compared to the volume of the aggregate. This is usually the case.

X1.3.3 *Apparatus*:

X1.3.3.1 *Analytical Balance*—with a precision of 0.001 g.

X1.3.3.2 *Drying Oven*— capable of maintaining a temperature of 100 to 110°C.

X1.3.4 *Reagents*:

X1.3.4.1 *Ammonium Acetate Solution (250 g/L)*—dissolve 250 g of ammonium acetate ($NH_4C_2H_3O_2$) in water and dilute to 1 L.

X1.3.4.2 *Ammonium Hydroxide (1+59)*—Mix one volume of concentrated (NH_4OH) (sp gr 0.90) with 59 volumes of water.

X1.3.5 *Procedure*:

X1.3.5.1 Accurately weigh 40 ± 0.05 g of the sample into a 1-L beaker. Add 600 to 700 mL of ($NH_4C_2H_3O_2$) solution that is slightly alkaline to litmus paper. If acidic, add a few mL of (NH_4OH) (1+59) to the stock ($NH_4C_2H_3O_2$) solution to render it slightly alkaline prior to the addition of the test sample.

X1.3.5.2 Warm the suspension to a temperature of 70 ± 5°C and stir continuously for 20 to 30 min. Filter the warm suspension through a small Buchner funnel or Gooch crucible in which filter paper has previously been formed, the funnel and mat having been dried at 110°C to a constant weight within 0.01 g. Refilter the first 100 mL of the filtrate. Wash the aggregate remaining in the beaker onto the filter with an additional 100 mL of warm ($NH_4C_2H_3O_2$) solution. Wash the beaker and residue with 200 to 300 mL of water, dry the funnel and aggregate at 100°C to constant weight.

X1.3.6 *Calculation and Report*:

X1.3.6.1 *Weight Ratio*— Calculate and report the weight ratio as pounds of aggregate/100 lbs (45 kg) of plaster per Eq X1.3.

$$W_R = \frac{w_1 - \frac{w_1 - w_2}{p}}{\frac{w_1 - w_2}{p}} \times 100 \qquad \text{(X1.3)}$$

where:

W_R = weight ratio, lbs of aggregate/100 lbs (45 kg) of plaster,
w_1 = Weight of original specimen, g,
w_2 = weight of insoluble residue retained on filter, g, and
p = Purity of gypsum plaster expressed as a decimal (that is, 85 % purity = 0.85). If purity is unknown use 0.9 (90 %) as an estimate.

X1.3.6.2 *Volume Ratio*— Calculate the volume ratio as cubic feet of aggregate/100 lbs (45 kg) of plaster per Eq X1.4.

$$V_R = \frac{v_1}{\frac{w_1 - w_2}{p}} \times 1.6 \qquad \text{(X1.4)}$$

where:

V_R = volume ratio, cubic feet of aggregate/100 lbs (45 kg) of plaster,
v_1 = volume of insoluble residue retained on filter, mL,
w_1 = weight of original specimen, g,
w_2 = weight of insoluble residue retained on filter, g, and
p = purity of gypsum plaster expressed as a decimal (that is, 85 % purity = 0.85). If purity is unknown use 0.9 (90 %) as an estimate.

X1.3.7 *Precision and Bias*:

X1.3.7.1 It is not practical to specify the precision or the bias of this test method because of the unknown variabilities in the purity of the plaster.

Designation: C29/C29M – 09

American Association of State
Highway and Transportation Officials Standard
AASHTO No.: T19/T19M

Standard Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate[1]

This standard is issued under the fixed designation C29/C29M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of bulk density ("unit weight") of aggregate in a compacted or loose condition, and calculated voids between particles in fine, coarse, or mixed aggregates based on the same determination. This test method is applicable to aggregates not exceeding 125 mm [5 in.] in nominal maximum size.

NOTE 1—Unit weight is the traditional terminology used to describe the property determined by this test method, which is weight per unit volume (more correctly, mass per unit volume or density).

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard, as appropriate for a specification with which this test method is used. An exception is with regard to sieve sizes and nominal size of aggregate, in which the SI values are the standard as stated in Specification E11. Within the text, inch-pound units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C125 Terminology Relating to Concrete and Concrete Aggregates

D123 Terminology Relating to Textiles

E11 Specification for Woven Wire Test Sieve Cloth and Test Sieves

2.2 *AASHTO Standard:*

T19/T19M Method of Test for Unit Weight and Voids in Aggregate[3]

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminology C125 unless otherwise indicated.

3.1.1 *bulk density*, *n—of aggregate*, the mass of a unit volume of bulk aggregate material, in which the volume includes the volume of the individual particles and the volume of the voids between the particles. Expressed in kg/m^3 [lb/ft^3].

3.1.2 *unit weight*, *n*—weight (mass) per unit volume. (Deprecated term used–preferred term **bulk density**.)

3.1.2.1 *Discussion*—Weight is equal to the mass of the body multiplied by the acceleration due to gravity. Weight may be expressed in absolute units (newtons, poundals) or in gravitational units (kgf, lbf), for example: on the surface of the earth, a body with a mass of 1 kg has a weight of 1 kgf (approximately 9.81 N), or a body with a mass of 1 lb has a weight of 1 lbf (approximately 4.45 N or 32.2 poundals). Since weight is equal to mass times the acceleration due to gravity, the weight of a body will vary with the location where the weight is determined, while the mass of the body remains constant. On the surface of the earth, the force of gravity imparts to a body that is free to fall an acceleration of approximately 9.81 m/s^2 [32.2 ft/s^2]. **D123**

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 1920. Last previous edition approved in 2007 as C29/C29M – 07. DOI: 10.1520/C0029_C0029M-09.

www.technobetar.ir

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *voids, n—in unit volume of aggregate,* the space between particles in an aggregate mass not occupied by solid mineral matter.

3.2.1.1 *Discussion*—Voids within particles, either permeable or impermeable, are not included in voids as determined by this test method.

4. Significance and Use

4.1 This test method is often used to determine bulk density values that are necessary for use for many methods of selecting proportions for concrete mixtures.

4.2 The bulk density also may be used for determining mass/volume relationships for conversions in purchase agreements. However, the relationship between degree of compaction of aggregates in a hauling unit or stockpile and that achieved in this test method is unknown. Further, aggregates in hauling units and stockpiles usually contain absorbed and surface moisture (the latter affecting bulking), while this test method determines the bulk density on a dry basis.

4.3 A procedure is included for computing the percentage of voids between the aggregate particles based on the bulk density determined by this test method.

5. Apparatus

5.1 *Balance*—A balance or scale accurate within 0.1 % of the test load at any point within the range of use, graduated to at least 0.05 kg [0.1 lb]. The range of use shall be considered to extend from the mass of the measure empty to the mass of the measure plus its contents at 1920 kg/m^3 [120 lb/ft^3].

5.2 *Tamping Rod*—A round, straight steel rod, 16 mm [⅝ in.] in diameter and approximately 600 mm [24 in.] in length, having the tamping end, or both ends, rounded to a hemispherical tip, the diameter of which is 16 mm [⅝ in.].

5.3 *Measure*—A cylindrical metal measure, preferably provided with handles. It shall be watertight, with the top and bottom true and even, and sufficiently rigid to retain its form under rough usage. The measure shall have a height approximately equal to the diameter, but in no case shall the height be less than 80 % nor more than 150 % of the diameter. The capacity of the measure shall conform to the limits in Table 1 for the aggregate size to be tested. The thickness of metal in the measure shall be as described in Table 2. The top rim shall be smooth and plane within 0.25 mm [0.01 in.] and shall be parallel to the bottom within 0.5° (See Note 2). The interior wall of the measure shall be a smooth and continuous surface.

TABLE 1 Capacity of Measures

Nominal Maximum Size of Aggregate		Capacity of Measure[A]	
mm	in.	m^3[L]	ft^3
12.5	½	0.0028[2.8]	1/10
25.0	1	0.0093 [9.3]	⅓
37.5	1½	0.014 [14]	½
75	3	0.028 [28]	1
100	4	0.070 [70]	2½
125	5	0.100 [100]	3½

[A] The indicated size of measure shall be used to test aggregates of a nominal maximum size equal to or smaller than that listed. The actual volume of the measure shall be at least 95 % of the nominal volume listed.

TABLE 2 Requirements for Measures

Capacity of Measure	Thickness of Metal, min		
	Bottom	Upper 38 mm or 1½ in. of wall[A]	Remainder of wall
Less than 11 L	5.0 mm	2.5 mm	2.5 mm
11 to 42 L, incl	5.0 mm	5.0 mm	3.0 mm
over 42 to 80 L, incl	10.0 mm	6.4 mm	3.8 mm
over 80 to 133 L, incl	13.0 mm	7.6 mm	5.0 mm
Less than 0.4 ft^3	0.20 in.	0.10 in.	0.10 in.
0.4 ft^3 to 1.5 ft^3, incl	0.20 in.	0.20 in.	0.12 in.
over 1.5 to 2.8 ft^3, incl	0.40 in.	0.25 in.	0.15 in.
over 2.8 to 4.0 ft^3, incl	0.50 in.	0.30 in.	0.20 in.

[A] The added thickness in the upper portion of the wall may be obtained by placing a reinforcing band around the top of the measure.

NOTE 2—The top rim is satisfactorily plane if a 0.25-mm [0.01-in.] feeler gage cannot be inserted between the rim and a piece of 6-mm [¼-in.] or thicker plate glass laid over the measure. The top and bottom are satisfactorily parallel if the slope between pieces of plate glass in contact with the top and bottom does not exceed 0.87 % in any direction.

5.3.1 If the measure is to also be used for testing for bulk density of freshly-mixed concrete according to Test Method C138/C138M, the measure shall be made of steel or other suitable metal not readily subject to attack by cement paste. Reactive materials, such as aluminum alloys are permitted, where as a consequence of an initial reaction, a surface film is formed which protects the metal against further corrosion.

5.3.2 Measures larger than nominal 28 L [1 ft^3] capacity shall be made of steel for rigidity, or the minimum thicknesses of metal listed in Table 2 shall be suitably increased.

5.4 *Shovel or Scoop*—A shovel or scoop of convenient size for filling the measure with aggregate.

5.5 *Calibration Equipment*:

5.5.1 *Plate Glass*—A piece of plate glass, at least 6 mm [¼ in.] thick and at least 25 mm [1 in.] larger than the diameter of the measure to be calibrated.

5.5.2 *Grease*—A supply of water-pump, chassis, or similar grease.

5.5.3 *Thermometer*—A thermometer having a range of at least 10 to 32 °C [50 to 90 °F] and that is readable to at least 0.5 °C [1 °F].

5.5.4 *Balance*—A balance as described in 5.1.

6. Sampling

6.1 Obtain the sample in accordance with Practice D75, and reduce to test sample size in accordance with Practice C702.

7. Test Sample

7.1 The size of the sample shall be approximately 125 to 200 % of the quantity required to fill the measure, and shall be handled in a manner to avoid segregation. Dry the aggregate sample to essentially constant mass, preferably in an oven at 110 ± 5 °C [230 ± 9 °F].

8. Calibration of Measure

8.1 Measures shall be recalibrated at least once a year or whenever there is reason to question the accuracy of the calibration.

8.2 Determine the mass of the plate glass and measure the nearest 0.05 kg [0.1 lb].

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:42 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.3 Place a thin layer of grease on the rim of the measure to prevent leakage of water from the measure.

8.4 Fill the measure with water that is at room temperature and cover with the plate glass in such a way as to eliminate bubbles and excess water. Remove any water that may have overflowed onto the measure or plate glass.

8.5 Determine the mass of the water, plate glass, and measure to the nearest 0.05 kg [0.1 lb].

8.6 Measure the temperature of the water to the nearest 0.5 °C [1 °F] and determine its density from Table 3, interpolating if necessary.

8.7 Calculate the volume, *V*, of the measure. Alternatively, calculate the factor, F, for the measure.

NOTE 3—For the calculation of bulk density, the volume of the measure in SI units should be expressed in cubic metres, or the factor as $1/m^3$. However, for convenience the size of the measure may be expressed in litres.

9. Selection of Procedure

9.1 The shoveling procedure for loose bulk density shall be used only when specifically stipulated. Otherwise, the compact bulk density shall be determined by the rodding procedure for aggregates having a nominal maximum size of 37.5 mm [1½ in.] or less, or by the jigging procedure for aggregates having a nominal maximum size greater than 37.5 mm [1½ in.] and not exceeding 125 mm [5 in.].

10. Rodding Procedure

10.1 Fill the measure one-third full and level the surface with the fingers. Rod the layer of aggregate with 25 strokes of the tamping rod evenly distributed over the surface. Fill the measure two-thirds full and again level and rod as above. Finally, fill the measure to overflowing and rod again in the manner previously mentioned. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

10.2 In rodding the first layer, do not allow the rod to strike the bottom of the measure forcibly. In rodding the second and third layers, use vigorous effort, but not more force than to cause the tamping rod to penetrate to the previous layer of aggregate.

NOTE 4—In rodding the larger sizes of coarse aggregate, it may not be possible to penetrate the layer being consolidated, especially with angular aggregates. The intent of the procedure will be accomplished if vigorous effort is used.

TABLE 3 Density of Water

Temperature		kg/m³	lb/ft³
°C	°F		
15.6	60	999.01	62.366
18.3	65	998.54	62.336
21.1	70	997.97	62.301
23.0	73.4	997.54	62.274
23.9	75	997.32	62.261
26.7	80	996.59	62.216
29.4	85	995.83	62.166

10.3 Determine the mass of the measure plus its contents, and the mass of the measure alone, and record the values to the nearest 0.05 kg [0.1 lb].

11. Jigging Procedure

11.1 Fill the measure in three approximately equal layers as described in 10.1, compacting each layer by placing the measure on a firm base, such as a cement-concrete floor, raising the opposite sides alternately about 50 mm [2 in.], and allowing the measure to drop in such a manner as to hit with a sharp, slapping blow. The aggregate particles, by this procedure, will arrange themselves in a densely compacted condition. Compact each layer by dropping the measure 50 times in the manner described, 25 times on each side. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

11.2 Determine the mass of the measure plus its contents, and the mass of the measure alone, and record the values to the nearest 0.05 kg [0.1 lb].

12. Shoveling Procedure

12.1 Fill the measure to overflowing by means of a shovel or scoop, discharging the aggregate from a height not to exceed 50 mm [2 in.] above the top of the measure. Exercise care to prevent, so far as possible, segregation of the particle sizes of which the sample is composed. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

12.2 Determine the mass of the measure plus its contents, and the mass of the measure alone, and record the values to the nearest 0.05 kg [0.1 lb].

13. Calculation

13.1 *Bulk Density*—Calculate the bulk density for the rodding, jigging, or shoveling procedure as follows:

$$M = (G - T)/V \quad (1)$$

or

$$M = (G - T) \times F \quad (2)$$

where:

M = bulk density of the aggregate, kg/m^3 [lb/ft^3],
G = mass of the aggregate plus the measure, kg [lb],
T = mass of the measure, kg [lb],
V = volume of the measure, m^3 [ft^3], and
F = factor for measure, m^{-3} [ft^{-3}].

13.1.1 The bulk density determined by this test method is for aggregate in an oven-dry condition. If the bulk density in terms of saturated-surface-dry (SSD) condition is desired, use the exact procedure in this test method, and then calculate the SSD bulk density using the following formula:

$$Mssd = M[1 + (A/100)] \quad (3)$$

where:

M_{SSD} = bulk density in SSD condition, kg/m^3 [lb/ft^3], and

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:42 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

A = % absorption, determined in accordance with Test Method C127 or Test Method C128.

13.2 *Void Content*—Calculate the void content in the aggregate using the bulk density determined by either the rodding, jigging, or shoveling procedure, as follows:

$$\%\ Voids = 100[(S \times W) - M]/(S \times W) \quad (4)$$

where:

M = bulk density of the aggregate, kg/m^3 [lb/ft^3],
S = bulk specific gravity (dry basis) as determined in accordance with Test Method C127 or Test Method C128, and
W = density of water, 998 kg/m^3 [62.3 lb/ft^3].

13.3 *Volume of Measure*—Calculate the volume of a measure as follows:

$$V = (W - M)/D \quad (5)$$

$$F = D/(W - M) \quad (6)$$

where:

V = volume of the measure, m^3 [ft^3]
W = mass of the water, plate glass, and measure, kg [lb]
M = mass of the plate glass and measure, kg [lb]
D = density of the water for the measured temperature, kg/m^3 [lb/ft^3], and
F = factor for the measure, 1/m^3 [1/ft^3]

14. Report

14.1 Report the results for the bulk density to the nearest 10 kg/m^3 [1 lb/ft^3] as follows:

14.1.1 Bulk density by rodding, or
14.1.2 Bulk density by jigging, or
14.1.3 Loose bulk density.

14.2 Report the results for the void content to the nearest 1 % as follows:

14.2.1 Voids in aggregate compacted by rodding, %, or
14.2.2 Voids in aggregate compacted by jigging, %, or
14.2.3 Voids in loose aggregate, %.

15. Precision and Bias

15.1 The following estimates of precision for this test method are based on results from the AASHTO Materials Reference Laboratory (AMRL) Proficiency Sample Program, with testing conducted using this test method and AASHTO Method T 19/T19M. There are no significant differences between the two test methods. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories.

15.2 *Coarse Aggregate (bulk density)*:

15.2.1 *Single-Operator Precision*—The single-operator standard deviation has been found to be 14 kg/m^3 [0.88 lb/ft^3] (1s). Therefore, results of two properly conducted tests by the same operator on similar material should not differ by more than 40 kg/m^3 [2.5 lb/ft^3] (d2s).

15.2.2 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 30 kg/m^3 [1.87 lb/ft^3] (1s). Therefore, results of two properly conducted tests from two different laboratories on similar material should not differ by more than 85 kg/m^3 [5.3 lb/ft^3] (d2s).

15.2.3 These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C670. The precision estimates were obtained from the analysis of AMRL proficiency sample data for bulk density by rodding of normal weight aggregates having a nominal maximum aggregate size of 25.0 mm [1 in.], and using a 14-L [½-ft^3] measure.

15.3 *Fine Aggregate (bulk density)*:

15.3.1 *Single-Operator Precision*—The single-operator standard deviation has been found to be 14 kg/m^3 [0.88 lb/ft^3] (1s). Therefore, results of two properly conducted tests by the same operator on similar material should not differ by more than 40 kg/m^3 [2.5 lb/ft^3] (d2s).

15.3.2 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 44 kg/m^3 [2.76 lb/ft^3] (1s). Therefore, results of two properly conducted tests from two different laboratories on similar material should not differ by more than 125 kg/m^3 [7.8 lb/ft^3] (d2s).

15.3.3 These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C670. The precision estimates were obtained from the analysis of AMRL proficiency sample data for loose bulk density from laboratories using a 2.8-L [⅒-ft^3] measure.

15.4 No precision data on void content are available. However, as the void content in aggregate is calculated from bulk density and bulk specific gravity, the precision of the voids content reflects the precision of these measured parameters given in 15.2 and 15.3 of this test method and in Test Methods C127 and C128.

15.5 *Bias*—The procedure in this test method for measuring bulk density and void content has no bias because the values for bulk density and void content can be defined only in terms of a test method.

16. Keywords

16.1 aggregates; bulk density; coarse aggregate; density; fine aggregate; unit weight; voids in aggregates

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C29/C29M – 07, that may impact the use of this test method. (Approved December 1, 2009)

(*1*) Revised 5.5.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C29/C29M – 09

American Association of State
Highway and Transportation Officials Standard
AASHTO No.: T19/T19M

Standard Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate[1]

This standard is issued under the fixed designation C29/C29M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of bulk density ("unit weight") of aggregate in a compacted or loose condition, and calculated voids between particles in fine, coarse, or mixed aggregates based on the same determination. This test method is applicable to aggregates not exceeding 125 mm [5 in.] in nominal maximum size.

NOTE 1—Unit weight is the traditional terminology used to describe the property determined by this test method, which is weight per unit volume (more correctly, mass per unit volume or density).

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard, as appropriate for a specification with which this test method is used. An exception is with regard to sieve sizes and nominal size of aggregate, in which the SI values are the standard as stated in Specification E11. Within the text, inch-pound units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2 *AASHTO Standard:*

T19/T19M Method of Test for Unit Weight and Voids in Aggregate[3]

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminology C125 unless otherwise indicated.

3.1.1 *bulk density*, *n—of aggregate*, the mass of a unit volume of bulk aggregate material, in which the volume includes the volume of the individual particles and the volume of the voids between the particles. Expressed in kg/m^3 [lb/ft^3].

3.1.2 *unit weight*, *n*—weight (mass) per unit volume. (Deprecated term used–preferred term **bulk density**.)

3.1.2.1 *Discussion*—Weight is equal to the mass of the body multiplied by the acceleration due to gravity. Weight may be expressed in absolute units (newtons, poundals) or in gravitational units (kgf, lbf), for example: on the surface of the earth, a body with a mass of 1 kg has a weight of 1 kgf (approximately 9.81 N), or a body with a mass of 1 lb has a weight of 1 lbf (approximately 4.45 N or 32.2 poundals). Since weight is equal to mass times the acceleration due to gravity, the weight of a body will vary with the location where the weight is determined, while the mass of the body remains constant. On the surface of the earth, the force of gravity imparts to a body that is free to fall an acceleration of approximately 9.81 m/s^2 [32.2 ft/s^2]. **D123**

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 1920. Last previous edition approved in 2007 as C29/C29M – 07. DOI: 10.1520/C0029_C0029M-09.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *voids, n—in unit volume of aggregate,* the space between particles in an aggregate mass not occupied by solid mineral matter.

3.2.1.1 *Discussion*—Voids within particles, either permeable or impermeable, are not included in voids as determined by this test method.

4. Significance and Use

4.1 This test method is often used to determine bulk density values that are necessary for use for many methods of selecting proportions for concrete mixtures.

4.2 The bulk density also may be used for determining mass/volume relationships for conversions in purchase agreements. However, the relationship between degree of compaction of aggregates in a hauling unit or stockpile and that achieved in this test method is unknown. Further, aggregates in hauling units and stockpiles usually contain absorbed and surface moisture (the latter affecting bulking), while this test method determines the bulk density on a dry basis.

4.3 A procedure is included for computing the percentage of voids between the aggregate particles based on the bulk density determined by this test method.

5. Apparatus

5.1 *Balance*—A balance or scale accurate within 0.1 % of the test load at any point within the range of use, graduated to at least 0.05 kg [0.1 lb]. The range of use shall be considered to extend from the mass of the measure empty to the mass of the measure plus its contents at 1920 kg/m^3 [120 lb/ft^3].

5.2 *Tamping Rod*—A round, straight steel rod, 16 mm [⅝ in.] in diameter and approximately 600 mm [24 in.] in length, having the tamping end, or both ends, rounded to a hemispherical tip, the diameter of which is 16 mm [⅝ in.].

5.3 *Measure*—A cylindrical metal measure, preferably provided with handles. It shall be watertight, with the top and bottom true and even, and sufficiently rigid to retain its form under rough usage. The measure shall have a height approximately equal to the diameter, but in no case shall the height be less than 80 % nor more than 150 % of the diameter. The capacity of the measure shall conform to the limits in Table 1 for the aggregate size to be tested. The thickness of metal in the measure shall be as described in Table 2. The top rim shall be smooth and plane within 0.25 mm [0.01 in.] and shall be parallel to the bottom within 0.5° (See Note 2). The interior wall of the measure shall be a smooth and continuous surface.

TABLE 1 Capacity of Measures

Nominal Maximum Size of Aggregate		Capacity of Measure[A]	
mm	in.	m^3[L]	ft^3
12.5	½	0.0028[2.8]	1/10
25.0	1	0.0093 [9.3]	⅓
37.5	1½	0.014 [14]	½
75	3	0.028 [28]	1
100	4	0.070 [70]	2½
125	5	0.100 [100]	3½

[A] The indicated size of measure shall be used to test aggregates of a nominal maximum size equal to or smaller than that listed. The actual volume of the measure shall be at least 95 % of the nominal volume listed.

TABLE 2 Requirements for Measures

Capacity of Measure	Thickness of Metal, min		
	Bottom	Upper 38 mm or 1½ in. of wall[A]	Remainder of wall
Less than 11 L	5.0 mm	2.5 mm	2.5 mm
11 to 42 L, incl	5.0 mm	5.0 mm	3.0 mm
over 42 to 80 L, incl	10.0 mm	6.4 mm	3.8 mm
over 80 to 133 L, incl	13.0 mm	7.6 mm	5.0 mm
Less than 0.4 ft^3	0.20 in.	0.10 in.	0.10 in.
0.4 ft^3 to 1.5 ft^3, incl	0.20 in.	0.20 in.	0.12 in.
over 1.5 to 2.8 ft^3, incl	0.40 in.	0.25 in.	0.15 in.
over 2.8 to 4.0 ft^3, incl	0.50 in.	0.30 in.	0.20 in.

[A] The added thickness in the upper portion of the wall may be obtained by placing a reinforcing band around the top of the measure.

NOTE 2—The top rim is satisfactorily plane if a 0.25-mm [0.01-in.] feeler gage cannot be inserted between the rim and a piece of 6-mm [¼-in.] or thicker plate glass laid over the measure. The top and bottom are satisfactorily parallel if the slope between pieces of plate glass in contact with the top and bottom does not exceed 0.87 % in any direction.

5.3.1 If the measure is to also be used for testing for bulk density of freshly-mixed concrete according to Test Method C138/C138M, the measure shall be made of steel or other suitable metal not readily subject to attack by cement paste. Reactive materials, such as aluminum alloys are permitted, where as a consequence of an initial reaction, a surface film is formed which protects the metal against further corrosion.

5.3.2 Measures larger than nominal 28 L [1 ft^3] capacity shall be made of steel for rigidity, or the minimum thicknesses of metal listed in Table 2 shall be suitably increased.

5.4 *Shovel or Scoop*—A shovel or scoop of convenient size for filling the measure with aggregate.

5.5 *Calibration Equipment*:

5.5.1 *Plate Glass*—A piece of plate glass, at least 6 mm [¼ in.] thick and at least 25 mm [1 in.] larger than the diameter of the measure to be calibrated.

5.5.2 *Grease*—A supply of water-pump, chassis, or similar grease.

5.5.3 *Thermometer*—A thermometer having a range of at least 10 to 32 °C [50 to 90 °F] and that is readable to at least 0.5 °C [1 °F].

5.5.4 *Balance*—A balance as described in 5.1.

6. Sampling

6.1 Obtain the sample in accordance with Practice D75, and reduce to test sample size in accordance with Practice C702.

7. Test Sample

7.1 The size of the sample shall be approximately 125 to 200 % of the quantity required to fill the measure, and shall be handled in a manner to avoid segregation. Dry the aggregate sample to essentially constant mass, preferably in an oven at 110 ± 5 °C [230 ± 9 °F].

8. Calibration of Measure

8.1 Measures shall be recalibrated at least once a year or whenever there is reason to question the accuracy of the calibration.

8.2 Determine the mass of the plate glass and measure the nearest 0.05 kg [0.1 lb].

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:48 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.3 Place a thin layer of grease on the rim of the measure to prevent leakage of water from the measure.

8.4 Fill the measure with water that is at room temperature and cover with the plate glass in such a way as to eliminate bubbles and excess water. Remove any water that may have overflowed onto the measure or plate glass.

8.5 Determine the mass of the water, plate glass, and measure to the nearest 0.05 kg [0.1 lb].

8.6 Measure the temperature of the water to the nearest 0.5 °C [1 °F] and determine its density from Table 3, interpolating if necessary.

8.7 Calculate the volume, *V*, of the measure. Alternatively, calculate the factor, F, for the measure.

NOTE 3—For the calculation of bulk density, the volume of the measure in SI units should be expressed in cubic metres, or the factor as $1/m^3$. However, for convenience the size of the measure may be expressed in litres.

9. Selection of Procedure

9.1 The shoveling procedure for loose bulk density shall be used only when specifically stipulated. Otherwise, the compact bulk density shall be determined by the rodding procedure for aggregates having a nominal maximum size of 37.5 mm [1½ in.] or less, or by the jigging procedure for aggregates having a nominal maximum size greater than 37.5 mm [1½ in.] and not exceeding 125 mm [5 in.].

10. Rodding Procedure

10.1 Fill the measure one-third full and level the surface with the fingers. Rod the layer of aggregate with 25 strokes of the tamping rod evenly distributed over the surface. Fill the measure two-thirds full and again level and rod as above. Finally, fill the measure to overflowing and rod again in the manner previously mentioned. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

10.2 In rodding the first layer, do not allow the rod to strike the bottom of the measure forcibly. In rodding the second and third layers, use vigorous effort, but not more force than to cause the tamping rod to penetrate to the previous layer of aggregate.

NOTE 4—In rodding the larger sizes of coarse aggregate, it may not be possible to penetrate the layer being consolidated, especially with angular aggregates. The intent of the procedure will be accomplished if vigorous effort is used.

TABLE 3 Density of Water

Temperature		kg/m³	lb/ft³
°C	°F		
15.6	60	999.01	62.366
18.3	65	998.54	62.336
21.1	70	997.97	62.301
23.0	73.4	997.54	62.274
23.9	75	997.32	62.261
26.7	80	996.59	62.216
29.4	85	995.83	62.166

10.3 Determine the mass of the measure plus its contents, and the mass of the measure alone, and record the values to the nearest 0.05 kg [0.1 lb].

11. Jigging Procedure

11.1 Fill the measure in three approximately equal layers as described in 10.1, compacting each layer by placing the measure on a firm base, such as a cement-concrete floor, raising the opposite sides alternately about 50 mm [2 in.], and allowing the measure to drop in such a manner as to hit with a sharp, slapping blow. The aggregate particles, by this procedure, will arrange themselves in a densely compacted condition. Compact each layer by dropping the measure 50 times in the manner described, 25 times on each side. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

11.2 Determine the mass of the measure plus its contents, and the mass of the measure alone, and record the values to the nearest 0.05 kg [0.1 lb].

12. Shoveling Procedure

12.1 Fill the measure to overflowing by means of a shovel or scoop, discharging the aggregate from a height not to exceed 50 mm [2 in.] above the top of the measure. Exercise care to prevent, so far as possible, segregation of the particle sizes of which the sample is composed. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

12.2 Determine the mass of the measure plus its contents, and the mass of the measure alone, and record the values to the nearest 0.05 kg [0.1 lb].

13. Calculation

13.1 *Bulk Density*—Calculate the bulk density for the rodding, jigging, or shoveling procedure as follows:

$$M = (G - T)/V \quad (1)$$

or

$$M = (G - T) \times F \quad (2)$$

where:

M = bulk density of the aggregate, kg/m^3 [lb/ft^3],
G = mass of the aggregate plus the measure, kg [lb],
T = mass of the measure, kg [lb],
V = volume of the measure, m^3 [ft^3], and
F = factor for measure, m^{-3} [ft^{-3}].

13.1.1 The bulk density determined by this test method is for aggregate in an oven-dry condition. If the bulk density in terms of saturated-surface-dry (SSD) condition is desired, use the exact procedure in this test method, and then calculate the SSD bulk density using the following formula:

$$Mssd = M[1 + (A/100)] \quad (3)$$

where:

M_{SSD} = bulk density in SSD condition, kg/m^3 [lb/ft^3], and

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:48 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

A = % absorption, determined in accordance with Test Method C127 or Test Method C128.

13.2 *Void Content*—Calculate the void content in the aggregate using the bulk density determined by either the rodding, jigging, or shoveling procedure, as follows:

$$\%\ Voids = 100[(S \times W) - M]/(S \times W) \quad (4)$$

where:

M = bulk density of the aggregate, kg/m^3 [lb/ft^3],
S = bulk specific gravity (dry basis) as determined in accordance with Test Method C127 or Test Method C128, and
W = density of water, 998 kg/m^3 [62.3 lb/ft^3].

13.3 *Volume of Measure*—Calculate the volume of a measure as follows:

$$V = (W - M)/D \quad (5)$$

$$F = D/(W - M) \quad (6)$$

where:

V = volume of the measure, m^3 [ft^3]
W = mass of the water, plate glass, and measure, kg [lb]
M = mass of the plate glass and measure, kg [lb]
D = density of the water for the measured temperature, kg/m^3 [lb/ft^3], and
F = factor for the measure, 1/m^3 [1/ft^3]

14. Report

14.1 Report the results for the bulk density to the nearest 10 kg/m^3 [1 lb/ft^3] as follows:

14.1.1 Bulk density by rodding, or
14.1.2 Bulk density by jigging, or
14.1.3 Loose bulk density.

14.2 Report the results for the void content to the nearest 1 % as follows:

14.2.1 Voids in aggregate compacted by rodding, %, or
14.2.2 Voids in aggregate compacted by jigging, %, or
14.2.3 Voids in loose aggregate, %.

15. Precision and Bias

15.1 The following estimates of precision for this test method are based on results from the AASHTO Materials Reference Laboratory (AMRL) Proficiency Sample Program, with testing conducted using this test method and AASHTO Method T 19/T19M. There are no significant differences between the two test methods. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories.

15.2 *Coarse Aggregate (bulk density)*:

15.2.1 *Single-Operator Precision*—The single-operator standard deviation has been found to be 14 kg/m^3 [0.88 lb/ft^3] (1s). Therefore, results of two properly conducted tests by the same operator on similar material should not differ by more than 40 kg/m^3 [2.5 lb/ft^3] (d2s).

15.2.2 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 30 kg/m^3 [1.87 lb/ft^3] (1s). Therefore, results of two properly conducted tests from two different laboratories on similar material should not differ by more than 85 kg/m^3 [5.3 lb/ft^3] (d2s).

15.2.3 These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C670. The precision estimates were obtained from the analysis of AMRL proficiency sample data for bulk density by rodding of normal weight aggregates having a nominal maximum aggregate size of 25.0 mm [1 in.], and using a 14-L [½-ft^3] measure.

15.3 *Fine Aggregate (bulk density)*:

15.3.1 *Single-Operator Precision*—The single-operator standard deviation has been found to be 14 kg/m^3 [0.88 lb/ft^3] (1s). Therefore, results of two properly conducted tests by the same operator on similar material should not differ by more than 40 kg/m^3 [2.5 lb/ft^3] (d2s).

15.3.2 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 44 kg/m^3 [2.76 lb/ft^3] (1s). Therefore, results of two properly conducted tests from two different laboratories on similar material should not differ by more than 125 kg/m^3 [7.8 lb/ft^3] (d2s).

15.3.3 These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C670. The precision estimates were obtained from the analysis of AMRL proficiency sample data for loose bulk density from laboratories using a 2.8-L [⅒-ft^3] measure.

15.4 No precision data on void content are available. However, as the void content in aggregate is calculated from bulk density and bulk specific gravity, the precision of the voids content reflects the precision of these measured parameters given in 15.2 and 15.3 of this test method and in Test Methods C127 and C128.

15.5 *Bias*—The procedure in this test method for measuring bulk density and void content has no bias because the values for bulk density and void content can be defined only in terms of a test method.

16. Keywords

16.1 aggregates; bulk density; coarse aggregate; density; fine aggregate; unit weight; voids in aggregates

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C29/C29M – 07, that may impact the use of this test method. (Approved December 1, 2009)

(*1*) Revised 5.5.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org). Permission rights to photocopy the standard may also be secured from the ASTM website (www.astm.org/COPYRIGHT/).

Designation: C 31/C 31M – 09

Standard Practice for Making and Curing Concrete Test Specimens in the Field[1]

This standard is issued under the fixed designation C 31/C 31M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This practice covers procedures for making and curing cylinder and beam specimens from representative samples of fresh concrete for a construction project.

1.2 The concrete used to make the molded specimens shall be sampled after all on-site adjustments have been made to the mixture proportions, including the addition of mix water and admixtures. This practice is not satisfactory for making specimens from concrete not having measurable slump or requiring other sizes or shapes of specimens.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to exposed skin and tissue upon prolonged exposure.[2])

1.5 The text of this standard references notes which provide explanatory material. These notes shall not be considered as requirements of the standard.

3. Terminology

3.1 For definitions of terms used in this practice, refer to Terminology C 125.

4. Significance and Use

4.1 This practice provides standardized requirements for making, curing, protecting, and transporting concrete test specimens under field conditions.

4.2 If the specimens are made and standard cured, as stipulated herein, the resulting strength test data when the specimens are tested are able to be used for the following purposes:

4.2.1 Acceptance testing for specified strength,

4.2.2 Checking adequacy of mixture proportions for strength, and

4.2.3 Quality control.

4.3 If the specimens are made and field cured, as stipulated herein, the resulting strength test data when the specimens are tested are able to be used for the following purposes:

4.3.1 Determination of whether a structure is capable of being put in service,

4.3.2 Comparison with test results of standard cured specimens or with test results from various in-place test methods,

4.3.3 Adequacy of curing and protection of concrete in the structure, or

4.3.4 Form or shoring removal time requirements.

5. Apparatus

5.1 *Molds, General*— Molds for specimens or fastenings thereto in contact with the concrete shall be made of steel, cast iron, or other nonabsorbent material, nonreactive with concrete containing portland or other hydraulic cements. Molds shall hold their dimensions and shape under all conditions of use. Molds shall be watertight during use as judged by their ability to hold water poured into them. Provisions for tests of water leakage are given in the Test Methods for Elongation, Absorption, and Water Leakage section of Specification C 470/C 470M. A suitable sealant, such as heavy grease, modeling clay, or microcrystalline wax shall be used where necessary to prevent leakage through the joints. Positive means shall be provided to hold base plates firmly to the molds. Reusable molds shall be lightly coated with mineral oil or a suitable nonreactive form release material before use.

5.2 *Cylinder Molds*— Molds for casting concrete test specimens shall conform to the requirements of Specification C 470/C 470M.

5.3 *Beam Molds*—Beam molds shall be of the shape and dimensions required to produce the specimens stipulated in 6.2. The inside surfaces of the molds shall be smooth. The sides, bottom, and ends shall be at right angles to each other and shall be straight and true and free of warpage. Maximum variation from the nominal cross section shall not exceed ⅛ in. [3 mm] for molds with depth or breadth of 6 in. [150 mm] or more. Molds shall produce specimens at least as long but not more than 1/16 in. [2 mm] shorter than the required length in 6.2.

5.4 *Tamping Rod*—A round, straight, steel rod with a diameter conforming to the requirements in Table 1. The length of the tamping rod shall be at least 4 in. [100 mm] greater than the depth of the mold in which rodding is being performed, but not greater than 24 in. [600 mm] in overall length (see Note 1). The length tolerance for the tamping rod shall be ± ⅛ in. [4 mm]. The rod shall have the tamping end or both ends rounded to a hemispherical tip of the same diameter as the rod.

NOTE 1—A rod length of 16 in. [400 mm] to 24 in. [600 mm] meets the requirements of the following: Practice C 31/C 31M, Test Method C 138/C 138M, Test Method C 143/C 143M, Test Method C 173/C 173M, and Test Method C 231.

5.5 *Vibrators*—Internal vibrators shall be used. The vibrator frequency shall be at least 9000 vibrations per minute [150 Hz] while the vibrator is operating in the concrete. The diameter of a round vibrator shall be no more than one-fourth the diameter of the cylinder mold or one-fourth the width of the beam mold. Other shaped vibrators shall have a perimeter equivalent to the circumference of an appropriate round vibrator. The combined length of the vibrator shaft and vibrating element shall exceed the depth of the section being vibrated by at least 3 in. [75 mm]. The vibrator frequency shall be checked periodically with a vibrating-reed tachometer or other suitable device.

TABLE 1 Tamping Rod Diameter Requirements

Diameter of Cylinder or Width of Beam in. [mm]	Diameter or Rod in. [mm]
<6 [150]	⅜ ± 1/16 [10 ± 2]
≥6 [150]	⅝ ± 1/16 [16 ± 2]

NOTE 2—For information on size and frequency of various vibrators and a method to periodically check vibrator frequency see ACI 309R.

5.6 *Mallet*—A mallet with a rubber or rawhide head weighing 1.25 ± 0.50 lb [0.6 ± 0.2 kg] shall be used.

5.7 *Placement Tools*—of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so concrete is not spilled during placement in the mold. For placing concrete in a cylinder mold, the acceptable tool is a scoop. For placing concrete in a beam mold, either a shovel or scoop is permitted.

5.8 *Finishing Tools*—a handheld float or a trowel.

5.9 *Slump Apparatus*— The apparatus for measurement of slump shall conform to the requirements of Test Method C 143/C 143M.

5.10 *Sampling Receptacle*—The receptacle shall be a suitable heavy gauge metal pan, wheelbarrow, or flat, clean nonabsorbent board of sufficient capacity to allow easy remixing of the entire sample with a shovel or trowel.

5.11 *Air Content Apparatus*—The apparatus for measuring air content shall conform to the requirements of Test Methods C 173/C 173M or C 231.

5.12 *Temperature Measuring Devices*—The temperature measuring devices shall conform to the applicable requirements of Test Method C 1064/C 1064M.

6. Testing Requirements

6.1 *Cylindrical Specimens*—Compressive or splitting tensile strength specimens shall be cylinders cast and allowed to set in an upright position. The number and size of cylinders cast shall be as directed by the specifier of the tests. In addition, the length shall be twice the diameter and the cylinder diameter shall be at least 3 times the nominal maximum size of the coarse aggregate. When the nominal maximum size of the coarse aggregate exceeds 2 in. [50 mm], the concrete sample shall be treated by wet sieving through a 2-in. [50-mm] sieve as described in Practice C 172. For acceptance testing for specified compressive strength, cylinders shall be 6 by 12 in. [150 by 300 mm] or 4 × 8 in. [100 × 200 mm] (Note 3).

NOTE 3—When molds in SI units are required and not available, equivalent inch-pound unit size mold should be permitted.

6.2 *Beam Specimens*— Flexural strength specimens shall be beams of concrete cast and hardened in the horizontal position. The number of beams cast shall be as directed by the specifier of the tests. The length shall be at least 2 in. [50 mm] greater than three times the depth as tested. The ratio of width to depth

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

as molded shall not exceed 1.5. The standard beam shall be 6 by 6 in. [150 by 150 mm] in cross section, and shall be used for concrete with nominal maximum size coarse aggregate up to 2 in. [50 mm]. When the nominal maximum size of the coarse aggregate exceeds 2 in. [50 mm], the smaller cross sectional dimension of the beam shall be at least three times the nominal maximum size of the coarse aggregate. Unless required by project specifications, beams made in the field shall not have a width or depth of less than 6 in. [150 mm].

6.3 *Field Technicians*—The field technicians making and curing specimens for acceptance testing shall be certified ACI Field Testing Technicians, Grade I or equivalent. Equivalent personnel certification programs shall include both written and performance examinations, as outlined in ACI CP-1.

7. Sampling Concrete

7.1 The samples used to fabricate test specimens under this standard shall be obtained in accordance with Practice C 172 unless an alternative procedure has been approved.

7.2 Record the identification of the sample with respect to the location of the concrete represented and the time of casting.

8. Slump, Air Content, and Temperature

8.1 *Slump*—Measure and record the slump of each batch of concrete from which specimens are made immediately after remixing in the receptacle, as required in Test Method C 143/C 143M.

8.2 *Air Content*— Determine and record the air content in accordance with either Test Method C 173/C 173M or Test Method C 231. The concrete used in performing the air content test shall not be used in fabricating test specimens.

8.3 *Temperature*— Determine and record the temperature in accordance with Test Method C 1064/C 1064M.

NOTE 4—Some specifications may require the measurement of the unit weight of concrete. The volume of concrete produced per batch may be desired on some projects. Also, additional information on the air content measurements may be desired. Test Method C 138/C 138M is used to measure the unit weight, yield, and gravimetric air content of freshly mixed concrete.

9. Molding Specimens

9.1 *Place of Molding*— Mold specimens promptly on a level, rigid surface, free of vibration and other disturbances, at a place as near as practicable to the location where they are to be stored.

9.2 *Casting Cylinders*—Select the proper tamping rod from 5.4 and Table 1 or the proper vibrator from 5.5. Determine the method of consolidation from Table 2, unless another method is specified. If the method of consolidation is rodding, determine molding requirements from Table 3. If the method of consolidation is vibration, determine molding requirements from Table 4. Select a scoop of the size described in 5.7. While placing the concrete in the mold, move the scoop around the perimeter of the mold opening to ensure an even distribution of the concrete with minimal segregation. Each layer of concrete shall be consolidated as required. In placing the final layer, add an amount of concrete that will fill the mold after consolidation.

TABLE 2 Method of Consolidation Requirements

Slump in. [mm]	Method of Consolidation
≥ 1 [25]	rodding or vibration
< 1 [25]	vibration

TABLE 3 Molding Requirements by Rodding

Specimen Type and Size	Number of Layers of Approximately Equal Depth	Number of Roddings per Layer
Cylinders:		
Diameter, in. [mm]		
4 [100]	2	25
6 [150]	3	25
9 [225]	4	50
Beams:		
Width, in. [mm]		
6 [150] to 8 [200]	2	see 9.3
>8 [200]	3 or more equal depths, each not to exceed 6 in. [150 mm].	see 9.3

TABLE 4 Molding Requirements by Vibration

Specimen Type and Size	Number of Layers	Number of Vibrator Insertions per Layer	Approximate Depth of Layer, in. [mm]
Cylinders:			
Diameter, in. [mm]			
4 [100]	2	1	one-half depth of specimen
6 [150]	2	2	one-half depth of specimen
9 [225]	2	4	one-half depth of specimen
Beams:			
Width, in. [mm]			
6 [150] to 8 [200]	1	see 9.4.2	depth of specimen
over 8 [200]	2 or more	see 9.4.2	8 [200] as near as practicable

9.3 *Casting Beams*— Select the proper tamping rod from 5.4 and Table 1 or proper vibrator from 5.5. Determine the method of consolidation from Table 2, unless another method is specified. If the method of consolidation is rodding, determine the molding requirements from Table 3. If the method of consolidation is vibration, determine the molding requirements from Table 4. Determine the number of roddings per layer, one for each 2 in.^{2} [14 cm^2] of the top surface area of the beam. Select a placement tool as described in 5.7. Using the scoop or shovel, place the concrete in the mold to the height required for each layer. Place the concrete so that it is uniformly distributed within each layer with minimal segregation. Each layer shall be consolidated as required. In placing the final layer, add an amount of concrete that will fill the mold after consolidation.

9.4 *Consolidation*— The methods of consolidation for this practice are rodding or internal vibration.

9.4.1 *Rodding*—Place the concrete in the mold in the required number of layers of approximately equal volume. Rod each layer uniformly over the cross section with the rounded end of the rod using the required number of strokes. Rod the bottom layer throughout its depth. In rodding this layer, use care not to damage the bottom of the mold. For each upper layer, allow the rod to penetrate through the layer being rodded and into the layer below approximately 1 in. [25 mm]. After

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

each layer is rodded, tap the outsides of the mold lightly 10 to 15 times with the mallet to close any holes left by rodding and to release any large air bubbles that may have been trapped. Use an open hand to tap light-gauge single-use cylinder molds which are susceptible to damage if tapped with a mallet. After tapping, spade each layer of the concrete along the sides and ends of beam molds with a trowel or other suitable tool. Underfilled molds shall be adjusted with representative concrete during consolidation of the top layer. Overfilled molds shall have excess concrete removed.

9.4.2 *Vibration*—Maintain a uniform duration of vibration for the particular kind of concrete, vibrator, and specimen mold involved. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator. Usually sufficient vibration has been applied as soon as the surface of the concrete has become relatively smooth and large air bubbles cease to break through the top surface. Continue vibration only long enough to achieve proper consolidation of the concrete (see Note 5). Fill the molds and vibrate in the required number of approximately equal layers. Place all the concrete for each layer in the mold before starting vibration of that layer. In compacting the specimen, insert the vibrator slowly and do not allow it to rest on the bottom or sides of the mold. Slowly withdraw the vibrator so that no large air pockets are left in the specimen. When placing the final layer, avoid overfilling by more than ¼ in. [6 mm].

NOTE 5—Generally, no more than 5 s of vibration should be required for each insertion to adequately consolidate concrete with a slump greater than 3 in. [75 mm]. Longer times may be required for lower slump concrete, but the vibration time should rarely have to exceed 10 s per insertion.

9.4.2.1 *Cylinders*—The number of insertions of the vibrator per layer is given in Table 4. When more than one insertion per layer is required distribute the insertion uniformly within each layer. Allow the vibrator to penetrate through the layer being vibrated, and into the layer below, about 1 in. [25 mm]. After each layer is vibrated, tap the outsides of the mold at least 10 times with the mallet, to close holes that remain and to release entrapped air voids. Use an open hand to tap cardboard and single-use metal molds that are susceptible to damage if tapped with a mallet.

9.4.2.2 *Beams*—Insert the vibrator at intervals not exceeding 6 in. [150 mm] along the center line of the long dimension of the specimen. For specimens wider than 6 in., use alternating insertions along two lines. Allow the shaft of the vibrator to penetrate into the bottom layer about 1 in. [25 mm]. After each layer is vibrated, tap the outsides of the mold sharply at least 10 times with the mallet to close holes left by vibrating and to release entrapped air voids.

9.5 *Finishing*—Perform all finishing with the minimum manipulation necessary to produce a flat even surface that is level with the rim or edge of the mold and that has no depressions or projections larger than ⅛ in. [3.3 mm].

9.5.1 *Cylinders*—After consolidation, finish the top surfaces by striking them off with the tamping rod where the consistency of the concrete permits or with a handheld float or trowel. If desired, cap the top surface of freshly made cylinders with a thin layer of stiff portland cement paste which is permitted to harden and cure with the specimen. See section on Capping Materials of Practice C 617.

9.5.2 *Beams*—After consolidation of the concrete, use a handheld float or trowel to strike off the top surface to the required tolerance to produce a flat, even surface.

9.6 *Identification*— Mark the specimens to positively identify them and the concrete they represent. Use a method that will not alter the top surface of the concrete. Do not mark the removable caps. Upon removal of the molds, mark the test specimens to retain their identities.

10. Curing

10.1 *Standard Curing*— Standard curing is the curing method used when the specimens are made and cured for the purposes stated in 4.2.

10.1.1 *Storage*—If specimens cannot be molded at the place where they will receive initial curing, immediately after finishing move the specimens to an initial curing place for storage. The supporting surface on which specimens are stored shall be level to within ¼ in. per ft [20 mm per m]. If cylinders in the single use molds are moved, lift and support the cylinders from the bottom of the molds with a large trowel or similar device. If the top surface is marred during movement to place of initial storage, immediately refinish.

10.1.2 *Initial Curing*— Immediately after molding and finishing, the specimens shall be stored for a period up to 48 h in a temperature range from 60 and 80 °F [16 and 27 °C] and in an environment preventing moisture loss from the specimens. For concrete mixtures with a specified strength of 6000 psi [40 MPa] or greater, the initial curing temperature shall be between 68 and 78 °F [20 and 26 °C]. Various procedures are capable of being used during the initial curing period to maintain the specified moisture and temperature conditions. An appropriate procedure or combination of procedures shall be used (Note 6). Shield all specimens from the direct sunlight and, if used, radiant heating devices. The storage temperature shall be controlled by use of heating and cooling devices, as necessary. Record the temperature using a maximum-minimum thermometer. If cardboard molds are used, protect the outside surface of the molds from contact with wet burlap or other sources of water.

NOTE 6—A satisfactory moisture environment can be created during the initial curing of the specimens by one or more of the following procedures: (1) immediately immerse molded specimens with plastic lids in water saturated with calcium hydroxide, (2) store in properly constructed wooden boxes or structures, (3) place in damp sand pits, (4) cover with removable plastic lids, (5) place inside plastic bags, or (6) cover with plastic sheets or nonabsorbent plates if provisions are made to avoid drying and damp burlap is used inside the enclosure, but the burlap is prevented from contacting the concrete surfaces. A satisfactory temperature environment can be controlled during the initial curing of the specimens by one or more of the following procedures: (1) use of ventilation, (2) use of ice, (3) use of thermostatically controlled heating or cooling devices, or (4) use of heating methods such as stoves or light bulbs. Other suitable methods may be used provided the requirements limiting specimen storage temperature and moisture loss are met. For concrete mixtures with a specified strength of 6000 psi [40 MPa] or greater, heat generated during the early ages may raise the temperature above the required storage temperature. Immersion in water saturated with calcium hydroxide may be the easiest method to maintain the required storage temperature. When specimens are to be immersed in water

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

saturated with calcium hydroxide, specimens in cardboard molds or other molds that expand when immersed in water should not be used. Early-age strength test results may be lower when stored at 60 °F [16 °C] and higher when stored at 80 °F [27 °C]. On the other hand, at later ages, test results may be lower for higher initial storage temperatures.

10.1.3 *Final Curing:*

10.1.3.1 *Cylinders*—Upon completion of initial curing and within 30 min after removing the molds, cure specimens with free water maintained on their surfaces at all times at a temperature of 73.5 ± 3.5 °F [23.0 ± 2.0 °C] using water storage tanks or moist rooms complying with the requirements of Specification C 511, except when capping with sulfur mortar capping compound and immediately prior to testing. When capping with sulfur mortar capping compound, the ends of the cylinder shall be dry enough to preclude the formation of steam or foam pockets under or in cap larger than ¼ in. [6 mm] as described in Practice C 617. For a period not to exceed 3 h immediately prior to test, standard curing temperature is not required provided free moisture is maintained on the cylinders and ambient temperature is between 68 and 86 °F [20 and 30 °C].

10.1.3.2 *Beams*—Beams are to be cured the same as cylinders (see 10.1.3.1) except that they shall be stored in water saturated with calcium hydroxide at 73.5 ± 3.5 °F [23.0 ± 2.0 °C] at least 20 h prior to testing. Drying of the surfaces of the beam shall be prevented between removal from water storage and completion of testing.

NOTE 7—Relatively small amounts of surface drying of flexural specimens can induce tensile stresses in the extreme fibers that will markedly reduce the indicated flexural strength.

10.2 *Field Curing*— Field curing is the curing method used for the specimens made and cured as stated in 4.3.

10.2.1 *Cylinders*—Store cylinders in or on the structure as near to the point of deposit of the concrete represented as possible. Protect all surfaces of the cylinders from the elements in as near as possible the same way as the formed work. Provide the cylinders with the same temperature and moisture environment as the structural work. Test the specimens in the moisture condition resulting from the specified curing treatment. To meet these conditions, specimens made for the purpose of determining when a structure is capable of being put in service shall be removed from the molds at the time of removal of form work.

10.2.2 *Beams*—As nearly as practicable, cure beams in the same manner as the concrete in the structure. At the end of 48 ± 4 h after molding, take the molded specimens to the storage location and remove from the molds. Store specimens representing pavements of slabs on grade by placing them on the ground as molded, with their top surfaces up. Bank the sides and ends of the specimens with earth or sand that shall be kept damp, leaving the top surfaces exposed to the specified curing treatment. Store specimens representing structure concrete as near the point in the structure they represent as possible, and afford them the same temperature protection and moisture environment as the structure. At the end of the curing period leave the specimens in place exposed to the weather in the same manner as the structure. Remove all beam specimens from field storage and store in water saturated with calcium hydroxide at 73.5 ± 3.5 °F [23.0 ± 2.0 °C] for 24 ± 4 h immediately before time of testing to ensure uniform moisture condition from specimen to specimen. Observe the precautions given in 10.1.3.2 to guard against drying between time of removal from curing to testing.

10.3 *Structural Lightweight Concrete Curing*—Cure structural lightweight concrete cylinders in accordance with Specification C 330.

11. Transportation of Specimens to Laboratory

11.1 Prior to transporting, cure and protect specimens as required in Section 10. Specimens shall not be transported until at least 8 h after final set. (See Note 8). During transporting, protect the specimens with suitable cushioning material to prevent damage from jarring. During cold weather, protect the specimens from freezing with suitable insulation material. Prevent moisture loss during transportation by wrapping the specimens in plastic, wet burlap, by surrounding them with wet sand, or tight fitting plastic caps on plastic molds. Transportation time shall not exceed 4 h.

NOTE 8—Setting time may be measured by Test Method C 403/C 403M.

12. Report

12.1 Report the following information to the laboratory that will test the specimens:

12.1.1 Identification number,

12.1.2 Location of concrete represented by the samples,

12.1.3 Date, time and name of individual molding specimens,

12.1.4 Slump, air content, and concrete temperature, test results and results of any other tests on the fresh concrete and any deviations from referenced standard test methods, and

12.1.5 Curing method. For standard curing method, report the initial curing method with maximum and minimum temperatures and final curing method. For field curing method, report the location where stored, manner of protection from the elements, temperature and moisture environment, and time of removal from molds.

13. Keywords

13.1 beams; casting samples; concrete; curing; cylinders; testing

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 31/C 31M – 08b, that may impact the use of this practice. (Approved May 1, 2009)

(*1*) Revised 5.4, Table 1, and 9.4.1 so that similar wording is used in several standards regarding the requirements for the tamping rod.

(*2*) Added new Note 1 to describe an acceptable tamping rod length for several standards.

(*3*) Revised 5.5 to change the vibrator frequency from 7000 vibrations per minute to 9000 vibrations per minute

Committee C09 has identified the location of selected changes to this practice since the last issue, C 31/C 31M – 08a, that may impact the use of this practice. (Approved December 15, 2008)

(*1*) Changed the laboratory curing temperature range from "73 ± 3 °F [23 ± 2 °C]" to "73.5 ± 3.5 °F [23.0 ± 2.0 °C]" in 10.1.3.1, 10.1.3.2, and 10.2.2.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 31/C 31M – 08, that may impact the use of this practice. (Approved April 1, 2008)

(*1*) Revised 5.5, 5.7, 9.2, 9.3, and 9.5.

(*2*) Added new 5.8 and renumbered subsequent paragraphs.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 31/C 31M – 06, that may impact the use of this practice. (Approved February 1, 2008)

(*1*) Revised 6.1.

(*2*) Revised 6.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 31/C 31M – 09

Standard Practice for Making and Curing Concrete Test Specimens in the Field[1]

This standard is issued under the fixed designation C 31/C 31M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This practice covers procedures for making and curing cylinder and beam specimens from representative samples of fresh concrete for a construction project.

1.2 The concrete used to make the molded specimens shall be sampled after all on-site adjustments have been made to the mixture proportions, including the addition of mix water and admixtures. This practice is not satisfactory for making specimens from concrete not having measurable slump or requiring other sizes or shapes of specimens.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to exposed skin and tissue upon prolonged exposure.[2])

1.5 The text of this standard references notes which provide explanatory material. These notes shall not be considered as requirements of the standard.

2. Referenced Documents

309R Guide for Consolidation of Concrete

3. Terminology

3.1 For definitions of terms used in this practice, refer to Terminology C 125.

4. Significance and Use

4.1 This practice provides standardized requirements for making, curing, protecting, and transporting concrete test specimens under field conditions.

4.2 If the specimens are made and standard cured, as stipulated herein, the resulting strength test data when the specimens are tested are able to be used for the following purposes:

4.2.1 Acceptance testing for specified strength,

4.2.2 Checking adequacy of mixture proportions for strength, and

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved May 1, 2009. Published May 2009. Originally approved in 1920. Last previous edition approved in 2008 as C 31/C 31M – 08b.

4.2.3 Quality control.

4.3 If the specimens are made and field cured, as stipulated herein, the resulting strength test data when the specimens are tested are able to be used for the following purposes:

4.3.1 Determination of whether a structure is capable of being put in service,

4.3.2 Comparison with test results of standard cured specimens or with test results from various in-place test methods,

4.3.3 Adequacy of curing and protection of concrete in the structure, or

4.3.4 Form or shoring removal time requirements.

5. Apparatus

5.1 *Molds, General*— Molds for specimens or fastenings thereto in contact with the concrete shall be made of steel, cast iron, or other nonabsorbent material, nonreactive with concrete containing portland or other hydraulic cements. Molds shall hold their dimensions and shape under all conditions of use. Molds shall be watertight during use as judged by their ability to hold water poured into them. Provisions for tests of water leakage are given in the Test Methods for Elongation, Absorption, and Water Leakage section of Specification C 470/C 470M. A suitable sealant, such as heavy grease, modeling clay, or microcrystalline wax shall be used where necessary to prevent leakage through the joints. Positive means shall be provided to hold base plates firmly to the molds. Reusable molds shall be lightly coated with mineral oil or a suitable nonreactive form release material before use.

5.2 *Cylinder Molds*— Molds for casting concrete test specimens shall conform to the requirements of Specification C 470/C 470M.

5.3 *Beam Molds*—Beam molds shall be of the shape and dimensions required to produce the specimens stipulated in 6.2. The inside surfaces of the molds shall be smooth. The sides, bottom, and ends shall be at right angles to each other and shall be straight and true and free of warpage. Maximum variation from the nominal cross section shall not exceed ⅛ in. [3 mm] for molds with depth or breadth of 6 in. [150 mm] or more. Molds shall produce specimens at least as long but not more than 1/16 in. [2 mm] shorter than the required length in 6.2.

5.4 *Tamping Rod*—A round, straight, steel rod with a diameter conforming to the requirements in Table 1. The length of the tamping rod shall be at least 4 in. [100 mm] greater than the depth of the mold in which rodding is being performed, but not greater than 24 in. [600 mm] in overall length (see Note 1). The length tolerance for the tamping rod shall be ± ⅛ in. [4 mm]. The rod shall have the tamping end or both ends rounded to a hemispherical tip of the same diameter as the rod.

NOTE 1—A rod length of 16 in. [400 mm] to 24 in. [600 mm] meets the requirements of the following: Practice C 31/C 31M, Test Method C 138/C 138M, Test Method C 143/C 143M, Test Method C 173/C 173M, and Test Method C 231.

5.5 *Vibrators*—Internal vibrators shall be used. The vibrator frequency shall be at least 9000 vibrations per minute [150 Hz] while the vibrator is operating in the concrete. The diameter of a round vibrator shall be no more than one-fourth the diameter of the cylinder mold or one-fourth the width of the beam mold. Other shaped vibrators shall have a perimeter equivalent to the circumference of an appropriate round vibrator. The combined length of the vibrator shaft and vibrating element shall exceed the depth of the section being vibrated by at least 3 in. [75 mm]. The vibrator frequency shall be checked periodically with a vibrating-reed tachometer or other suitable device.

TABLE 1 Tamping Rod Diameter Requirements

Diameter of Cylinder or Width of Beam in. [mm]	Diameter or Rod in. [mm]
<6 [150]	⅜ ± 1/16 [10 ± 2]
≥6 [150]	⅝ ± 1/16 [16 ± 2]

NOTE 2—For information on size and frequency of various vibrators and a method to periodically check vibrator frequency see ACI 309R.

5.6 *Mallet*—A mallet with a rubber or rawhide head weighing 1.25 ± 0.50 lb [0.6 ± 0.2 kg] shall be used.

5.7 *Placement Tools*—of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so concrete is not spilled during placement in the mold. For placing concrete in a cylinder mold, the acceptable tool is a scoop. For placing concrete in a beam mold, either a shovel or scoop is permitted.

5.8 *Finishing Tools*—a handheld float or a trowel.

5.9 *Slump Apparatus*— The apparatus for measurement of slump shall conform to the requirements of Test Method C 143/C 143M.

5.10 *Sampling Receptacle*—The receptacle shall be a suitable heavy gauge metal pan, wheelbarrow, or flat, clean nonabsorbent board of sufficient capacity to allow easy remixing of the entire sample with a shovel or trowel.

5.11 *Air Content Apparatus*—The apparatus for measuring air content shall conform to the requirements of Test Methods C 173/C 173M or C 231.

5.12 *Temperature Measuring Devices*—The temperature measuring devices shall conform to the applicable requirements of Test Method C 1064/C 1064M.

6. Testing Requirements

6.1 *Cylindrical Specimens*—Compressive or splitting tensile strength specimens shall be cylinders cast and allowed to set in an upright position. The number and size of cylinders cast shall be as directed by the specifier of the tests. In addition, the length shall be twice the diameter and the cylinder diameter shall be at least 3 times the nominal maximum size of the coarse aggregate. When the nominal maximum size of the coarse aggregate exceeds 2 in. [50 mm], the concrete sample shall be treated by wet sieving through a 2-in. [50-mm] sieve as described in Practice C 172. For acceptance testing for specified compressive strength, cylinders shall be 6 by 12 in. [150 by 300 mm] or 4 × 8 in. [100 × 200 mm] (Note 3).

NOTE 3—When molds in SI units are required and not available, equivalent inch-pound unit size mold should be permitted.

6.2 *Beam Specimens*— Flexural strength specimens shall be beams of concrete cast and hardened in the horizontal position. The number of beams cast shall be as directed by the specifier of the tests. The length shall be at least 2 in. [50 mm] greater than three times the depth as tested. The ratio of width to depth

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:53 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

as molded shall not exceed 1.5. The standard beam shall be 6 by 6 in. [150 by 150 mm] in cross section, and shall be used for concrete with nominal maximum size coarse aggregate up to 2 in. [50 mm]. When the nominal maximum size of the coarse aggregate exceeds 2 in. [50 mm], the smaller cross sectional dimension of the beam shall be at least three times the nominal maximum size of the coarse aggregate. Unless required by project specifications, beams made in the field shall not have a width or depth of less than 6 in. [150 mm].

6.3 *Field Technicians*—The field technicians making and curing specimens for acceptance testing shall be certified ACI Field Testing Technicians, Grade I or equivalent. Equivalent personnel certification programs shall include both written and performance examinations, as outlined in ACI CP-1.

7. Sampling Concrete

7.1 The samples used to fabricate test specimens under this standard shall be obtained in accordance with Practice C 172 unless an alternative procedure has been approved.

7.2 Record the identification of the sample with respect to the location of the concrete represented and the time of casting.

8. Slump, Air Content, and Temperature

8.1 *Slump*—Measure and record the slump of each batch of concrete from which specimens are made immediately after remixing in the receptacle, as required in Test Method C 143/C 143M.

8.2 *Air Content*— Determine and record the air content in accordance with either Test Method C 173/C 173M or Test Method C 231. The concrete used in performing the air content test shall not be used in fabricating test specimens.

8.3 *Temperature*— Determine and record the temperature in accordance with Test Method C 1064/C 1064M.

NOTE 4—Some specifications may require the measurement of the unit weight of concrete. The volume of concrete produced per batch may be desired on some projects. Also, additional information on the air content measurements may be desired. Test Method C 138/C 138M is used to measure the unit weight, yield, and gravimetric air content of freshly mixed concrete.

9. Molding Specimens

9.1 *Place of Molding*— Mold specimens promptly on a level, rigid surface, free of vibration and other disturbances, at a place as near as practicable to the location where they are to be stored.

9.2 *Casting Cylinders*—Select the proper tamping rod from 5.4 and Table 1 or the proper vibrator from 5.5. Determine the method of consolidation from Table 2, unless another method is specified. If the method of consolidation is rodding, determine molding requirements from Table 3. If the method of consolidation is vibration, determine molding requirements from Table 4. Select a scoop of the size described in 5.7. While placing the concrete in the mold, move the scoop around the perimeter of the mold opening to ensure an even distribution of the concrete with minimal segregation. Each layer of concrete shall be consolidated as required. In placing the final layer, add an amount of concrete that will fill the mold after consolidation.

TABLE 2 Method of Consolidation Requirements

Slump in. [mm]	Method of Consolidation
≥ 1 [25]	rodding or vibration
< 1 [25]	vibration

TABLE 3 Molding Requirements by Rodding

Specimen Type and Size	Number of Layers of Approximately Equal Depth	Number of Roddings per Layer
Cylinders:		
Diameter, in. [mm]		
4 [100]	2	25
6 [150]	3	25
9 [225]	4	50
Beams:		
Width, in. [mm]		
6 [150] to 8 [200]	2	see 9.3
>8 [200]	3 or more equal depths, each not to exceed 6 in. [150 mm].	see 9.3

TABLE 4 Molding Requirements by Vibration

Specimen Type and Size	Number of Layers	Number of Vibrator Insertions per Layer	Approximate Depth of Layer, in. [mm]
Cylinders:			
Diameter, in. [mm]			
4 [100]	2	1	one-half depth of specimen
6 [150]	2	2	one-half depth of specimen
9 [225]	2	4	one-half depth of specimen
Beams:			
Width, in. [mm]			
6 [150] to 8 [200]	1	see 9.4.2	depth of specimen
over 8 [200]	2 or more	see 9.4.2	8 [200] as near as practicable

9.3 *Casting Beams*— Select the proper tamping rod from 5.4 and Table 1 or proper vibrator from 5.5. Determine the method of consolidation from Table 2, unless another method is specified. If the method of consolidation is rodding, determine the molding requirements from Table 3. If the method of consolidation is vibration, determine the molding requirements from Table 4. Determine the number of roddings per layer, one for each 2 in.^{2} [14 cm^2] of the top surface area of the beam. Select a placement tool as described in 5.7. Using the scoop or shovel, place the concrete in the mold to the height required for each layer. Place the concrete so that it is uniformly distributed within each layer with minimal segregation. Each layer shall be consolidated as required. In placing the final layer, add an amount of concrete that will fill the mold after consolidation.

9.4 *Consolidation*— The methods of consolidation for this practice are rodding or internal vibration.

9.4.1 *Rodding*—Place the concrete in the mold in the required number of layers of approximately equal volume. Rod each layer uniformly over the cross section with the rounded end of the rod using the required number of strokes. Rod the bottom layer throughout its depth. In rodding this layer, use care not to damage the bottom of the mold. For each upper layer, allow the rod to penetrate through the layer being rodded and into the layer below approximately 1 in. [25 mm]. After

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:53 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

each layer is rodded, tap the outsides of the mold lightly 10 to 15 times with the mallet to close any holes left by rodding and to release any large air bubbles that may have been trapped. Use an open hand to tap light-gauge single-use cylinder molds which are susceptible to damage if tapped with a mallet. After tapping, spade each layer of the concrete along the sides and ends of beam molds with a trowel or other suitable tool. Underfilled molds shall be adjusted with representative concrete during consolidation of the top layer. Overfilled molds shall have excess concrete removed.

9.4.2 *Vibration*—Maintain a uniform duration of vibration for the particular kind of concrete, vibrator, and specimen mold involved. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator. Usually sufficient vibration has been applied as soon as the surface of the concrete has become relatively smooth and large air bubbles cease to break through the top surface. Continue vibration only long enough to achieve proper consolidation of the concrete (see Note 5). Fill the molds and vibrate in the required number of approximately equal layers. Place all the concrete for each layer in the mold before starting vibration of that layer. In compacting the specimen, insert the vibrator slowly and do not allow it to rest on the bottom or sides of the mold. Slowly withdraw the vibrator so that no large air pockets are left in the specimen. When placing the final layer, avoid overfilling by more than ¼ in. [6 mm].

NOTE 5—Generally, no more than 5 s of vibration should be required for each insertion to adequately consolidate concrete with a slump greater than 3 in. [75 mm]. Longer times may be required for lower slump concrete, but the vibration time should rarely have to exceed 10 s per insertion.

9.4.2.1 *Cylinders*—The number of insertions of the vibrator per layer is given in Table 4. When more than one insertion per layer is required distribute the insertion uniformly within each layer. Allow the vibrator to penetrate through the layer being vibrated, and into the layer below, about 1 in. [25 mm]. After each layer is vibrated, tap the outsides of the mold at least 10 times with the mallet, to close holes that remain and to release entrapped air voids. Use an open hand to tap cardboard and single-use metal molds that are susceptible to damage if tapped with a mallet.

9.4.2.2 *Beams*—Insert the vibrator at intervals not exceeding 6 in. [150 mm] along the center line of the long dimension of the specimen. For specimens wider than 6 in., use alternating insertions along two lines. Allow the shaft of the vibrator to penetrate into the bottom layer about 1 in. [25 mm]. After each layer is vibrated, tap the outsides of the mold sharply at least 10 times with the mallet to close holes left by vibrating and to release entrapped air voids.

9.5 *Finishing*—Perform all finishing with the minimum manipulation necessary to produce a flat even surface that is level with the rim or edge of the mold and that has no depressions or projections larger than ⅛ in. [3.3 mm].

9.5.1 *Cylinders*—After consolidation, finish the top surfaces by striking them off with the tamping rod where the consistency of the concrete permits or with a handheld float or trowel. If desired, cap the top surface of freshly made cylinders with a thin layer of stiff portland cement paste which is permitted to harden and cure with the specimen. See section on Capping Materials of Practice C 617.

9.5.2 *Beams*—After consolidation of the concrete, use a handheld float or trowel to strike off the top surface to the required tolerance to produce a flat, even surface.

9.6 *Identification*— Mark the specimens to positively identify them and the concrete they represent. Use a method that will not alter the top surface of the concrete. Do not mark the removable caps. Upon removal of the molds, mark the test specimens to retain their identities.

10. Curing

10.1 *Standard Curing*— Standard curing is the curing method used when the specimens are made and cured for the purposes stated in 4.2.

10.1.1 *Storage*—If specimens cannot be molded at the place where they will receive initial curing, immediately after finishing move the specimens to an initial curing place for storage. The supporting surface on which specimens are stored shall be level to within ¼ in. per ft [20 mm per m]. If cylinders in the single use molds are moved, lift and support the cylinders from the bottom of the molds with a large trowel or similar device. If the top surface is marred during movement to place of initial storage, immediately refinish.

10.1.2 *Initial Curing*— Immediately after molding and finishing, the specimens shall be stored for a period up to 48 h in a temperature range from 60 and 80 °F [16 and 27 °C] and in an environment preventing moisture loss from the specimens. For concrete mixtures with a specified strength of 6000 psi [40 MPa] or greater, the initial curing temperature shall be between 68 and 78 °F [20 and 26 °C]. Various procedures are capable of being used during the initial curing period to maintain the specified moisture and temperature conditions. An appropriate procedure or combination of procedures shall be used (Note 6). Shield all specimens from the direct sunlight and, if used, radiant heating devices. The storage temperature shall be controlled by use of heating and cooling devices, as necessary. Record the temperature using a maximum-minimum thermometer. If cardboard molds are used, protect the outside surface of the molds from contact with wet burlap or other sources of water.

NOTE 6—A satisfactory moisture environment can be created during the initial curing of the specimens by one or more of the following procedures: (1) immediately immerse molded specimens with plastic lids in water saturated with calcium hydroxide, (2) store in properly constructed wooden boxes or structures, (3) place in damp sand pits, (4) cover with removable plastic lids, (5) place inside plastic bags, or (6) cover with plastic sheets or nonabsorbent plates if provisions are made to avoid drying and damp burlap is used inside the enclosure, but the burlap is prevented from contacting the concrete surfaces. A satisfactory temperature environment can be controlled during the initial curing of the specimens by one or more of the following procedures: (1) use of ventilation, (2) use of ice, (3) use of thermostatically controlled heating or cooling devices, or (4) use of heating methods such as stoves or light bulbs. Other suitable methods may be used provided the requirements limiting specimen storage temperature and moisture loss are met. For concrete mixtures with a specified strength of 6000 psi [40 MPa] or greater, heat generated during the early ages may raise the temperature above the required storage temperature. Immersion in water saturated with calcium hydroxide may be the easiest method to maintain the required storage temperature. When specimens are to be immersed in water

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:56:53 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

saturated with calcium hydroxide, specimens in cardboard molds or other molds that expand when immersed in water should not be used. Early-age strength test results may be lower when stored at 60 °F [16 °C] and higher when stored at 80 °F [27 °C]. On the other hand, at later ages, test results may be lower for higher initial storage temperatures.

10.1.3 *Final Curing:*

10.1.3.1 *Cylinders*—Upon completion of initial curing and within 30 min after removing the molds, cure specimens with free water maintained on their surfaces at all times at a temperature of 73.5 ± 3.5 °F [23.0 ± 2.0 °C] using water storage tanks or moist rooms complying with the requirements of Specification C 511, except when capping with sulfur mortar capping compound and immediately prior to testing. When capping with sulfur mortar capping compound, the ends of the cylinder shall be dry enough to preclude the formation of steam or foam pockets under or in cap larger than ¼ in. [6 mm] as described in Practice C 617. For a period not to exceed 3 h immediately prior to test, standard curing temperature is not required provided free moisture is maintained on the cylinders and ambient temperature is between 68 and 86 °F [20 and 30 °C].

10.1.3.2 *Beams*—Beams are to be cured the same as cylinders (see 10.1.3.1) except that they shall be stored in water saturated with calcium hydroxide at 73.5 ± 3.5 °F [23.0 ± 2.0 °C] at least 20 h prior to testing. Drying of the surfaces of the beam shall be prevented between removal from water storage and completion of testing.

NOTE 7—Relatively small amounts of surface drying of flexural specimens can induce tensile stresses in the extreme fibers that will markedly reduce the indicated flexural strength.

10.2 *Field Curing*— Field curing is the curing method used for the specimens made and cured as stated in 4.3.

10.2.1 *Cylinders*—Store cylinders in or on the structure as near to the point of deposit of the concrete represented as possible. Protect all surfaces of the cylinders from the elements in as near as possible the same way as the formed work. Provide the cylinders with the same temperature and moisture environment as the structural work. Test the specimens in the moisture condition resulting from the specified curing treatment. To meet these conditions, specimens made for the purpose of determining when a structure is capable of being put in service shall be removed from the molds at the time of removal of form work.

10.2.2 *Beams*—As nearly as practicable, cure beams in the same manner as the concrete in the structure. At the end of 48 ± 4 h after molding, take the molded specimens to the storage location and remove from the molds. Store specimens representing pavements of slabs on grade by placing them on the ground as molded, with their top surfaces up. Bank the sides and ends of the specimens with earth or sand that shall be kept damp, leaving the top surfaces exposed to the specified curing treatment. Store specimens representing structure concrete as near the point in the structure they represent as possible, and afford them the same temperature protection and moisture environment as the structure. At the end of the curing period leave the specimens in place exposed to the weather in the same manner as the structure. Remove all beam specimens from field storage and store in water saturated with calcium hydroxide at 73.5 ± 3.5 °F [23.0 ± 2.0 °C] for 24 ± 4 h immediately before time of testing to ensure uniform moisture condition from specimen to specimen. Observe the precautions given in 10.1.3.2 to guard against drying between time of removal from curing to testing.

10.3 *Structural Lightweight Concrete Curing*—Cure structural lightweight concrete cylinders in accordance with Specification C 330.

11. Transportation of Specimens to Laboratory

11.1 Prior to transporting, cure and protect specimens as required in Section 10. Specimens shall not be transported until at least 8 h after final set. (See Note 8). During transporting, protect the specimens with suitable cushioning material to prevent damage from jarring. During cold weather, protect the specimens from freezing with suitable insulation material. Prevent moisture loss during transportation by wrapping the specimens in plastic, wet burlap, by surrounding them with wet sand, or tight fitting plastic caps on plastic molds. Transportation time shall not exceed 4 h.

NOTE 8—Setting time may be measured by Test Method C 403/C 403M.

12. Report

12.1 Report the following information to the laboratory that will test the specimens:

12.1.1 Identification number,

12.1.2 Location of concrete represented by the samples,

12.1.3 Date, time and name of individual molding specimens,

12.1.4 Slump, air content, and concrete temperature, test results and results of any other tests on the fresh concrete and any deviations from referenced standard test methods, and

12.1.5 Curing method. For standard curing method, report the initial curing method with maximum and minimum temperatures and final curing method. For field curing method, report the location where stored, manner of protection from the elements, temperature and moisture environment, and time of removal from molds.

13. Keywords

13.1 beams; casting samples; concrete; curing; cylinders; testing

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 31/C 31M – 08b, that may impact the use of this practice. (Approved May 1, 2009)

(*1*) Revised 5.4, Table 1, and 9.4.1 so that similar wording is used in several standards regarding the requirements for the tamping rod.

(*2*) Added new Note 1 to describe an acceptable tamping rod length for several standards.

(*3*) Revised 5.5 to change the vibrator frequency from 7000 vibrations per minute to 9000 vibrations per minute

Committee C09 has identified the location of selected changes to this practice since the last issue, C 31/C 31M – 08a, that may impact the use of this practice. (Approved December 15, 2008)

(*1*) Changed the laboratory curing temperature range from "73 ± 3 °F [23 ± 2 °C]" to "73.5 ± 3.5 °F [23.0 ± 2.0 °C]" in 10.1.3.1, 10.1.3.2, and 10.2.2.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 31/C 31M – 08, that may impact the use of this practice. (Approved April 1, 2008)

(*1*) Revised 5.5, 5.7, 9.2, 9.3, and 9.5.

(*2*) Added new 5.8 and renumbered subsequent paragraphs.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 31/C 31M – 06, that may impact the use of this practice. (Approved February 1, 2008)

(*1*) Revised 6.1.

(*2*) Revised 6.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 33/C 33M – 08

Standard Specification for Concrete Aggregates[1]

This standard is issued under the fixed designation C 33/C 33M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification defines the requirements for grading and quality of fine and coarse aggregate (other than lightweight or heavyweight aggregate) for use in concrete.[2]

1.2 This specification is for use by a contractor, concrete supplier, or other purchaser as part of the purchase document describing the material to be furnished.

NOTE 1—This specification is regarded as adequate to ensure satisfactory materials for most concrete. It is recognized that, for certain work or in certain regions, it may be either more or less restrictive than needed. For example, where aesthetics are important, more restrictive limits may be considered regarding impurities that would stain the concrete surface. The specifier should ascertain that aggregates specified are or can be made available in the area of the work, with regard to grading, physical, or chemical properties, or combination thereof.

1.3 This specification is also for use in project specifications to define the quality of aggregate, the nominal maximum size of the aggregate, and other specific grading requirements. Those responsible for selecting the proportions for the concrete mixture shall have the responsibility of determining the proportions of fine and coarse aggregate and the addition of blending aggregate sizes if required or approved.

1.4 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.5 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this standard.

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C 29/C 29M Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate

3. Terminology

3.1 For definitions of terms used in this standard, refer to Terminology C 125.

4. Ordering and Specifying Information

4.1 The direct purchaser of aggregates shall include the information in 4.2 in the purchase order as applicable. A project specifier shall include in the project documents information to describe the aggregate to be used in the project from the applicable items in 4.3.

4.2 Include in the purchase order for aggregates the following information, as applicable:

4.2.1 Reference to this specification, as C 33____,

4.2.2 Whether the order is for fine aggregate or for coarse aggregate,

4.2.3 Quantity, in metric tons or tons,

4.2.4 When the order is for fine aggregate:

4.2.4.1 Whether the restriction on reactive materials in 7.3 applies,

4.2.4.2 In the case of the sulfate soundness test (see 8.1) which salt is to be used. If none is stated, either sodium sulfate or magnesium sulfate shall be used,

4.2.4.3 The appropriate limit for material finer than 75-µm (No. 200) sieve (see Table 1). If not stated, the 3.0 % limit shall apply,

4.2.4.4 The appropriate limit for coal and lignite (see Table 1). If not stated, the 1.0 % limit shall apply,

4.2.5 When the order is for coarse aggregate:

4.2.5.1 The grading (size number) (see 10.1 and Table 2), or alternate grading as agreed between the purchaser and aggregate supplier.

4.2.5.2 The class designation (see 11.1 and Table 3),

4.2.5.3 Whether the restriction on reactive materials in 11.2 applies,

4.2.5.4 In the case of the sulfate soundness test (see Table 3), which salt is to be used. If none is stated, either sodium sulfate or magnesium sulfate shall be used, and

4.2.6 Any exceptions or additions to this specification (see Note 1).

4.3 Include in project specifications for aggregates the following information, as applicable:

4.3.1 Reference to this specification, as C 33____.

4.3.2 When the aggregate being described is fine aggregate:

4.3.2.1 Whether the restriction on reactive materials in 7.3 applies,

4.3.2.2 In the case of the sulfate soundness test (see 8.1) which salt is to be used. If none is stated, either sodium sulfate or magnesium sulfate shall be used.

4.3.2.3 The appropriate limit for material finer than the 75-µm (No. 200) sieve (see Table 1). If not stated, the 3.0 % limit shall apply, and

4.3.2.4 The limit that applies with regard to coal and lignite (Table 1). If not stated, the 1.0 % limit shall apply.

TABLE 1 Limits for Deleterious Substances in Fine Aggregate for Concrete

Item	Mass Percent of Total Sample, max
Clay lumps and friable particles	3.0
Material finer than 75-µm (No. 200) sieve:	
Concrete subject to abrasion	3.0[A]
All other concrete	5.0[A]
Coal and lignite:	
Where surface appearance of concrete is of importance	0.5
All other concrete	1.0

[A] In the case of manufactured sand, if the material finer than the 75-µm (No. 200) sieve consists of the dust of fracture, essentially free of clay or shale, these limits are permitted to be increased to 5 and 7 %, respectively.

[4] Withdrawn. The last approved version of this historical standard is referenced on www.astm.org.

[A] Size number 9 aggregate is defined in Terminology C 125 as a fine aggregate. It is included as a coarse aggregate when it is combined with a size number 8 material to create a size number 89, which is a coarse aggregate as defined by Terminology C 125.

TABLE 3 Limits for Deleterious Substances and Physical Property Requirements of Coarse Aggregate for Concrete

NOTE 1—See Fig. 1 for the location of the weathering regions and Note 9 for guidance in using the map. The weathering regions are defined as follows:
(S) Severe Weathering Region—A cold climate where concrete is exposed to deicing chemicals or other aggressive agents, or where concrete may become saturated by continued contact with moisture or free water prior to repeated freezing and thawing.
(M) Moderate Weathering Region—A climate where occasional freezing is expected, but where concrete in outdoor service will not be continually exposed to freezing and thawing in the presence of moisture or to deicing chemicals.
(N) Negligible Weathering Region—A climate where concrete is rarely exposed to freezing in the presence of moisture.

Class Designation	Type or Location of Concrete Construction	Maximum Allowable, %						
		Clay Lumps and Friable Particles	Chert (Less Than 2.40 sp gr SSD)	Sum of Clay Lumps, Friable Particles, and Chert (Less Than 2.40 sp gr SSD)	Material Finer Than 75-µm (No. 200) Sieve	Coal and Lignite	Abrasion[A]	Magnesium Sulfate Soundness (5 cycles)[B]
		Severe Weathering Regions						
1S	Footings, foundations, columns and beams not exposed to the weather, interior floor slabs to be given coverings	10.0	...	...	1.0[C]	1.0	50	...
2S	Interior floors without coverings	5.0	...	...	1.0[C]	0.5	50	...

[A] Crushed air-cooled blast-furnace slag is excluded from the abrasion requirements. The rodded or jigged bulk density (unit weight) of crushed air-cooled blast-furnace slag shall be not less than 1120 kg/m ^{3} [70 lb/ft^3]. The grading of slag used in the bulk density (unit weight) test shall conform to the grading to be used in the concrete. Abrasion loss of gravel, crushed gravel, or crushed stone shall be determined on the test size or sizes most nearly corresponding to the grading or gradings to be used in the concrete. When more than one grading is to be used, the limit on abrasion loss shall apply to each.

[B] The allowable limits for soundness shall be 12 % if sodium sulfate is used.

[C] This percentage under either of the following conditions: (*1*) is permitted to be increased to 1.5 if the material is essentially free of clay or shale; or (*2*) if the source of the fine aggregate to be used in the concrete is known to contain less than the specified maximum amount passing the 75-µm (No. 200) sieve (Table 1) the percentage limit *(L)* on the amount in the coarse aggregate is permitted to be increased to $L = 1 + [(P)/(100 - P)] (T - A)$, where P = percentage of sand in the concrete as a percent of total aggregate, T = the Table 1 limit for the amount permitted in the fine aggregate, and A = the actual amount in the fine aggregate. (This provides a weighted calculation designed to limit the maximum mass of material passing the 75-µm (No. 200) sieve in the concrete to that which would be obtained if both the fine and coarse aggregate were supplied at the maximum tabulated percentage for each of these ingredients.)

www.technobetar.ir

4.3.3 When the aggregate being described is coarse aggregate, include:

4.3.3.1 The nominal maximum size or sizes permitted, based on thickness of section or spacing of reinforcing bars or other criteria. In lieu of stating the nominal maximum size, the specifier shall designate an appropriate size number or numbers (see 10.1 and Table 2). Designation of a size number to indicate a nominal size shall not restrict the person responsible for selecting proportions from combining two or more gradings of aggregate to obtain a desired grading, provided that the gradings are not otherwise restricted by the project specifier and the nominal maximum size indicated by the size number is not exceeded,

4.3.3.2 The class designation (see 11.1 and Table 3),

4.3.3.3 Whether the restriction on reactive materials in 11.2 applies,

4.3.3.4 In the case of the sulfate soundness test (see Table 3), which salt is to be used. If none is stated, either sodium sulfate or magnesium sulfate shall be used, and

4.3.4 The person responsible for selecting the concrete proportions if other than the concrete producer.

4.3.5 Any exceptions or additions to this specification (see Note 1).

FINE AGGREGATE

5. General Characteristics

5.1 Fine aggregate shall consist of natural sand, manufactured sand, or a combination thereof.

6. Grading

6.1 *Sieve Analysis*—Fine aggregate, except as provided in 6.2 and 6.3 shall be graded within the following limits:

Sieve (Specification E 11)	Percent Passing
9.5-mm (⅜-in.)	100
4.75-mm (No. 4)	95 to 100
2.36-mm (No. 8)	80 to 100
1.18-mm (No. 16)	50 to 85
600-µm (No. 30)	25 to 60
300-µm (No. 50)	5 to 30
150-µm (No. 100)	0 to 10

NOTE 2—Concrete with fine aggregate gradings near the minimums for percent passing the 300 µm (No.50) and 150 µm (No.100) sometimes have difficulties with workability, pumping or excessive bleeding. The addition of entrained air, additional cement, or the addition of an approved mineral admixture to supply the deficient fines, are methods used to alleviate such difficulties.

6.2 The fine aggregate shall have not more than 45 % passing any sieve and retained on the next consecutive sieve of those shown in 6.1, and its fineness modulus shall be not less than 2.3 nor more than 3.1.

6.3 Fine aggregate failing to meet these grading requirements shall meet the requirements of this section provided that the supplier can demonstrate to the purchaser or specifier that concrete of the class specified, made with fine aggregate under consideration, will have relevant properties (see Note 4) at least equal to those of concrete made with the same ingredients, with the exception that the reference fine aggregate shall be selected from a source having an acceptable performance record in similar concrete construction.

NOTE 3—Fine aggregate that conforms to the grading requirements of a specification, prepared by another organization such as a state transportation agency, which is in general use in the area, should be considered as having a satisfactory service record with regard to those concrete properties affected by grading.

NOTE 4—Relevant properties are those properties of the concrete that are important to the particular application being considered. STP 169D[5] provides a discussion of important concrete properties.

6.4 For continuing shipments of fine aggregate from a given source, the fineness modulus shall not vary more than 0.20 from the base fineness modulus. The base fineness modulus shall be that value that is typical of the source. The purchaser or specifier has the authority to approve a change in the base fineness modulus.

NOTE 5—The base fineness modulus should be determined from previous tests, or if no previous tests exist, from the average of the fineness modulus values for the first ten samples (or all preceding samples if less than ten) on the order. The proportioning of a concrete mixture may be dependent on the base fineness modulus of the fine aggregate to be used. Therefore, when it appears that the base fineness modulus is considerably different from the value used in the concrete mixture, a suitable adjustment in the mixture may be necessary.

7. Deleterious Substances

7.1 The amount of deleterious substances in fine aggregate shall not exceed the limits prescribed in Table 1.

7.2 *Organic Impurities*:

7.2.1 Fine aggregate shall be free of injurious amounts of organic impurities. Except as herein provided, aggregates subjected to the test for organic impurities and producing a color darker than the standard shall be rejected.

7.2.2 Use of a fine aggregate failing in the test is not prohibited, provided that the discoloration is due principally to the presence of small quantities of coal, lignite, or similar discrete particles.

7.2.3 Use of a fine aggregate failing in the test is not prohibited, provided that, when tested for the effect of organic impurities on strength of mortar, the relative strength at 7 days, calculated in accordance with Test Method C 87, is not less than 95 %.

7.3 Fine aggregate for use in concrete that will be subject to wetting, extended exposure to humid atmosphere, or contact with moist ground shall not contain any materials that are deleteriously reactive with the alkalies in the cement in an amount sufficient to cause excessive expansion of mortar or concrete, except that if such materials are present in injurious amounts, use of the fine aggregate is not prohibited when used with a cement containing less than 0.60 % alkalies calculated as sodium oxide equivalent ($Na_2O + 0.658K_2O$) or with the addition of a material that has been shown to prevent harmful expansion due to the alkali-aggregate reaction. (See Appendix X1.)

8. Soundness

8.1 Except as provided in 8.2 and 8.3, fine aggregate subjected to five cycles of the soundness test shall have a

[5] *Significance of Tests and Properties of Concrete and Concrete Making Materials, STP 169D*, ASTM, 2006.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

weighted average loss not greater than 10 % when sodium sulfate is used or 15 % when magnesium sulfate is used.

8.2 Fine aggregate failing to meet the requirements of 8.1 shall be regarded as meeting the requirements of this section provided that the supplier demonstrates to the purchaser or specifier that concrete of comparable properties, made from similar aggregate from the same source, has given satisfactory service when exposed to weathering similar to that to be encountered.

8.3 Fine aggregate not having a demonstrable service record and failing to meet the requirements of 8.1 shall be regarded as meeting the requirements of this section provided that the supplier demonstrates to the purchaser or specifier it gives satisfactory results in concrete subjected to freezing and thawing tests (see Test Method C 666/C 666M).

COARSE AGGREGATE

9. General Characteristics

9.1 Coarse aggregate shall consist of gravel, crushed gravel, crushed stone, air-cooled blast furnace slag, or crushed hydraulic-cement concrete (see Note 6), or a combination thereof, conforming to the requirements of this specification.

NOTE 6—Although crushed hydraulic-cement concrete has been used as an aggregate with reported satisfactory results, its use may require some additional precautions. Mixing water requirements may be increased because of the harshness of the aggregate. Partially deteriorated concrete, used as aggregate, may reduce freeze-thaw resistance, affect air void properties or degrade during handling, mixing, or placing. Crushed concrete may have constituents that would be susceptible to alkali-aggregate reactivity or sulfate attack in the new concrete or may bring sulfates, chlorides, or organic material to the new concrete in its pore structure.

10. Grading

10.1 Coarse aggregates shall conform to the requirements prescribed in Table 2 for the size number specified.

NOTE 7—The ranges shown in Table 2 are by necessity very wide in order to accommodate nationwide conditions. For quality control of any specific operation, a producer should develop an average grading for the particular source and production facilities, and should control the production gradings within reasonable tolerances from this average. Where coarse aggregate size numbers 357 or 467 are used, the aggregate should be furnished in at least two separate sizes.

11. Deleterious Substances

11.1 Except for the provisions of 11.3, the limits given in Table 3 shall apply for the class of coarse aggregate designated in the purchase order or other document (see Note 8 and Note 9). If the class is not specified, the requirements for Class 3S, 3M, or 1N shall apply in the severe, moderate, and negligible weathering regions, respectively (see Table 3 and Fig. 1).

NOTE 8—The specifier of the aggregate should designate the class of coarse aggregate to be used in the work, based on weathering severity, abrasion, and other factors of exposure (see Table 3 and Fig. 1) . The limits

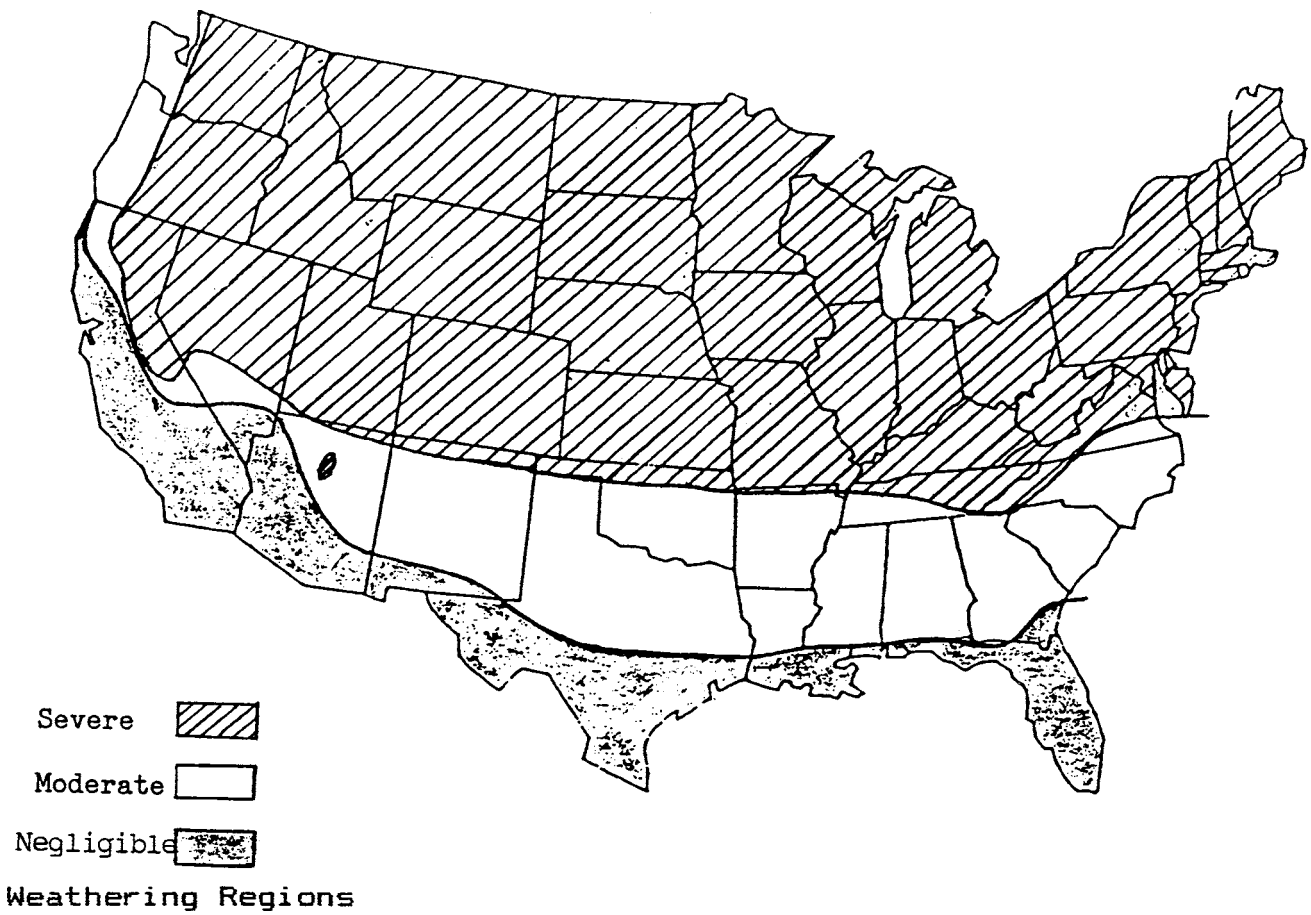

FIG. 1 Location of Weathering Regions

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

for coarse aggregate corresponding to each class designation are expected to ensure satisfactory performance in concrete for the respective type and location of construction. Selecting a class with unduly restrictive limits may result in unnecessary cost if materials meeting those requirements are not locally available. Selecting a class with lenient limits may result in unsatisfactory performance and premature deterioration of the concrete. While concrete in different parts of a single structure may be adequately made with different classes of coarse aggregate, the specifier may wish to require the coarse aggregate for all concrete to conform to the same more restrictive class to reduce the chance of furnishing concrete with the wrong class of aggregate, especially on smaller projects.

NOTE 9—For coarse aggregate in concrete exposed to weathering, the map with the weathering regions shown in Fig. 1 is intended to serve only as a guide to probable weathering severity. Those undertaking construction, especially near the boundaries of weathering regions, should consult local weather bureau records for amount of winter precipitation and number of freeze-thaw cycles to be expected, for determining the weathering severity for establishing test requirements of the coarse aggregate. For construction at altitudes exceeding 1520 m [5000 ft] above sea level, the likelihood of more severe weathering than indicated by the map should be considered. In arid areas, severity of weathering may be less than that indicated. In either case, the definitions of weathering severity in Table 3 would govern. If there is doubt in choosing between two regions, select the more severe weathering region.

11.2 Coarse aggregate for use in concrete that will be subject to wetting, extended exposure to humid atmosphere, or contact with moist ground shall not contain any materials that are deleteriously reactive with the alkalies in the cement in an amount sufficient to cause excessive expansion of mortar or concrete except that if such materials are present in injurious amounts, the coarse aggregate is not prohibited when used with a cement containing less than 0.60 % alkalies calculated as sodium oxide equivalent ($Na_2O + 0.658K_2O$) or with the addition of a material that has been shown to prevent harmful expansion due to the alkali-aggregate reaction. (See Appendix X1.)

11.3 Coarse aggregate having test results exceeding the limits specified in Table 3 shall be regarded as meeting the requirements of this section provided the supplier demonstrates to the purchaser or specifier that concrete made with similar aggregate from the same source has given satisfactory service when exposed in a similar manner to that to be encountered; or, in the absence of a demonstrable service record, provided that the aggregate produces concrete having satisfactory relevant properties (see Note 4).

METHODS OF SAMPLING AND TESTING

12. Methods of Sampling and Testing

12.1 Sample and test the aggregates in accordance with the following methods, except as otherwise provided in this specification. Make the required tests on test specimens that comply with requirements of the designated test methods. It is not prohibited to use the same test specimen for sieve analysis and for determination of material finer than the 75-µm (No. 200) sieve. The use of separated sizes from the sieve analysis is acceptable for soundness or abrasion tests, however, additional test specimen preparation is required (see Note 10). For other test procedures and the evaluation of potential alkali reactivity, when required, use independent test specimens.

NOTE 10—The material used for the soundness test requires resieving to allow proper test specimen preparation as specified in Test Method C 88.

12.1.1 *Sampling*—Practice D 75 and Practice D 3665.

12.1.2 *Grading and Fineness Modulus*—Test Method C 136.

12.1.3 *Amount of Material Finer than 75-µm (No. 200) Sieve*—Test Method C 117.

12.1.4 *Organic Impurities*—Test Method C 40.

12.1.5 *Effect of Organic Impurities on Strength*—Test Method C 87.

12.1.6 *Soundness*—Test Method C 88.

12.1.7 *Clay Lumps and Friable Particles*— Test Method C 142.

12.1.8 *Coal and Lignite*—Test Method C 123, using a liquid of 2.0 specific gravity to remove the particles of coal and lignite. Only material that is brownish-black, or black, shall be considered coal or lignite. Coke shall not be classed as coal or lignite.

12.1.9 *Bulk Density (Unit Weight) of Slag*—Test Method C 29/C 29M.

12.1.10 *Abrasion of Coarse Aggregate*—Test Method C 131 or Test Method C 535.

12.1.11 *Reactive Aggregates*—See Appendix X1.

12.1.12 *Freezing and Thawing*—Procedures for making freezing and thawing tests of concrete are described in Test Method C 666/C 666M.

12.1.13 *Chert*—Test Method C 123 is used to identify particles in a sample of coarse aggregate lighter than 2.40 specific gravity, and Guide C 295 to identify which of the particles in the light fraction are chert.

APPENDIX

(Nonmandatory Information)

X1. METHODS FOR EVALUATING POTENTIAL FOR DELETERIOUS EXPANSION DUE TO ALKALI REACTIVITY OF AN AGGREGATE

X1.1 Introduction

X1.1.1 *Laboratory Methods*—Many test methods for evaluating the potential for deleterious expansion due to alkali reactivity of an aggregate have been proposed and some have been adopted as ASTM standards. However, there is no general agreement on the relation between the results of these tests and the amount of expansion to be expected or tolerated in service. Therefore, evaluation of the suitability of an aggregate should be based upon judgment, interpretation of test data, and results of examinations of concrete structures containing the same aggregates and similar cementitious materials having similar levels of alkalies. Results of the tests referred to in this appendix may assist in making the evaluation. When interpreting expansion of laboratory specimens, consideration should be given not only to expansion values at specific ages, but also to the shape of the expansion curve, which may indicate whether the expansion is leveling off or continuing at a constant or accelerating rate.

X1.1.2 *Service Record Evaluation*—Valid, comparable concrete service record data, if available, should take precedence over laboratory test results in most cases. To be considered valid, a record of satisfactory service should be available for at least 10 years for aggregates, cementitious materials, and exposures sufficiently similar to those in which an aggregate is being considered for future use. Longer periods of documented service may be required for proposed work designed for a particularly long service life in moist conditions, or if laboratory test results show that the aggregate may be deleteriously reactive.

X1.1.3 *Mitigation of Alkali-Aggregate Reaction*—If an aggregate has been judged to be potentially deleteriously reactive in concrete either through laboratory or service record evaluation, use of the aggregate should be considered with measures known to prevent excessive expansion due to alkali-aggregate reaction. See the mitigation sections in this appendix under X1.3 Alkali-Silica Reaction and X1.4 Alkali-Carbonate Rock Reaction and References cited for discussion of prevention strategies for new concrete.

X1.2 Background

X1.2.1 Background information on alkali-aggregate reaction can be found in Ref **(1)**[6], Descriptive Nomenclature C 294, and Guide C 295 as discussed as follows. Additional discussion is included in Refs **(2)** **(3)**. These references address both alkali-silica reaction and alkali-carbonate rock reaction.

X1.2.1.1 *Descriptive Nomenclature C 294 for Constituents of Concrete Aggregates*—This nomenclature provides descriptions of constituents of mineral aggregates and includes discussion of which have been associated with deleterious expansion due to alkali reaction.

X1.2.1.2 *Guide C 295 (Petrographic Examination of Aggregates)*—This guide outlines the procedures for examining an aggregate sample or a sample from a potential aggregate source to determine whether substances that are potentially deleteriously reactive are present; and, if so, in what amounts.

X1.2.1.3 *Alkali-Silica Reaction*—Certain materials are known to be potentially deleteriously alkali-silica reactive. These include forms of silica such as opal, chalcedony, tridymite, and cristobalite; cryptocrystalline and microcrystalline, strained, or highly fractured quartz; and intermediate to acid (silica-rich) volcanic glass such as is likely to occur in rhyolite, andesite, or dacite. Determination of the presence and quantities of these materials by petrographic examination is helpful in evaluating potential alkali reactivity. An aggregate can be potentially deleteriously reactive when some of these materials, such as opal, are present in very small quantities (for example, 1 %).

X1.2.1.4 *Alkali-Carbonate Rock Reaction*—The reaction of dolomite in certain carbonate rocks with alkalies has been associated with deleterious expansion of concrete containing such rocks as coarse aggregate. The most rapidly reactive carbonate rocks possess a characteristic texture in which relatively large crystals of dolomite are scattered in a finer-grained matrix of calcite and clay. These rocks also have a composition in which the carbonate portion consists of substantial amounts of both dolomite and calcite, and the acid-insoluble residue contains a significant amount of clay. Certain purely dolomitic rocks also may produce slow expansion in concrete.

X1.3 Alkali-Silica Reaction

X1.3.1 *Test Method C 289 (Chemical Method)*—The results of the test are values for the quantities of dissolved silica (S_c) and reduction in alkalinity (R_c) for each of the three test portions from the prepared aggregate test sample. Aggregates represented by plotted points (S_c, R_c), which lie on the deleterious side of the solid curve of Fig. X1.1 of Test Method C 289 usually should be considered potentially reactive. Three regions are delineated in the figure: (*1*) aggregates considered innocuous; (*2*) aggregates considered potentially deleterious; and (*3*) aggregates considered deleterious. Aggregates represented by points lying in the potentially deleterious region above the dashed line in Fig. X1.1 of Test Method C 289 may give relatively low expansions in mortar or concrete even though they are extremely reactive with alkalies. The test can be made quickly and can provide helpful information, except for slowly reactive rocks such as some granitic gneiss and quartzite. Also, as pointed out in the appendix to Test Method C 289, the results may not be correct for aggregates containing

[6] The boldface numbers in parentheses refer to the list of references at the end of this standard.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

carbonates or magnesium silicates, such as antigorite (serpentine), or constituents producing late-slow reactivity. See the appendix to Test Method C 289 for a discussion of the interpretation of results and applicable references. If test results indicate deleterious or potentially deleterious character, the aggregates should be tested in accordance with Test Methods C 227 or C 1293 to verify the potential for expansion in concrete.

X1.3.2 *Test Method C 227 (Mortar-Bar Method for Cement-Aggregate Combinations)*—The results of this test method, when a high-alkali cement is used, furnish information on the likelihood of potentially deleterious expansion occurring. The alkali content of the portland cement should be at least 0.8 %, expressed as percent sodium oxide equivalent ($\%Na_2O + 0.658 \times \%K_2O$). Combinations of aggregate and cementitious materials that have produced excessive expansions in this test method should be considered potentially reactive. While the line of demarcation between innocuous and potentially deleterious combinations is not clearly defined, expansion is generally considered to be excessive if it exceeds 0.05 % at 3 months or 0.10 % at 6 months. Expansions greater than 0.05 % at 3 months should not be considered excessive when the 6-month expansion remains below 0.10 %. Data for the 3-month tests should be considered only when 6-month results are not available. The limits may not be conservative for slowly reactive aggregates. Test Method C 227 is not suitable for slowly reactive aggregates, and its use for this purpose is not advised (**1, 2**). Aggregates suspected of being slowly reactive should be evaluated using Test Method C 1260 or Test Method C 1293. Test Method C 227 is also used with a specific reactive glass aggregate to verify the mitigation effectiveness of blended cements meeting Specification C 595, with the Table 2 optional mortar expansion requirement, and meeting Performance Specification C 1157 with Option R. These procedures are similar to the provisions of Test Method C 441 discussed as follows for mineral admixtures and ground slag.

X1.3.3 *Test Method C 342 (Mortar Bars Subjected to Changes in Moisture and Temperature)*—This withdrawn test method was intended for research concerning the potential expansion of cement-aggregate combinations involving selected aggregates found in parts of Oklahoma, Kansas, Nebraska, and Iowa. Due to the specimen conditioning procedures, the expansion of mortar bars in this test method may not be related to alkali-silica reaction under normal-temperature conditioning. Data on the use of this test method are given in the references cited in a footnote in the test method. It is indicated that cement-aggregate combinations tested by this procedure in which expansion equals or exceeds 0.20 % at an age of 1 year may be considered unsatisfactory for use in concrete exposed to wide variations of temperature and degree of saturation with water. This test method is not recommended for use in regions other than previously cited.

X1.3.4 *Test Method C 1260 (Mortar-Bar Method for Potential Alkali Reactivity of Aggregate)*—This test method is an accelerated screening technique developed for the detection of materials that develop deleterious expansions slowly over a long period of time. Some aggregates that perform well in the field have been shown to fail this test (**4, 5**). Results of this test method should not be used for rejection of aggregates unless it has been established using the sources of supplementary information cited in the test method that the detected expansion is actually due to alkali-silica reaction. There is good agreement in the published literature cited in the test method for the expansion limits: (*1*) expansions of less than 0.10 % at 16 days after casting are indicative of innocuous behavior in most cases; (*2*) expansions of more than 0.20 % at 16 days are indicative of potentially deleterious expansion; and (*3*) expansions between 0.10 and 0.20 % at 16 days include both aggregates that are known to be innocuous and deleterious in field performance. If test results indicate expansion greater than 0.10 % at 16 days, the aggregate should be tested in accordance with Test Method C 1293 unless appropriate field experience demonstrates that it does not cause deleterious expansion in concrete. (See X1.3.6.)

X1.3.5 *Test Method C 1293 (Concrete Prism Method for Alkali-Silica Reactivity)*—The test method evaluates the aggregates independently, or combinations of aggregate with pozzolan or slag for potential alkali-silica reaction expansion using concrete prisms. The test method is accelerated by using an elevated alkali content and Test Method C 227 exposure conditions. The appendix to Test Method C 1293 provides guidance on interpretation of the results. When evaluating aggregates independently, those with expansions equal to or greater than 0.04 % at one year are considered potentially deleteriously reactive. When evaluating combinations of pozzolan or slag, the test is extended to two years using the 0.04 % expansion limit. This test method is considered to be the most reliable procedure among ASTM Test Methods for the evaluation of aggregates for alkali-silica reaction.

X1.3.6 *Mitigation of Alkali-Silica Reaction*—Normally if an aggregate is shown to be nonreactive or innocuous by producing little or no expansion in Test Method C 1260 or Test Method C 1293, no mitigation is necessary. Similarly, if the aggregate has a long satisfactory service record with similar cementitious materials having similar or higher alkali levels, no mitigation is necessary. On the other hand, use of aggregates judged to be potentially deleteriously alkali-silica reactive should be considered with the use of measures known to prevent excessive expansion. These include measures such as: low-alkali cement (Specification C 150 with the low-alkali option); blended cements (Specification C 595 with the Table 2 optional mortar expansion requirement or Performance Specification C 1157 with Option R); pozzolanic materials (meeting the optional physical requirement on effectiveness in controlling alkali-silica reaction in Specification C 618 or reactivity with cement alkalies in Specification C 1240 for silica fume); or ground slag (shown to be effective in preventing excessive expansion of concrete due to alkali-aggregate reaction as discussed in Appendix X3 of Specification C 989). The effectiveness of the cementitious materials or admixtures, or both, chosen to mitigate a potentially reactive aggregate should be demonstrated through tests of the individual materials, or tests of the proposed combination in concrete.

X1.3.7 *Test Method C 441 (Mortar-Bar Method for Effectiveness of Mineral Admixtures or Ground Blast-Furnace Slag in Preventing Excessive Expansion of Concrete Due to the*

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Alkali-Silica Reaction)—This test method evaluates cementitious materials in mortar bars as in Test Method C 227 using highly-reactive borosilicate glass as the aggregate. Specification C 618 provides a criterion for its use as applied to fly ash and raw or calcined natural pozzolans when sampled and tested in accordance with Test Methods C 311 by comparison with a control mortar made with low-alkali cement. Specification C 1240 provides criteria for the use of Test Method C 441 to evaluate silica fume for controlling expansion. Appendix X3 to Specification C 989 describes its use for ground granulated blast-furnace slag. Project specific materials can be evaluated by proportioning the mortars according to the *Job Mixture* clause. In evaluating the results of this test, it should be recognized that borosilicate glass is more reactive than most construction aggregates; therefore, the amount of a given pozzolan or ground slag necessary to control expansion with a portland cement of given alkali content may be higher than needed to avoid deleterious expansion with a particular construction aggregate.

X1.3.8 *Test Method C 1567 (Accelerated Mortar-Bar Method for Determining the Potential Alkali-Silica Reactivity of Combinations of Cementitious Materials and Aggregate)*—This test method evaluates specific combinations of aggregate and cementitious materials composed of hydraulic cement and pozzolans or ground granulated blast-furnace slag under storage conditions described in Test Method C 1260. Since the mortar specimens are stored in 1N NaOH solution, the test may underestimate the effectiveness of cementitious materials that rely to a significant degree on low alkali content for mitigation. In general, expansions less than 0.10 % at 16 days are considered to indicate effective control of potential ASR-related expansion of the aggregate by the specific combination of cementitious materials.

X1.3.9 The use of Test Method C 1293 to evaluate the mitigation of potentially reactive aggregates is discussed in X1.3.5.

X1.4 Alkali-Carbonate Rock Reaction

X1.4.1 *Test Method C 586 (Rock Cylinders Method for Alkali-Carbonate Rock Reaction)*—Rocks that are capable of potentially deleterious carbonate rock reaction are relatively infrequent and seldom constitute a significant proportion of a deposit of rock being considered for use in making aggregate for concrete. Test Method C 586 has been successfully used in research and in preliminary screening of aggregate sources to indicate the presence of material with a potential for deleterious expansions when used in concrete.

X1.4.2 *Test Method C 1105 (Concrete-Prism Method for Alkali-Carbonate Rock Reaction)*—This test method is intended to evaluate specific combinations of materials in concrete when the aggregate is regarded as susceptible to deleterious expansion in service due to the alkali-carbonate rock reaction. The appendix to Test Method C 1105 provides general information and references concerning the interpretation of results. A cement-aggregate combination might reasonably be classified as potentially deleteriously reactive if the average expansion of six concrete specimens is equal to or greater than: 0.015 % at 3 months; 0.025 % at 6 months; or 0.030 % at 1 year. Data for later ages are preferred.

X1.4.3 *Mitigation of Alkali-Carbonate Rock Reaction*—Normally, if a carbonate rock does not show the characteristic texture and composition associated with this type of reaction, or if it does not produce expansion in rock cylinders (Test Method C 586) or concrete prisms (Test Method C 1105), no mitigation is necessary for alkali-carbonate rock reaction. Similarly, if the aggregate has a long satisfactory service record with similar materials and conditions, no mitigation is necessary. On the other hand, use of aggregates judged to be potentially deleteriously alkali-carbonate reactive in concrete is not recommended unless it can be shown that mitigation methods will be effective. Pozzolans generally have not been found to control alkali-carbonate rock reaction. Measures suggested for mitigation includes: avoiding reactive carbonate rocks; selective quarrying; diluting reactive rock to less than 20 % of the aggregate in the concrete; use of smaller maximum size; and the use of very low alkali cement.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 33 – 07, that may impact the use of this specification. (Approved December 1, 2008)

(*1*) Revised the document as a combined units specification.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 33 – 03, that may impact the use of this specification. (Approved December 15, 2007)

(*1*) Updated reference in Note 4.
(*2*) Reversed the order of X1.3.6 and X1.3.7 and added information regarding Test Method C 441 in X1.3.7.
(*3*) Revised X1.3.5.
(*4*) Added new X1.3.8 to reference Test Method C 1567.
(*5*) Added new X1.3.9 to reference Test Method C 1293.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 35 – 01 (Reapproved 2009)

Standard Specification for Inorganic Aggregates for Use in Gypsum Plaster[1]

This standard is issued under the fixed designation C 35; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers perlite, vermiculite, natural and manufactured sand for use as gypsum plaster aggregates.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this specification references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 29/C 29M Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate

C 40 Test Method for Organic Impurities in Fine Aggregates for Concrete

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 471M Test Methods for Chemical Analysis of Gypsum and Gypsum Products (Metric)

D 75 Practice for Sampling Aggregates

E 11 Specification for Woven Wire Test Sieve Cloth and Test Sieves

3. Terminology

3.1 Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *manufactured sand*, *n*—the fine material resulting from the crushing and classification by screening, or otherwise, of rock, gravel, or blast furnace slag.

3.2.2 *natural sand*, *n*—the fine granular material resulting from the natural disintegration of rock or from the crushing of friable sandstone.

3.2.3 *perlite aggregate*, *n*—a siliceous volcanic glass expanded by heat.

3.2.4 *vermiculite aggregate*, *n*—a micaceous mineral expanded by heat.

4. Chemical Composition

4.1 Water-soluble impurities in sand shall not exceed 0.15 weight % and sodium ion content shall not exceed 0.02 weight % when tested in accordance with Section 7.

4.2 Sand shall develop a color no darker than the standard, when subjected to the colorimetric test for organic impurities in accordance with Test Method C 40, unless it is established by adequate tests that the impurities causing the color are not harmful in plaster.

5. Mechanical Requirements

5.1 *Grading*—Shall be as follows when tested in accordance with Section 7:

5.1.1 Perlite and vermiculite shall be graded within the limits specified in Table 1.

5.1.2 *Natural and Manufactured Sand*—Shall be graded with not more than 50 % retained between any two consecutive sieves shown in Table 1, nor more than 25 % between the No. 50 (300 µm) and No. 100 (150 µm) sieves.

5.2 *Density*:

5.2.1 Perlite shall have a density of not less than 6 nor more than 12 lb/ft^3(96 to 192 kg/m^3) when tested in accordance with Test Method C 29/C 29M using the shoveling procedure.

5.2.2 Vermiculite shall have a density of not less than 6 nor more than 10 lb/ft^3(96 to 160 kg/m^3) when tested in accordance with Test Method C 29/C 29M using the shoveling procedure.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved Sept. 1, 2009. Published September 2009. Originally approved in 1921. Last previous edition approved in 2005 as C 35 – 01(2005).

TABLE 1 Grading Requirements

Sieve Size	Percentage Retained on Each Sieve, Cumulative					
	Perlite, by volume		Vermiculite, by volume		Sand, by weight	
	Max	Min	Max	Min	Max	Min
No. 4 (4.75-mm)	0	...	0	...	0	...
No. 8 (2.36-mm)	5	0	10	0	5	0
No. 16 (1.18-mm)	60	5	75	40	30	5
No. 30 (600-µm)	95	45	95	65	65	30
No. 50 (300-µm)	98	75	98	75	95	65
No. 100 (150-µm)	100	85	100	90	100	90
No. 200 (15-µm)					100	95

6. Sampling

6.1 *Apparatus*—Suitable thief tube.

6.2 *Bulk Aggregate*—Obtain specimens of sand in accordance with Practice D 75.

6.3 *Bagged Aggregate*—Obtain from 1 bag randomly selected from each 100 bags but not less than 6 bags from the shipment. For smaller shipments, not less than 6 % of the number of bags shall constitute the sample.

6.3.1 Secure specimens by inserting a suitable thief tube the full distance between diagonally opposite corners of the bag with the bag lying in a horizontal position. Combine the portions to produce a composite specimen having a volume not less than 1 ft^3(0.028 m^3). Prepare and test not less than 1 composite specimen separately for each 2000 bags of aggregate.

6.4 Reduce specimens obtained in accordance with 6.2 or 6.3 by quartering or riffling to obtain specimens of proper size for individual tests.

7. Test Methods

7.1 *Apparatus*:

7.1.1 *Sieve*—Specification E 11, Nos. 4, 8, 16, 30, 50, 100, 200 (4.75, 2.36, 1.18 mm, 600 µm, 300 µm, 150 µm, 15 µm).

7.1.2 *Graduated 250 mL Cylinder.*

7.1.3 *250 mL Beaker.*

7.1.4 *Tared Evaporating Dish.*

7.1.5 *Fast Paper Filter.*

7.1.6 *100 mL Volumetric Flask.*

7.1.7 *Deionized Water.*

7.1.8 *Spatula.*

7.1.9 *Weighing Scale.*

7.1.10 *Oven.*

7.1.11 *Desiccator.*

7.1.12 *Mechanical Shaker.*

7.1.13 *500 mL Graduated Cylinder.*

7.2 *Sieve Analysis for Sand*—Use Test Method C 136.

7.3 *Sieve Analysis for Perlite or Vermiculite*—Use Test Method C 136 except as modified as follows:

7.3.1 Use a specimen of 500 mL bulk volume.

7.3.1.1 Measure the volume of each sieve fraction in a 250 mL graduated cylinder. Pour the specimen loosely into the graduate without tamping or shaking. Level the surface with a spatula and read the volume to within ±2 mL.

7.3.2 Express the volumes of the individual sieve fractions as percentages of the sum of the volumes of all fractions.

7.3.3 Calculate the cumulative percentages on each designated sieve by summing the individual percentages of all fractions larger than that sieve.

7.4 *Density of Lightweight Aggregate*— Test Method C 29/C 29M; use shoveling procedure.

7.5 *Water Soluble Impurities of Sand*:

7.5.1 *Significance and Use*—Impurities can affect the setting properties, strength, and bond performance of gypsum plaster. These procedures determine the water soluble impurities of the sand being evaluated.

7.5.2 *Apparatus*:

7.5.2.1 *Analytical Balance*, with a precision of 0.0001 g.

7.5.2.2 *Balance*, capable of weighing at least 10 g to a precision of 0.1 g.

7.5.2.3 *Desiccator*, containing calcium chloride or equivalent desiccant.

7.5.2.4 *Drying Oven*, capable of being controlled to 250°F (121°C).

7.5.2.5 *Filter Paper*—A "fast" filter paper shall be used.[3]

7.5.2.6 *Atomic Absorption or Ion Chromatography Equipment.*

7.5.2.7 *Mechanical Shaker.*

7.5.3 *Procedure (Water Soluble Impurities)*:

7.5.3.1 Weigh approximately 10 g of air-dried sand and record the weight to 0.1 g. Transfer to a 250-mL beaker. Add 100 mL of distilled water. Heat to boiling and allow to simmer on a hot plate for 5 min. Filter through a fast paper into a tared evaporating dish. Wash with hot distilled water until the volume of filtrate is about 125 mL. Evaporate to dryness in an oven without allowing the temperature of the dish to rise above 250°F (121°C). Cool residue in a dessicator, weigh to 0.001 g and calculate the percentage of residue on the initial weight of sand.

7.5.3.2 *Report*—Report percentage as water soluble impurities.

7.5.3.3 *Precision and Bias*—No estimate of the precision or bias, or both, is available at this time.

7.5.4 *Procedure (Sodium Ion Content)*:

7.5.4.1 Weigh approximately 5 g of sand and record the weight to 0.01 g. Transfer to 100-mL volumetric flask. Add approximately 80 mL of deionized water to the flask. Shake on a mechanical shaker for 4 h. Remove and bring to a full volume with deionized water and allow to settle. Analyze for Na ion according to general atomic absorption in accordance with Test Methods C 471M or ion chromatography procedures.[4]

NOTE 1—To minimize contamination, care must be exercised to be sure all equipment is clean.

7.5.4.2 *Calculation and Report*—Calculate and report the percent Na as follows:

[3] The sole source of supply of the apparatus known to the committee at this time is VWR Scientific. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

[4] The sole source of supply of ion chromatographs known to the committee at this time is Dionex Inc., Sunnyvale, CA. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

www.technobetar.ir

$$\mu g/g = \frac{\text{Curve concentration} \times \text{any dilution factor} \times 100 \text{ mL final volume}}{\text{initial weight of sample}}$$

$$\frac{\mu g/g}{10\,000} = \%\ \text{metal ion } (Na^{+})$$

7.5.4.3 *Precision and Bias*—No estimate of the precision or bias is available at this time.

7.5.5 *Organic Impurities*—Test Method C 40.

8. Inspection

8.1 Inspection of the material shall be agreed upon between the purchaser and the producer or supplier as part of the purchase agreement.

9. Rejection and Rehearing

9.1 Rejection of material shall be reported to the producer or supplier within ten working days from the receipt of the shipment by the purchaser. Rejection of the material shall be based either on the specific cause of failure to conform to the requirements of this specification or the failure of the material to meet the minimum weight or approximate volume as stated on the shipment.

9.2 Failure to meet the minimum weight or approximate volume shall be determined as follows:

9.2.1 *Individual Packages*:

9.2.1.1 The contents, on a weight basis, are 5 % less than that indicated on the packages, or

9.2.1.2 The contents, on a volume basis, are 10 % less than that indicated on the package.

9.2.2 *The Entire Shipment*:

9.2.2.1 On a weight basis when the average contents of 2 packages for each 100 but not less than 6 packages selected at random, in any one shipment, are less than that indicated on the package. The net weight of the contents shall be determined by weighing the package or packages and deducting the weight of the container.

9.2.2.2 On a volume basis when the average contents of 2 packages for each 100 but not less than 6 packages selected at random, in any one shipment, differ by more than 5 % more or 10 % less from that indicated on the package. The volume of the contents in the package shall be calculated by determining the weight of the contents of the package and then obtaining the weight per unit of volume of the aggregate, from an average weight package of the samples selected in 6.3.1, by the shoveling procedure given in Test Method C 29/C 29M, and then dividing the weight of the contents of the bag by the unit of volume of the aggregate.

10. Certification

10.1 When specified in the purchase order, the producer's or supplier's certification shall be furnished to the purchaser stating that the material was prepared or manufactured in accordance with this specification and has been found to meet the specified requirements.

11. Packaging and Package Marking

11.1 When lightweight aggregates covered by this specification are delivered in packages, the name of the type of aggregate, and minimum weight and approximate volume of the contents shall be plainly indicated thereon.

11.2 When delivered in bulk quantities, the bill of lading shall show the quantity by weight or unit of volume, and the name of the supplier.

11.2.1 Bulk materials shall be delivered in clean transport vessels, free of contaminants.

12. Keywords

12.1 aggregates; gypsum plaster; inorganic; manufactured sand; natural sand; perlite; vermiculite

Designation: C39/C39M – 09a

Standard Test Method for Compressive Strength of Cylindrical Concrete Specimens[1]

This standard is issued under the fixed designation C39/C39M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers determination of compressive strength of cylindrical concrete specimens such as molded cylinders and drilled cores. It is limited to concrete having a density in excess of 800 kg/m^3 [50 lb/ft^3].

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The inch-pound units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Means should be provided to contain concrete fragments during sudden rupture of specimens. Tendency for sudden rupture increases with increasing concrete strength and it is more likely when the testing machine is relatively flexible. The safety precautions given in the Manual of Aggregate and Concrete Testing are recommended.)

1.4 The text of this standard references notes which provide explanatory material. These notes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C31/C31M Practice for Making and Curing Concrete Test Specimens in the Field

C42/C42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C192/C192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C617 Practice for Capping Cylindrical Concrete Specimens

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C873 Test Method for Compressive Strength of Concrete Cylinders Cast in Place in Cylindrical Molds

C1077 Practice for Laboratories Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation

C1231/C1231M Practice for Use of Unbonded Caps in Determination of Compressive Strength of Hardened Concrete Cylinders

E4 Practices for Force Verification of Testing Machines

E74 Practice of Calibration of Force-Measuring Instruments for Verifying the Force Indication of Testing Machines

Manual of Aggregate and Concrete Testing

3. Summary of Test Method

3.1 This test method consists of applying a compressive axial load to molded cylinders or cores at a rate which is within a prescribed range until failure occurs. The compressive strength of the specimen is calculated by dividing the maximum load attained during the test by the cross-sectional area of the specimen.

4. Significance and Use

4.1 Care must be exercised in the interpretation of the significance of compressive strength determinations by this test method since strength is not a fundamental or intrinsic property of concrete made from given materials. Values obtained will depend on the size and shape of the specimen, batching, mixing

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved Dec. 15, 2009. Published February 2010. Originally approved in 1921. Last previous edition approved in 2009 as C39/C39M – 09. DOI: 10.1520/C0039_C0039M-09a.

www.technobetar.ir

procedures, the methods of sampling, molding, and fabrication and the age, temperature, and moisture conditions during curing.

4.2 This test method is used to determine compressive strength of cylindrical specimens prepared and cured in accordance with Practices C31/C31M, C192/C192M, C617, and C1231/C1231M and Test Methods C42/C42M and C873.

4.3 The results of this test method are used as a basis for quality control of concrete proportioning, mixing, and placing operations; determination of compliance with specifications; control for evaluating effectiveness of admixtures; and similar uses.

4.4 The individual who tests concrete cylinders for acceptance testing shall meet the concrete laboratory technician requirements of Practice C1077, including an examination requiring performance demonstration that is evaluated by an independent examiner.

NOTE 1—Certification equivalent to the minimum guidelines for ACI Concrete Laboratory Technician, Level I or ACI Concrete Strength Testing Technician will satisfy this requirement.

5. Apparatus

5.1 *Testing Machine*—The testing machine shall be of a type having sufficient capacity and capable of providing the rates of loading prescribed in 7.5.

5.1.1 Verify calibration of the testing machines in accordance with Practices E4, except that the verified loading range shall be as required in 5.3. Verification is required under the following conditions:

5.1.1.1 At least annually, but not to exceed 13 months,

5.1.1.2 On original installation or immediately after relocation,

5.1.1.3 Immediately after making repairs or adjustments that affect the operation of the force applying system or the values displayed on the load indicating system, except for zero adjustments that compensate for the mass of bearing blocks or specimen, or both, or

5.1.1.4 Whenever there is reason to suspect the accuracy of the indicated loads.

5.1.2 *Design*—The design of the machine must include the following features:

5.1.2.1 The machine must be power operated and must apply the load continuously rather than intermittently, and without shock. If it has only one loading rate (meeting the requirements of 7.5), it must be provided with a supplemental means for loading at a rate suitable for verification. This supplemental means of loading may be power or hand operated.

5.1.2.2 The space provided for test specimens shall be large enough to accommodate, in a readable position, an elastic calibration device which is of sufficient capacity to cover the potential loading range of the testing machine and which complies with the requirements of Practice E74.

NOTE 2—The types of elastic calibration devices most generally available and most commonly used for this purpose are the circular proving ring or load cell.

5.1.3 *Accuracy*—The accuracy of the testing machine shall be in accordance with the following provisions:

5.1.3.1 The percentage of error for the loads within the proposed range of use of the testing machine shall not exceed ±1.0 % of the indicated load.

5.1.3.2 The accuracy of the testing machine shall be verified by applying five test loads in four approximately equal increments in ascending order. The difference between any two successive test loads shall not exceed one third of the difference between the maximum and minimum test loads.

5.1.3.3 The test load as indicated by the testing machine and the applied load computed from the readings of the verification device shall be recorded at each test point. Calculate the error, E, and the percentage of error, E_p, for each point from these data as follows:

$$E = A - B \tag{1}$$

$$E_p = 100(A - B)/B$$

where:

A = load, kN [lbf] indicated by the machine being verified, and

B = applied load, kN [lbf] as determined by the calibrating device.

5.1.3.4 The report on the verification of a testing machine shall state within what loading range it was found to conform to specification requirements rather than reporting a blanket acceptance or rejection. In no case shall the loading range be stated as including loads below the value which is 100 times the smallest change of load estimable on the load-indicating mechanism of the testing machine or loads within that portion of the range below 10 % of the maximum range capacity.

5.1.3.5 In no case shall the loading range be stated as including loads outside the range of loads applied during the verification test.

5.1.3.6 The indicated load of a testing machine shall not be corrected either by calculation or by the use of a calibration diagram to obtain values within the required permissible variation.

5.2 The testing machine shall be equipped with two steel bearing blocks with hardened faces (Note 3), one of which is a spherically seated block that will bear on the upper surface of the specimen, and the other a solid block on which the specimen shall rest. Bearing faces of the blocks shall have a minimum dimension at least 3 % greater than the diameter of the specimen to be tested. Except for the concentric circles described below, the bearing faces shall not depart from a plane by more than 0.02 mm [0.001 in.] in any 150 mm [6 in.] of blocks 150 mm [6 in.] in diameter or larger, or by more than 0.02 mm [0.001 in.] in the diameter of any smaller block; and new blocks shall be manufactured within one half of this tolerance. When the diameter of the bearing face of the spherically seated block exceeds the diameter of the specimen by more than 13 mm [0.5 in.], concentric circles not more than 0.8 mm [0.03 in.] deep and not more than 1 mm [0.04 in.] wide shall be inscribed to facilitate proper centering.

NOTE 3—It is desirable that the bearing faces of blocks used for compression testing of concrete have a Rockwell hardness of not less than 55 HRC.

5.2.1 Bottom bearing blocks shall conform to the following requirements:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:59:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

5.2.1.1 The bottom bearing block is specified for the purpose of providing a readily machinable surface for maintenance of the specified surface conditions (Note 4). The top and bottom surfaces shall be parallel to each other. If the testing machine is so designed that the platen itself is readily maintained in the specified surface condition, a bottom block is not required. Its least horizontal dimension shall be at least 3 % greater than the diameter of the specimen to be tested. Concentric circles as described in 5.2 are optional on the bottom block.

NOTE 4—The block may be fastened to the platen of the testing machine.

5.2.1.2 Final centering must be made with reference to the upper spherical block. When the lower bearing block is used to assist in centering the specimen, the center of the concentric rings, when provided, or the center of the block itself must be directly below the center of the spherical head. Provision shall be made on the platen of the machine to assure such a position.

5.2.1.3 The bottom bearing block shall be at least 25 mm [1 in.] thick when new, and at least 22.5 mm [0.9 in.] thick after any resurfacing operations.

5.2.2 The spherically seated bearing block shall conform to the following requirements:

5.2.2.1 The maximum diameter of the bearing face of the suspended spherically seated block shall not exceed the values given below:

Diameter of Test Specimens, mm [in.]	Maximum Diameter of Bearing Face, mm [in.]
50 [2]	105 [4]
75 [3]	130 [5]
100 [4]	165 [6.5]
150 [6]	255 [10]
200 [8]	280 [11]

NOTE 5—Square bearing faces are permissible, provided the diameter of the largest possible inscribed circle does not exceed the above diameter.

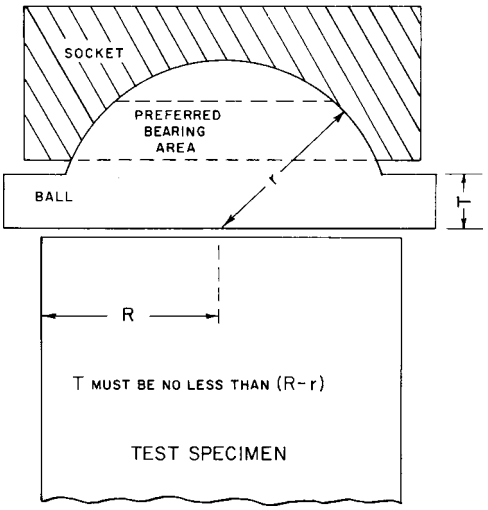
5.2.2.2 The center of the sphere shall coincide with the surface of the bearing face within a tolerance of ±5 % of the radius of the sphere. The diameter of the sphere shall be at least 75 % of the diameter of the specimen to be tested.

5.2.2.3 The ball and the socket shall be designed so that the steel in the contact area does not permanently deform when loaded to the capacity of the testing machine.

NOTE 6—The preferred contact area is in the form of a ring (described as "preferred bearing area") as shown on Fig. 1.

5.2.2.4 The curved surfaces of the socket and of the spherical portion shall be kept clean and shall be lubricated with a petroleum-type oil such as conventional motor oil, not with a pressure type grease. After contacting the specimen and application of small initial load, further tilting of the spherically seated block is not intended and is undesirable.

5.2.2.5 If the radius of the sphere is smaller than the radius of the largest specimen to be tested, the portion of the bearing face extending beyond the sphere shall have a thickness not less than the difference between the radius of the sphere and radius of the specimen. The least dimension of the bearing face shall be at least as great as the diameter of the sphere (see Fig. 1).



NOTE—Provision shall be made for holding the ball in the socket and for holding the entire unit in the testing machine.

FIG. 1 Schematic Sketch of a Typical Spherical Bearing Block

5.2.2.6 The movable portion of the bearing block shall be held closely in the spherical seat, but the design shall be such that the bearing face can be rotated freely and tilted at least 4° in any direction.

5.2.2.7 If the ball portion of the upper bearing block is a two-piece design composed of a spherical portion and a bearing plate, a mechanical means shall be provided to ensure that the spherical portion is fixed and centered on the bearing plate.

5.3 *Load Indication*:

5.3.1 If the load of a compression machine used in concrete testing is registered on a dial, the dial shall be provided with a graduated scale that is readable to at least the nearest 0.1 % of the full scale load (Note 7). The dial shall be readable within 1 % of the indicated load at any given load level within the loading range. In no case shall the loading range of a dial be considered to include loads below the value that is 100 times the smallest change of load that can be read on the scale. The scale shall be provided with a graduation line equal to zero and so numbered. The dial pointer shall be of sufficient length to reach the graduation marks; the width of the end of the pointer shall not exceed the clear distance between the smallest graduations. Each dial shall be equipped with a zero adjustment located outside the dialcase and easily accessible from the front of the machine while observing the zero mark and dial pointer. Each dial shall be equipped with a suitable device that at all times, until reset, will indicate to within 1 % accuracy the maximum load applied to the specimen.

NOTE 7—Readability is considered to be 0.5 mm [0.02 in.] along the arc described by the end of the pointer. Also, one half of a scale interval is readable with reasonable certainty when the spacing on the load indicating mechanism is between 1 mm [0.04 in.] and 2 mm [0.06 in.]. When the spacing is between 2 and 3 mm [0.06 and 0.12 in.], one third of a scale interval is readable with reasonable certainty. When the spacing is 3 mm [0.12 in.] or more, one fourth of a scale interval is readable with reasonable certainty.

5.3.2 If the testing machine load is indicated in digital form, the numerical display must be large enough to be easily read.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:59:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

The numerical increment must be equal to or less than 0.10 % of the full scale load of a given loading range. In no case shall the verified loading range include loads less than the minimum numerical increment multiplied by 100. The accuracy of the indicated load must be within 1.0 % for any value displayed within the verified loading range. Provision must be made for adjusting to indicate true zero at zero load. There shall be provided a maximum load indicator that at all times until reset will indicate within 1 % system accuracy the maximum load applied to the specimen.

6. Specimens

6.1 Specimens shall not be tested if any individual diameter of a cylinder differs from any other diameter of the same cylinder by more than 2 %.

NOTE 8—This may occur when single use molds are damaged or deformed during shipment, when flexible single use molds are deformed during molding, or when a core drill deflects or shifts during drilling.

6.2 Prior to testing, neither end of test specimens shall depart from perpendicularity to the axis by more than 0.5° (approximately equivalent to 1 mm in 100 mm [0.12 in. in 12 in.]). The ends of compression test specimens that are not plane within 0.050 mm [0.002 in.] shall be sawed or ground to meet that tolerance, or capped in accordance with either Practice C617 or, when permitted, Practice C1231/C1231M. The diameter used for calculating the cross-sectional area of the test specimen shall be determined to the nearest 0.25 mm [0.01 in.] by averaging two diameters measured at right angles to each other at about midheight of the specimen.

6.3 The number of individual cylinders measured for determination of average diameter is not prohibited from being reduced to one for each ten specimens or three specimens per day, whichever is greater, if all cylinders are known to have been made from a single lot of reusable or single-use molds which consistently produce specimens with average diameters within a range of 0.5 mm [0.02 in.]. When the average diameters do not fall within the range of 0.5 mm [0.02 in.] or when the cylinders are not made from a single lot of molds, each cylinder tested must be measured and the value used in calculation of the unit compressive strength of that specimen. When the diameters are measured at the reduced frequency, the cross-sectional areas of all cylinders tested on that day shall be computed from the average of the diameters of the three or more cylinders representing the group tested that day.

6.4 If the purchaser of the testing services requests measurement of density of test specimens, determine the mass of specimens before capping. Remove any surface moisture with a towel and measure the mass of the specimen using a balance or scale that is accurate to within 0.3 % of the mass being measured. Measure the length of the specimen to the nearest 1 mm [0.05 in.] at three locations spaced evenly around the circumference. Compute the average length and record to the nearest 1 mm [0.05 in.]. Alternatively, determine the cylinder density by weighing the cylinder in air and then submerged under water at 23.0 ± 2.0 °C [73.5 ± 3.5 °F], and computing the volume according to 8.3.1.

6.5 When density determination is not required and the length to diameter ratio is less than 1.8 or more than 2.2, measure the length of the specimen to the nearest 0.05 D.

7. Procedure

7.1 Compression tests of moist-cured specimens shall be made as soon as practicable after removal from moist storage.

7.2 Test specimens shall be kept moist by any convenient method during the period between removal from moist storage and testing. They shall be tested in the moist condition.

7.3 All test specimens for a given test age shall be broken within the permissible time tolerances prescribed as follows:

Test Age	Permissible Tolerance
24 h	± 0.5 h or 2.1 %
3 days	2 h or 2.8 %
7 days	6 h or 3.6 %
28 days	20 h or 3.0 %
90 days	2 days 2.2 %

7.4 *Placing the Specimen*—Place the plain (lower) bearing block, with its hardened face up, on the table or platen of the testing machine directly under the spherically seated (upper) bearing block. Wipe clean the bearing faces of the upper and lower bearing blocks and of the test specimen and place the test specimen on the lower bearing block. Carefully align the axis of the specimen with the center of thrust of the spherically seated block.

7.4.1 *Zero Verification and Block Seating*—Prior to testing the specimen, verify that the load indicator is set to zero. In cases where the indicator is not properly set to zero, adjust the indicator (Note 9). As the spherically seated block is brought to bear on the specimen, rotate its movable portion gently by hand so that uniform seating is obtained.

NOTE 9—The technique used to verify and adjust load indicator to zero will vary depending on the machine manufacturer. Consult your owner's manual or compression machine calibrator for the proper technique.

7.5 *Rate of Loading*—Apply the load continuously and without shock.

7.5.1 The load shall be applied at a rate of movement (platen to crosshead measurement) corresponding to a stress rate on the specimen of 0.25 ± 0.05 MPa/s [35 ± 7 psi/s] (See Note 10). The designated rate of movement shall be maintained at least during the latter half of the anticipated loading phase.

NOTE 10—For a screw-driven or displacement-controlled testing machine, preliminary testing will be necessary to establish the required rate of movement to achieve the specified stress rate. The required rate of movement will depend on the size of the test specimen, the elastic modulus of the concrete, and the stiffness of the testing machine.

7.5.2 During application of the first half of the anticipated loading phase, a higher rate of loading shall be permitted. The higher loading rate shall be applied in a controlled manner so that the specimen is not subjected to shock loading.

7.5.3 Make no adjustment in the rate of movement (platen to crosshead) as the ultimate load is being approached and the stress rate decreases due to cracking in the specimen.

7.6 Apply the compressive load until the load indicator shows that the load is decreasing steadily and the specimen displays a well-defined fracture pattern (Types 1 to 4 in Fig. 2). For a testing machine equipped with a specimen break detector,

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

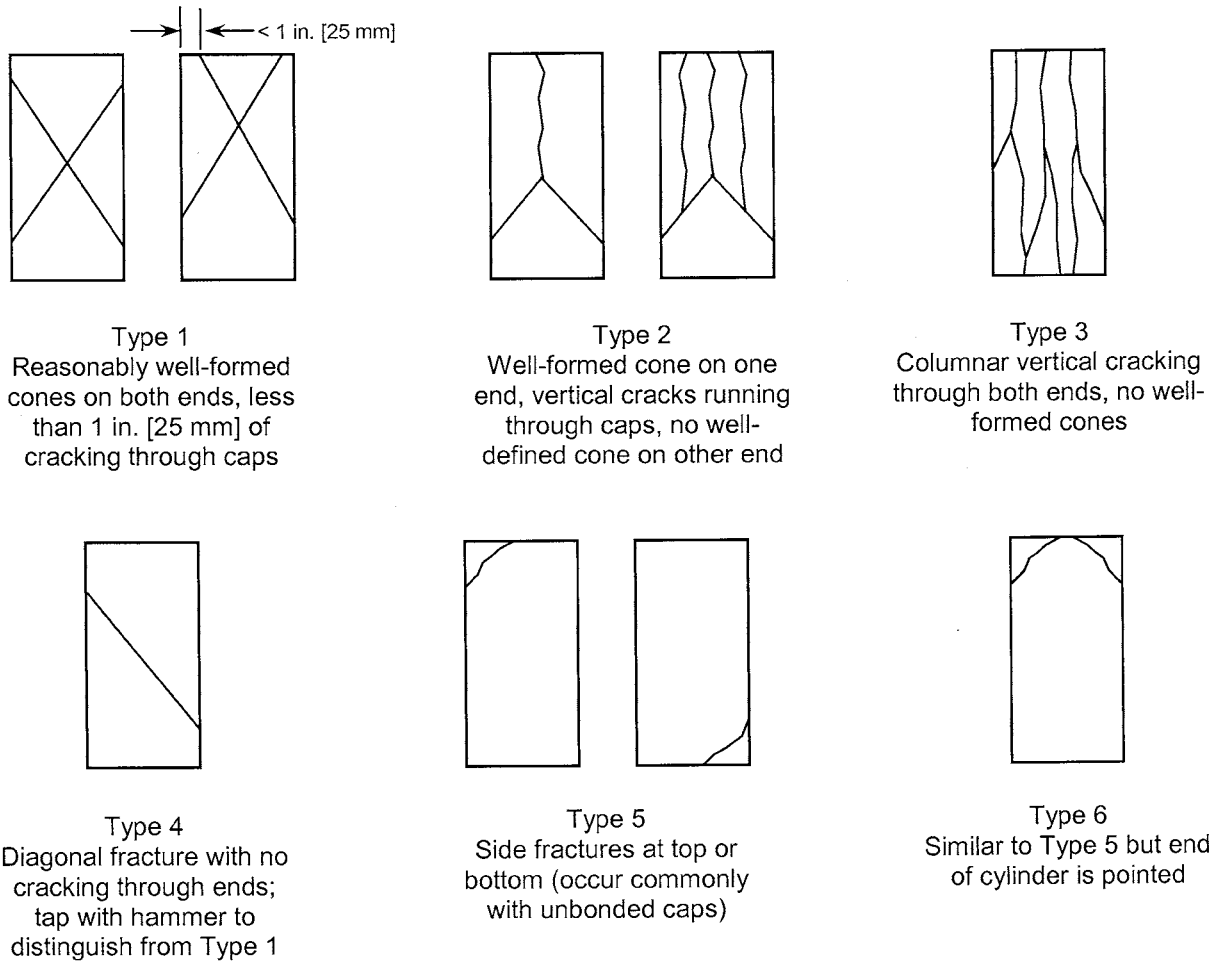

FIG. 2 Schematic of Typical Fracture Patterns

automatic shut-off of the testing machine is prohibited until the load has dropped to a value that is less than 95 % of the peak load. When testing with unbonded caps, a corner fracture similar to a Type 5 or 6 pattern shown in Fig. 2 may occur before the ultimate capacity of the specimen has been attained. Continue compressing the specimen until the user is certain that the ultimate capacity has been attained. Record the maximum load carried by the specimen during the test, and note the type of fracture pattern according to Fig. 2. If the fracture pattern is not one of the typical patterns shown in Fig. 2, sketch and describe briefly the fracture pattern. If the measured strength is lower than expected, examine the fractured concrete and note the presence of large air voids, evidence of segregation, whether fractures pass predominantly around or through the coarse aggregate particles, and verify end preparations were in accordance with Practice C617 or Practice C1231/C1231M.

8. Calculation

8.1 Calculate the compressive strength of the specimen by dividing the maximum load carried by the specimen during the test by the average cross-sectional area determined as described in Section 6 and express the result to the nearest 0.1 MPa [10 psi].

8.2 If the specimen length to diameter ratio is 1.75 or less, correct the result obtained in 8.1 by multiplying by the appropriate correction factor shown in the following table Note 11:

L/D:	1.75	1.50	1.25	1.00
Factor:	0.98	0.96	0.93	0.87

Use interpolation to determine correction factors for L/D values between those given in the table.

NOTE 11—Correction factors depend on various conditions such as moisture condition, strength level, and elastic modulus. Average values are given in the table. These correction factors apply to low-density concrete weighing between 1600 and 1920 kg/m^3 [100 and 120 lb/ft^3] and to normal-density concrete. They are applicable to concrete dry or soaked at the time of loading and for nominal concrete strengths from 14 to 42 MPa [2000 to 6000 psi]. For strengths higher than 42 MPai [6000 ps] correction factors may be larger than the values listed above[3].

8.3 When required, calculate the density of the specimen to the nearest 10 kg/m^3 [1 lb/ft^3] as follows:

$$Density = \frac{W}{V} \quad (2)$$

[3] Bartlett, F.M. and MacGregor, J.G., "Effect of Core Length-to-Diameter Ratio on Concrete Core Strength," *ACI Materials Journal*, Vol 91, No. 4, July-August, 1994 , pp. 339-348.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

where:
W = mass of specimen, kg [lb], and
V = volume of specimen computed from the average diameter and average length or from weighing the cylinder in air and submerged, m^3 [ft^3]

8.3.1 When the volume is determined from submerged weighing, calculate the volume as follows:

$$V = \frac{W - W_s}{\gamma_w} \quad (3)$$

where:
W_s = apparent mass of submerged specimen, kg [lb], and
γ_w = density of water at 23 °C [73.5 °F] = 997.5 kg/m^3 [62.27 lbs/ft^3].

9. Report

9.1 Report the following information:
9.1.1 Identification number,
9.1.2 Diameter (and length, if outside the range of 1.8 *D* to 2.2 *D*), in millimetres [inches],
9.1.3 Cross-sectional area, in square millimetres [square inches],
9.1.4 Maximum load, in kilonewtons [pounds-force],
9.1.5 Compressive strength calculated to the nearest 0.1 MPa [10 psi],
9.1.6 Type of fracture, if other than the usual cone (see Fig. 2),
9.1.7 Defects in either specimen or caps, and,
9.1.8 Age of specimen.
9.1.9 When determined, the density to the nearest 10 kg/m^3 [1 lb/ft^3].

10. Precision and Bias

10.1 *Precision*

10.1.1 *Within-Test Precision*—The following table provides the within-test precision of tests of 150 by 300 mm [6 by 12 in.] and 100 by 200 mm [4 by 8 in.] cylinders made from a well-mixed sample of concrete under laboratory conditions and under field conditions (see 10.1.2).

	Coefficient of Variation[4]	Acceptable Range[4] of Individual Cylinder Strengths	
		2 cylinders	3 cylinders
150 by 300 mm [6 by 12 in.]			
Laboratory conditions	2.4 %	6.6 %	7.8 %
Field conditions	2.9 %	8.0 %	9.5 %
100 by 200 mm [4 by 8 in.]			
Laboratory conditions	3.2 %	9.0 %	10.6 %

10.1.2 The within-test coefficient of variation represents the expected variation of measured strength of companion cylinders prepared from the same sample of concrete and tested by one laboratory at the same age. The values given for the within-test coefficient of variation of 150 by 300 mm [6 by 12 in.] cylinders are applicable for compressive strengths between 2000 and 15 to 55 MPa [8000 psi] and those for 100 by 200 mm [4 by 8 in.] cylinders are applicable for compressive strengths between 17 to 32 MPa [2500 and 4700 psi]. The within-test coefficients of variation for 150 by 300 mm [6 by 12 in.] cylinders are derived from CCRL concrete proficiency sample data for laboratory conditions and a collection of 1265 test reports from 225 commercial testing laboratories in 1978.[5] The within-test coefficient of variation of 100 by 200 mm [4 by 8 in.] cylinders are derived from CCRL concrete proficiency sample data for laboratory conditions.

10.1.3 *Multilaboratory Precision*—The multi-laboratory coefficient of variation for compressive strength test results of 150 by 300 mm [6 by 12 in.] cylinders has been found to be 5.0 %[4]; therefore, the results of properly conducted tests by two laboratories on specimens prepared from the same sample of concrete are not expected to differ by more than 14 %[4] of the average (See Note 12). A strength test result is the average of two cylinders tested at the same age.

NOTE 12—The multilaboratory precision does not include variations associated with different operators preparing test specimens from split or independent samples of concrete. These variations are expected to increase the multilaboratory coefficient of variation.

10.1.4 The multilaboratory data were obtained from six separate organized strength testing round robin programs where 150 x 300 mm [6 x 12 in.] cylindrical specimens were prepared at a single location and tested by different laboratories. The range of average strength from these programs was 17.0 to 90 MPa [2500 to 13 000 psi].

NOTE 13—Subcommittee C09.61 will continue to examine recent concrete proficiency sample data and field test data and make revisions to precisions statements when data indicate that they can be extended to cover a wider range of strengths and specimen sizes.

10.2 *Bias*—Since there is no accepted reference material, no statement on bias is being made.

[4] These numbers represent respectively the (1s %) and (d2s %) limits as described in Practice C670.

[5] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR:C09-1006.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C39/C39M–09, that may impact the use of this test method. (Approved December 15, 2009)

(*1*) Revised 1.1 to replace the term "unit weight" with the preferred term "density."

Committee C09 has identified the location of selected changes to this test method since the last issue, C39/C39M–05$^{\varepsilon 2}$, that may impact the use of this test method. (Approved November 1, 2009)

(*1*) Revised Note 6 to clarify the reference to Fig. 1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 40 – 04

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T 21

Standard Test Method for Organic Impurities in Fine Aggregates for Concrete[1]

This standard is issued under the fixed designation C 40; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers two procedures for an approximate determination of the presence of injurious organic impurities in fine aggregates that are to be used in hydraulic cement mortar or concrete. One procedure uses a standard color solution and the other uses a glass color standard.

1.2 The values given in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 33 Specification for Concrete Aggregates
C 87 Test Method for Effect of Organic Impurities in Fine Aggregate on Strength of Mortar
C 125 Terminology Relating to Concrete and Concrete Aggregates
C 702 Practice for Reducing Samples of Aggregate to Testing Size
D 75 Practice for Sampling Aggregates
D 1544 Test Method for Color of Transparent Liquids (Gardner Color Scale)

3. Significance and Use

3.1 This test method is used in making a preliminary determination of the acceptability of fine aggregates with respect to the requirements of Specification C 33 that relate to organic impurities.

3.2 The principal value of this test method is to furnish a warning that injurious amounts of organic impurities may be present. When a sample subjected to this test produces a color darker than the standard color it is advisable to perform the test for the effect of organic impurities on the strength of mortar in accordance with Test Method C 87.

4. Apparatus

4.1 *Glass Bottles*—Colorless glass graduated bottles, approximately 240 to 470-mL (8 to 16-oz) nominal capacity, equipped with watertight stoppers or caps, not soluble in the specified reagents. In no case shall the maximum outside thickness of the bottles, measured along the line of sight used for the color comparison, be greater than 63.5 mm (2.5 in.) or less than 38.1 mm (1.5 in.). The graduations on the bottles shall be in millilitres, or ounces (U.S. fluid), except that unmarked bottles may be calibrated and scribed with graduations by the user. In such case, graduation marks are required at only three points as follows:

4.1.1 *Standard Color Solution Level*—75 mL (2½ oz (U.S. fluid)),

4.1.2 *Fine Aggregate Level*—130 mL (4½ oz (U.S. fluid)), and

4.1.3 *NaOH Solution Level*—200 mL (7 oz (U.S. fluid)).

4.2 *Glass Color Standard*

4.2.1 Glass standard colors shall be used as described in Table 1 of Test Method D 1544.

NOTE 1—A suitable instrument consists of five glass color standards mounted in a plastic holder. Only the glass identified as Gardner Color Standard No. 11 is to be used as the Glass Color Standard in 9.2.

5. Reagent and Standard Color Solution

5.1 *Reagent Sodium Hydroxide Solution (3 %)*—Dissolve 3 parts by mass of reagent grade sodium hydroxide (NaOH) in 97 parts of water.

5.2 *Standard Color Solution*—Dissolve reagent grade potassium dichromate ($K_2Cr_2O_7$) in concentrated sulfuric acid (sp gr 1.84) at the rate of 0.250 g/100 mL of acid. The solution must be freshly made for the color comparison using gentle heat if necessary to effect solution.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved Jan. 1, 2004. Published January 2004. Originally approved in 1921. Last previous edition approved in 1999 as C 40 – 99.

www.technobetar.ir

6. Sampling

6.1 The sample shall be selected in general accordance with Practice D 75.

7. Test Sample

7.1 The test sample shall have a mass of about approximately 450 g (1 lb) and be taken from the larger sample in accordance with Practice C 702.

8. Procedure

8.1 Fill a glass bottle to the approximately 130-mL (4½-fluid oz) level with the sample of the fine aggregate (see Terminology C 125) to be tested.

8.2 Add the sodium hydroxide solution until the volume of the fine aggregate and liquid, indicated after shaking, is approximately 200 mL (7 fluid oz).

8.3 Stopper the bottle, shake vigorously, and then allow to stand for 24 h.

9. Determination of Color Value

9.1 *Standard Color Solution Procedure*—At the end of the 24-h standing period, fill a glass bottle to the approximately 75-mL (2½-fluid oz) level with the fresh standard color solution, prepared not longer than 2 h previously, as prescribed in 5.2. Hold the bottle with the test sample and the bottle with the standard color solution side-by-side, and compare the color of light transmitted through the supernatant liquid above the sample with the color of light transmitted through the standard color solution. Record whether the color of the supernatant liquid is lighter, darker, or equal to the color of the standard color solution.

9.2 *Glass Color Standard Procedure*—To define more precisely the color of the supernatant liquid of the test sample, five glass standard colors shall be used using the following colors:

Gardner Color Standard No.	Organic Plate No.
5	1
8	2
11	3 (standard)
14	4
16	5

The comparison procedure described in 9.1 shall be used, except that the organic plate number which is nearest the color of the supernatant liquid above the test specimen shall be reported. When using this procedure, it is not necessary to prepare the standard color solution.

10. Interpretation

10.1 When a sample subjected to this procedure produces a color darker than the standard color, or Organic Plate No. 3 (Gardner Color Standard No. 11), the fine aggregate under test shall be considered to possibly contain injurious organic impurities. It is advisable to perform further tests before approving the fine aggregate for use in concrete.

11. Precision and Bias

11.1 Since this test produces no numerical values, determination of the precision and bias is not possible.

12. Keywords

12.1 colorimetric test; fine aggregate; organic impurities

Designation: C 42/C 42M – 04

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T24

Standard Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete[1]

This standard is issued under the fixed designation C 42/C 42M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers obtaining, preparing, and testing (*1*) cores drilled from concrete for length or compressive strength or splitting tensile strength determinations and (*2*) beams sawed from concrete for flexural strength determinations.

1.2 The values stated in either inch-pound units or SI units shall be regarded separately as standard. SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 *This standard does not purport to address the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2 *ACI Standards:*

318 Building Code Requirements for Structural Concrete[3]

3. Significance and Use

3.1 This test method provides standardized procedures for obtaining and testing specimens to determine the compressive, splitting tensile, and flexural strength of in-place concrete.

3.2 Generally, test specimens are obtained when doubt exists about the in-place concrete quality due either to low strength test results during construction or signs of distress in the structure. Another use of this method is to provide strength information on older structures.

3.3 Concrete strength is affected by the location of the concrete in a structural element, with the concrete at the bottom tending to be stronger than the concrete at the top. Core strength is also affected by core orientation relative to the horizontal plane of the concrete as placed, with strength tending to be lower when measured parallel to the horizontal plane.[4] These factors shall be considered in planning the locations for obtaining concrete samples and in comparing strength test results.

3.4 The strength of concrete measured by tests of cores and beams is affected by the amount and distribution of moisture in the specimen at the time of test. There is no standard procedure to condition a specimen that will ensure that, at the time of test,

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved July 1, 2004. Published July 2004. Originally approved in 1921. Last previous edition approved in 2003 as C 42/C 42M – 03.

www.technobetar.ir

it will be in the identical moisture condition as concrete in the structure. The moisture conditioning procedures in this test method are intended to provide reproducible moisture conditions that minimize within-laboratory and between-laboratory variations and to reduce the effects of moisture introduced during specimen preparation.

3.5 There is no universal relationship between the compressive strength of a core and the corresponding compressive strength of standard-cured molded cylinders. The relationship is affected by many factors such as the strength level of the concrete, the in-place temperature and moisture history, and the strength gain characteristics of the concrete. Historically, it has been assumed that core strengths are generally 85 % of the corresponding standard-cured cylinder strengths, but this is not applicable to all situations. The acceptance criteria for core strength are to be established by the specifier of the tests. ACI 318 provides core strength acceptance criteria for new construction.

4. Apparatus

4.1 *Core Drill*, for obtaining cylindrical core specimens with diamond impregnated bits attached to a core barrel.

4.2 *Saw*, for cutting beam specimens to size for flexural strength tests and to trim ends of cores. The saw shall have a diamond or silicon-carbide cutting edge and shall be capable of cutting specimens that conform to the prescribed dimensions, without excessive heating or shock.

5. Sampling

5.1 *General*:

5.1.1 Samples of hardened concrete for use in the preparation of strength test specimens shall not be taken until the concrete is strong enough to permit sample removal without disturbing the bond between the mortar and the coarse aggregate (see Note 1 and Note 2). When preparing strength test specimens from samples of hardened concrete, samples that have been damaged during removal shall not be used unless the damaged portion(s) are removed and the resulting test specimen is of suitable length (see 7.2). Samples of defective or damaged concrete that cannot be tested shall be reported along with the reason that prohibits use of the sample for preparing strength test specimens.

NOTE 1—Practice C 823 provides guidance on the development of a sampling plan for concrete in constructions.

NOTE 2—It is not possible to specify a minimum age when concrete is strong enough to withstand damage during removal, because the strength at any age depends on the curing history and strength grade of the concrete. If time permits, the concrete should not be removed before it is 14 days old. If this is not practical, removal of concrete can proceed if the cut surfaces do not display erosion of the mortar and the exposed coarse aggregate particles are embedded firmly in the mortar. In-place test methods may be used to estimate the level of strength development prior to attempting removal of concrete samples.

5.1.2 Specimens containing embedded reinforcement shall not be used for determining compressive, splitting tensile, or flexural strength.

5.2 *Core Drilling*—A core specimen shall be drilled perpendicular to the surface and not near formed joints or obvious edges of a unit of deposit. Record and report the approximate angle between the longitudinal axis of the drilled core and the horizontal plane of the concrete as placed. A specimen drilled perpendicular to a vertical surface, or perpendicular to a surface with a batter, shall be taken from near the middle of a unit of deposit when possible.

5.3 *Slab Removal*—Remove a slab sufficiently large to secure the desired test specimens without the inclusion of any concrete that has been cracked, spalled, undercut, or otherwise damaged.

DRILLED CORES

6. Measuring the Length of Drilled Cores

6.1 Cores for determining the thickness of pavements, slabs, walls or other structural elements shall have a diameter of at least 3.75 in. [95 mm] when the lengths of such cores are stipulated to be measured in accordance with Test Method C 174/C 174M.

6.2 For cores that are not intended for determining structural dimensions, measure the longest and shortest lengths on the cut surface along lines parallel to the core axis. Record the average length to the nearest ¼ in. [5 mm].

7. Cores for Compressive Strength

7.1 *Diameter*—The diameter of core specimens for the determination of compressive strength in load bearing structural members shall be at least 3.70 in. [94 mm]. For non-load bearing structural members or when it is impossible to obtain cores with length-diameter ratio (L/D) greater than or equal to 1, core diameters less than 3.70 in. [94 mm] are not prohibited (see Note 3). For concrete with nominal maximum aggregate size greater than or equal to 1½ in. [37.5 mm], the core diameters shall be as directed by the specifier of the tests (see Note 4).

NOTE 3—The compressive strengths of nominal 2-in. [50-mm] diameter cores are known to be somewhat lower and more variable than those of nominal 4-in. [100-mm] diameter cores. In addition, smaller diameter cores appear to be more sensitive to the effect of the length-diameter ratio.[5]

NOTE 4—The preferred minimum core diameter is three times the nominal maximum size of the coarse aggregate, but it should be at least two times the nominal maximum size of the coarse aggregate.

7.2 *Length*—The preferred length of the capped or ground specimen is between 1.9 and 2.1 times the diameter. If the ratio of the length to the diameter (L/D) of the core exceeds 2.1, reduce the length of the core so that the ratio of the capped or ground specimen is between 1.9 and 2.1. Core specimens with length-diameter ratios equal to or less than 1.75 require corrections to the measured compressive strength (see 7.9.1). A strength correction factor is not required for L/D greater than 1.75. A core having a maximum length of less than 95 % of its diameter before capping or a length less than its diameter after capping or end grinding shall not be tested.

7.3 *Moisture Conditioning*—Test cores after moisture conditioning as specified in this test method or as directed by the

[5] Bartlett, F.M. and MacGregor, J.G., "Effect of Core Diameter on Concrete Core Strengths," *ACI Materials Journal*, Vol. 91, No. 5, September-October 1994, pp. 460-470.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

specifier of the tests. The moisture conditioning procedures specified in this test method are intended to preserve the moisture of the drilled core and to provide a reproducible moisture condition that minimizes the effects of moisture gradients introduced by wetting during drilling and specimen preparation.

7.3.1 After cores have been drilled, wipe off surface drill water and allow remaining surface moisture to evaporate. When surfaces appear dry, but not later than 1 h after drilling, place cores in separate plastic bags or nonabsorbent containers and seal to prevent moisture loss. Maintain cores at ambient temperature, and protect cores from exposure to direct sunlight. Transport the cores to the testing laboratory as soon as possible. Keep cores in the sealed plastic bags or nonabsorbent containers at all times except during end preparation and for a maximum time of 2 h to permit capping before testing.

7.3.2 If water is used during sawing or grinding of core ends, complete these operations as soon as possible, but no later than 2 days after drilling of cores unless stipulated otherwise by the specifier of tests. After completing end preparation, wipe off surface moisture, allow the surfaces to dry, and place the cores in sealed plastic bags or nonabsorbent containers. Minimize the duration of exposure to water during end preparation.

7.3.3 Allow the cores to remain in the sealed plastic bags or nonabsorbent containers for at least 5 days after last being wetted and before testing, unless stipulated otherwise by the specifier of tests.

NOTE 5—The waiting period of at least 5 days is intended to reduce moisture gradients introduced when the core is drilled or wetted during sawing or grinding.

7.3.4 When direction is given to test cores in a moisture condition other than achieved by conditioning according to 7.3.1, 7.3.2, and 7.3.3, report the alternative procedure.

7.4 *Sawing of Ends*—The ends of core specimens to be tested in compression shall be flat, and perpendicular to the longitudinal axis in accordance with Test Method C 39/C 39M. If necessary, saw the ends of cores that will be capped so that prior to capping, the following requirements are met:

7.4.1 Projections, if any, shall not extend more than 0.2 in. [5 mm] above the end surfaces.

7.4.2 The end surfaces shall not depart from perpendicularity to the longitudinal axis by a slope of more than 1:8*d* or [1:0.3*d*] where *d* is the average core diameter in inches [or mm].

7.5 *Density*—When required by the specifier of the tests, determine the density by weighing the core before capping and dividing the mass by the volume of the core calculated from the average diameter and length. Alternatively, determine the density from the mass in air and submerged mass in accordance with Test Method C 642. After submerged weighing, dry cores in accordance with 7.3.2 and store in sealed plastic bags or nonabsorbent containers for at least 5 days before testing.

7.6 *Capping*—If the ends of the cores do not conform to the perpendicularity and planeness requirements of Test Method C 39/C 39M, they shall be sawed or ground to meet those requirements or capped in accordance with Practice C 617. If cores are capped in accordance with Practice C 617, the capping device shall accommodate actual core diameters and produce caps that are concentric with the core ends. Measure core lengths to the nearest 0.1 in. [2 mm] before capping. Unbonded caps in accordance with Practice C 1231/C 1231M are not permitted.

7.7 *Measurement*—Before testing, measure the length of the capped or ground specimen to the nearest 0.1 in. [2 mm] and use this length to compute the length-diameter (L/D) ratio. Determine the average diameter by averaging two measurements taken at right angles to each other at the mid-height of the specimen. Measure core diameters to the nearest 0.01 in. [0.2 mm] when the difference in core diameters does not exceed 2 % of their average, otherwise measure to the nearest 0.1 in. [2 mm]. Do not test cores if the difference between the largest and smallest diameter exceeds 5 % of their average.

7.8 *Testing*—Test the specimens in accordance with Test Method C 39/C 39M. Test the specimens within 7 days after coring, unless specified otherwise.

7.9 *Calculation*—Calculate the compressive strength of each specimen using the computed cross-sectional area based on the average diameter of the specimen.

7.9.1 If the ratio of length to diameter (L/D) of the specimen is 1.75 or less, correct the result obtained in 7.9 by multiplying by the appropriate correction factor shown in the following table (see Note 6):

Ratio of Length to Diameter (L/D)	Strength Correction Factor
1.75	0.98
1.50	0.96
1.25	0.93
1.00	0.87

Use interpolation to determine correction factors for L/D values not given in the table.

NOTE 6—Correction factors depend on various conditions such as moisture condition, strength level, and elastic modulus. Average values for corrections due to length-diameter ratio are given in the table. These correction factors apply to low-density concrete having a density between 100 and 120 lb/ft^3 [1600 and 1920 kg/m^3] and to normal density concrete. They are applicable to both dry and wet concrete for strengths between 2000 psi and 6000 psi [14 MPa to 42 MPa]. For strengths above 10 000 psi [70 MPa], test data on cores show that the correction factors may be larger than the values listed above.[6]

7.10 *Report*—Report the results as required by Test Method C 39/C 39M with the addition of the following information:

7.10.1 Length of core as drilled to the nearest ¼ in. [5 mm],

7.10.2 Length of test specimen before and after capping or end grinding to the nearest 0.1 in. [2 mm], and average diameter of core to the nearest 0.01 in. [0.2 mm] or 0.1 in. [2 mm],

7.10.3 Compressive strength to the nearest 10 psi [0.1 MPa] when the diameter is measured to the nearest 0.01 in. [0.2 mm] and to the nearest 50 psi [0.5 MPa] when the diameter is measured to the nearest 0.1 in. [2 mm], after correction for length-diameter ratio when required,

[6] Bartlett, F.M. and MacGregor, J.G, "Effect of Core Length-to-Diameter Ratio on Concrete Core Strengths," *ACI Materials Journal*, Vol. 91, No. 4, July-August 1994, pp. 339-348.

www.technobetar.ir

7.10.4 Direction of application of the load on the specimen with respect to the horizontal plane of the concrete as placed,

7.10.5 The moisture conditioning history:

7.10.5.1 The date and time core was obtained and first placed in sealed bag or nonabsorbent container,

7.10.5.2 If water was used during end preparation, the date and time end preparation was completed and core placed in sealed bag or nonabsorbent container,

7.10.6 The date and time when tested,

7.10.7 Nominal maximum size of concrete aggregate.

7.10.8 If determined, the density,

7.10.9 If applicable, description of defects in cores that could not be tested, and

7.10.10 If any deviation from this test method was required, describe the deviation and explain why it was necessary.

7.11 *Precision:*[7]

7.11.1 The single-operator coefficient of variation on cores has been found to be 3.2 %[8] for a range of compressive strength between 4500 psi [32.0 MPa] and 7000 psi [48.3 MPa]. Therefore, results of two properly conducted tests of single cores by the same operator on the same sample of material should not differ from each other by more than 9 %[8] of their average.

7.11.2 The multi-laboratory coefficient of variation on cores has been found to be 4.7 %[8] for a range of compressive strength between 4500 psi [32.0 MPa] and 7000 psi [48.3 MPa]. Therefore, results of two properly conducted tests on cores sampled from the same hardened concrete (where a single test is defined as the average of two observations (cores), each made on separate adjacent drilled 4 in. [100 mm] diameter cores), and tested by two different laboratories should not differ from each other by more than 13 %[8] of their average.

7.12 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

8. Cores for Splitting Tensile Strength

8.1 *Test Specimens*—The specimens shall conform to the dimensional requirements in 7.1, 7.2, 7.4.1, and 7.4.2. Ends are not to be capped.

8.2 *Moisture Conditioning*—Condition the specimens as described in 7.3, or as directed by the specifier of tests.

8.3 *Bearing Surfaces*—The line of contact between the specimen and each bearing strip shall be straight and free of any projections or depressions higher or deeper than 0.01 in. [0.2 mm]. When the line of contact is not straight or contains projections or depressions having heights or depths greater than 0.01 in., grind or cap the specimen so as to produce bearing lines meeting these requirements. Do not test specimens with projections or depressions greater than 0.1 in. [2.0 mm]. When capping is employed, the caps shall be as thin as practicable and shall be formed of high-strength gypsum plaster.

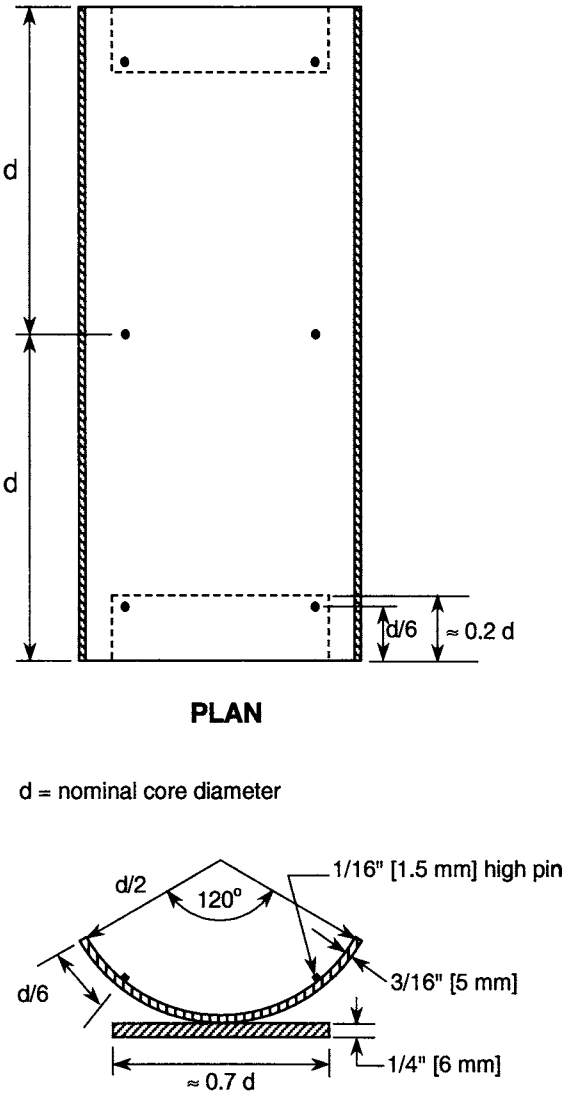

FIG. 1 Suitable Capping Device for Splitting Tensile Strength Test

NOTE 7—Fig. 1 illustrates a device suitable for applying caps to the bearing surfaces of core specimens.

8.4 *Testing*—Test the specimens in accordance with Test Method C 496.

8.5 *Calculation and Report*—Calculate the splitting tensile strength and report the results as required in Test Method C 496. When grinding or capping of the bearing surfaces is required, measure the diameter between the finished surfaces. Indicate that the specimen was a core and provide the moisture conditioning history as in 7.10.5.

8.6 *Precision:*[9]

8.6.1 The within laboratory single operator coefficient of variation for splitting tensile strength between 520 psi [3.6 MPa] and 590 psi [4.1 MPa] of cores has been found to be

[7] Bollin, G. E., "Development of Precision and Bias Statements for Testing Drilled Cores in Accordance with ASTM C 42," *ASTM Journal of Cement, Concrete, and Aggregates*, Vol 15, No. 1, 1993.

[8] These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

[9] Steele, G.W., "Portland Cement Concrete Core Proficiency Sample Program," Strategic Highway Research Program, SHRP-P-636, National Research Council, Washington, D.C., 1993.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

5.3 %.[8] Therefore, results of two properly conducted tests by the same operator in the same laboratory on the same sample of material should not differ by more than 14.9 %[8] of their average.

8.6.2 The multi-laboratory coefficient of variation for splitting tensile strength between 520 psi [3.6 MPa] and 590 psi [4.1 MPa] of cores has been found to be 15.0 %.[8] Therefore, results of two properly conducted tests on the same sample of material of hardened concrete and tested by two different laboratories should not differ from each other by more than 42.3 %[8] of their average.

8.7 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

BEAMS FOR FLEXURAL TESTING

9. Flexural Strength

9.1 *Test Specimens*—Unless otherwise specified, a beam specimen for the determination of flexural strength shall have a nominal cross section of 6 by 6 in. [150 by 150 mm] (Note 8). The specimen shall be at least 21 in. [530 mm] in length, but when two tests for flexural strength are to be made in one beam specimen, it shall be at least 33 in. [840 mm] in length. Perform the sawing operation so that the concrete will not be weakened by shock or by heating. The sawed surfaces shall be smooth, plane, parallel, and free from steps, ridges, and grooves. Take care in handling sawed beam specimens to avoid chipping or cracking.

NOTE 8—In many cases, particularly with prisms cut from pavement slabs, the width will be governed by the size of the coarse aggregate and the depth by the thickness of the slab.

9.2 *Moisture Conditioning*—Protect the surfaces of sawed specimens from evaporation by covering them with wet burlap and plastic sheeting during transportation and storage. Test the specimens within 7 days of sawing. Submerge the test specimens in lime-saturated water at 73.5 ± 3.5°F [23.0 ± 2.0°C] for at least 40 h immediately prior to the flexure test. Test the specimens promptly after removal from water storage. During the period between removal from water storage and testing, keep the specimens moist by covering with a wet blanket of burlap or other suitable absorbent fabric.

9.2.1 When the specifier of tests so directs, beams shall be tested in a moisture condition other than that achieved by conditioning in accordance with 9.2.

NOTE 9—Relatively small amounts of drying of the surface of flexural specimens induce tensile stresses in the extreme fibers that will markedly reduce the indicated flexural strength.

9.3 *Testing*—Test the specimens in accordance with the applicable provisions of Test Method C 78.

NOTE 10—Sawing may greatly reduce the indicated flexural strength; beams shall, therefore, be tested with a molded surface in tension whenever possible. The location of the tension face with respect to the position of the concrete as placed and the position of the sawed surfaces should be reported.

9.4 *Report*—Report the results in accordance with the applicable provisions of Test Method C 78 and the requirements of this test method, including the moisture condition at the time of testing. Identify orientation of the specimen's finished, sawed, and tension faces with respect to their positions in the test apparatus.

10. Precision and Bias

10.1 *Precision*—Data are not available for preparing a statement on the precision of flexural strength measured on sawed beams.

NOTE 11—Users of this method who have replicate test data that may be appropriate for a statement on repeatability are encouraged to contact the chairman of the subcommittee.

10.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

11. Keywords

11.1 compressive strength; concrete coring; concrete sawing; concrete strength; flexural strength; splitting tensile strength

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue (C 42/C 42M – 03) that may impact its use (Approved July 1, 2004).

(1) The wording in 7.4 was clarified and the requirements in 7.4.2 were revised.

Designation: C 50 – 00 (Reapproved 2006)

Standard Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products[1]

This standard is issued under the fixed designation C 50; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This practice covers procedures for the collection and reduction of samples of lime and limestone products to be used for physical and chemical tests.

1.2 This practice further covers inspection, rejection, retesting, packing, and marking of lime and limestone products as it may be used in the chemical, agricultural, and process industries.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

C 702 Practice for Reducing Samples of Aggregate to Testing Size

D 75 Practice for Sampling Aggregates

E 141 Practice for Acceptance of Evidence Based on the Results of Probability Sampling

E 177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods

3. Terminology

3.1 *accuracy*—a term generally used to indicate the reliability of a sample, a measurement, or an observation and is a measure of closeness of agreement between an experimental result and the true value.

3.2 *bias (systematic error)*—an error that is consistently negative or consistently positive. The mean of errors resulting from a series of observations which does not tend towards zero.

3.3 *chance error*—error that has equal probability of being positive or negative. The mean of the chance errors resulting from a series of observations that tends toward zero as the number of observations approach infinity.

3.4 *combined water*—water that is chemically bonded to calcium or magnesium oxide to form hydrate.

3.5 *error*—the difference of an observation or a group of observations from the best obtainable estimate of the true value.

3.6 *free water*—water that is not chemically bonded to calcium or magnesium oxide.

3.7 *gross sample*—a sample representing one lot of material and composed of a number of increments on which neither reduction nor division has been performed.

3.8 *increment*—a small portion of the lot collected by one operation of a sampling device and normally combined with other increments from the lot to make a gross sample.

3.9 *laboratory sample*—refers to the sample after the initial preparation from which the analytical sample is obtained.

3.10 *lot*—a discrete quantity of material for which the overall quality to a particular precision needs to be determined.

3.11 *precision*—a term used to indicate the capability of a person, an instrument, or a method to obtain repeatable results; specifically, a measure of the chance error as expressed by the variance, the standard error, or a multiple of the standard error (see Practice E 177).

[1] This practice is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.06 on Physical Tests.

Current edition approved Nov. 15, 2006. Published December 2006. Originally approved in 1922. Last previous edition approved in 2000 as C 50 – 00.

www.technobetar.ir

3.12 *representative sample*—a sample collected in such a manner that every particle in the lot to be sampled is equally represented in the gross or divided sample.

3.13 *sample*—a quantity of material taken from a larger quantity for the purpose of estimating properties or composition of the larger quantity.

3.14 *sample division*—the process whereby a sample is reduced in weight without change in particle size.

3.15 *sample preparation*—the process that may include crushing, dividing, and mixing of a gross or divided sample for the purpose of obtaining a representative analysis sample.

3.16 *sampling unit*—a quantity of material from which a gross sample is obtained. A lot may contain several sampling units.

3.17 *segregation variance of increment collection, Ss^2*—the variance caused by nonrandom distribution of inert material or other constituent in the lot.

3.18 *size consist*—the particle size distribution of quicklime or hydrated lime.

3.19 *standard deviation*—the square root of the variance.

3.20 *subsample*—a sample taken from another sample.

3.21 *top size*—the opening of the smallest screen in the series upon which is retained less than 5 % of the sample.

3.22 *total variance, So^2*—the overall variance resulting from collecting single increments, and including division and analysis of the single increments.

3.23 *unbiased sample*—a sample free of bias or a representative sample.

3.24 *unit variance (random variance of increment collection), Sr^2*—the theoretical variance calculated for a uniformly mixed lot and extrapolate to 0.5-kg (1-lb) increment size.

3.25 *variance*—the mean square of deviation (or errors) of a set of observations; the sum of squared deviations (or errors) of individual observations with respect to their arithmetic mean divided by the number of observations less one (degrees of freedom); the square of the standard deviation (or standard error).

4. Significance and Use

4.1 The following practices are to be used in obtaining samples that are representative of the lot being sampled. The methodology used will be dependent upon the size and type of material sampled and testing requirements.

4.2 The following practices are intended for use in obtaining samples from material that is ready for sale and are not intended as sampling procedures for quality control purposes. These practices are to be used in obtaining a laboratory sample that will yield results serving as a basis for acceptance or rejection of the lot of material sampled. This does not preclude the use of these practices for quality control purposes.

4.3 The following practices can be used to eliminate bias in sampling. The person or persons responsible for using these practices must be trained and they will be conscientious and timely in their use.

4.4 An agreement between the producer and the consumer on location of sampling, either at the producer's plant or at the destination, is encouraged. Product quality can be affected through careless handling, improper protection, and delayed shipment. It is preferable to sample at the point of loading. The consumer has the right to witness the sampling practices being used.

4.5 This practice may be used to provide a representative sample of lime or limestone products. Due to the variability of limestone and lime and the wide variety of sampling equipment, caution must be exercised in all stages of sampling, from system specification and equipment procurement to equipment acceptance testing and actually taking the final sample.

5. Incremental Collection

5.1 For the number and weight of increments refer to Practice E 122.

5.2 The number of samples required depends on the intended use of the material, the quantity of material involved, and the variations both in quality and size. A sufficient number of samples shall be obtained to cover all variations in the material.

5.3 The quantity of sample to be taken will depend on the size of the material to be sampled and the amount of information to be obtained from the sample. Caution must be taken to ensure a statistically correct amount of material is selected for all testing, and sufficient quantities of material retained for reserved purposes. Recommended reference documents would include Practices E 105 and E 122.

5.4 *Particle Size*:

5.4.1 Generally, a large range of particle sizes for a given material requires a larger bulk sample size. The amount of the sample increment is then dependent upon the largest particle size encountered. The sample amount is determined by repeated testing to determine the bias between successive increments, and then to reduce this bias to acceptable limits.

5.4.2 The chemistry may change relative to the particle size. It is important that all particle sizes proportioned relative to their distribution be in the parent material.

5.5 Large material transfer rates result in large incremental samples. The sample must be representative of the entire cross-section flow of material. The amount of sample and number of increments must be determined prior to sampling. Randomized sampling should be used where appropriate to minimize unintentional bias.

6. Random Sampling

6.1 Practices D 3665, E 105, and E 122 can be used to minimize unintentional bias when obtaining a representative sample. Depending upon what comprises the lot of material, sampling can be extended to specific shipping units chosen on a random basis.

6.2 Collect increments with such frequency that the entire quantity of material will be represented in the gross sample. Due to the variability of lime and limestone products and the wide variety of sampling equipment, caution must exercised in all stages of sampling.

7. Sampling Plan

7.1 *Purpose*:

7.1.1 Adequate methods for obtaining representative samples for testing the chemical and physical properties of a

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:59:56 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

shipment of lime or limestone are essential. The sale and use are dependent upon the chemical or physical properties, or both.

7.1.2 The sampling plan specifies the minimum weights and the number of increments required in each step of the procedure to meet the objectives of the testing.

7.1.3 The sampling plan should include the personnel doing the sampling, preservation or protection of the samples, location of sampling, the sampling procedure to be used, sample preparation required, and the tests to be performed.

7.1.4 Proper sampling involves understanding and consideration of the minimum number and weight of increments, the particle size of the material, sample preparation, variability of the constituent sought, and the degree of precision required.

7.2 *Personnel*:

7.2.1 It is imperative that a sample is collected carefully and conscientiously. If the sampling is done improperly, the sample is in error and any subsequent analysis is not representative of the lot being sampled. Further, a second sample may be impossible to obtain. If an analysis is in error, another analysis is impractical on an incorrectly obtained sample. Whereas, a second analysis is possible, if the first was in error, if the initial sampling was correct.

7.2.2 Because of the importance of proper sampling and the resulting information, individuals engaged in sampling and sample preparation must be qualified by training and experience and possess a thorough understanding of sampling practices and techniques or under the direct supervision of such an individual.

7.3 *Preservation of Sample*:

7.3.1 Due to the hygroscopic nature of quicklime, samples must be immediately stored in airtight, moisture-proof containers to avoid air-slaking and subsequent absorption of carbon dioxide.

7.3.2 Due to the generally soft characteristics of quicklime, proper handling to avoid degradation must be practiced if the sample is to be used for particle size determination.

7.4 *Location of Sampling*—The process type and the process measurements required determine the sampling location. Sites should be selected to allow for safe, easy access to a representative cross section of the process material.

7.5 *Choice of Sampling Procedure*—The choice of sampling procedure to be used is dependent on three things. First, it is necessary to define the lot or batch of material to be sampled. Second, it is necessary to determine the number of incremental samples to be taken from the lot. Third, the choice of sampling procedure needs to be determined from Section 8 utilizing the preceding criteria.

7.6 *Recommended Number and Weight of Increments*:

7.6.1 Refer to Table 1 for the recommended number and weight of increments for general purpose sampling. The number of increments required listed in Table 1 are based upon a 1000–ton lot size. To determine the number of increments recommended for a specific lot size, use Eq 1. To determine the recommended weight for a bulk sample, multiply the increment requirement times the minimum increment weight from Table 1.

TABLE 1 Recommended Number and Weight of Increments for General Purpose Sampling

Particle Size	– 1/4 in.	+ 1/4 by – 3/4 in.	+ 3/4 in.
Minimum number of increments	10	10	10
Minimum weight of increment, lb	5	10	15

7.6.2 The increments and weights listed in Table 1 are only recommendations and are not based upon a statistical model. For more accurate methods to determine weights and increments required, refer to Practices E 105, E 122, and E 141 and Test Methods D 2234.

7.6.3 For randomized sampling, refer to Practice D 3665.

$$N_2 = N_1\ [\text{specific lot size (tons)} / 1000\ \text{tons}]^{1/2} \quad (1)$$

where:

N_1 = minimum increments required, per 1000 ton lot, and
N_2 = increments required for specified lot size.

7.7 *Mechanical Sampling Devices*—There are several different types of mechanical sampling devices available for many of the sampling procedures mentioned in Section 8. Due to the variety of types, it is impractical to specifically identify each device. Prior to using any mechanical sampling device, it needs to be determined that the device is capable of taking an unbiased, representative sample of the material in question.

8. Sampling Procedures (See Sampling Procedure Flow Chart (Fig. 1) for Location of Specific Methods)

LIMESTONE

8.1 *Surface Sampling*:

8.1.1 Surface sampling is limited in use due to the nonrepresentative sample obtained. For exploration purposes, a surface sample can produce information with respect to the characteristics of a deposit. It is critical to remember that a surface sample is not representative and can only be used to determine if more detailed sampling and testing may be justified.

8.1.2 Obtain the necessary information to determine a suitable location for sampling. Choose sites that will best satisfy the purpose of sampling. Describe and record observations on the characteristics of the portion of the deposit being sampled to the extent required by the sampling plan. It is imperative for the sample collected to be of sufficient size to perform any required testing.

8.2 *Face Sampling*—Describe and record observations on the characteristics of the portion of the face being sampled to the extent required by the sampling plan. With suitable marking equipment, identify the sampling site in accordance with the sampling plan. It is imperative for the sample collected to be of sufficient size to perform any required testing.

8.3 *Drill Hole Samples*—The type of drilling equipment required will be determined by the sampling plan. Sample the drill hole in intervals as specified in the sampling plan.

8.3.1 *Drill Cuttings*:

8.3.1.1 Drill cuttings are deposited on the surface by the drilling equipment. Many drills use compressed air to blow the drill cuttings out of the drill hole. These cuttings collect on the surface in a circular mound surrounding the hole. Collect a

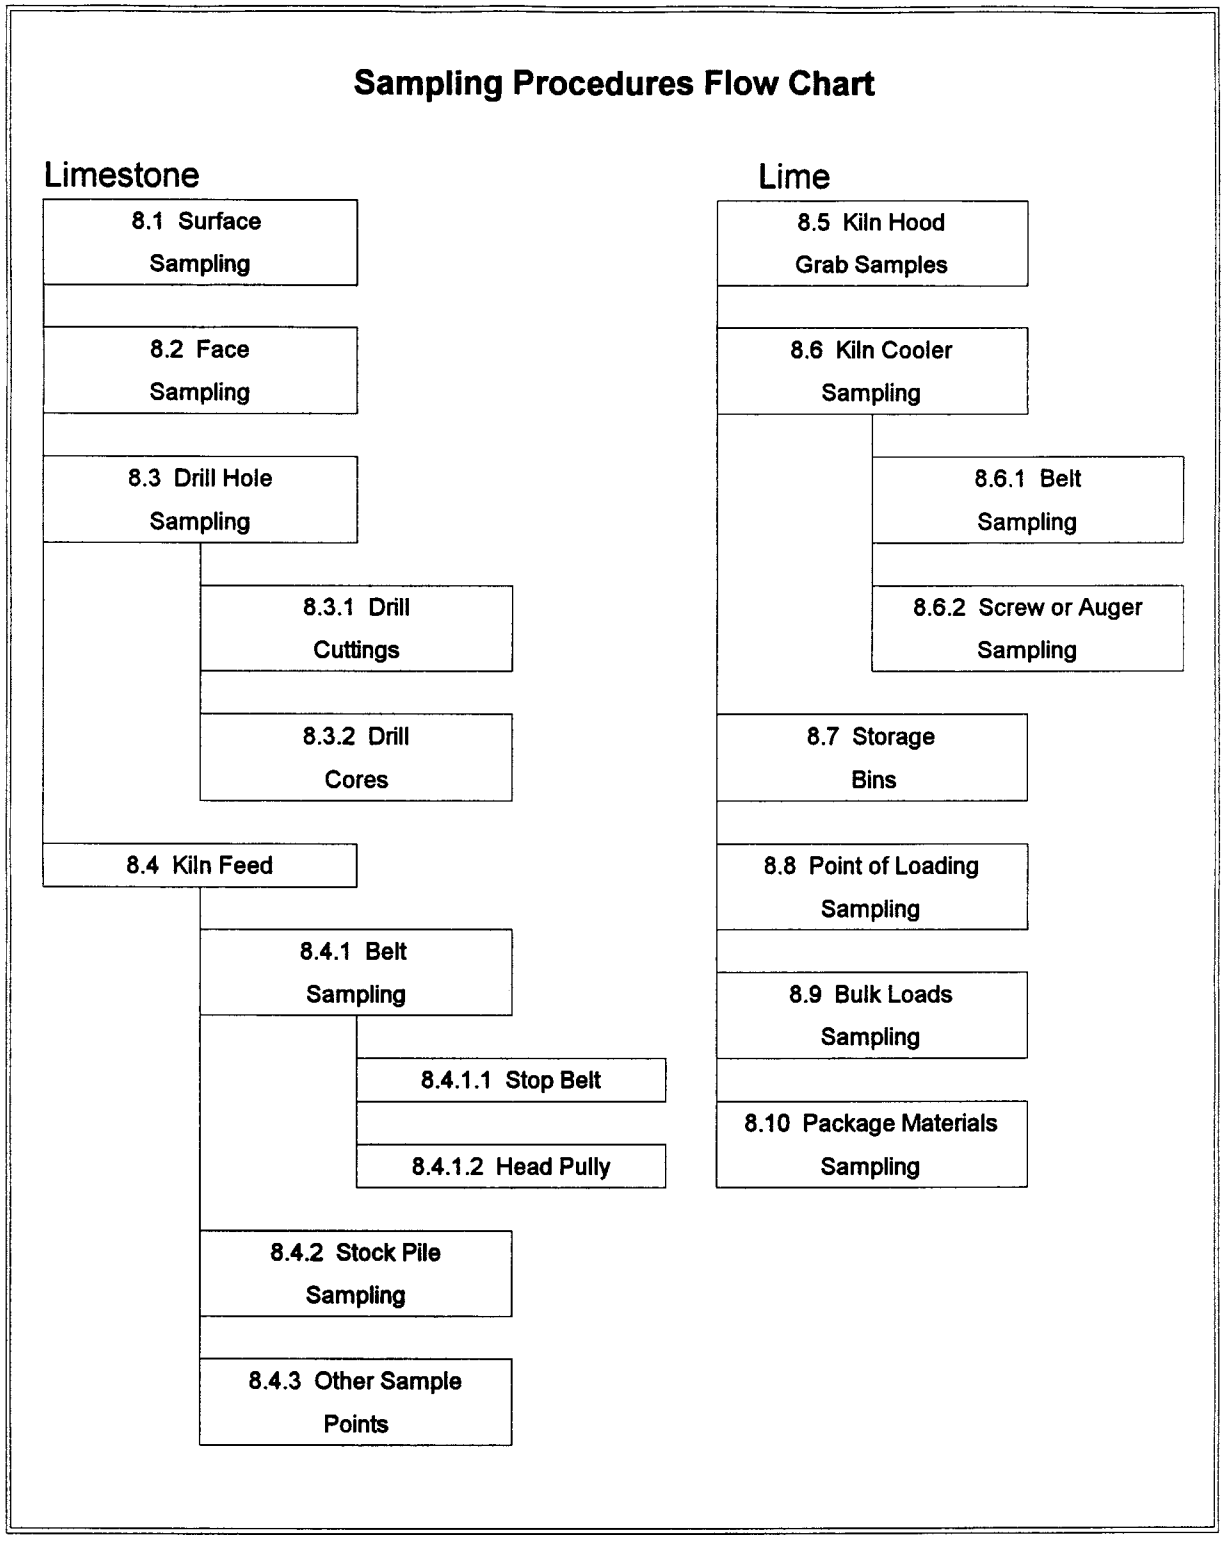

FIG. 1 Sampling Procedures Flow Chart

crosscut representative sample of the drill cuttings, taking care not to contaminate with surface material.

8.3.1.2 Recirculated drill cuttings are produced from another type of drilling equipment using compressed air to blow the drill cuttings through the hollow center of equipment drill steel into a collection chamber. Empty this chamber at intervals determined in the sampling plan.

8.3.2 *Drill Core*:

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.3.2.1 Some drilling equipment cuts and removes solid cylindrical cores of material from a drill hole. Sample these drill cores at intervals determined in the sampling plan.

8.3.2.2 Drill cores are split as determined by the sampling plans. One portion of the split core is preserved intact, maintaining its orientation and order as it is removed from the drill hole. These samples are invaluable for historical purposes and are often saved for the life of the quarry.

8.4 *Limestone Kiln Feed Sampling*:

8.4.1 *Belt Sampling*—Two conditions exist from which samples can manually be obtained from a conveyor belt.

8.4.1.1 *Stop-Belt Sample*:

(1) Before stopping, the conveyor must be loaded with a constant flow of material in order to be sampled. The conveyor must then be secured consistent with proper safety procedures.

(2) Carefully remove the sample increment of material from completely across the belt, removing all material in the selected area including fines with, for example, a brush. Templates, whose bottom edge are shaped to match the belt contour, are useful in bracketing the sample location, thus preventing contamination of sample from material adjacent to the sampling area. It is important that the sample increment is composed of the entire cross section of material flow. Repeat the preceding process to remove the number of increments necessary to compose the bulk sample.

8.4.1.2 *Head-Pulley Sample*:

(1) When looking at a granular or pebble material conveyed with a belt, the fines tend to sift though the coarser material and ride on the bottom and toward the middle of the belt. The coarse and fines thus become segregated to an extent dependent upon gradation and physical conditions of the material being sampled. As the material is projected from the head-pulley, the coarser material is thrown slightly further with the fines dropping closer to the head-pulley. The most important considerations, therefore, in sampling at a head-pulley is that the entire cross section of material flow (fines and coarse) is obtained with the pass of the sampling apparatus. And further, that the movement of the sampling apparatus is accomplished in a timely manner, so as to reduce any bias in sampling from the lateral movement of the sampler.

(2) Head-pulley sampling can only be accomplished manually if the flow of material is at a minimum for safety reasons, otherwise an automatic sampler is recommended.

8.4.2 *Stockpile Sampling*:

8.4.2.1 Sampling from stockpiles, although occasionally necessary, is not recommended, because of the difficulty in guaranteeing an unbiased sample. When sized material is stockpiled, segregation occurs, with coarser particles rolling to the outside base of the pile and finer particles sifting toward the center. It is very difficult to ensure representative samples, due to the segregation, which usually occurs when material is stockpiled, with the coarser particles rolling to the outside base of the pile. When it is necessary to sample stockpiles, every effort should be made to enlist the services of power equipment that is capable of exposing the material at various levels and locations. Separate samples shall be taken from different areas of the stockpiles to represent the material in that portion. Test results of the individual samples will indicate the extent of segregation existing in the stockpiles.

8.4.2.2 If it is necessary to sample stockpiles, numerous increments should be obtained from various points and combined to create the bulk sample. The number of increments must be sufficient to indicate the degree of variability existing within the pile. This is of particular importance when testing for material gradation.

8.4.2.3 If power equipment is available, larger increments can be obtained and then combined to form a smaller stockpile from which the bulk sample can be removed. The increments must be of a sufficient number and from various locations on the main stockpile to ensure formation of a representative and unbiased sampling stockpile. After mixing the smaller stockpile, several increments from different locations can be combined to form the bulk sample. Depending upon the size of the main stockpile, several sampling stockpiles can be formed from which bulk samples can be then obtained.

8.4.2.4 When manually sampling a stockpile (see Note 1), its shape dictates the methodology to be used. If the stockpile has a large flat upper surface, increments can be taken from various locations on the top surface. Otherwise, increments must be taken from the side, on a line from the base to the top of the stockpile. At no time should material be taken directly from the surface, but should be obtained from at least a foot below the surface, because of segregation. When a stockpile is active, increments can be obtained from the working location.

NOTE 1—Safety is a major concern when taking this type of sample due to material slides. Caution must be used at all times, as the individual sampling is at risk. Two people should be involved in this type of sampling with one individual at a distance from the pile, mindful of the sampler's safety. An inspection of the locations must be made beforehand for possible sliding hazards with those locations avoided. This is not a recommended practice.

8.4.2.5 When sampling from the side of a stockpile, on a line from top to bottom, select a minimum of five locations from which increments are to be taken (refer to Practice E 122). Remove the surface material from the increment location to the proper depth in order to create a small working bench. Use of a shield is recommended above the sampling point to prevent further segregation and contamination. From the exposed bench remove an increment from as far inside the pile as possible. Repeat this procedure for each of the selected locations and composite increments to form the bulk sample.

8.4.2.6 When sampling on top of a flat stockpile, increment locations must be spaced over the entire surface and be of a number to ensure a representative bulk sample. Again, the increments must come from a depth of at least 1 ft.

8.4.2.7 When sampling from the working face of an active stockpile, select a minimum of five to ten spots from the entire working face for which to withdraw an increment. The increment sites should be at least 2 ft from the base of the stockpile, and must not include accumulated material, which has fallen from the sides of the active face due to further segregation. Combine the increments to form the bulk sample.

8.4.3 *Other Sampling Points*:

8.4.3.1 Other sampling points include stockpile feeders, cascade feeders, chutes, and so forth. As before, the most

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:59:56 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

important consideration is in obtaining a representative sample. This means obtaining a complete cross section of the material flow.

NOTE 2—Consideration must be given to the flow of material to the sampling point from a surge (from a bin, stockpile, etc.). As material goes into a surge point, segregation of material occurs. Likewise, as material flows from a surge, its character can change with time. As sample increments are obtained, an unintentional bias can be obtained relative to the bulk sample. This may not be the case if the flow of material is directly from a process or system, such as a specific screening deck. In any case, misleading results can be obtained if this consideration is ignored, even with conscientious sampling techniques.

LIME

8.5 *Kiln Hood Grab Sample*:

8.5.1 The Kiln Hood Grab Sample is a nonrepresentative and bias sample that only indicates chemical condition of the material flow from which it was obtained. It indicates the degree of calcination, relative to particle size, at that point in time and assists the operator in making decisions concerning the operation of the kiln. Because of the nature of the kiln calcination process, it is the closest to the process and most timely indication of the material quality that can be obtained. Therefore, is very important, regardless of the bias nature of the sample.

NOTE 3—Safety issues, relative to the kiln process, involve the high-calcination temperatures and draft conditions at the time of sampling. Protective equipment must be used.

8.5.2 A scoop or large ladle attached to a long metal pole is used to obtain the sample. It is passed parallel to the axis of the kiln through the process flow to obtain all size fractions of the material. Several increments, to increase the probability of representation, should be obtained and combined to form the bulk sample. This is extremely critical as chemistry can vary with particle (pebble) size. It is also preferable that several minutes elapse between incremental addition to the bulk sample as particle size of the material flow can change. The sample should be stored in a large dust-protected container, allowed to cool to ambient temperature, and then processed for chemical analysis.

8.5.3 To increase the homogeneity, the entire bulk sample must be crushed initially before reduction in the amount of material.

8.6 *Kiln Cooler Sampling*—As with Kiln discharge samples, the purpose of sampling dictates the methods to be used. If chemical results are required as a process control, the frequency of increments and amount of material composing a bulk sample may be reduced. If the results are to be used as a tool for process control, the timing becomes critical, and a snapshot of the chemical characteristics of the process product becomes more important. The frequency of sampling is then determined by the variability of the process and the resulting product. This would be true for any of the methods used for sampling.

8.6.1 *Belt Sampling, Pans or Chutes*—Cooler sampling can involve a number of different methods. As with sampling limestones, many of the techniques are similar, such as with belts. Other techniques involve discharge points, such as chutes and feeders. For these techniques please refer to the previous sections referring to limestone sampling.

NOTE 4—When sampling at a kiln cooler, the material may be quite hot and the area very dusty. Appropriate safety precautions must be followed.

8.6.2 *Screw or Auger*:

8.6.2.1 One method involves the use of an opening placed along the axis of the screw conveyor, which is closed off by either a gate or valve. The smallest dimension of the opening must be at a minimum of three times the longest dimension of the largest particle of the material being conveyed.

NOTE 5—In obtaining samples from a screw or auger, the particle size can be altered as a result of the conveying process. Therefore a sample obtained in this fashion can not be used to determine sizing characteristics. The chemical nature of the material, though, can be determined from samples obtained in this fashion.

8.6.2.2 This is important to obtain a free flow of material into the sampling apparatus, and to ensure a representative sample relative to the material chemical characteristics. The number of increments and their amounts to compose the bulk sample must be determined beforehand, so as to obtained an unbiased, representative sample (refer to Practice E 122).

8.6.2.3 A second method involves sampling the discharge of the screw or auger. In this case, the entire cross section of material flow must be obtained for proper representation. Again the number of increments and their amounts must be determined beforehand (refer to Practice E 122).

8.7 *Storage Bins*—If the samples are taken from a bin, they shall be taken from the entire cross section of the flow of material as it is being discharged. At the beginning of the discharge from the bins, sufficient material should be permitted to flow to ensure normal uniformity before the sample is collected.

8.8 *Sampling at Point of Loading*:

NOTE 6—The sampling plan including sample size, frequency of sampling, and so forth (as well as possible problems with sampling, such as product degradation) should be reviewed with customers prior to purchase.

8.8.1 Bins, railcars, trucks, and barges should be sampled while being loaded. Sampling from bulk shipments (trucks, railcars, or barges) is not a recommended practice, because of the bias relative to particle size and obtaining a representative sample. If there is a bias, it is generally proportional to the particle size range. True particle representation from bulk shipments is difficult to obtain. Safety is a major concern when sampling from bulk shipments. It is preferred, whenever practical, to sample product as it is being transferred to a shipping unit.

8.8.2 Sampling may be done by cutting the stream of material going into the bin, railcar, truck, or barge with a suitable sampling device, diverting the entire product stream briefly to a sample container, or by stopping a belt and thoroughly cleaning the material into a sample container. For sampling practices involving conveyor belts, refer to 8.4.1.

8.8.3 If loading directly from a chute or a bin, it may not be practical to sample the stream, because of the volume, weight and speed of the material. For sampling practices involving bins, refer to 8.7.1.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:59:56 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.8.4 Sampling may also consist of intermittent cutting of a stream with a suitable automatic sampling device to yield a representative composite sample. Mechanical sampling systems must be checked to ensure that the particle size is not degraded.

8.8.5 If necessary, fine lime products can be sampled from bulk shipments with the use of special devises that allow sampling through the depth of the shipping unit. These devises generally consist of two cylindrical hollow spears, one inside the other with consistent openings. The narrowest dimension of the openings must allow free flow in the material being sampled. As one spear is rotated the openings close or open, relative to the positions of both spears. The spear is forced down through the depth of the product with the openings closed. At maximum depth, the one spear is rotated to allow the product to flow into the inner spear and thus to collect a sample. The spear is rotated to close the openings and the sampling device is withdrawn from the material. The sample is collected from the top of the hollow spears. It is recommended that a number of increments be obtained from different equally spaced locations across the shipping unit to compose the bulk sample relative to the size of the shipping unit and sampling plan.

8.9 *Sampling of Bulk Loads*:

8.9.1 If necessary, for methods of sampling directly from bulk shipments use those practices in accordance with 8.4.2.

8.9.2 Separate samples shall be taken from as many points in the shipment unit as necessary to represent the material, realizing the probability of segregation as the material was loaded. These separate samples will usually be combined to form a composite sample. This sample shall be reduced, but if information on variation is desired, the separate samples shall be tested.

8.10 *Sampling of Packaged Material*:

8.10.1 *Random Sample*—Random sample may be taken using a combination of methods. Bags may be taken at random from within the pallet or among multiple pallets. A sample may then be taken from each bag. A composite of all bags is then formed and tested.

8.10.2 *Thief Sample*—Material to be taken from a bag may be taken from the available opening (see 8.8.5).

8.10.3 Samples must not be taken from packages whose integrity has been compromised.

9. Preparation of Laboratory Samples

9.1 Sample preparation is the reduction of the bulk sample in both particle size and amount of material to the suitable laboratory sample, so as to maintain representation of the initial bulk sample. Procedures as outlined must be followed in a conscientious and thorough manner in order to maintain that representation. The method of sample preparation to be used depends upon the type of material, tests to be performed, and the characteristics of the bulk sample in relation to particle size and quantity of material.

9.2 Generally when a screen analysis is required, a larger bulk sample is needed compared to a chemical analysis. But the key objective is to maintain representation of the bulk sample, so that the final test values reflect the characteristics of the initial material. Working with coarse materials, segregation of the different size fractions is a major problem, as different size fractions will have varying properties. Segregation must be avoided through the conscientious use of splitting devices and strict adherence to procedure.

9.3 Splitting gross samples can be accomplished in multiple stages of reduction in both size and amount. Reduction in the particle size of the material or crushing should precede the lowering in the amount or splitting of the gross sample to retain the representative nature of the initial sample, and is relative to the amount of material present at each stage of reduction.

NOTE 7—High-moisture content in limestone causes problems relative to reduction of the bulk sample (splitting) to the test sample, as well as, in the sizing operations. In this case drying becomes a necessity.

9.4 *Splitting Devices*:

9.4.1 *Riffle Splitter*—A riffle splitter is a device that should have an equal number of adjacent chutes of identical widths opening into adjacent buckets or collection pans. The bucket or pan feeding an open splitter should be of an identical width to the chutes. The width of the chutes should be at least three times the width of the nominal top size of the material being split. Some splitters have a catch basin, which holds the material before reduction. In this case, the material must be spread across the entire width of the splitter. The important consideration is that each chute has an equal selection probability.

9.4.2 *Sectorial Splitter*—A sectorial splitter is a radial device with either a revolving or stationary feeder, useful for obtaining identical samples for comparative testing. With this type of device, the revolving speed and material flow rate must be as constant and uniform as possible. All sectors of the splitter must be radial and equal in size with no escape of material from any sector.

9.4.3 *Coning and Quartering*—Coning and quartering is an old method that can be used for small or large lots, in which a conical pile is created and quartered to obtain a sample.

9.4.3.1 Mix and spread the sample material on a clean surface, and then heap into a conical pile by placing shovels of material onto the apex of the cone. Flatten the cone symmetrically from the center to form flat circular pile.

9.4.3.2 The divide the pile into equal and identical quarters with a shovel or straightedge. Randomly select the subsample from one or more of the quarters. To further divide the subsample, the coning and quartering process must be repeated.

9.5 *Sizing Samples for Laboratory Analysis*:

9.5.1 As necessary, crush the sample (Note 8) by a suitable means to a size small enough to be easily handled by the laboratory's pulverizing equipment or to a size required by the analytical method.

NOTE 8—If physical testing is to be carried out on the sample, it is recommended that a second sample be sent to the laboratory solely for the purpose of physical testing. If screening of the sample is required to determine physical size characteristics, the second sample, or a representative subsample of the original sample, must not be further prepared from "as received" by the laboratory.

9.5.2 Utilizing suitable pulverizing equipment, further reduce the sample (or subsample) to an appropriate size for the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:59:56 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

analytical procedure to be performed on the sample. (Note 9). Please refer to Table 2 as a reference for pulverizing.

NOTE 9—When pulverizing sample to a specific mesh size, it is incorrect to screen a sample on the desired mesh and discard the fraction of the sample retained on the sieve. It is imperative that the whole (total) sample be used. Through previous experience with the particular grinding equipment, the grind produced should already be known so that no actual screening is required.

10. Rejection

10.1 Specific circumstances between the manufacturer and the purchaser may dictate that contractual agreements will supersede the recommendations of rejection.

10.2 Rejection of material based on failure to pass tests prescribed in the specification shall be reported to the manufacturer within 1 week after tests have been completed or within 30 days after shipment has been received, and the cause for rejection shall be stated.

10.3 The samples that represent rejected material shall be kept in airtight, moisture-proof containers for at least 2 weeks from the date of the original test report as reported to the manufacturer.

11. Retesting

11.1 Specific circumstances between the manufacturer and the purchaser may dictate that contractual agreements will supercede the recommendations of retesting.

11.2 Either of the contracting parties may make claim for a retest within 2 weeks of the date of the original test report. The expense of the retest shall be borne by the party demanding such retest.

11.3 Should the contracting parties be unable to reach a mutually satisfactory agreement based upon the results of the original test, the third sample of the material shall be delivered unopened to a mutually satisfactory referee laboratory for test. The results of this referee test shall be binding on both parties.

12. Packaging

12.1 Lime and limestone products may be shipped in bulk or in containers agreed upon between the manufacturer and the purchaser.

12.2 All packages shall be in good condition at the time of inspection.

13. Marking

13.1 Unless otherwise agreed upon between the manufacturer and the purchaser, each package shall have legibly marked thereon the name of the product, the net weight of its contents, the name of the manufacturer, the place of manufacture, and the brand name, if any.

13.2 In addition to the preceding information, the following may be marked on each package of shipment: “The contents meet the requirements of ASTM Practice C 50.”

TABLE 2 Sample Preparation Equipment[A,B,C]

Sample Size	Particle Size of Analytical Sample (Nominal Top Size)	Type of Equipment	Applicable Test Procedures
> 50 grams	6 mesh	Jaw Crusher Hammermill Roll Crusher Disc Mill Others- if adjustable	C 110
> 1 gram < 50 grams	50 mesh	Hammermill (with appropriate discharge screen) Disc Mill	C 25 C 110 C 400
> 0.5 gram < 1 gram	100 mesh	Mechanical Mortar and Pestle[D] Ring and Puck Mill	C 25
< 0.5 gram	< 200 mesh	Mechanical Mortar and Pestle[D] Ring and Puck Mill	C 25 C 1271[E] C 1301[E]

[A] The Precision, associated with specific analytical procedures in relation to the sample weight, can be greatly effected by the particle size of the analytical sample. Therefore this chart is provided as a guide to obtain the desired particle size with the equipment suggested.

[B] Depending upon the testing requirements, such as for color (whiteness) or trace elements (iron, aluminum, chrome, nickel, tungsten, etc.), contamination may result from the preparation equipment, particularly when grinding to finer than 50 mesh. Therefore, materials of equipment construction must be considered in regard to testing requirements and sample particle size.

[C] The above list is not complete as comparable equipment may exist.

[D] Due to the hydroscopic nature of quicklime and the time involved in pulverizing, use of a hand Mortar is not recommended.

[E] Because of the nature of the test described within this standard, a finely pulverized homogenous sample is required regardless of the analytical sample size.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 51 – 07

Standard Terminology Relating to Lime and Limestone (as used by the Industry)[1]

This standard is issued under the fixed designation C 51; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This terminology refers to the terms relating to lime and limestone products as used by the industry.

1.2 Where appropriate, the various terms defined below should be prefixed with one or other of the adjectives "high-calcium," "magnesian," or "dolomitic." (Examples: dolomitic quicklime; high-calcium hydraulic hydrated lime; magnesian or dolomitic limestone.)

1.3 The composition of a limestone should be given in terms of a percentage of the carbonates present. In limestone of interest to the lime industry, it is usually assumed that the material consists almost entirely of carbonates. Where this assumption is not valid, the percentage of noncarbonate material should be determined, and the composition expressed in terms of the carbonate material present.

1.4 For specific application of lime or a limestone product, see the appropriate ASTM specification.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 270 Specification for Mortar for Unit Masonry

C 602 Specification for Agricultural Liming Materials

3. Terminology

agricultural lime—either ground quicklime or hydrated lime whose calcium and magnesium content is capable of neutralizing soil acidity.

agricultural limestone—ground or pulverized limestone whose calcium and magnesium content is capable of neutralizing soil acidity.

DISCUSSION—Agricultural lime is a very powerful neutralizing agent. Agricultural limestone, often referred to as "aglime" is the predominate material for soil pH adjustment. See Specification C 602.

air-slaked lime—the product containing various proportions of the oxides, hydroxides, and carbonates of calcium and magnesium which results from the exposure of quicklime to the air in sufficient quantity to show physical signs of hydration (difficult to determine visually in pulverized quicklime).

alkaline earth solutions (AES)—an aqueous solution of the oxide or hydroxide of an element of group IIa in the periodic table, such as calcium or magnesium. These solutions may be strongly alkaline. See **pH**.

available lime index—those constituents of a lime which enter into a desired reaction under the conditions of a specific method or process.

building or construction lime—a lime whose chemical and physical characteristics and method of processing make it suitable for the ordinary or special construction uses of the product.

by-product lime—by-product limes include a variety of Calcium and/or Calcium/Magnesium compounds that are usable for specific applications but generally do not meet one or more specifications required of primary lime products. Examples include lime kiln dust and lime hydrator rejects. It is advised that the specific compositions, physical properties, performance characteristics, and anticipated variabilities of such materials be evaluated for the service intended.

calcareous—originating from predominately calcium carbonate or one of its derivative forms.

calcia—the chemical compound calcium oxide (CaO).

calcined pozzolans—materials that are produced by calcination of natural siliceous or alumino-siliceous earths, such calcination being for the purpose of activation of pozzolanic properties.

Cement-Lime Mortar—Cement-Lime Mortar primarily consists of hydraulic cement, hydrated lime or lime putty, mason's sand and water.

DISCUSSION—These mortars can be specified by proportions or properties indicated in Specification C 270.

chemical lime—a quicklime or hydrated lime whose chemical and physical characteristics and method of processing make it suitable for one or more of the many and varied chemical

[1] This terminology is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.08 on Editorial and Nomenclature

Current edition approved July 15, 2007. Published August 2007. Originally approved in 1922. Last previous edition approved in 2006 as C 51 – 06.

www.technobetar.ir

and industrial uses of the product.

DISCUSSION—The chemical forms of calcium oxide (CaO), calcium hydroxide ($Ca(OH)_2$), magnesium oxide (MgO), or magnesium hydroxide ($Mg(OH)_2$) alone or in combination may be produced either primarily or as a by-product of materials other than limestone, for example, $Ca(OH)_2$ formed by acetylene generation from calcium carbide (CaC_2), water treatment sludges, etc.

dead burned dolomite—dolomitic limestone that has been heated with or without additives to a temperature sufficiently high and for a long enough time to decompose the carbonate structure so as to form calcium oxide and periclase in a matrix that provides resistance to subsequent hydration and recombination with carbon dioxide.

dolomitic—indicates the presence of 35 to 46 % magnesium carbonate ($MgCO_3$) in the limestone from which the material was formed.

dolomitic limestone—see **limestone.**

di-hydrated or double hydrated lime—dolomitic lime which has been hydrated under greater than atmospheric pressure and contains less than 8 % unhydrated oxides.

finishing hydrated lime—hydrated lime suitable for use in the finish coat of plaster.

finishing quicklime—quicklime suitable (after slaking to a lime putty) for use in the finish coat of plaster.

fluxing lime—a term referring to quicklime used as an agent in the manufacture of steel or glass.

fluxstone—a term referring to limestone (high-calcium, magnesian, or dolomitic) used as an agent in the manufacture of iron and steel or glass.

high-calcium—indicates the presence of 0 to 5 % magnesium carbonate ($MgCO_3$) in the limestone from which the material was formed.

high-calcium limestone—see **limestone.**

hydrated lime—a dry powder obtained by treating quicklime with water enough to satisfy its chemical affinity for water under the conditions of its hydration. It consists essentially of calcium hydroxide or a mixture of calcium hydroxide and magnesium oxide or magnesium hydroxide, or both.

DISCUSSION—The chemical forms of calcium oxide (CaO), calcium hydroxide ($Ca(OH)_2$), magnesium oxide (MgO), or magnesium hydroxide ($Mg(OH)_2$) alone or in combination may be produced either primarily or as a by-product of materials other than limestone, for example, $Ca(OH)_2$ formed by acetylene generation from calcium carbide (CaC_2), water treatment sludges, etc.

hydraulic hydrated lime—the hydrated dry cementitious product obtained by calcining a limestone containing silica and alumina to a temperature short of incipient fusion so as to form sufficient free lime (CaO) to permit hydration, and at the same time, leaving unhydrated sufficient calcium silicates to give a dry powder meeting hydraulic property requirements.

lime—a general term which includes the various chemical and physical forms of quicklime, hydrated lime, and hydraulic lime. It may be high-calcium, magnesian, or dolomitic.

DISCUSSION—The chemical forms of calcium oxide (CaO), calcium hydroxide ($Ca(OH)_2$), magnesium oxide (MgO), or magnesium hydroxide ($Mg(OH)_2$) alone or in combination may be produced either primarily or as a by-product of materials other than limestone, for example, $Ca(OH)_2$ formed by acetylene generation from calcium carbide (CaC_2), water treatment sludges, etc.

lime mortar—a lime putty mixed with an aggregate, suitable for masonry purposes.

lime putty—the product obtained by slaking quicklime with water according to the directions of the manufacturer or by mixing hydrated lime and water to a desired consistency.

limestone—an initially sedimentary rock consisting chiefly of calcium carbonate or of the carbonates of calcium and magnesium. Limestone may be of high calcium, magnesian, or dolomitic.

(*1*) *dolomitic limestone*—limestone containing from 35 to 46 % magnesium carbonate ($MgCO_3$).

(*2*) *magnesium limestone*—a limestone containing from 5 to 35 % $MgCO_3$.

(*3*) *high-calcium limestone*—a limestone containing from 0 to 5 % $MgCO_3$.

liming material—a general term which includes the various chemical and physical forms of matierals such as lime, limestone, mollusk shells, marl, byproduct lime, and slag whose calcium and magnesium compounds are capable of neutralizing acidity.

magnesia—the chemical compound magnesium oxide (MgO).

magnesian—indicates the presence of 5 to 35 % magnesium carbonate ($MgCO_3$) in the limestone from which the material was formed.

magnesian limestone—see **limestone.**

masons hydrated lime—hydrated lime suitable for use for masonry purposes.

masons quicklime—quicklime suitable (after slaking to a lime putty) for use for masonry purposes.

milk of lime—a suspension of hydrated lime (or slaked quicklime) in water in such proportions as to resemble milk in appearance.

DISCUSSION—The chemical forms of calcium oxide (CaO), calcium hydroxide ($Ca(OH)_2$), magnesium oxide (MgO), or magnesium hydroxide ($Mg(OH)_2$) alone or in combination may be produced either primarily or as a by-product of materials other than limestone, for example, $Ca(OH)_2$ formed by acetylene generation from calcium carbide (CaC_2), water treatment sludges, etc.

mono-hydrated lime—dolomitic lime which has been hydrated at atmospheric pressure and contains more than 8 % unhydrated oxides.

natural pozzolans—materials that, in the natural state, exhibit pozzolanic properties, such as some volcanic ash and lava deposits.

non-volatile—term used to denote the calculated chemical basis of a material in which the volatile fraction of that material is removed, relative to a specific temperature. For example, in lime and limestone, the loss on ignition is considered to be the volatile fraction.

pH—the negative logarithm of the hydrogen ion concentration, which can be greatly affected by temperature, particularly under alkaline conditions. It is therefore important to measure alkaline earth solutions (AES) at a specific recommended temperature of 25 °C.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

plasticity—a comparative physical property of a standard consistency lime putty to resist the loss of plastic state workability when subjected to pressure against the suction of an absorptive surface as measured by the Emley Plasticimeter.

Portland Cement-Lime Mortar (PCL)—See Cement-Lime Mortar.

pozzolan—a siliceous or alumino-siliceous material that in itself possesses little or no cementitious value but that in finely divided form and in the presence of moisture will chemically react with alkali and alkaline earth hydroxides at ordinary temperatures to form or assist in forming compounds possessing cementitious properties.

quicklime—a calcined limestone, the major part of which is calcium oxide or calcium oxide in association with magnesium oxide, capable of slaking with water.

DISCUSSION—The chemical forms of calcium oxide (CaO), calcium hydroxide ($Ca(OH)_2$), magnesium oxide (MgO), or magnesium hydroxide ($Mg(OH)_2$) alone or in combination may be produced either primarily or as a by-product of materials other than limestone, for example, $Ca(OH)_2$ formed by acetylene generation from calcium carbide (CaC_2), water treatment sludges, etc.

quicklime sizes—the different sizes depending upon the type of limestone, kind of kiln used, or treatment subsequent to calcining. The sizes commonly recognized are as follows:

(*1*) *large lump*—8 in. (203 mm) and smaller,

(*2*) *pebble or crushed*—2½ in. (64 mm) and smaller,

(*3*) *ground, screened or granular*—¼ in. (6.4 mm) and smaller, and

(*4*) *pulverized*—substantially all passing a No. 20 (850-μm) sieve.

reactivity—reactivity is the reaction between substances, which can be monitored by some measure, either qualitative or quantitative. In the Lime Industry, it is commonly used to refer to the reaction between limestone, quicklime and/or a related material and another substance such as water, acid or SO_x

refractory lime—lime (usually of a dolomitic type) that has been extremely hard burned so that it will possess little or no tendency for conversion of the oxides to hydroxides.

run-of-kiln quicklime—quicklime as drawn or discharged from a kiln.

slaking—the chemical reaction that produces hydrated lime when quicklime and water are mixed.

spray lime—a hydrated lime of such fineness that at least 95 % of the particles will pass a No. 325 (45-μm) sieve.

stucco—an exterior cementious-lime-finishing system applied to a suitable substrate on the surfaces of buildings and structures.

white wash—a combination of hydrated lime (or slaked quicklime), water, and other materials to be used as a paintlike coating.

SUMMARY OF CHANGES

Committee C07 has identified the location of selected changes to this terminology since the last issue, C51–06, that may impact the use of this terminology. (Approved July 15, 2007)

(*1*) Added a Discussion to **agricultural limestone**.

(*2*) Revised the definition of **liming material**.

Designation: C 59/C 59M – 00 (Reapproved 2006)

Standard Specification for Gypsum Casting Plaster and Gypsum Molding Plaster[1]

This standard is issued under the fixed designation C 59/C 59M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers gypsum casting plaster and gypsum molding plaster materials consisting essentially of calcined gypsum.

1.2 The values stated in either inch-pound or SI (metric) units are to be regarded as standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be used independently of the other. Values from the two systems shall not be combined.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 471M Test Methods for Chemical Analysis of Gypsum and Gypsum Products [Metric]

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 Definitions of terms shall be in accordance with Terminology C 11.

3.2 *Description of Terms Specific to This Standard:*

3.2.1 *gypsum casting plaster, n*—a calcined gypsum plaster used primarily to form objects, such as lamp bases, art ware, and novelties, etc.

3.2.2 *gypsum molding plaster, n*—a calcined gypsum plaster used primarily for plaster casts or molds, sometimes used as a gauging plaster.

4. Chemical Composition

4.1 Gypsum casting plaster and gypsum molding plaster shall have a purity of not less than 85 % $CaSO_4 \cdot 2H_2O$ when tested in accordance with Test Methods C 471M.

5. Physical Properties

5.1 Specimens shall be tested in accordance with Test Methods C 472.

5.1.1 *Setting Time*—Gypsum casting plaster and gypsum molding plaster shall set in not less than 10 nor more than 50 min using the procedure for gypsum concrete and all gypsum plasters, except gypsum neat plaster.

5.1.2 *Compressive Strength*—Gypsum casting plaster and gypsum molding plaster shall have a compressive strength of not less than 1800 psi [12.4 MPa].

5.1.3 *Fineness*—Gypsum casting plaster and gypsum molding plaster shall all pass a No. 30 [600-μm] sieve and not less than 90 % shall pass a No. 100 [150-μm] sieve.[3]

6. Sampling

6.1 Randomly select not less than 1 % of the packages, but not less than 5 packages. Take samples of approximately equal amounts both from the outer portion and the center of each package. Mix the samples so obtained to provide a composite sample of not less than 7 lb [3 kg]. Immediately place the composite sample in a clean, dry, airtight container for delivery to the laboratory.

7. Inspection

7.1 Inspection of the gypsum casting and molding plaster shall be agreed upon by the purchaser and the supplier as part of the purchase agreement.

8. Rejection

8.1 Rejection of gypsum casting plaster and gypsum molding plaster that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the gypsum casting and molding plaster have failed to conform to the requirements of this specification.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved May 1, 2006. Published May 2006. Originally approved in 1926. Last previous edition approved in 2000 as C 59/C 59M – 00.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

[3] Detailed requirements for these sieves are given in ASTM Specification E 11.

9. Certification

9.1 When specified in the purchase agreement, a producer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

10. Packaging and Package Marking

10.1 Gypsum casting plaster and gypsum molding plasters shall be dry and free of lumps and shall be shipped in packages.

10.2 When shipped, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

10.2.1 Name of manufacturer or seller,

10.2.2 Brand,

10.2.3 Description, and

10.2.4 Net weight of package. Gross weight shall be shown where required.

11. Keywords

11.1 casting plaster; gypsum; gypsum plaster; molding plaster

Designation: C 61/C 61M – 00 (Reapproved 2006)

Standard Specification for Gypsum Keene's Cement[1]

This standard is issued under the fixed designation C 61/C 61M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers various grades of anhydrous calcined gypsum known as gypsum Keene's cement, designed for use in the base and finish coats of gypsum plaster.

NOTE 1—The setting time is accelerated by the addition of other materials.

NOTE 2—Keene's cements are generally available as quick-setting and standard-setting types. However, various grades of gypsum Keene's cement of different fineness and setting time are available. Grades intended for use in scagliola castings and other special purposes should conform to the requirements of this specification in all respects except fineness and setting time.

1.2 The values stated in either inch-pound or SI (metric) units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be used independently of the other. Values from the two systems shall not be combined.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

1.4 The following safety hazards caveat pertains only to the test method in the appendix of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 471M Test Methods for Chemical Analysis of Gypsum and Gypsum Products [Metric]

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 *Definitions*—Definitions of terms used in this specification shall be as defined in Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *scagliola*, *n*—an imitation marble used for ornamental interior work.

4. Chemical Composition

4.1 *Combined Water*—The cement shall show a combined water content not more than 2 % when tested in accordance with Test Methods C 471M.

5. Physical Properties

5.1 Testing shall be in accordance with Test Methods C 472, except that in the determination of the setting time and compressive strength, the consistency used shall be such that a 35–g conical plunger, described in Test Methods C 472, shall give a penetration of 30 ± 2 mm, 20 s after release, the measurement being made 5 min after the addition of the gypsum Keene's cement to the gauging water.

5.1.1 *Setting Time*— The cement shall set in not less than 20 min and not more than 6 h when determined by the Vicat method.

5.1.2 *Compressive Strength*—Gypsum Keene's cement shall have a compressive strength of not less than 2500 psi [17 MPa]. Soak standard Keene's cement in water for 20 min with occasional stirring before filling the mold in the compressive strength determination.

5.1.3 *Fineness*—The cement shall all pass a No. 14 [1.40 mm] sieve; not less than 98 % shall pass a No. 40 [425–μm] sieve, and not less than 80 % shall pass a No. 100 [150–μm] sieve.[3]

6. Sampling

6.1 Randomly select not less than 1 % of the packages, but not less than 5 packages. Take samples of approximately equal

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved May 1, 2006. Published May 2006. Originally approved in 1926. Last previous edition approved in 2000 as C 61/C 61M – 00.

amounts from both the outer portion and the center of each package. Mix the samples so obtained to provide a composite sample of not less than 15 lb [6.8 kg]. Immediately place the sample in a clean, dry, airtight container for delivery to the laboratory.

7. Inspection

7.1 Inspection of the gypsum Keene's cement shall be agreed upon between the producer or supplier and the purchaser as part of the purchase agreement.

8. Rejection

8.1 Rejection of gypsum Keene's cement that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The written notice of rejection shall contain a statement documenting how the gypsum Keene's cement has failed to conform to the requirements of this specification.

9. Certification

9.1 When specified in the purchase agreement, a producer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

10. Packaging and Marking

10.1 Gypsum Keene's cement shall be dry, free of lumps, and shipped in packages.

10.2 When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

10.2.1 Name of producer or supplier,

10.2.2 Brand,

10.2.3 Description, and

10.2.4 Net weight of package. Gross weight shall be shown where required.

11. Keywords

11.1 anhydrous gypsum; gypsum; gypsum Keene's cement; gypsum plaster; Keene's cement; plaster

APPENDIX

(Nonmandatory Information)

X1. FIELD TEST FOR GYPSUM KEENE'S CEMENT

X1.1 Scope

X1.1.1 This method is a simple field test for the identification of gypsum Keene's cement. It does not indicate the quality of the cement, which shall be determined by the laboratory tests in the body of this specification.

X1.2 Significance and Use

X1.2.1 This method is of value to users in determining whether the material at hand is gypsum Keene's cement or some other material.

X1.3 Procedure

X1.3.1 Take a cupful of the material, mix with water to the consistency of a thick paste, and transfer to a plate or piece of glass. Let stand until fairly firm and definite signs of set having begun are manifest. This will be some time less than 2 h, depending on climatic conditions.

X1.3.2 Divide the sample, allowing one half to remain undisturbed. Take the other half, add a little water, remix, and then allow it to "set up" again on the plate or glass.

X1.4 Interpretation of Results

X1.4.1 If the material is gypsum Keene's cement, the remixed portion will, within a few hours, become as hard and strong as the portion that was not remixed.

X1.5 Precision and Bias

X1.5.1 It is not possible to state either the precision or bias of this test method because the method only determines whether a material is or is not gypsum Keene's cement and there are no numerical results generated.

Designation: C 70 – 06

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T142

Standard Test Method for Surface Moisture in Fine Aggregate[1]

This standard is issued under the fixed designation C 70; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers field determination of the amount of surface moisture in fine aggregate by displacement in water.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in SI units are to be regarded as the standard. The values in parentheses are provided for information purposes only.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 128 Test Method for Density, Relative Density (Specific Gravity), and Absorption of Fine Aggregate

C 566 Test Method for Total Evaporable Moisture Content of Aggregate by Drying

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Significance and Use

3.1 This test method is not widely used. However, it is a convenient procedure for field or plant determination of moisture content of fine aggregate if specific gravity values are known and if drying facilities are not available. It can be used to adjust the aggregate mass for moisture content and to determine surface moisture contribution to mixing water in portland cement concrete.

3.2 The accuracy of the test method depends upon accurate information on the bulk specific gravity of the material in a saturated surface-dry condition.

4. Apparatus

4.1 *Balance*, having a capacity of 2 kg or more and sensitive to 0.5 g or less.

4.2 *Flask*—A suitable container or flask, preferably of glass or noncorrosive metal. The container may be a pycnometer, a volumetric flask, a graduated volumetric flask, or other suitable measuring device. The volume of the container shall be from two to three times the loose volume of the sample. The container shall be so designed that it can be filled to the mark, or the volume of its contents read, within 0.5 mL or less.

5. Sample

5.1 Select a representative sample of the fine aggregate to be tested for surface moisture content. It shall weigh not less than 200 g. Larger samples will yield more accurate results.

6. Procedure

6.1 The surface water content may be determined either by mass or volume. In each case the test shall be made at a temperature range of 18 to 29°C (65 to 85°F).

6.2 *Determination by Mass*—Determine the mass of the container, in grams, filled to the mark with only water. Before placing the sample into the container, adjust the level of the water so that it will be sufficient to cover the sample without going over the original mark. Introduce the weighed sample of fine aggregate into the container and remove the entrained air. Fill the container to the original mark, and determine the mass in grams. Calculate the amount of water displaced by the sample, as follows:

$$M_d = M_c + M_s - M \quad (1)$$

where:

M_d = mass of water displaced by the sample, g,
M_c = mass of container filled to the mark with water, g,
M_s = mass of sample, g, and
M = mass of container and sample, filled to the mark with water, g.

6.3 *Determination by Volume*—Measure a volume of water, in millilitres, sufficient to cover the sample and place in the container. Introduce the weighed sample of fine aggregate into the container and remove the entrained air. Determine the combined volume of the sample and the water by direct reading

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved Feb. 15, 2006. Published March 2006. Originally approved in 1970. Last previous edition approved in 2001 as C 70 – 94(2001).

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

when a graduated flask is used. When a pycnometer or volumetric flask of known volume is used, fill the container to the known volume mark with an additional measured volume of water. The flask or pycnometer volume is then equal to the combined volume of sample and water. Calculate the amount of water displaced by the sample, as follows:

$$V_s = V_2 - V_1 \quad (2)$$

where:

V_s = volume of water displaced by the sample, mL,
V_2 = combined volume of sample and water, mL, and
V_1 = total volume of water in the flask or pycnometer required to cover the sample and bring the level up to the known volume mark, mL.

7. Calculation

7.1 Calculate the percentage of surface moisture in terms of the saturated surface-dry fine aggregate (see Appendix X1), as follows:

$$P = [(M_d - V_d)/(M_s - M_d)] \times 100 \quad (3)$$

where:

P = surface moisture in terms of saturated surface-dry fine aggregate, %,
V_d = mass of the sample (M_s in 6.2) divided by the bulk specific gravity of the fine aggregate in a saturated surface-dry condition, determined as prescribed in Test Method C 128, and
M_d = mass of water displaced, g, and
M_s = mass of sample, g

7.2 Calculate the percentage of surface moisture in terms of dry aggregate if the absorption of the aggregate is known as follows:

$$P_d = P[1 + (P_a/100)] \quad (4)$$

where:

P_d = surface moisture in terms of dry fine aggregate, %, and
P_a = absorption of the fine aggregate, %, determined in accordance with Test Method C 128.

Total moisture content, on a dry aggregate basis, is the sum of the surface moisture, P_d, and the absorption, P_a.

8. Report

8.1 Report surface moisture test results as determined by this method to the nearest 0.1 %.

9. Precision and Bias

9.1 This procedure is estimated to be less precise than properly conducted moisture content tests by drying (Test Method C 566). Accurate specific gravity information is essential to the bias of this method. Test Method C 566 can be used to verify the level of bias.

9.2 *Precision*—These estimates of precision are based on results from the AASHTO Materials Reference Laboratory (AMRL) Proficiency Sample Program, of testing conducted on Fine Aggregate Proficiency Sample Numbers 99 and 100. The precision limits are based on test results submitted by 144 laboratories that tested two fine aggregate test samples of approximately 500 g mass with average surface moisture contents of 2.323 % and 2.075 % respectively.

9.2.1 *Single-Operator Precision*—The single-operator standard deviation of a single test result has been found to be 0.50 %.[3] Therefore, results of two properly conducted tests by the same operator should not differ by more than 1.39 %.

9.2.2 *Multilaboratory Precision*—The multilaboratory standard deviation of a single test result has been found to be 0.82 %.[3] Therefore, results of two properly conducted tests in different laboratories on the same material should not differ by more than 2.31 %.[3]

9.3 *Bias*—Since there is no accepted reference material suitable for determining the bias of this test procedure, no statement on bias (other than that in 9.1) is made.

10. Keywords

10.1 fine aggregate; fine aggregate moisture; surface moisture

[3] These numbers represent, respectively, the (1s) and d2s) limits as described in Practice C 670.

APPENDIX

(Nonmandatory Information)

X1. DEVELOPMENT OF EQUATIONS

X1.1 These equations are readily derived from basic relationships. For convenience express P in terms of the ratio r, that is, the ratio of the mass of surface moisture to the mass of the saturated, surface-dry sample. It follows that:

$$r = \frac{M_s - [M_s/(1 + r)]}{M_s/(1 + r)} \quad (X1.1)$$

X1.1.1 If G is bulk specific gravity of the saturated, surface-dry fine aggregate, then

$$M_d = \frac{M_s}{G(1 + r)} + M_s - \frac{M_s}{1 + r} \quad (X1.2)$$

where the first term gives the water displaced by the saturated surface-dry fine aggregate and the second that displaced by the surface moisture.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:00:06 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X1.1.2 From Eq X1.2:

$$\frac{M_s}{1+r} = \frac{M_d - M_s}{\frac{1}{\overline{G}} - 1} \quad \text{(X1.3)}$$

By definition,

$$M_s = V_d G \quad \text{(X1.4)}$$

X1.1.3 Substituting for $M_s/(1 + r)$ and M_s in Eq X1.1 and simplifying,

$$r = (M_d - V_d)/(M_s - M_d) \quad \text{(X1.5)}$$

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 70 – 94(2001), that may impact the use of this test method. (Approved February 15, 2006)

(*1*) Added new paragraph 1.3.
(*2*) Revised paragraph 6.1.
(*3*) Changed "weight" to "mass" throughout.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Designation: C 78 – 09

Standard Test Method for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)[1]

This standard is issued under the fixed designation C 78; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the flexural strength of concrete by the use of a simple beam with third-point loading.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 617 Practice for Capping Cylindrical Concrete Specimens

C 1077 Practice for Laboratories Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation

E 4 Practices for Force Verification of Testing Machines

3. Significance and Use

3.1 This test method is used to determine the flexural strength of specimens prepared and cured in accordance with Test Methods C 42/C 42M or Practices C 31/C 31M or C 192/C 192M. Results are calculated and reported as the modulus of rupture. The strength determined will vary where there are differences in specimen size, preparation, moisture condition, curing, or where the beam has been molded or sawed to size.

3.2 The results of this test method may be used to determine compliance with specifications or as a basis for proportioning, mixing and placement operations. It is used in testing concrete for the construction of slabs and pavements.

4. Apparatus

4.1 The testing machine shall conform to the requirements of the sections on Basis of Verification, Corrections, and Time Interval Between Verifications of Practices E 4. Hand operated testing machines having pumps that do not provide a continuous loading in one stroke are not permitted. Motorized pumps or hand operated positive displacement pumps having sufficient volume in one continuous stroke to complete a test without requiring replenishment are permitted and shall be capable of applying loads at a uniform rate without shock or interruption.

4.2 *Loading Apparatus*—The third point loading method shall be used in making flexure tests of concrete employing bearing blocks which will ensure that forces applied to the beam will be perpendicular to the face of the specimen and applied without eccentricity. A diagram of an apparatus that accomplishes this purpose is shown in Fig. 1.

4.2.1 All apparatus for making flexure tests of concrete shall be capable of maintaining the specified span length and distances between load-applying blocks and support blocks constant within ±0.05 in. (±1.3 mm).

4.2.2 The ratio of the horizontal distance between the point of application of the load and the point of application of the nearest reaction to the depth of the beam shall be 1.0 ± 0.03.

4.2.3 If an apparatus similar to that illustrated in Fig. 1 is used: the load-applying and support blocks should not be more than 2½ in. (64 mm) high, measured from the center or the axis of pivot, and should extend entirely across or beyond the full width of the specimen. Each case-hardened bearing surface in contact with the specimen shall not depart from a plane by more than 0.002 in. (0.05 mm) and shall be a portion of a cylinder, the axis of which is coincidental with either the axis of the rod or center of the ball, whichever the block is pivoted

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved July 1, 2009. Published August 2009. Originally approved in 1930. Last previous edition approved in 2008 as C 78 – 08.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

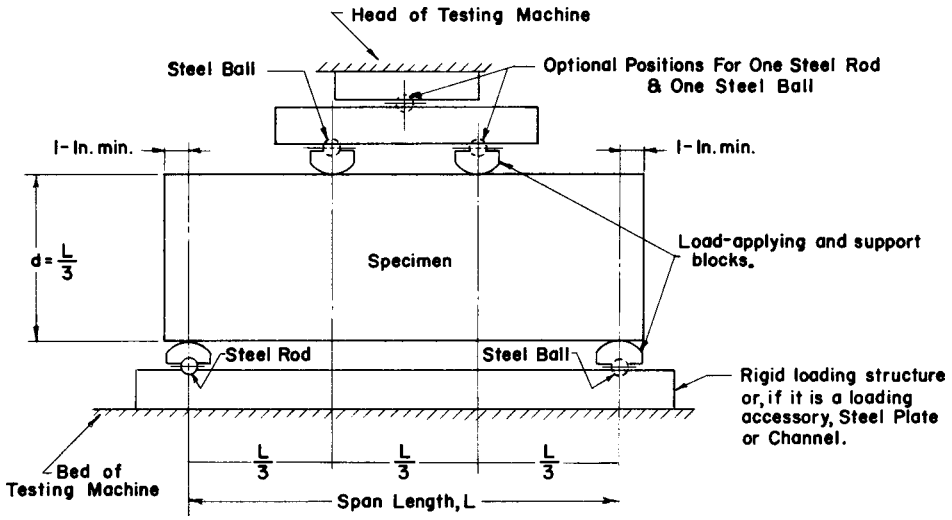
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir



NOTE 1—This apparatus may be used inverted. If the testing machine applies force through a spherically seated head, the center pivot may be omitted, provided one load-applying block pivots on a rod and the other on a ball.

NOTE 2—1 in. = 25.4 mm.

FIG. 1 Diagrammatic View of a Suitable Apparatus for Flexure Test of Concrete by Third-Point Loading Method

upon. The angle subtended by the curved surface of each block should be at least 45° (0.79 rad). The load-applying and support blocks shall be maintained in a vertical position and in contact with the rod or ball by means of spring-loaded screws that hold them in contact with the pivot rod or ball. The uppermost bearing plate and center point ball in Fig. 1 may be omitted when a spherically seated bearing block is used, provided one rod and one ball are used as pivots for the upper load-applying blocks.

5. Testing

5.1 The test specimen shall conform to all requirements of Test Method C 42/C 42M or Practices C 31/C 31M or C 192/C 192M applicable to beam specimens and shall have a test span within 2 % of being three times its depth as tested. The sides of the specimen shall be at right angles with the top and bottom. All surfaces shall be smooth and free of scars, indentations, holes, or inscribed identification marks.

5.2 The individual who tests concrete beams for acceptance testing shall meet the concrete laboratory technician requirements of Practice C 1077 including Test Method C 78 as a relevant test.

NOTE 1—The testing laboratory performing this test method may be evaluated in accordance with Practice C 1077.

6. Procedure

6.1 Flexural tests of moist-cured specimens shall be made as soon as practical after removal from moist storage. Surface drying of the specimen results in a reduction in the measured flexural strength.

6.2 When using molded specimens, turn the test specimen on its side with respect to its position as molded and center it on the support blocks. When using sawed specimens, position the specimen so that the tension face corresponds to the top or bottom of the specimen as cut from the parent material. Center the loading system in relation to the applied force. Bring the load-applying blocks in contact with the surface of the specimen at the third points and apply a load of between 3 and 6 % of the estimated ultimate load. Using 0.004 in. (0.10 mm) and 0.015 in. (0.38 mm) leaf-type feeler gages, determine whether any gap between the specimen and the load-applying or support blocks is greater or less than each of the gages over a length of 1 in. (25 mm) or more. Grind, cap, or use leather shims on the specimen contact surface to eliminate any gap in excess of 0.004 in. (0.10 mm) in width. Leather shims shall be of uniform ¼ in. (6.4 mm) thickness, 1 to 2 in. (25 to 50 mm) width, and shall extend across the full width of the specimen. Gaps in excess of 0.015 in. (0.38 mm) shall be eliminated only by capping or grinding. Grinding of lateral surfaces should be minimized inasmuch as grinding may change the physical characteristics of the specimens. Capping shall be in accordance with the applicable sections of Practice C 617.

6.3 Load the specimen continuously and without shock. The load shall be applied at a constant rate to the breaking point. Apply the load at a rate that constantly increases the maximum stress on the tension face between 125 and 175 psi/min (0.86 and 1.21 MPa/min) until rupture occurs. The loading rate is calculated using the following equation:

$$r = Sbd^2/L \quad (1)$$

where:

r = loading rate, lb/min (N/min),
S = rate of increase in maximum stress on the tension face, psi/min (MPa/min),
b = average width of the specimen as oriented for testing, in. (mm),
d = average depth of the specimen as oriented for testing, in. (mm), and

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:00 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

L = span length, in (mm).

7. Measurement of Specimens After Test

7.1 To determine the dimensions of the specimen cross section for use in calculating modulus of rupture, take measurements across one of the fractured faces after testing. The width and depth are measured with the specimen as oriented for testing. For each dimension, take one measurement at each edge and one at the center of the cross section. Use the three measurements for each direction to determine the average width and the average depth. Take all measurements to the nearest 0.05 in. (1 mm). If the fracture occurs at a capped section, include the cap thickness in the measurement.

8. Calculation

8.1 If the fracture initiates in the tension surface within the middle third of the span length, calculate the modulus of rupture as follows:

$$R = PL/bd^2 \quad (2)$$

where:

R = modulus of rupture, psi, or MPa,
P = maximum applied load indicated by the testing machine, lbf, or N,
L = span length, in., or mm,
b = average width of specimen, in., or mm, at the fracture, and
d = average depth of specimen, in., or mm, at the fracture.

NOTE 2—The weight of the beam is not included in the above calculation.

8.2 If the fracture occurs in the tension surface outside of the middle third of the span length by not more than 5 % of the span length, calculate the modulus of rupture as follows:

$$R = 3Pa/bd^2 \quad (3)$$

where:

a = average distance between line of fracture and the nearest support measured on the tension surface of the beam, in., (or mm).

NOTE 3—The weight of the beam is not included in the above calculation.

8.3 If the fracture occurs in the tension surface outside of the middle third of the span length by more than 5 % of the span length, discard the results of the test.

9. Report

9.1 Report the following information:
9.1.1 Identification number,
9.1.2 Average width to the nearest 0.05 in. (1 mm),
9.1.3 Average depth to the nearest 0.05 in. (1 mm),
9.1.4 Span length in inches (or millimeters),
9.1.5 Maximum applied load in pound-force (or newtons),
9.1.6 Modulus of rupture calculated to the nearest 5 psi (0.05 MPa),
9.1.7 Curing history and apparent moisture condition of the specimens at the time of test,
9.1.8 If specimens were capped, ground, or if leather shims were used,
9.1.9 Whether sawed or molded and defects in specimens, and
9.1.10 Age of specimens.

10. Precision and Bias

10.1 *Precision*—The coefficient of variation of test results has been observed to be dependent on the strength level of the beams.[3] The single operator coefficient of variation has been found to be 5.7 %. Therefore, results of two properly conducted tests by the same operator on beams made from the same batch sample should not differ from each other by more than 16 %. The multilaboratory coefficient of variation has been found to be 7.0 %. Therefore, results of two different laboratories on beams made from the same batch sample should not differ from each other by more than 19 %.

10.2 *Bias*—Since there is no accepted standard for determining bias in this test method, no statement on bias is made.

11. Keywords

11.1 beams; concrete; flexural strength testing; modulus of rupture

[3] See "Improved Concrete Quality Control Procedures Using Third Point Loading" by P. M. Carrasquillo and R. L. Carrasquillo, Research Report 119-1F, Project 3-9-87-1119, Center For Transportation Research, The University of Texas at Austin, November 1987, for possible guidance as to the relationship of strength and variability.

Designation: C 87 – 05

Standard Test Method for Effect of Organic Impurities in Fine Aggregate on Strength of Mortar[1]

This standard is issued under the fixed designation C 87; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the effect on mortar strength of the organic impurities in fine aggregate, whose presence is indicated using Test Method C 40. Comparison is made between compressive strengths of mortar made with washed and unwashed fine aggregate.

1.2 The SI values shown are to be regarded as the standard. The inch-pound values shown in parentheses are provided for information purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*(**Warning—**Fresh hydraulic cementitous mixtures are caustic and may cause chemical burns to exposed skin and tissue upon prolonged exposure.)[2]

C 702 Practice for Reducing Samples of Aggregate to Testing Size

D 75 Practice for Sampling Aggregates

D 3665 Practice for Random Sampling of Construction Materials

3. Summary of Test Method

3.1 A portion of the fine aggregate that produced a color darker than the standard in Test Method C 40 is used to prepare mortar cube specimens. A separate portion of the same fine aggregate is washed in sodium hydroxide solution to remove the organic impurities that caused the failing result when tested in accordance with Test Method C 40, and that washed fine aggregate is used to prepare another set of mortar cube specimens.

3.2 After curing for a stated period, the compressive strengths of the two sets of cube specimens are determined and compared.

4. Significance and Use

4.1 This test method is of significance in making a final determination of the acceptability of fine aggregates with respect to the requirements of Specification C 33 concerning organic impurities.

4.2 This test method is applicable to those samples which, when tested in accordance with Test Method C 40, have produced a supernatant liquid with a color darker than standard color plate No. 3 or color solution.

4.3 Many specifications provide for the acceptance of fine aggregate producing a darker color in the Test Method C 40 test, when testing by this test method indicates the strength of the mortar cubes prepared with the unwashed fine aggregate is comparable to the strength of mortar cubes made with the washed fine aggregate.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved July 1, 2005. Published July 2005. Originally approved in 1931. Last previous edition approved in 2004 as C 87 – 04.

5. Apparatus

5.1 *Flow Table, Flow Mold, and Caliper*, as described in Specification C 230.

5.2 *Tamper, Trowel, Cube Molds, and Testing Machine*, as described in Test Method C 109/C 109M.

5.3 *Mixer, Bowl, and Paddle*, as described in Practice C 305.

5.4 *Curing Apparatus*, as described in Specification C 511.

5.5 *pH Paper*, 0–14.

5.6 *pH Meter*, capable of reading to 0.1 pH units or better.

6. Reagents and Materials

6.1 Portland cement shall be Type I or Type II, meeting the requirements of Specification C 150.

6.2 *Sodium Hydroxide Solution (3 %)*—Dissolve 3 parts by mass of sodium hydroxide (NaOH) in 97 parts water.

6.3 *Phenolphthalein*—Dissolve 1 g of reagent grade phenolphthalein in 1 L of 95 % reagent grade ethyl alcohol.

7. Sampling and Sample Preparation

7.1 If sufficient material remains from the sample used for testing in accordance with Test Method C 40, use this material for the tests described in this test method. If there is insufficient material remaining, obtain another field sample from the same source in accordance with Practice D 75 and Practice D 3665.

NOTE 1—At least 20 kg of fine aggregate should be available for the testing described herein.

7.2 If the fine aggregate contains particles coarser than the 4.75-mm (No.4) sieve, remove the coarser particles by sieving on the 4.75-mm (No.4) sieve, so that when the particles are mixed in the designated mixer, there will be no damage to the mixer or crushing of the fine aggregate particles. Determine the percentage of the sample removed. (**Warning**—The clearances between the paddle and the bowl specified in Practice C 305 are suitable when using the mortar made with graded standard sand. To permit the mixer to operate freely and to avoid serious damage to the paddle and bowl when coarser aggregates are used, it may be necessary to set the clearance adjustment bracket to provide greater clearances than specified. A clearance of approximately 4.0 mm is required in Practice C 305; a clearance of approximately 5.0 mm has been found to be satisfactory for this method when used with fine aggregate from which the material retained on the 4.75-mm (No. 4) sieve has been removed.)

7.3 Split the fine aggregate to be used for these tests into two approximately equal portions, using the procedure described in Practice C 702. Set one portion aside to be used in the unwashed condition. The second portion is to be washed before use.

7.4 *Preparing Washed Fine Aggregate*:

7.4.1 Perform the washing and rinsing of the fine aggregate with care to minimize the loss of fines, so that the aggregate after washing and rinsing has a fineness modulus within 0.10 of that of the unwashed aggregate.

7.4.2 *Establishing a Standard for Thoroughness of Rinsing*—Place a small amount of the water to be used for washing and rinsing in a clean, clear container, and determine the pH of the water by use of pH paper, pH meter, or add a drop of phenolphthalein to the wash water and retain for later comparison.

7.4.3 *Washing the Aggregate*—Place sufficient quantity of fine aggregate for three batches in a suitable container, flood with the sodium hydroxide solution, and agitate thoroughly with a spoon or trowel. At the end of the washing and after allowing to stand for fines to settle, siphon off as much of the sodium hydroxide solution as possible, without removing any of the aggregate fines.

7.4.4 *Rinsing the Aggregate* —Add a large quantity of water to the washed aggregate, agitate, allow to stand for fines to settle, and then siphon off the rinse water. Repeat this operation several times, until the water used for rinsing has a pH equal to or lower than the pH of the water prior to contact with the fine aggregate. If phenolphthalein was used as an indicator, the color of the wash water is to be equal or lighter in color than the solution prepared in 7.4.2.

7.4.5 *Verifying Removal of Organic Impurities*—Repeat the Test Method C 40 procedure to determine if the washing has removed sufficient organic impurities to produce a satisfactory result (color lighter than the standard). If the fine aggregate continues to produce an unsatisfactory result (color darker than the standard), repeat the washing and rinsing procedure (described in 7.4.3 and 7.4.4) as many times as necessary until a satisfactory result is obtained by Test Method C 40.

8. Procedure

8.1 *Number of Test Batches*—Prepare three batches of mortar using the washed aggregate and three batches of mortar using the unwashed aggregate, on the same day. Mix the batches, alternating between the washed and unwashed aggregate.

8.2 *Fine Aggregate*—For both the washed and the unwashed fine aggregates, bring the portions of fine aggregate to the saturated surface dry condition as described in Test Method C 128. Prepare a quantity of aggregate of known mass (*the aggregate specimen*) that is slightly more than needed to produce a single batch of the desired consistency.

8.2.1 *Optionally*, if the absorption has been determined in accordance with Test Method C 128, prepare the aggregate for test by adding to a known mass of dry aggregate the amount of water it will absorb, mixing thoroughly, and permitting the aggregate to stand in a covered pan for 30 min before use.

8.3 *Preparation of Mortar*—Prepare the mortar in a mechanical mixer in accordance with the procedure for mixing mortars described in Practice C 305, as modified below.

8.3.1 Use water and cement in quantities that will yield a water-cement ratio of 0.6 by mass (See Note 2). The mixing water shall be at a temperature of 23.0 ± 2.0 °C (73.5 ± 3.5 °F). The mortar shall be proportioned to produce a consistency of 100 ± 5 % as determined by the Section on Flow Test (see 8.4.1).

NOTE 2—It has been found that 600 g of cement and 360 mL of water will usually be adequate for a 6-cube batch. The flow is adjusted by the quantity of fine aggregate added to the mixture.

8.3.2 After placing all the mixing water in the bowl, add the cement to the water. Start the mixer and mix at the slow speed

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

(140 ±5 r/min) for 30 s. While still mixing at slow speed over a 30-s period, add a measured quantity of aggregate estimated to provide the proper consistency.

NOTE 3—The quantity of aggregate used may be determined by subtracting from a known quantity of prepared aggregate the mass of the portion remaining after mixing.

8.3.3 Stop the mixer, change to medium speed (285 ± 10 r/min), and mix for 30 s.

8.3.4 Stop the mixer and let the mortar stand for 1.5 min. During the first 15 s of this interval, quickly scrape down into the batch any mortar that may have collected on the side of the bowl, then for the remainder of this interval, cover the bowl with the lid.

8.3.5 Finish by mixing for 1 min at medium speed. If the flow appears to be too high during the first 30 s of this period, stop the mixer briefly, add additional fine aggregate, and then complete the final 30 s of mixing.

8.3.6 In any case requiring a remixing interval, any mortar adhering to the side of the bowl shall be quickly scraped down into the batch with the scraper prior to remixing.

8.3.7 Make a determination of the flow.

8.4 *Flow Test*:

8.4.1 Carefully wipe the flow table clean. Dry the surface and place the flow mold at the center. Immediately after completing the mixing operation, place a layer of mortar approximately 25 mm (1 in.) in thickness in the mold and tamp 20 times with the tamper. The tamping pressure shall be just sufficient to ensure uniform filling of the mold. Slightly overfill the mold with mortar and tamp as specified for the first layer. Cut off the mortar to a plane surface, flush with the top of the mold, by drawing the straight edge of the trowel (held nearly perpendicular to the mold) with a sawing motion across the top of the mold. Wipe the table top clean and dry, being especially careful to remove any water from around the edge of the flow mold. Lift the mold away from the mortar 1 min after completing the mixing operation. Immediately drop the table through a height of 12.7 mm (0.5 in.) ten times in 6 s. The flow is the resulting increase in average diameter of the mortar specimen, measured on at least four diameters at approximately equal angles, expressed as a percentage of the original diameter.

8.4.2 Should the flow be too great, return the mortar to the mixing vessel, add additional fine aggregate, mix for 30 s at medium speed, and make another determination of the flow. If more than two trials must be made to obtain a flow of 100 ± 5 %, consider the mortar as a trial mortar, and prepare a new batch.

8.4.3 If the mortar is too dry, discard the batch and prepare a new batch starting with a smaller quantity of fine aggregate.

8.4.4 Determine the quantity of fine aggregate used by subtracting the mass of the portion remaining from the original mass of the aggregate specimen.

8.5 *Molding Mortar Cubes*—Immediately following completion of a flow test that indicates acceptable consistency, return the mortar from the flow table to the mixing bowl, scrape down the bowl, and then remix the entire batch for 15 s at medium speed. Upon completion of mixing, shake the excess mortar from the paddle into the bowl. Mold one set (three cubes) from each batch, in accordance with Test Method C 109/C 109M.

8.6 *Curing and Testing Mortar Cubes*—Store the test specimens in a moist cabinet or moist room maintained at a temperature of 23.0 ± 2.0 °C (73.5 ± 3.5 °F) and relative humidity not less than 95 % for 24 ± ½ h. Additional curing shall be by immersion in saturated lime water maintained at a temperature of 23.0 ± 2.0 °C (73.5 ± 3.5 °F). Determine the compressive strength of the cubes at 7 days in accordance with Test Method C 109/C 109M.

9. Calculation and Report

9.1 Calculate the compressive strength of each specimen by dividing the maximum load it carried during the test by the cross-sectional area. Average the strengths of the three specimens from each batch. Calculate three strength ratios by dividing the average strength for a batch containing unwashed fine aggregate by the average strength for the corresponding (in respective order of mixing) batch containing washed fine aggregate.

9.2 Report the average of the three ratios, expressed as a percentage (to the nearest 1 %), as the relative strength for the fine aggregate under test.

9.3 If the fine aggregate was sieved to remove particles coarser than the 4.75 mm (No. 4) sieve (as described in 7.2), so state in the report and indicate the quantity of material removed as a percentage of the original sample mass.

10. Precision and Bias

10.1 The following precision statement is applicable when a test result is the average ratio, as defined by this test method, of three pairs of mortar batch strength tests with all the batches mixed on the same day and tested at the same age.

10.2 The single laboratory coefficient of variation has been determined to be 5.4 % (See Note 4). Therefore, strength ratios of two properly conducted tests in the same laboratory are not expected to differ from each other by more than 15.3 % (See Note 4) of their average. The maximum range (difference between highest and lowest) of the three individual ratios used in calculating the average are not expected to exceed 17 % (See Note 4).

NOTE 4—These numbers represent respectively the (1s %) and (d2s %) limits as described in Practice C 670, calculated as described in the section on *Form of Statement for Which a Test Result is Defined as the Average of a Specified Number of Measurements* in Practice C 670.

11. Keywords

11.1 aggregate; fine aggregate; organic impurities; mortar strength

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 87 – 04, that may impact the use of this test method. (Approved July 1, 2005)

(*1*) Moved old Note 3 into 8.2.1 and revised 8.3.1.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 87 – 03, that may impact the use of this test method. (Approved August 1, 2004)

(*1*) Revised Sections 4-10.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 88 – 05

Standard Test Method for Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate[1]

This standard is issued under the fixed designation C 88; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the testing of aggregates to estimate their soundness when subjected to weathering action in concrete or other applications. This is accomplished by repeated immersion in saturated solutions of sodium or magnesium sulfate followed by oven drying to partially or completely dehydrate the salt precipitated in permeable pore spaces. The internal expansive force, derived from the rehydration of the salt upon re-immersion, simulates the expansion of water on freezing. This test method furnishes information helpful in judging the soundness of aggregates when adequate information is not available from service records of the material exposed to actual weathering conditions.

1.2 The values given in parentheses are provided for information purposes only.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 33 Specification for Concrete Aggregates

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 702 Practice for Reducing Samples of Aggregate to Testing Size

D 75 Practice for Sampling Aggregates

E 11 Specification for Wire Cloth Sieves for Testing Purposes

E 100 Specification for ASTM Hydrometers

E 323 Specification for Perforated-Plate Sieves for Testing Purposes

3. Significance and Use

3.1 This test method provides a procedure for making a preliminary estimate of the soundness of aggregates for use in concrete and other purposes. The values obtained may be compared with specifications, for example Specification C 33, that are designed to indicate the suitability of aggregate proposed for use. Since the precision of this test method is poor (Section 12), it may not be suitable for outright rejection of aggregates without confirmation from other tests more closely related to the specific service intended.

3.2 Values for the permitted-loss percentage by this test method are usually different for fine and coarse aggregates, and attention is called to the fact that test results by use of the two salts differ considerably and care must be exercised in fixing proper limits in any specifications that include requirements for these tests. The test is usually more severe when magnesium sulfate is used; accordingly, limits for percent loss allowed when magnesium sulfate is used are normally higher than limits when sodium sulfate is used.

NOTE 1—Refer to the appropriate sections in Specification C 33 establishing conditions for acceptance of coarse and fine aggregates which fail to meet requirements based on this test.

4. Apparatus

4.1 *Sieves*—With square openings of the following sizes conforming to Specifications E 11 or E 323, for sieving the samples in accordance with Sections 6, 7, and 9:

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved July 15, 2005. Published August 2005. Originally approved in 1931. Last previous edition approved in 1999 as C 88 – 99a.

150 µm (No. 100)	8.0 mm (5⁄16 in.)
	9.5 mm (3⁄8 in.)
300 µm (No. 50)	12.5 mm (1⁄2 in.)
	16.0 mm (5⁄8 in.)
600 µm (No. 30)	19.0 mm (3⁄4 in.)
	25.0 mm (1 in.)
1.18 mm (No. 16)	31.5 mm (1 1⁄4 in.)
2.36 mm (No. 8)	37.5 mm (1 1⁄2 in.)
	50 mm (2 in.)
4.00 mm (No. 5)	63 mm (2 1⁄2 in.)
	larger sizes by
4.75 mm (No. 4)	12.5-mm (1⁄2-in.)
	spread

4.2 *Containers*—Containers for immersing the samples of aggregate in the solution, in accordance with the procedure described in this test method, shall be perforated in such a manner as to permit free access of the solution to the sample and drainage of the solution from the sample without loss of aggregate.

NOTE 2—Baskets made of suitable wire mesh or sieves with suitable openings are satisfactory containers for the samples.

4.3 *Temperature Regulation*—Suitable means for regulating the temperature of the samples during immersion in the sodium sulfate or magnesium sulfate solution shall be provided.

4.4 *Balances*—For fine aggregate, a balance or scale accurate within 0.1 g over the range required for this test; for coarse aggregate, a balance or scale accurate within 0.1 % or 1 g, whichever is greater, over the range required for this test.

4.5 *Drying Oven*—The oven shall be capable of being heated continuously at 230 ± 9 °F (110 ± 5 °C) and the rate of evaporation, at this range of temperature, shall be at least 25 g/h for 4 h, during which period the doors of the oven shall be kept closed. This rate shall be determined by the loss of water from 1-L Griffin low-form beakers, each initially containing 500 g of water at a temperature of 70 ± 3 °F (21 ± 2 °C), placed at each corner and the center of each shelf of the oven. The evaporation requirement is to apply to all test locations when the oven is empty except for the beakers of water.

4.6 *Specific Gravity Measurement*—Hydrometers conforming to the requirements of Specification E 100, or a suitable combination of graduated glassware and balance, capable of measuring the solution specific gravity within ±0.001.

5. Special Solutions Required

5.1 Prepare the solution for immersion of test samples from either sodium or magnesium sulfate in accordance with 5.1.1 or 5.1.2 (Note 3). The volume of the solution shall be at least five times the solid volume of all samples immersed at any one time.

NOTE 3—Some aggregates containing carbonates of calcium or magnesium are attacked chemically by fresh sulfate solution, resulting in erroneously high measured losses. If this condition is encountered or is suspected, repeat the test using a filtered solution that has been used previously to test the same type of carbonate rock, provided that the solution meets the requirements of 5.1.1 and 5.1.2 for specific gravity.

5.1.1 *Sodium Sulfate Solution*—Prepare a saturated solution of sodium sulfate by dissolving a USP or equal grade of the salt in water at a temperature of 77 to 86 °F (25 to 30 °C). Add sufficient salt (Note 4), of either the anhydrous (Na_2SO_4) or the crystalline ($Na_2SO_4·10H_2O$) form,[3] to ensure not only saturation but also the presence of excess crystals when the solution is ready for use in the tests. Thoroughly stir the mixture during the addition of the salt and stir the solution at frequent intervals until used. To reduce evaporation and prevent contamination, keep the solution covered at all times when access is not needed. Allow the solution to cool to 70 ± 2 °F (21 ± 1 °C). Again stir, and allow the solution to remain at the designated temperature for at least 48 h before use. Prior to each use, break up the salt cake, if any, in the container, stir the solution thoroughly, and determine the specific gravity of the solution. When used, the solution shall have a specific gravity not less than 1.151 nor more than 1.174. Discard a discolored solution, or filter it and check for specific gravity.

NOTE 4—For the solution, 215 g of anhydrous salt or 700 g of the decahydrate per litre of water are sufficient for saturation at 71.6 °F (22 °C). However, since these salts are not completely stable and since it is desirable that an excess of crystals be present, the use of not less than 350 g of the anhydrous salt or 750 g of the decahydrate salt per litre of water is recommended.

5.1.2 *Magnesium Sulfate Solution*—Prepare a saturated solution of magnesium sulfate by dissolving a USP or equal grade of the salt in water at a temperature of 77 to 86 °F (25 to 30 °C). Add sufficient salt (Note 5), of either the anhydrous ($MgSO_4$) or the crystalline ($MgSO_4·7H_2O$) (Epsom salt) form, to ensure saturation and the presence of excess crystals when the solution is ready for use in the tests. Thoroughly stir the mixture during the addition of the salt and stir the solution at frequent intervals until used. To reduce evaporation and prevent contamination, keep the solution covered at all times when access is not needed. Allow the solution to cool to 70 ± 2 °F (21 ± 1 °C). Again stir, and allow the solution to remain at the designated temperature for at least 48 h before use. Prior to each use, break up the salt cake, if any, in the container, stir the solution thoroughly, and determine the specific gravity of the solution. When used, the solution shall have a specific gravity not less than 1.295 nor more than 1.308. Discard a discolored solution, or filter it and check for specific gravity.

NOTE 5—For the solution, 350 g of anhydrous salt or 1230 g of the heptahydrate per litre of water are sufficient for saturation at 73.4 °F (23 °C). However, since these salts are not completely stable, with the hydrous salt being the more stable of the two, and since it is desirable that an excess of crystals be present, it is recommended that the heptahydrate salt be used and in an amount of not less than 1400 g/litre of water.

5.1.3 *Barium Chloride Solution*—Prepare 100 mL of 5 % barium chloride solution by dissolving 5 g of $BaCl_2$ in 100 mL of distilled water.

6. Samples

6.1 The sample shall be obtained in general accordance with Practice D 75 and reduced to test portion size in accordance with Practice C 702.

[3] Experience with the test method indicates that a grade of sodium sulfate designated by the trade as dried powder, which may be considered as approximately anhydrous, is the most practical for use. That grade is more economically available than the anhydrous form. The decahydrate sodium sulfate presents difficulties in compounding the required solution on account of its cooling effect on the solution.

www.technobetar.ir

6.2 *Fine Aggregate*—Fine aggregate for the test shall be passed through a 9.5-mm (⅜-in.) sieve. The sample shall be of such size that it will yield not less than 100 g of each of the following sizes, which shall be available in amounts of 5 % or more, expressed in terms of the following sieves:

Passing Sieve	Retained on Sieve
600 µm (No. 30)	300 µm (No. 50)
1.18 mm (No. 16)	600 µm (No. 30)
2.36 mm (No. 8)	1.18 mm (No. 16)
4.75 mm (No. 4)	2.36 mm (No. 8)
9.5 mm (⅜ in.)	4.75 mm (No. 4)

6.3 *Coarse Aggregate*—Coarse aggregate for the test shall consist of material from which the sizes finer than the No. 4 sieve have been removed. The sample shall be of such a size that it will yield the following amounts of the indicated sizes that are available in amounts of 5 % or more:

Size (Square-Opening Sieves)	Mass, g
9.5 mm (⅜ in.) to 4.75 mm (No. 4)	300 ± 5
19.0 mm (¾ in.) to 9.5 mm (⅜ in.)	1000 ± 10
Consisting of:	
12.5-mm (½-in.) to 9.5-mm (⅜-in.) material	330 ± 5
19.0-mm (¾-in.) to 12.5-mm (½-in.) material	670 ± 10
37.5-mm (1 ½-in.) to 19.0-mm (¾ in.)	1500 ± 50
Consisting of:	
25.0-mm (1-in.) to 19.0-mm (¾-in.) material	500 ± 30
37.5-mm (1 ½-in.) to 25.0-mm (1-in.) material	1000 ± 50
63-mm (2 ½ in.) to 37.5-mm (1 ½ in.)	5000 ± 300
Consisting of:	
50-mm (2 in.) to 37.5-mm (1 ½-in.) material	2000 ± 200
63-mm (2 ½-in.) to 50-mm (2-in.) material	3000 ± 300
Larger sizes by nominal 12.5-mm (½-in.) spread in sieve size, each fraction	
Consisting of:	
75-mm (3-in.) to 63-mm (2 ½-in.) material	7000 ± 1000
90-mm (3 ½-in.) to 75-mm (3-in.) material	7000 ± 1000
100-mm (4-in.) to 90-mm (3 ½-in.) material	7000 ± 1000

6.4 When an aggregate to be tested contains appreciable amounts of both fine and coarse material, having a grading with more than 10 weight % coarser than the 9.5-mm (⅜-in.) sieve and, also, more than 10 weight % finer than the 4.75-mm (No. 4) sieve, test separate samples of the minus No. 4 fraction and the plus No. 4 fraction in accordance with the procedures for fine aggregate and coarse aggregate, respectively. Report the results separately for the fine-aggregate fraction and the coarse-aggregate fraction, giving the percentages of the coarse- and fine-size fractions in the initial grading.

7. Preparation of Test Sample

7.1 *Fine Aggregate*—Thoroughly wash the sample of fine aggregate on a 300-µm (No. 50) sieve, dry to constant weight at 230 ± 9 °F (110 ± 5 °C), and separate into the different sizes by sieving, as follows: Make a rough separation of the graded sample by means of a nest of the standard sieves specified in 6.2. From the fractions obtained in this manner, select samples of sufficient size to yield 100 g after sieving to refusal. (In general, a 110-g sample will be sufficient.) Do not use fine aggregate sticking in the meshes of the sieves in preparing the samples. Weigh samples consisting of 100 ± 0.1 g out of each of the separated fractions after final sieving and place in separate containers for the test.

7.2 *Coarse Aggregate*—Thoroughly wash and dry the sample of coarse aggregate to constant weight at 230 ± 9 °F (110 ± 5 °C) and separate it into the different sizes shown in 6.3 by sieving to refusal. Weigh out quantities of the different sizes within the tolerances of 6.3 and, where the test portion consists of two sizes, combine them to the designated total weight. Record the weights of the test samples and their fractional components. In the case of sizes larger than 19.0 mm (¾ in.), record the number of particles in the test samples.

8. Procedure

8.1 *Storage of Samples in Solution*—Immerse the samples in the prepared solution of sodium sulfate or magnesium sulfate for not less than 16 h nor more than 18 h in such a manner that the solution covers them to a depth of at least ½ in. (Note 6). Cover the containers to reduce evaporation and prevent the accidental addition of extraneous substances. Maintain the samples immersed in the solution at a temperature of 70 ± 2 °F (21 ± 1 °C) for the immersion period.

NOTE 6—Suitably weighted wire grids placed over the sample in the containers will permit this coverage to be achieved with very lightweight aggregates.

8.2 *Drying Samples After Immersion*—After the immersion period, remove the aggregate sample from the solution, permit it to drain for 15 ± 5 min, and place in the drying oven. The temperature of the oven shall have been brought previously to 230 ± 9 °F (110 ± 5 °C). Dry the samples at the specified temperature until constant weight has been achieved. Establish the time required to attain constant weight as follows: with the oven containing the maximum sample load expected, check the weight losses of test samples by removing and weighing them, without cooling, at intervals of 2 to 4 h; make enough checks to establish required drying time for the least favorable oven location (see 4.5) and sample condition (Note 7). Constant weight will be considered to have been achieved when weight loss is less than 0.1 % of sample weight in 4 h of drying. After constant weight has been achieved, allow the samples to cool to room temperature, when they shall again be immersed in the prepared solution as described in 8.1.

NOTE 7—Drying time required to reach constant weight may vary considerably for several reasons. Efficiency of drying will be reduced as cycles accumulate because of salt adhering to particles and, in some cases, because of increase in surface area due to breakdown. The different size fractions of aggregate will have differing drying rates. The smaller sizes will tend to dry more slowly because of their larger surface area and restricted interparticle voids, but this tendency may be altered by the effects of container size and shape.

8.3 *Number of Cycles*—Repeat the process of alternate immersion and drying until the required number of cycles is obtained.

8.4 After the completion of the final cycle and after the sample has cooled, wash the sample free from the sodium sulfate or magnesium sulfate as determined by the reaction of the wash water with barium chloride ($BaCl_2$). Wash by circulating water at 110 ± 10 °F (43 ± 6 °C) through the samples in their containers. This may be done by placing them in a tank into which the hot water can be introduced near the bottom and allowed to overflow. In the washing operation, the samples shall not be subjected to impact or abrasion that may tend to break up particles.

www.technobetar.ir

NOTE 8—Tap water containing sulfates when used for the wash water will cloud when tested with the barium chloride solution. The cloudiness of a solution of tap water and the barium chloride solution should be judged so that tested wash water with the same degree of cloudiness can be assumed to be free of sulfates from the test.

9. Quantitative Examination

9.1 Make the quantitative examination as follows:

9.1.1 After the sodium sulfate or magnesium sulfate has been removed, dry each fraction of the sample to constant weight at 230 ± 9 °F (110 ± 5 °C). Sieve the fine aggregate over the same sieve on which it was retained before the test, and sieve the coarse aggregate over the sieve shown below for the appropriate size of particle. For fine aggregate, the method and duration of sieving shall be the same as were used in preparing the test samples. For coarse aggregate, sieving shall be by hand, with agitation sufficient only to assure that all undersize material passes the designated sieve. No extra manipulation shall be employed to break up particles or cause them to pass the sieves. Weigh the material retained on each sieve and record each amount. The difference between each of these amounts and the initial weight of the fraction of the sample tested is the loss in the test and is to be expressed as a percentage of the initial weight for use in Table 1.

Size of Aggregate	Sieve Used to Determine Loss
100 mm (4 in.) to 90 mm (3 ½ in.)	75 mm (3 in.)
90 mm (3 ½ in.) to 75 mm (3 in.)	63 mm (2 ½ in.)
75 mm (3 in.) to 63 mm (2 ½ in.)	50 mm (2 in.)
63 mm (2 ½ in.) to 37.5 mm (1 ½ in.)	31.5 mm (1 ¼ in.)
37.5 mm (1 ½ in.) to 19.0 mm (¾ in.)	16.0 mm (⅝ in.)
19 mm (¾ in.) to 9.5 mm (⅜ in.)	8.0 mm (5⁄16 in.)
9.5 mm (⅜ in.) to 4.75 mm (No. 4)	4.0 mm (No. 5)

10. Qualitative Examination

10.1 Make a qualitative examination of test samples coarser than 19.0 mm (¾ in.) as follows (Note 9):

10.1.1 Separate the particles of each test sample into groups according to the action produced by the test (Note 9).

10.1.2 Record the number of particles showing each type of distress.

NOTE 9—Many types of action may be expected. In general, they may be classified as disintegration, splitting, crumbling, cracking, flaking, etc. While only particles larger than ¾ in. in size are required to be examined qualitatively, it is recommended that examination of the smaller sizes be made in order to determine whether there is any evidence of excessive splitting.

11. Report

11.1 Report the following data (Note 10):

11.1.1 Weight of each fraction of each sample before test,

11.1.2 Material from each fraction of the sample finer than the sieve designated in 9.1.1 for sieving after test, expressed as a percentage of the original weight of the fraction,

11.1.3 Weighted average calculated in accordance with Test Method C 136 from the percentage of loss for each fraction, based on the grading of the sample as received for examination or, preferably, on the average grading of the material from that portion of the supply of which the sample is representative except that:

11.1.3.1 For fine aggregates (with less than 10 % coarser than the 9.5-mm (⅜-in.) sieve), assume sizes finer than the 300-µm (No. 50) sieve to have 0 % loss and sizes coarser than the 9.5-mm (⅜-in.) sieve to have the same loss as the next smaller size for which test data are available.

TABLE 1 Suggested Form for Recording Test Data (with Illustrative Test Values)

Sieve Size			Grading of Original Sample, %	Weight of Test Fractions Before Test, g	Percentage Passing Designated Sieve After Test	Weighted Percentage Loss
Soundness Test of Fine Aggregate						
Minus 150 µm (No. 100)			6	...	...	...
300 µm (No. 50) to No. 100			11	...	...	...
600 µm (No. 30) to No. 50			26	100	4.2	1.1
1.18 mm (No. 16) to No. 30			25	100	4.8	1.2
2.36 mm (No. 8) to No. 16			17	100	8.0	1.4
4.75 mm (No. 4) to No. 8			11	100	11.2	1.2
9.5 mm (⅜ in.) to No. 4			4	...	11.2[A]	0.4
Totals			100.0	...	...	5
Soundness Test of Coarse Aggregate						
63 mm (2 ½ in.) to 50 mm (2 in.) 50 mm (2 in.) to 37.5 mm (1 ½ in.)	2825 *g* 1958 *g*	2 ½ to 1 ½ in.	20	4783	4.8	1.0
37.5 mm (1 ½ in.) to 25.0 mm (1 in.) 25 mm (1 in.) to 19.0 mm (¾ in.)	1012 *g* 513 *g*	1 ½ to ¾ in.	45	1525	8.0	3.6
19.0 mm (¾ in.) to 12.5 mm (½ in.) 12.5 mm (in.) to 9.5 mm (in.)	675 *g* 333 *g*	¾ to ⅜ in.	23	1008	9.6	2.2
9.5 mm (⅜ in.) to 4.75 mm (No. 4)	298 *g*		12	298	11.2	1.3
Totals			100	...	...	8

[A] The percentage loss (11.2 %) of the next smaller size is used as the percentage loss for this size, since this size contains less than 5 % of the original sample as received. See 11.1.3.4.

TABLE 2 Suggested Form for Qualitative Examination (with Illustrative Test Values)

Sieve Size	Qualitative Examination of Coarse Sizes								
	Particles Exhibiting Distress								
	Splitting		Crumbling		Cracking		Flaking		Total No. of Particles Before Test
	No.	%	No.	%	No.	%	No.	%	
63 mm (2 ½ in.) to 37.5 mm (1 ½ in.)	2	7	...	...	2	7	...	...	29
37.5 mm (1 ½ in.) to 19.0 mm (¾ in.)	5	10	1	2	4	8	...	...	50

11.1.3.2 For coarse aggregate (with less than 10 % finer than the 4.75-mm (No. 4) sieve), assume sizes finer than the 4.75-mm (No. 4) sieve to have the same loss as the next larger size for which test data are available.

11.1.3.3 For an aggregate containing appreciable amounts of both fine and coarse material tested as two separate samples as required in 6.4, compute the weighted average losses separately for the minus No. 4 and plus No. 4 fractions based on recomputed gradings considering the fine fraction as 100 % and the coarse fraction as 100 %. Report the results separately giving the percentage of the minus No. 4 and plus No. 4 material in the initial grading.

11.1.3.4 For the purpose of calculating the weighted average, consider any sizes in 6.2 or 6.3 that contain less than 5 % of the sample to have the same loss as the average of the next smaller and the next larger size, or if one of these sizes is absent, to have the same loss as the next larger or next smaller size, whichever is present.

11.1.4 Report the weighted percentage loss to the nearest whole number,

11.1.5 In the case of particles coarser than 19.0 mm (¾ in.) before test: (*1*) The number of particles in each fraction before test, and (*2*) the number of particles affected, classified as to number disintegrating, splitting, crumbling, cracking, flaking, etc., as shown in Table 2, and

11.1.6 Kind of solution (sodium or magnesium sulfate) and whether the solution was freshly prepared or previously used.

NOTE 10—Table 1, shown with test values inserted for purpose of illustration, is a suggested form for recording test data. The test values shown might be appropriate for either salt, depending on the quality of the aggregate.

12. Precision

12.1 *Precision*—For coarse aggregate with weighted average sulfate soundness losses in the ranges of 6 to 16 % for sodium and 9 to 20 % for magnesium, the precision indexes are as follows:

	Coefficient of Variation (1S %), %[A]	Difference Between Two Tests (D2S %), % of Average[A]
Multilaboratory:		
Sodium sulfate	41	116
Magnesium sulfate	25	71
Single-Operator:		
Sodium sulfate	24	68
Magnesium sulfate	11	31

[A] These numbers represent, respectively, the (1S %) and (D2S %) limits as described in Practice C 670.

12.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for this procedure, no statement on bias is being made.

13. Keywords

13.1 aggregates; magnesium sulfate; sodium sulfate; soundness; weathering

Designation: C 91 – 05

Standard Specification for Masonry Cement[1]

This standard is issued under the fixed designation C 91; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers three types of masonry cement for use where mortar for masonry is required.

1.2 The values stated in SI units are to be regarded as the standard. Values in SI units shall be obtained by measurement in SI units or by appropriate conversion of measurements made in other units, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10.

1.3 The text of this standard refers to notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 The following safety hazards caveat pertains only to Sections 16 and 17 of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 430 Test Method for Fineness of Hydraulic Cement by the 45-μm (No. 325) Sieve

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 778 Specification for Standard Sand

C 1506 Test Method for Water Retention of Hydraulic Cement-Based Mortars and Plasters

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Terminology

3.1 *Definitions:*

3.1.1 *masonry cement*—a hydraulic cement, primarily used in masonry and plastering construction, consisting of a mixture of portland or blended hydraulic cement and plasticizing materials (such as limestone, hydrated or hydraulic lime) together with other materials introduced to enhance one or more properties such as setting time, workability, water retention, and durability.

3.1.2 Other terms used in this specification are defined in Terminology C 219.

4. Classification

4.1 *Type N*—For use in preparation of Specification C 270 Type N mortar without further addition of cements or hydrated lime, and for use in preparation of Specification C 270 Type S

[1] This specification is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.11 on Masonry Cement.

Current edition approved September 15, 2005. Published October 2005. Originally approved in 1932. Last previous edition approved in 2003 as C 91 – 03a.

[2] *Annual Book of ASTM Standards*, Vol 04.01. See the section on Safety Precautions in the Manual of Cement Testing.

www.technobetar.ir

or Type M mortar when cement is added in accordance with the requirements of C 270.

4.2 *Type S*—For use in preparation of Specification C 270 Type S mortar without further addition of cements or hydrated lime.

4.3 *Type M*—For use in preparation of Specification C 270 Type M mortar without further addition of cements or hydrated lime.

5. Physical Properties

5.1 Masonry cement shall conform to the applicable requirements prescribed in Table 1 for its classification.

6. Sampling

6.1 The masonry cement shall be sampled in accordance with Practice C 183.

7. Temperature and Humidity

7.1 The temperature and relative humidity of the air in the vicinity of the mixing slab and dry materials, molds, base plates, and mixing bowl shall conform to the requirements of Test Method C 109/C 109M.

7.2 The moist cabinet or moist room shall conform to the requirements of Specification C 511.

8. Fineness

8.1 Determine the residue on the 45-μm (No. 325) sieve in accordance with Test Method C 430.

9. Normal Consistency

9.1 Determine normal consistency by the Vicat apparatus in accordance with Test Method C 187.

10. Autoclave Expansion

10.1 Determine autoclave expansion in accordance with Test Method C 151. After molding, store the bars in the moist cabinet or room for 48 h ± 30 min before removal from the molds for measurement and testing in the autoclave. Calculate the difference in length of the test specimen before and after autoclaving to the nearest 0.01 % of the effective gauge length and report as the autoclave expansion of the masonry cement.

11. Time of Setting

11.1 Determine the time of setting by the Gillmore needle method in accordance with Test Method C 266.

12. Density

12.1 Determine the density of the masonry cement in accordance with Test Method C 188, using kerosine as the liquid. Use the density so determined in the calculation of the air content of the mortars.

13. Blended Sand

13.1 The sand shall be a blend of equal parts by weight of graded standard sand and standard 20–30 sand conforming to Specification C 778.

14. Preparation of Mortar

14.1 *Proportions for Mortar*—Mortar for air entrainment, compressive strength, and water retention tests shall be proportioned to contain 1620 g of sand and a mass of cement, in grams, in accordance with Table 2. The sand shall consist of 810 g of graded standard sand and 810 g of 20–30 standard sand (Note 1). The quantity of water, measured in millilitres shall be such as to produce a flow of 110 ± 5 as determined by Test Method C 109/C 109M.

NOTE 1—Historically, field-mixed mortar has been proportioned by volume measured in increments or fractions of ft^3. The comparable whole SI-unit volume to 1 ft^3 is 28 L. The specified mortar proportions approximate the 1:3 nominal proportions by volume, commonly specified for construction, on the basis of the following assumed mass and volume relationships:

The mass of dry sand in 28 L of loose damp sand is 36 kg.
28 L Type N masonry cement has a mass of 32 kg.
28 L Type S masonry cement has a mass of 34 kg.
28 L Type M masonry cement has a mass of 36 kg.

For example, the amount of cement needed to provide a 1:3 volume proportion of cement to sand using a Type N masonry cement is as follows:

$$A = 1620 \times (C/B) = 1620 \times (32/108) = 480 \quad (1)$$

TABLE 1 Physical Requirements

Masonry Cement Type	N	S	M
Fineness, residue on a 45-μm (No. 325) sieve, max, %	24	24	24
Autoclave expansion, max, %	1.0	1.0	1.0
Time of setting, Gillmore method:			
Initial set, minutes, not less than	120	90	90
Initial set, minutes, not more than	1000	1000	1000
Compressive strength (average of 3 cubes): The compressive strength of mortar cubes, composed of 1 part cement and 3 parts blended sand (half graded standard sand, and half standard 20–30 sand) by volume, prepared and tested in accordance with this specification shall be equal to or higher than the values specified for the ages indicated below:			
7 days, MPa (psi)	3.4 (500)	9.0 (1300)	12.4 (1800)
28 days, MPa (psi)	6.2 (900)	14.5 (2100)	20.0 (2900)
Air content of mortar, prepared and tested in accordance with requirements of this specification:			
Min, volume %	8	8	8
Max, volume %	21	19	19
Water retention value, min, % of original flow	70	70	70

www.technobetar.ir

TABLE 2 Cement in Laboratory Batch of Mortar

Masonry Cement Type	Mass of Cement, g
N	480
S	510
M	540

where:

A = number of grams of cement to be used in the mortar with 1620 g of sand,

B = 3 × 36 = 108 kg, the mass of dry sand in 84 (or 3 × 28) L of loose damp sand, and

C = mass of Type N masonry cement per 28 L.

14.2 *Mixing of Mortars*—Mix the mortar in accordance with Practice C 305.

15. Air Entrainment

15.1 *Procedure*—If the mortar has the correct flow, use a separate portion of the mortar for the determination of entrained air. Determine the mass of 400 mL of mortar in accordance with Test Method C 185.

15.2 *Calculation*—Calculate the air content of the mortar and report it to the nearest 1 % as follows:

$$D = (W_1 + W_2 + V_w)/[(W_1/S_1) + (W_2/S_2) + V_w] \quad (2)$$

$$A = 100 - (W_m/4D)$$

where:

D = density of air-free mortar, g/cm^3,

W_1 = mass of cement, g,

W_2 = mass of sand, g,

V_w = millilitres-grams of water used,

S_1 = density of cement, g/cm^3

S_2 = density of standard sand, 2.65 g/cm^3,

A = volume percent of entrained air, and

W_m = mass of 400 mL of mortar, g.

16. Compressive Strength

16.1 *Test Specimens*:

16.1.1 *Molding*—Immediately after determining the flow and mass of 400 mL of mortar, return all of the mortar to the mixing bowl and remix for 15 s at the medium speed. Then mold the test specimens in accordance with Test Method C 109/C 109M, except that the elapsed time for mixing mortar, determining flow, determining air entrainment, and starting the molding of cubes shall be within 8 min.

16.1.2 *Storage*—Immediately after molding, store all test specimens in the molds on plane plates in a moist cabinet or moist room for 48 to 52 h in such a manner that the upper surfaces shall be exposed to the moist air. Then remove the cubes from the molds, and place them in the moist cabinet or moist room for 5 days in such a manner as to allow free circulation of air around at least five faces of the specimens. At the age of 7 days, immerse the cubes for the 28-day tests in saturated lime water in storage tanks of noncorrodible materials.

16.2 *Procedure*:

16.2.1 Test the cube specimens immediately after their removal from the moist cabinet or moist room for 7-day specimens, and immediately after their removal from storage water for all other specimens. If more than one specimen at a time is removed from the moist cabinet or moist room for 7-day tests, cover these cubes with a damp cloth until the time of testing.

16.2.2 The remainder of the testing procedure shall conform to Test Method C 109/C 109M.

17. Water Retention

17.1 Water retention shall be determined in accordance with the procedures in Test Method C 1506.

18. Storage

18.1 The cement shall be stored in such a manner as to permit easy access for the proper inspection and identification of each shipment, and in a suitable weathertight building that will protect the cement from dampness and minimize warehouse set.

19. Inspection

19.1 Every facility shall be provided to the purchaser for the necessary inspection and sampling.

19.2 All packages shall be in good condition at the time of inspection.

20. Rejection

20.1 At the option of the purchaser, the cement shall be rejected if it fails to meet any of the requirements of this specification.

20.2 At the option of the purchaser, packages more than 2 % below the mass marked thereon shall be rejected. At the option of the purchaser, the entire shipment represented shall be rejected if the average mass of packages in any shipment as shown by weighing fifty packages taken at random is less than that marked on the packages.

20.3 At the option of the purchaser, cement remaining in storage prior to shipment for a period greater than six months after testing shall be retested and, at the option of the purchaser shall be rejected if it fails to meet any of the requirements of this specification.

21. Manufacturer's Certification

21.1 Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at the time of shipment stating the results of the tests made on samples of the material taken during production or transfer and certifying that the applicable requirements of this specification have been met.

22. Packaging and Package Marking

22.1 When masonry cement is delivered in packages, the brand, name of the manufacturer, type of masonry cement, and net mass of the package in kilograms (see Note 2) shall be indicated plainly thereon. Similar information shall be provided in the shipping documents accompanying the shipment of masonry cement in bulk.

NOTE 2—To facilitate the change to SI units, a standard SI package size of 32 kg for Type N, 34 kg for Type S, and 36 kg for Type M will provide convenient mass increments reasonably similar to the traditional 70-, 75-, and 80-lb packages.

Designation: C94/C94M – 09a

Standard Specification for Ready-Mixed Concrete[1]

This standard is issued under the fixed designation C94/C94M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers ready-mixed concrete as defined in 3.2.2. Requirements for quality of concrete shall be either as hereinafter specified or as specified by the purchaser. In any case where the requirements of the purchaser differ from these in this specification, the purchaser's specification shall govern. This specification does not cover the placement, consolidation, curing, or protection of the concrete after delivery to the purchaser.

1.2 The values stated in either SI units, shown in brackets, or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 As used throughout this specification the manufacturer produces ready-mixed concrete. The purchaser buys ready-mixed concrete.

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.5 *This standard does not purport to address all the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged use.[2])

2.3 *Other Documents:*

Bureau of Reclamation Concrete Manual [5]

3. Terminology

3.1 *Definitions*:

The terms used in this specification are defined in Terminology C125.

3.2 Definitions of Terms Specific to This Standard:

3.2.1 *concrete, central-mixed*, *n*—concrete mixed completely in a stationary mixer.

3.2.2 *concrete, ready-mixed*, *n*—concrete manufactured and delivered to a purchaser in a fresh state.

3.2.3 *concrete, shrink-mixed*, *n*—concrete partially mixed in a stationary mixer with mixing completed in a truck mixer.

3.2.4 *concrete, truck-mixed*, *n*—concrete completely mixed in a truck mixer.

4. Basis of Purchase

4.1 The basis of purchase shall be a cubic yard or cubic metre of fresh concrete as discharged from the transportation unit.

4.2 The volume of fresh concrete in a given batch shall be determined from the total mass of the batch divided by the density of the concrete. The total mass of the batch shall be determined as the net mass of the concrete in the batch as delivered, including the total mixing water as defined in 9.3. The density shall be determined in accordance with Test Method C138/C138M. The yield shall be determined as the average of at least three measurements, one from each of three different transportation units sampled in accordance with Practice C172.

NOTE 1—It should be understood that the volume of hardened concrete may be, or appear to be, less than expected due to waste and spillage, over-excavation, spreading forms, some loss of entrained air, or settlement of wet mixtures, none of which are the responsibility of the producer.

[4] Available from American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333-9094, http://www.concrete.org.

[5] Available from Superintendent of Documents, U. S. Government Printing Office, Washington, DC 20402.

5. Materials

5.1 In the absence of designated applicable materials specifications, the following materials specifications shall be used:

5.2 *Cementitious Materials*

5.2.1 *Hydraulic Cement*—Hydraulic cement shall conform to Specification C150, Specification C595, or Specification C1157.

5.2.2 *Supplementary Cementitious Materials*—Coal fly ash or natural pozzolans shall conform to Specification C618. Ground granulated blast furnace slag shall conform to Specification C989. Silica fume shall conform to Specification C1240.

5.2.3 *Cementitious concrete mixtures*—Cementitious concrete mixtures shall contain the kind(s) and class(es) of hydraulic cement(s) and the kind(s) and class(es) of supplementary cementitious material(s) as specified by the purchaser. If hydraulic cement specification or type is not provided then the requirements of portland cement Type I or Type II conforming to Specification C150 shall apply or other cementitious materials that have a demonstrated ability to satisfy the intended use.

5.3 *Aggregates*—Normal weight aggregates shall conform to Specification C33. Lightweight aggregates shall conform to Specification C330 and heavyweight aggregates shall conform to Specification C637.

5.4 *Water*—Water shall conform to Specification C1602/C1602M.

5.5 *Air-Entraining Admixtures*—Air-entraining admixtures shall conform to Specification C260 (Note 2).

5.6 *Chemical Admixtures*—Chemical admixtures shall conform to either Specification C494/C494M or C1017/C1017M as applicable (Note 2).

NOTE 2—In any given instance, the required dosage of air-entraining, accelerating, and retarding admixtures may vary. Therefore, a range of dosages should be allowed which will permit obtaining the desired effect.

NOTE 3—Interchanging kinds, characteristics, types, classes, or grades of the materials permitted in ready-mixed concrete may produce concrete of different properties.

6. Ordering Information

6.1 In the absence of designated applicable general specifications, the purchaser shall specify the following:

6.1.1 Designated size, or sizes, of coarse aggregate,

6.1.2 Slump, or slumps, desired at the point of delivery (see Section 7 for acceptable tolerances),

6.1.3 Slump flow, or flows, desired at the point of delivery (see Section 7 for acceptable tolerances),

6.1.4 When air-entrained concrete is specified, the air content of the samples taken at the point of discharge from the transportation unit (see Section 8 and Table 1 for the total air content and tolerances) (Note 4),

6.1.5 Which of Options A, B, or C shall be used as a basis for determining the proportions of the concrete to produce the required quality,

6.1.6 When structural lightweight concrete is specified, the mass per unit volume as wet mass, air-dry mass, or oven-dry mass (Note 5), and

6.1.7 If desired, any of the optional requirements of Table 2 in Specification C1602/C1602M.

www.technobetar.ir

TABLE 1 Recommended Total Air Content for Air-Entrained Concrete[A,B]

Exposure Condition[C]	Total Air Content, % — Nominal Maximum Sizes of Aggregate, in. [mm]						
	⅜ [9.5]	½ [12.5]	¾ [19.0]	1 [25.0]	1½ [37.5]	2 [50.0]	3 [75.0]
Mild	4.5	4.0	3.5	3.0	2.5	2.0	1.5
Moderate	6.0	5.5	5.0	4.5	4.5	4.0	3.5
Severe	7.5	7.0	6.0	6.0	5.5	5.0	4.5

[A] For air-entrained concrete, when specified.
[B] Unless exposure conditions dictate otherwise, it is permissible to reduce air contents recommended above by up to 1 % for concretes with specified compressive strength, f'_c, of 5000 psi [35 MPa] or above.
[C] For description of exposure conditions, refer to Standard Practice ACI 211.1, Section 6.3.3, with attention to accompanying footnotes.

NOTE 4—In selecting the specified air content, the purchaser should consider the exposure conditions to which the concrete will be subjected. Air contents less than shown in Table 1 may not give the required resistance to freezing and thawing, which is the primary purpose of air-entrained concrete. Air contents higher than the levels shown may reduce strength without contributing any further improvement of durability.

NOTE 5—The mass per unit volume of fresh concrete, which is the only unit mass determinable at the time of delivery, is always higher than the air-dry or oven-dry mass. Definitions of, and methods for determining or calculating air-dry and oven-dry masses, are covered by Test Method C567.

6.2 *Option A*:

6.2.1 When the purchaser requires the manufacturer to assume full responsibility for the selection of the proportions for the concrete mixture (Note 6), the purchaser shall also specify the following:

6.2.1.1 Requirements for compressive strength as determined on samples taken from the transportation unit at the point of discharge evaluated in accordance with Section 18. The purchaser shall specify the requirements in terms of the compressive strength of standard specimens cured under standard laboratory conditions for moist curing (see Section 18). Unless otherwise specified the age at test shall be 28 days.

NOTE 6—The purchaser, in selecting requirements for which he assumes responsibility should give consideration to requirements for workability, placeability, durability, surface texture, and density, in addition to those for structural design. The purchaser is referred to Standard Practice ACI 211.1 and Standard Practice ACI 211.2 for the selection of proportions that will result in concrete suitable for various types of structures and conditions of exposure. The water-cement ratio of most structural lightweight concretes cannot be determined with sufficient accuracy for use as a specification basis.

6.2.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of the concrete, furnish a statement to the purchaser, giving the dry masses of cement and saturated surface-dry-masses of fine and coarse aggregate and quantities, type, and name of admixtures (if any) and of water per cubic yard or cubic metre of concrete that will be used in the manufacture of each class of concrete ordered by the purchaser. He shall also furnish evidence satisfactory to the purchaser that the materials to be used and proportions selected will produce concrete of the quality specified.

6.3 *Option B*:

6.3.1 When the purchaser assumes responsibility for the proportioning of the concrete mixture, he shall also specify the following:

6.3.1.1 Cement content in bags or pounds per cubic yard [kilograms per cubic metre] of concrete,

6.3.1.2 Maximum allowable water content in gallons per cubic yard [litres per cubic metre] of concrete, including surface moisture on the aggregates, but excluding water of absorption (Note 6), and

6.3.1.3 If admixtures are required, the type, name, and dosage to be used. The cement content shall not be reduced when admixtures are used under this option without the written approval of the purchaser.

6.3.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of the concrete, furnish a statement to the purchaser giving the sources, densities, and sieve analyses of the aggregates and the dry masses of cement and saturated-surface-dry masses of fine and coarse aggregate and quantities, type and name of admixture (if any) and of water per cubic yard or cubic metre of concrete that will be used in the manufacture of each class of concrete ordered by the purchaser.

6.4 *Option C*:

6.4.1 When the purchaser requires the manufacturer to assume responsibility for the selection of the proportions for the concrete mixture with the minimum allowable cement content specified (Note 7), the purchaser shall also specify the following:

6.4.1.1 Required compressive strength as determined on samples taken from the transportation unit at the point of discharge evaluated in accordance with Section 18. The purchaser shall specify the requirements for strength in terms of tests of standard specimens cured under standard laboratory conditions for moist curing (see Section 18). Unless otherwise specified the age at test shall be 28 days.

6.4.1.2 Minimum cement content in bags or pounds per cubic yard [kilograms per cubic metre] of concrete.

6.4.1.3 If admixtures are required, the type, name, and dosage to be used. The cement content shall not be reduced when admixtures are used.

NOTE 7—Option C can be distinctive and useful only if the designated minimum cement content is at about the same level that would ordinarily be required for the strength, aggregate size, and slump or slump flow specified. At the same time, it must be an amount that will be sufficient to ensure durability under expected service conditions, as well as satisfactory surface texture and density, in the event specified strength is attained with it. For additional information refer to Standard Practice ACI 211.1 and Standard Practice 211.2 referred to in Note 6.

6.4.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of the concrete, furnish a statement to the purchaser, giving the dry masses of cement and saturated surface-dry masses of fine and coarse aggregate and quantities,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:09 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

type, and name of admixture (if any) and of water per cubic yard or cubic metre of concrete that will be used in the manufacture of each class of concrete ordered by the purchaser. He shall also furnish evidence satisfactory to the purchaser that the materials to be used and proportions selected will produce concrete of the quality specified. Whatever strengths are attained the quantity of cement used shall not be less than the minimum specified.

6.5 The proportions arrived at by Options A, B, or C for each class of concrete and approved for use in a project shall be assigned a designation to facilitate identification of each concrete mixture delivered to the project. This is the designation required in 14.1.7 and supplies information on concrete proportions when they are not given separately on each delivery ticket as outlined in 14.2. A certified copy of all proportions as established in Options A, B, or C shall be on file at the batch plant.

6.6 The purchaser shall ensure that the manufacturer is provided copies of all reports of tests performed on concrete samples taken to determine compliance with specification requirements. Reports shall be provided on a timely basis.

7. Tolerances in Slump or Slump Flow

7.1 Unless other tolerances are included in the project specifications, the following shall apply.

7.1.1 When the project specifications for slump are written as a "maximum" or "not to exceed" requirement:

	Specified slump:	
	If 3 in. [75 mm] or less	If more than 3 in. [75 mm]
Plus tolerance:	0	0
Minus tolerance:	1½ in. [40 mm]	2½ in. [65 mm]

This option is to be used only if one addition of water is permitted on the job provided such addition does not increase the water-cement ratio above the maximum permitted by the specifications.

7.1.2 When the project specifications for slump are *not* written as a "maximum" or "not to exceed" requirement:

Tolerances for Nominal Slumps

For Specified Slump of:	Tolerance
2 in. [50 mm] and less	±½ in. [15 mm]
More than 2 through 4 in. [50 to 100 mm]	±1 in. [25 mm]
More than 4 in. [100 mm]	±1½ in. [40 mm]

7.1.3 When the project specifications indicate a slump flow requirement for self-consolidating concrete:

Tolerances for Slump Flow

For Specified Slump Flow	Tolerance
Less than or equal to 22 in. [550 mm]	± 1 ½ in. [40 mm]
More than 22 in [550 mm]	± 2 ½ in. [65 mm]

7.2 Concrete shall be available within the permissible range of slump or slump flow for a period of 30 min starting either on arrival at the job site or after the initial slump adjustment permitted in 12.7, whichever is later. The first and last ¼ yd^3 or ¼ m^3 discharged are exempt from this requirement. If the user is unprepared for discharge of the concrete from the vehicle, the producer shall not be responsible for the limitation of minimum slump or slump flow after 30 min have elapsed starting either on arrival of the vehicle at the prescribed destination or at the requested delivery time, whichever is later.

8. Air-Entrained Concrete

8.1 When air-entrained concrete is desired the purchaser shall specify the total air content of the concrete. See Table 1 for recommended total air contents (Note 2).

8.2 The air content of air-entrained concrete when sampled from the transportation unit at the point of discharge shall be within a tolerance of ± 1.5 of the specified value.

8.3 When a preliminary sample taken within the time limits of 12.7 and prior to discharge for placement shows an air content below the specified level by more than the allowable tolerance in accordance with 8.2, the manufacturer may use additional air entraining admixture to achieve the desired air content level, followed by a minimum of 30 revolutions at mixing speed, so long as the revolution limit of 12.7 is not exceeded (see Note 8).

NOTE 8—Acceptance sampling and testing in accordance with Practice C172 is not obviated by this provision.

9. Measuring Materials

9.1 Except as otherwise specifically permitted, cementitious materials shall be measured by mass. When supplementary cementitious materials are used in the concrete mixtures, the cumulative mass is permitted to be measured with hydraulic cement, but in a batch hopper and on a scale which is separate and distinct from those used for other materials. The mass of the hydraulic cement shall be measured before supplementary cementitious materials. When the quantity of cementitious material exceeds 30 % of the full capacity of the scale, the measured quantity of the hydraulic cement shall be within ± 1 % of the required mass, and the cumulative measured quantity of hydraulic cement plus supplementary cementitious materials shall also be within ± 1 % of the required cumulative mass at each intermediate weighing. For smaller batches to a minimum of 1 yd^3 [1 m^3], the measured quantity of the hydraulic cement and the measured cumulative quantity of hydraulic cement plus supplementary cementitious materials used shall be not less than the required amount nor more than 4 % in excess. Under special circumstances approved by the purchaser, hydraulic cement is permitted to be measured in bags of standard mass (Note 9). No fraction of a bag of hydraulic cement shall be used unless its mass has been determined.

NOTE 9—In the United States the standard mass of a bag of portland cement is 94 lb [42.6 kg] ± 3 %.

9.2 Aggregate shall be measured by mass. Batch mass measurements shall be based on dry materials and shall be the required masses of dry materials plus the total mass of moisture (both absorbed and surface) contained in the aggregate. The quantity of aggregate used in any batch of concrete as indicated by the scale shall be within ±2 % of the required mass when the mass is measured in individual aggregate weigh batchers. In a cumulative aggregate weigh batcher, the cumulative weight after each successive weighing shall be within ±1 % of the required cumulative amount up to that point when the scale is used in excess of 30 % of its capacity. For cumulative

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:09 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

weights for less than 30 % of scale capacity, the tolerance shall be ±0.3 % of scale capacity or ±3 % of the required cumulative weight, whichever is less.

9.3 Mixing water shall consist of water added to the batch, ice added to the batch, water occurring as surface moisture on the aggregates, and water introduced in the form of admixtures. The added water shall be measured by weight or volume to an accuracy of 1 % of the required total mixing water. Added ice shall be measured by weight. In the case of truck mixers, any wash water retained in the drum for use in the next batch of concrete shall be accurately measured; if this proves impractical or impossible the wash water shall be discharged prior to loading the next batch of concrete. Total water (including any wash water) shall be measured or weighed to an accuracy of ±3 % of the specified total amount.

9.4 Chemical admixtures in powdered form shall be measured by mass. Liquid chemical admixtures shall be batched by mass or volume. Admixtures measured by either mass or volume, shall be batched with an accuracy of ±3 % of the total amount required or plus or minus the amount or dosage required for 100 lb [50 kg] of hydraulic cement, whichever is greater.

NOTE 10—Admixture dispensers of the mechanical type capable of adjustment for variation of dosage, and of simple calibration, are recommended.

10. Batching Plant

10.1 Bins with adequate separate compartments shall be provided in the batching plant for fine and for each required size of coarse aggregate. Each bin compartment shall be designed and operated so as to discharge efficiently and freely, with minimum segregation, into the weighing hopper. Means of control shall be provided so that, as the quantity desired in the weighing hopper is approached, the material shall be shut off with precision. Weighing hoppers shall be constructed so as to eliminate accumulations of tare materials and to discharge fully.

10.2 Indicating devices shall be in full view and near enough to be read accurately by the operator while charging the hopper. The operator shall have convenient access to all controls.

10.3 Scales shall be considered accurate when at least one static load test within each quarter of the scale capacity can be shown to be within ±0.15 % of the total capacity of the scale or 0.4 % of the net applied load, whichever is greater.

10.4 Adequate standard test weights shall be available for checking accuracy. All exposed fulcrums, clevises, and similar working parts of scales shall be kept clean. Beam scales shall be equipped with a balance indicator sensitive enough to show movement when a weight equal to 0.1 % of the nominal capacity of the scale is placed in the batch hopper. Pointer travel shall be a minimum of 5 % of the net-rated capacity of the largest weigh beam for underweight and 4 % for overweight.

10.5 The device for the measurement of the added water shall be capable of delivering to the batch the quantity required within the accuracy required in 9.3. The device shall be so arranged that the measurements will not be affected by variable pressures in the water supply line. Measuring tanks shall be equipped with outside taps and valves to provide for checking their calibration unless other means are provided for readily and accurately determining the amount of water in the tank.

NOTE 11—The scale accuracy limitations of the National Ready Mixed Concrete Association Plant Certification meet the requirements of this specification.

11. Mixers and Agitators

11.1 Mixers will be stationary mixers or truck mixers. Agitators will be truck mixers or truck agitators.

11.1.1 Stationary mixers shall be equipped with a metal plate or plates on which are plainly marked the mixing speed of the drum or paddles, and the maximum capacity in terms of the volume of mixed concrete. When used for the complete mixing of concrete, stationary mixers shall be equipped with an acceptable timing device that will not permit the batch to be discharged until the specified mixing time has elapsed.

11.1.2 Each truck mixer or agitator shall have attached thereto in a prominent place a metal plate or plates on which are plainly marked the gross volume of the drum, the capacity of the drum or container in terms of the volume of mixed concrete, and the minimum and maximum mixing speeds of rotation of the drum, blades, or paddles. When the concrete is truck mixed as described in 12.5, or shrink mixed as described in 12.4, the volume of mixed concrete shall not exceed 63 % of the total volume of the drum or container. When the concrete is central mixed as described in 12.3, the volume of concrete in the truck mixer or agitator shall not exceed 80 % of the total volume of the drum or container. Truck mixers and agitators shall be equipped with means to readily verify the number of revolutions of the drum, blades, or paddles.

11.2 All stationary and truck mixers shall be capable of combining the ingredients of the concrete within the specified time or the number of revolutions specified in 11.5, into a thoroughly mixed and uniform mass and of discharging the concrete so that not less than five of the six requirements shown in Table A1.1 shall have been met.

NOTE 12—The sequence or method of charging the mixer will have an important effect on the uniformity of the concrete.

11.3 The agitator shall be capable of maintaining the mixed concrete in a thoroughly mixed and uniform mass and of discharging the concrete with a satisfactory degree of uniformity as defined by Annex A1.

11.4 Slump tests of individual samples taken after discharge of approximately 15 % and 85 % of the load will provide a quick check of the probable degree of uniformity (Note 13). These two samples shall be obtained within an elapsed time of not more than 15 min. If these slumps differ more than that specified in Annex A1, the mixer or agitator shall not be used unless the condition is corrected, except as provided in 11.5.

NOTE 13—No samples should be taken before 10 % or after 90 % of the batch has been discharged. Due to the difficulty of determining the actual quantity of concrete discharged, the intent is to provide samples that are representative of widely separated portions, but not the beginning and end of the load.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11.5 Use of the equipment is permitted when operation with a longer mixing time, a smaller load, or a more efficient charging sequence will permit the requirements of Annex A1 to be met.

11.6 Mixers and agitators shall be examined or their mass determined as frequently as necessary to detect changes in condition due to accumulations of hardened concrete or mortar and examined to detect wear of blades. When such changes are extensive enough to affect the mixer performance, the proof-tests described in Annex A1 shall be performed to show whether the correction of deficiencies is required.

12. Mixing and Delivery

12.1 Ready-mixed concrete shall be mixed and delivered to the point designated by the purchaser by means of one of the following combinations of operations:

12.1.1 *Central-Mixed Concrete*.

12.1.2 *Shrink-Mixed Concrete*.

12.1.3 *Truck-Mixed Concrete*.

12.2 Mixers and agitators shall be operated within the limits of capacity and speed of rotation designated by the manufacturer of the equipment.

12.3 *Central-Mixed Concrete*—Concrete that is mixed completely in a stationary mixer and transported to the point of delivery either in a truck agitator, or a truck mixer operating at agitating speed, or in nonagitating equipment approved by the purchaser and meeting the requirements of Section 13, shall conform to the following: The mixing time shall be counted from the time all the solid materials are in the drum. The batch shall be so charged into the mixer that some water will enter in advance of the cement and aggregate, and all water shall be in the drum by the end of the first one fourth of the specified mixing time.

12.3.1 Where no mixer performance tests are made, the acceptable mixing time for mixers having capacities of 1 yd^3 [0.76 m^3] or less shall be not less than 1 min. For mixers of greater capacity, this minimum shall be increased 15 s for each cubic yard [cubic metre] or fraction thereof of additional capacity (See Note 14).

NOTE 14—Stationary mixers of similar design bearing a Performance Rated plate of the Concrete Plant Manufacturers Bureau have been tested to produce uniformly mixed concrete in accordance with Annex A1 for low slump (< 2 in. [50 mm]) and normal slump (4–6 in. [100–150 mm]) concrete in a mixing time between 30 and 90 sec.

12.3.2 Where mixer performance tests have been made on given concrete mixtures in accordance with the testing program set forth in the following paragraphs, and the mixers have been charged to their rated capacity, the acceptable mixing time is permitted to be reduced for those particular circumstances to a point at which satisfactory mixing defined in 12.3.3 shall have been accomplished. When the mixing time is so reduced the maximum time of mixing shall not exceed this reduced time by more than 60 s for air-entrained concrete.

12.3.3 *Sampling for Uniformity Tests of Stationary Mixers*—Samples of concrete for comparative purposes shall be obtained immediately after arbitrarily designated mixing times, in accordance with one of the following procedures:

12.3.3.1 *Alternative Procedure 1*—The mixer shall be stopped, and the required samples removed by any suitable means from the concrete at approximately equal distances from the front and back of the drum, or

12.3.3.2 *Alternative Procedure 2*—As the mixer is being emptied, individual samples shall be taken after discharge of approximately 15 % and 85 % of the load. The method of sampling shall provide that the samples are representative of widely separated portions, but not from the very ends of the batch (Note 13).

12.3.3.3 The samples of concrete shall be tested in accordance with Section 18, and differences in test results for the two samples shall not exceed those given in Annex A1. Mixer performance tests shall be repeated whenever the appearance of the concrete or the coarse aggregate content of samples selected as outlined in this section indicates that adequate mixing has not been accomplished.

12.4 *Shrink-Mixed Concrete*—Concrete that is first partially mixed in a stationary mixer, and then mixed completely in a truck mixer, shall conform to the following: The time of partial mixing shall be minimum required to intermingle the ingredients. After transfer to a truck mixer the amount of mixing at the designated mixing speed will be that necessary to meet the requirements for uniformity of concrete as indicated in Annex A1. Tests to confirm such performance shall be made in accordance with 12.3.3 and 12.3.3.3. Additional turning of the mixer, if any, shall be at a designated agitating speed.

12.5 *Truck-Mixed Concrete*—Concrete that is completely mixed in a truck mixer, 70 to 100 revolutions at the mixing speed designated by the manufacturer to produce the uniformity of concrete indicated in Annex A1 (see Note 15). Concrete uniformity tests shall be made in accordance with 12.5.1 and if requirements for uniformity of concrete indicated in Annex A1 are not met with 100 revolutions of mixing, after all ingredients including water, are in the drum, that mixer shall not be used until the condition is corrected, except as provided in 11.5. When satisfactory performance is found in one truck mixer, the performance of mixers of substantially the same design and condition of blades are permitted to be regarded as satisfactory. Additional revolutions of the mixer beyond the number found to produce the required uniformity of concrete shall be at a designated agitating speed.

NOTE 15—Truck mixers of similar design bearing a Performance Rated plate of the Truck Mixer Manufacturers Bureau have been tested to produce uniformly mixed concrete in accordance with Annex A1.

12.5.1 *Sampling for Uniformity of Concrete Produced in Truck Mixers*—The concrete shall be discharged at the normal operating rate for the mixer being tested, with care being exercised not to obstruct or retard the discharge by an incompletely opened gate or seal. Separate samples, each consisting of approximately 2 ft^3 [0.1 m^3 approximately] shall be taken after discharge of approximately 15 % and 85 % of the load (Note 13). These samples shall be obtained within an elapsed time of not more than 15 min. The samples shall be secured in accordance with Practice C172, but shall be kept separate to represent specific points in the batch rather than combined to form a composite sample. Between samples, where necessary to maintain slump, the mixer shall be turned in mixing

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

direction at agitating speed. During sampling the receptacle shall receive the full discharge of the chute. Sufficient personnel must be available to perform the required tests promptly. Segregation during sampling and handling must be avoided. Each sample shall be remixed the minimum amount to ensure uniformity before specimens are molded for a particular test.

12.6 When a truck mixer or truck agitator is used for transporting concrete that has been completely mixed in a stationary mixer, any turning during transportation shall be at the speed designated by the manufacturer of the equipment as agitating speed.

12.7 For truck mixers satisfying the requirements of 11.5 for mixing concrete, no water from the truck water system or elsewhere shall be added after the initial introduction of mixing water for the batch except when on arrival at the job site the slump or slump flow of the concrete is less than that specified. If the desired slump or slump flow is less than specified, and unless otherwise stated, obtain the desired slump or slump flow within the tolerances stated in 7.1.1, 7.1.2, or 7.1.3 with a one-time addition of water. Do not exceed the maximum water content for the batch as established by the designed mixture proportion. A one-time addition of water is not prohibited from being several distinct additions of water provided that no concrete has been discharged except for slump or slump flow testing. All water additions shall be completed within 15 min from the start of the first water addition. Such additional water shall be injected into the mixer under such pressure and direction of flow to allow for proper distribution within the mixer. The drum shall be turned an additional 30 revolutions, or more if necessary, at mixing speed to ensure that a homogenous mixture is attained. Water shall not be added to the batch at any later time. Discharge of the concrete shall be completed within 1½ h, or before the drum has revolved 300 revolutions, whichever comes first, after the introduction of the mixing water to the cement and aggregates or the introduction of the cement to the aggregates. These limitations are permitted to be waived by the purchaser if the concrete is of such slump or slump flow after the 1½-h time or 300-revolution limit has been reached that it can be placed, without the addition of water, to the batch. In hot weather, or under conditions contributing to quick stiffening of the concrete, a time less than 1½ h is permitted to be specified by the purchaser.

12.8 Concrete delivered in cold weather shall have the applicable minimum temperature indicated in the following table. (The purchaser shall inform the producer as to the type of construction for which the concrete is intended.)

Minimum Concrete Temperature as Placed

Section Size, in. [mm]	Temperature, min, °F [°C]
<12 [<300]	55 [13]
12–36 [300–900]	50 [10]
36–72 [900–1800]	45 [7]
>72 [>1800]	40 [5]

The maximum temperature of concrete produced with heated aggregates, heated water, or both, shall at no time during its production or transportation exceed 90 °F [32 °C].

NOTE 16—When hot water is used rapid stiffening may occur if hot water is brought in direct contact with the cement. Additional information on cold weather concreting is contained in ACI 306R.

12.9 The producer shall deliver the ready mixed concrete during hot weather at concrete temperatures as low as practicable, subject to the approval of the purchaser.

NOTE 17—In some situations difficulty may be encountered when concrete temperatures approach 90 °F [32 °C]. Additional information may be found in the Bureau of Reclamation Concrete Manual and in ACI 305R.

13. Use of Nonagitating Equipment

13.1 When the use of non-agitating transportation equipment is approved by the purchaser, the concrete shall be manufactured in a central mix plant. The proportions of the concrete shall be approved by the purchaser and the following limitations shall apply:

13.2 Bodies of nonagitating equipment shall be smooth, watertight, metal containers equipped with gates that will permit control of the discharge of the concrete. Covers shall be provided for protection against the weather when required by the purchaser.

13.3 The concrete shall be delivered to the site of the work in a thoroughly mixed and uniform mass and discharged with a satisfactory degree of uniformity as prescribed in Annex A1.

13.4 Slump tests of individual samples taken after discharge of approximately 15 % and 85 % of the load will provide for a quick check of the probable degree of uniformity (Note 13). These two samples shall be obtained within an elapsed time of not more than 15 min. If these slumps differ more than that specified in Table A1.1, the nonagitating equipment shall not be used unless the conditions are corrected as provided in 13.5.

13.5 If the requirements of Annex A1 are not met when the nonagitating equipment is operated for the maximum time of haul, and with the concrete mixed the minimum time, the equipment shall only be used when operated using shorter hauls, or longer mixing times, or combinations thereof that will result in the requirements of Annex A1 being met.

14. Batch Ticket Information

14.1 The manufacturer of the concrete shall furnish to the purchaser with each batch of concrete before unloading at the site, a delivery ticket on which is printed, stamped, or written, information concerning said concrete as follows:

14.1.1 Name of ready-mix company and batch plant, or batch plant number,

14.1.2 Serial number of ticket,

14.1.3 Date,

14.1.4 Truck number,

14.1.5 Name of purchaser,

14.1.6 Specific designation of job (name and location),

14.1.7 Specific class or designation of the concrete in conformance with that employed in job specifications,

14.1.8 Amount of concrete in cubic yards (or cubic metres),

14.1.9 Time loaded or of first mixing of cement and aggregates, and

14.1.10 Water added by receiver of concrete and his initials.

14.2 Additional information for certification purposes as designated by the purchaser and required by the job specifications shall be furnished when requested; such information as:

14.2.1 Reading of revolution counter at the first addition of water,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:09 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

14.2.2 Type, brand, and amount of cement,

14.2.3 Class, brand, and amount of coal fly ash, or raw or calcined natural pozzolans,

14.2.4 Grade, brand, and amount of ground granulated blast-furnace slag,

14.2.5 Type, brand, and amount of silica fume,

14.2.6 Type, brand, and amount of admixtures

14.2.7 Type, brand, and amount of fiber reinforcement,

14.2.8 Source and amount of each metered or weighed water or recycled slurry,

14.2.9 Information necessary to calculate the total mixing water. Total mixing water includes free water on aggregates, batch water (metered or weighed) including ice batched at the plant, wash water retained in the mixing drum, and water added by the truck operator from the mixer tank,

14.2.10 Maximum size of aggregate,

14.2.11 Mass (amount) of fine and coarse aggregate,

14.2.12 Ingredients certified as being previously approved, and

14.2.13 Signature or initials of producer's representative.

15. Plant Inspection

15.1 The manufacturer shall afford the inspector all reasonable access, without charge, for making necessary checks of the production facilities and for securing necessary samples to determine if the concrete is being produced in accordance with this specification. All tests and inspection shall be so conducted as not to interfere unnecessarily with the manufacture and delivery of concrete.

16. Practices, Test Methods, and Reporting

16.1 Test ready-mixed concrete in accordance with the following methods:

16.1.1 *Compression Test Specimens*—Practice C31/C31M, using standard moist curing in accordance with the applicable provisions of Practice C31/C31M.

16.1.2 *Compression Tests*—Test Method C39/C39M.

16.1.3 *Yield, Mass per Cubic Foot*—Test Method C138/C138M.

16.1.4 *Air Content*—Test Method C138/C138M; Test Method C173/C173M or Test Method C231.

16.1.5 *Slump*—Test Method C143/C143M.

16.1.6 *Slump Flow*—Test Method C1611/C1611M.

16.1.7 *Sampling Fresh Concrete*—Practice C172.

16.1.8 *Temperature*—Test Method C1064/C1064M.

16.2 The testing laboratory performing acceptance tests of concrete shall meet the requirements of Practice C1077.

16.3 Laboratory reports of concrete test results used to determine compliance with this specification shall include a statement that all tests performed by the laboratory or its agents were in accordance with the applicable test methods or shall note all known deviations from the prescribed procedures (Note 18). The reports shall also list any part of the test methods not performed by the laboratory.

NOTE 18—Deviation from standard test methods may adversely affect test results.

NOTE 19—Deviation from standard moisture and temperature curing conditions is often a reason for low strength test results. Such deviations may invalidate the use of such test results as a basis for rejection of the concrete.

17. Sampling and Testing Fresh Concrete

17.1 The contractor shall afford the inspector all reasonable access and assistance, without charge, for the procurement of samples of fresh concrete at time of placement to determine conformance of it to this specification.

17.2 Tests of concrete required to determine compliance with this specification shall be made by a certified ACI Concrete Field Testing Technician, Grade I or equivalent. Equivalent personnel certification programs shall include both written and performance examinations as outlined in ACI CP-1.

17.3 Samples of concrete shall be obtained in accordance with Practice C172, except when taken to determine uniformity of slump within any one batch or load of concrete (11.4, 12.3.3, 12.5.1, and 13.4).

17.4 Slump or slump flow, air-content, density, and temperature tests shall be made at the time of placement at the option of the inspector as often as is necessary for control checks. In addition, these tests shall be made when specified and always when strength specimens are made.

17.5 Strength tests as well as slump or slump flow, temperature, density, and air content tests shall generally be made with a frequency of not less than one test for each 150 yd^3 (115 m^3). Each test shall be made from a separate batch. On each day concrete is delivered, at least one strength test shall be made for each class of concrete.

17.6 If preliminary checks of slump, slump flow, or air content are made, a single sample shall be taken after the discharge of not less than ¼ yd^3 or ¼ m^3. All other requirements of Practice C172 shall be retained. If the preliminary measurement of slump (12.7) or air content (8.3) falls outside the specified limits, address as indicated in section 17.6.1 or 17.6.2 as appropriate.

17.6.1 If the measured slump or slump flow, or air content, or both is greater than the specified upper limit, a check test shall be made immediately on a new test sample. In the event the check test fails, the concrete shall be considered to have failed the requirements of the specification.

17.6.2 If the measured slump or slump flow, or air content, or both is less than the lower limit, permit adjustments in accordance with 12.7 or 8.3 or both, as appropriate, and obtain a new sample. If the sample of the adjusted concrete fails, a check test shall be made immediately on a new sample of the adjusted concrete. In the event the check test fails, the concrete shall be considered to have failed the requirements of the specification.

18. Strength

18.1 When strength is used as a basis for acceptance of concrete, standard specimens shall be made in accordance to Practice C31/C31M. The specimens shall be cured under standard moisture and temperature conditions in accordance with the applicable provisions of Practice C31/C31M. The technician performing the strength test shall be certified as an

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:09 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

ACI Concrete Strength Testing Technician, Concrete Laboratory Testing Technician—Grade II or by an equivalent written and performance test program covering the relevant test methods. If acceptance is based upon compressive strength test results, the certification requirement is satisfied by certification as an ACI Concrete Laboratory Testing Technician—Grade I or by an equivalent written and performance test program.

18.2 For a strength test, at least two standard test specimens shall be made from a composite sample secured as required in Section 17. A test shall be the average of the strengths of the specimens tested at the age specified in 6.2.1.1 or 6.4.1.1 (Note 20). If a specimen shows definite evidence other than low strength, of improper sampling, molding, handling, curing, or testing, it shall be discarded and the strength of the remaining cylinder shall then be considered the test result.

NOTE 20—Additional tests may be made at other ages to obtain information for determining form removal time or when a structure may be put in service. Specimens for such tests are cured according to the section on Field Curing in Practice C31/C31M.

18.3 The representative of the purchaser shall ascertain and record the delivery-ticket number for the concrete and the exact location in the work at which each load represented by a strength test is deposited.

18.4 To conform to the requirements of this specification, strength tests representing each class of concrete must meet the following two requirements (Note 21):

18.4.1 The average of any three consecutive strength tests shall be equal to, or greater than, the specified strength, f'_c, and

18.4.2 When the specified strength is 5000 psi [35 MPa] or less, no individual strength test (average of two cylinder tests) shall be more than 500 psi [3.5 MPa] below the specified strength, f'_c.

NOTE 21—Due to variations in materials, operations, and testing, the average strength necessary to meet these requirements will be substantially higher than the specified strength. The amount higher depends upon the standard deviation of the test results and the accuracy with which that value can be estimated from prior data as explained in ACI 318 and ACI 301. Pertinent data are given in Appendix X1.

18.4.3 When the specified strength is greater than 5000 psi [35 MPa], no individual strength test (average of two cylinder tests) shall be less than 0.90 f'_c.

19. Failure to Meet Strength Requirements

19.1 In the event that concrete tested in accordance with the requirements of Section 18 fails to meet the strength requirements of this specification, the manufacturer of the ready-mixed concrete and the purchaser shall confer to determine whether agreement can be reached as to what adjustment, if any, shall be made. If an agreement on a mutually satisfactory adjustment cannot be reached by the manufacturer and the purchaser, a decision shall be made by a panel of three qualified engineers, one of whom shall be designated by the purchaser, one by the manufacturer, and the third chosen by these two members of the panel. The question of responsibility for the cost of such arbitration shall be determined by the panel. Its decision shall be binding, except as modified by a court decision.

ANNEX

(Mandatory Information)

A1. CONCRETE UNIFORMITY REQUIREMENTS

A1.1 The variation within a batch as provided in Table A1.1 shall be determined for each property listed as the difference between the highest value and the lowest value obtained from the different portions of the same batch. For this specification the comparison will be between two samples, representing the first and last portions of the batch being tested. Test results

TABLE A1.1 Requirements for Uniformity of Concrete

Test	Requirement, Expressed as Maximum Permissible Difference in Results of Tests of Samples Taken from Two Locations in the Concrete Batch
Mass per cubic foot [mass per cubic meter] calculated to an air-free basis, lb/ft^3[kg/m^3]	1.0 [16]
Air content, volume % of concrete	1.0
Slump:	
If average slump is 4 in. [100 mm] or less, in. [mm]	1.0 [25]
If average slump is 4 to 6 in. [100 to 150 mm], in. [mm]	1.5 [40]
Coarse aggregate content, portion by mass of each sample retained on No. 4 [4.75-mm] sieve, %	6.0
Mass per unit volume of air-free mortar[A] based on average for all comparative samples tested, %.	1.6
Average compressive strength at 7 days for each sample,[B] based on average strength of all comparative test specimens, %	7.5[C]

[A] "Test for Variability of Constituents in Concrete," Designation 26, *Bureau of Reclamation Concrete Manual,* 7th Edition.[5]
[B] Not less than 3 cylinders will be molded and tested from each of the samples.
[C] Approval of the mixer shall be tentative, pending results of the 7-day compressive strength tests.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

conforming to the limits of five of the six tests listed in Table A1.1 shall indicate uniform concrete within the limits of this specification.

A1.2 *Coarse Aggregate Content,* using the washout test, shall be computed from the following relations:

$$P = (c/b) \times 100 \quad \text{(A1.1)}$$

where:

P = mass % of coarse aggregate in concrete,
c = saturated-surface-dry mass in lb [kg] of aggregate retained on the No. 4 [4.75-mm] sieve, resulting from washing all material finer than this sieve from the fresh concrete, and
b = mass of sample of fresh concrete in mass per unit volume container, lb [kg].

A1.3 *Mass per Unit Volume of Air Free Mortar* shall be calculated as follows:

Inch-pound units:

$$M = \frac{b - c}{V - \left(\frac{V \times A}{100} + \frac{c}{G}\right)} \quad \text{(A1.2)}$$

SI units:

$$M = \frac{b - c}{V - \left(\frac{V \times A}{100} + \frac{c}{G}\right)} \quad \text{(A1.3)}$$

where:

M = mass per unit volume of air-free mortar, lb/ft^3 [kg/m^3],
b = mass of concrete sample in mass container, lb [kg],
c = saturated-surface-dry mass of aggregate retained on No. 4 [4.75-mm] sieve, lb [kg],
V = volume of mass per unit volume container, ft^3 [m^3],
A = air content of concrete, %, measured in accordance with 16.1.4 on the sample being tested, and
G = density of coarse aggregate (SSD).

APPENDIX

(Nonmandatory Information)

X1. Calculation of the Average Compressive Strength (f'_{cr}), Necessary to Meet the Strength Requirements of Sections 18.4.1, 18.4.2, and 18.4.3

X1.1 Section 18.4 of this specification contains the same strength requirements as those contained in ACI 318 and ACI 301, except it does not require the submittal of the data and calculation of the average strength, f'_{cr} necessary to meet those ACI Code and Specifications. This Appendix does not include all of the detailed requirements of the ACI Code and Specification that will govern a submittal for their respective purposes. The following material is intended to guide users of this specification when no formal submittal is required.

X1.1.1 Table X1.1 provides the statistical formulas that can be used to calculate the required average strength f'_{cr} when historical statistical data are available. The formula to achieve a satisfactory average of three consecutive strength tests as

TABLE X1.1 Required Average Compressive Strength when Data are Available to Establish a Standard Deviation

Inch-pound System			SI System		
Specified Strength f'_c, psi	Required Average Strength f'_{cr}, psi		Specified Strength f'_c, MPa	Required Average Strength f'_{cr}, MPa	
f'_c equal to or less than 5000	Use the larger from Eq X1.1 and X1.2		f'_c equal to or less than 35	Use the larger from Eq X1.1 and X1.2m	
	$f'_{cr} = f'_c + 1.34s$	(X1.1)		$f'_{cr} = f'_c + 1.34s$	(X1.1)
	$f'_{cr} = f'_c + 2.33s - 500$	(X1.2)		$f'_{cr} = f'_c + 2.33s - 3.45$	(X1.2m)
greater than 5000	Use the larger from Eq X1.1 and X1.3		greater than 35	Use the larger from Eq X1.1 and X1.3	
	$f'_{cr} = f'_c + 1.34s$	(X1.1)		$f'_{cr} = f'_c + 1.34s$	(X1.1)
	$f'_{cr} = 0.90f'_c + 2.33s$	(X1.3)		$f'_{cr} = 0.90f'_c + 2.33s$	(X1.3)

where:

f'_c = the specified compressive strength
f'_{cr} = the required average compressive strength
s = the standard deviation

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:09 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

required in 18.4.1 is (Eq. X1.1) of Table X1.1. The formulas for the minimum strength of an individual strength test result as required in 18.4.2 and 18.4.3 are (Eq. X1.2) and (Eq. X1.3) in Table X1.1. Since the average strength, f'_{cr}, must be high enough to conform to both averages of three consecutive tests and the requirements on minimum strength of a test, the one which requires highest average strength (f'_{cr}) governs.

X1.1.2 The first step in the process of calculating the over-design above f'_c or the required average strength is to determine if a record of 30 consecutive tests is available for the proposed mixture or similar mixture with a design strength within 1000 psi [6.6 MPa] of the specified compressive strength proposed for use. If it is a new mixture or strength level and no standard deviation data is available then Table X1.2 provides default levels of over-design equal to 1000, 1200 or ($1.10f'_c$ +700) psi.

X1.1.3 Table X1.3 provides calculated values of over-design and required average strength for selected standard deviations and specified strength levels. Because of the large ranges of strength and standard deviations, the gray shaded areas are considered unusual or not likely to be encountered.

TABLE X1.2 Required Average Compressive Strength When Data Are Not Available to Establish a Standard Deviation

Inch-pound System		SI System	
Specified Strength f'_c, psi	Required Average Strength f'_{cr}, psi	Specified Strength f'_c, MPa	Required Average Strength f'_{cr}, MPa
Less than 3000	f'_c + 1000	Less than 21	f'_c + 7.0
3000 to 5000	f'_c + 1200	21 to 35	f'_c + 8.5
greater than 5000	$1.10f'_c$ + 700	greater than 35	$1.10f'_c$ + 5.0

where:
f'_c = the specified compressive strength
f'_{cr} = the required average compressive strength
s = the standard deviation

Shaded Areas identify levels of specified strength where the standard deviations should be considered unusual or inappropiate.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C94/C94M – 09, that may impact the use of this specification. (Approved November 1, 2009)

(*1*) Revised the standard throughout to add slump flow. Added new 6.1.3, 7.1.3, and 16.1.6 and renumbered subsequent paragraphs.

Committee C09 has identified the location of selected changes to this specification since the last issue, C94/C94M – 07, that may impact the use of this specification. (Approved January 1, 2009)

(*1*) Revised 1.1, 4.1, 4.2, 9.1, and 9.4.
(*2*) Added new definitions in Section 3.
(*3*) Added new Note 14 and Note 15.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org). Permission rights to photocopy the standard may also be secured from the ASTM website (www.astm.org/COPYRIGHT/).

Designation: C 109/C 109M – 08

Standard Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)[1]

This standard is issued under the fixed designation C 109/C 109M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers determination of the compressive strength of hydraulic cement mortars, using 2-in. or [50-mm] cube specimens.

NOTE 1—Test Method C 349 provides an alternative procedure for this determination (not to be used for acceptance tests).

1.2 This test method covers the application of the test using either inch-pound or SI units. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in Standard IEEE/ASTM SI 10, of measurements made in other units.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. (***Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

C 1329 Specification for Mortar Cement

C 1437 Test Method for Flow of Hydraulic Cement Mortar

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Summary of Test Method

3.1 The mortar used consists of 1 part cement and 2.75 parts of sand proportioned by mass. Portland or air-entraining portland cements are mixed at specified water/cement ratios. Water content for other cements is that sufficient to obtain a flow of 110 ± 5 in 25 drops of the flow table. Two-inch or [50-mm] test cubes are compacted by tamping in two layers.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.27 on Strength.

Current edition approved Dec. 1, 2008. Published January 2009. Originally approved in 1934. Last previous edition approved in 2007 as C 109/C 109M – 07$^{\varepsilon 1}$.

The cubes are cured one day in the molds and stripped and immersed in lime water until tested.

4. Significance and Use

4.1 This test method provides a means of determining the compressive strength of hydraulic cement and other mortars and results may be used to determine compliance with specifications. Further, this test method is referenced by numerous other specifications and test methods. Caution must be exercised in using the results of this test method to predict the strength of concretes.

5. Apparatus

5.1 *Weights and Weighing Devices*, shall conform to the requirements of Specification C 1005. The weighing device shall be evaluated for precision and accuracy at a total load of 2000 g.

5.2 *Glass Graduates*, of suitable capacities (preferably large enough to measure the mixing water in a single operation) to deliver the indicated volume at 20 °C. The permissible variation shall be ±2 mL. These graduates shall be subdivided to at least 5 mL, except that the graduation lines may be omitted for the lowest 10 mL for a 250-mL graduate and for the lowest 25 mL of a 500-mL graduate. The main graduation lines shall be circles and shall be numbered. The least graduations shall extend at least one seventh of the way around, and intermediate graduations shall extend at least one fifth of the way around.

5.3 *Specimen Molds*, for the 2-in. or [50-mm] cube specimens shall be tight fitting. The molds shall have not more than three cube compartments and shall be separable into not more than two parts. The parts of the molds when assembled shall be positively held together. The molds shall be made of hard metal not attacked by the cement mortar. For new molds the Rockwell hardness number of the metal shall be not less than 55 HRB. The sides of the molds shall be sufficiently rigid to prevent spreading or warping. The interior faces of the molds shall be plane surfaces and shall conform to the tolerances of Table 1.

5.4 *Mixer, Bowl and Paddle*, an electrically driven mechanical mixer of the type equipped with paddle and mixing bowl, as specified in Practice C 305.

5.5 *Flow Table and Flow Mold*, conforming to the requirements of Specification C 230/C 230M.

5.6 *Tamper*, a nonabsorptive, nonabrasive, nonbrittle material such as a rubber compound having a Shore A durometer hardness of 80 ± 10 or seasoned oak wood rendered nonabsorptive by immersion for 15 min in paraffin at approximately 392 °F or [200 °C], shall have a cross section of about ½ by 1 in. or [13 by 25 mm] and a convenient length of about 5 to 6 in. or [120 to 150 mm]. The tamping face shall be flat and at right angles to the length of the tamper.

5.7 *Trowel*, having a steel blade 4 to 6 in. [100 to 150 mm] in length, with straight edges.

5.8 *Moist Cabinet or Room,* conforming to the requirements of Specification C 511.

5.9 *Testing Machine*, either the hydraulic or the screw type, with sufficient opening between the upper bearing surface and the lower bearing surface of the machine to permit the use of verifying apparatus. The load applied to the test specimen shall be indicated with an accuracy of ±1.0 %. If the load applied by the compression machine is registered on a dial, the dial shall be provided with a graduated scale that can be read to at least the nearest 0.1 % of the full scale load (Note 2). The dial shall be readable within 1 % of the indicated load at any given load level within the loading range. In no case shall the loading range of a dial be considered to include loads below the value that is 100 times the smallest change of load that can be read on the scale. The scale shall be provided with a graduation line equal to zero and so numbered. The dial pointer shall be of sufficient length to reach the graduation marks; the width of the end of the pointer shall not exceed the clear distance between the smallest graduations. Each dial shall be equipped with a zero adjustment that is easily accessible from the outside of the dial case, and with a suitable device that at all times until reset, will indicate to within 1 % accuracy the maximum load applied to the specimen.

5.9.1 If the testing machine load is indicated in digital form, the numerical display must be large enough to be easily read. The numerical increment must be equal to or less than 0.10 % of the full scale load of a given loading range. In no case shall the verified loading range include loads less than the minimum numerical increment multiplied by 100. The accuracy of the indicated load must be within 1.0 % for any value displayed within the verified loading range. Provision must be made for adjusting to indicate true zero at zero load. There shall be provided a maximum load indicator that at all times until reset will indicate within 1 % system accuracy the maximum load applied to the specimen.

NOTE 2—As close as can be read is considered 1/50 in. or [0.5 mm] along the arc described by the end of the pointer. Also, one half of the scale interval is about as close as can reasonably be read when the spacing on the load indicating mechanism is between 1/25 in. or [1 mm] and 1/16 in. or [1.6 mm]. When the spacing is between 1/16 in. or [1.6 mm] and 1/8 in. or [3.2 mm], one third of the scale interval can be read with reasonable certainty. When the spacing is 1/8 in. or [3.2 mm] or more, one fourth of the scale interval can be read with reasonable certainty.

TABLE 1 Permissible Variations of Specimen Molds

	2-in. Cube Molds		[50-mm] Cube Molds	
Parameter	New	In Use	New	In Use
Planeness of sides	<0.001 in.	<0.002 in.	[<0.025 mm]	[<0.05 mm]
Distance between opposite sides	2 in. ± 0.005	2 in. ± 0.02	[50 mm ± 0.13 mm]	[50 mm ± 0.50 mm]
Height of each compartment	2 in. + 0.01 in. to – 0.005 in.	2 in. + 0.01 in. to – 0.015 in.	[50 mm + 0.25 mm to – 0.13 mm]	[50 mm + 0.25 mm to – 0.38 mm]
Angle between adjacent faces[A]	90 ± 0.5°	90 ± 0.5°	90 ± 0.5°	90 ± 0.5°

[A] Measured at points slightly removed from the intersection. Measured separately for each compartment between all the interior faces and the adjacent face and between interior faces and top and bottom planes of the mold.

www.technobetar.ir

5.9.2 The upper bearing shall be a spherically seated, hardened metal block firmly attached at the center of the upper head of the machine. The center of the sphere shall lie at the center of the surface of the block in contact with the specimen. The block shall be closely held in its spherical seat, but shall be free to tilt in any direction. A hardened metal bearing block shall be used beneath the specimen to minimize wear of the lower platen of the machine. To facilitate accurate centering of the test specimen in the compression machine, one of the two surfaces of the bearing blocks shall have a diameter or diagonal of between 2.83 in. [70.7 mm] (See Note 3) and 2.9 in. [73.7 mm]. When the upper block bearing surface meets this requirement, the lower block bearing surface shall be greater than 2.83 in. [70.7 mm]. When the lower block bearing surface meets this requirement, the diameter or diagonal of upper block bearing surface shall be between 2.83 and 3⅛ in. [70.7 and 79.4 mm]. When the lower block is the only block with a diameter or diagonal between 2.83 and 2.9 in. [70.7 and 73.7 mm], the lower block shall be used to center the test specimen. In that case, the lower block shall be centered with respect to the upper bearing block and held in position by suitable means. The bearing block surfaces intended for contact with the specimen shall have a Rockwell harness number not less than 60 HRC. These surfaces shall not depart from plane surfaces by more than 0.0005 in. [0.013 mm] when the blocks are new and shall be maintained within a permissible variation of 0.001 in. or [0.025 mm].

NOTE 3—The diagonal of a 2 in. [50 mm] cube is 2.83 in. [70.7 mm].

6. Materials

6.1 *Graded Standard Sand*:

6.1.1 The sand (Note 4) used for making test specimens shall be natural silica sand conforming to the requirements for graded standard sand in Specification C 778.

NOTE 4—*Segregation of Graded Sand*—The graded standard sand should be handled in such a manner as to prevent segregation, since variations in the grading of the sand cause variations in the consistency of the mortar. In emptying bins or sacks, care should be exercised to prevent the formation of mounds of sand or craters in the sand, down the slopes of which the coarser particles will roll. Bins should be of sufficient size to permit these precautions. Devices for drawing the sand from bins by gravity should not be used.

7. Temperature and Humidity

7.1 *Temperature*—The temperature of the air in the vicinity of the mixing slab, the dry materials, molds, base plates, and mixing bowl, shall be maintained between 73.5 ± 5.5 °F or [23.0 ± 3.0 °C]. The temperature of the mixing water, moist closet or moist room, and water in the storage tank shall be set at 73.5 ± 3.5 °F or [23 ± 2 °C].

7.2 *Humidity*—The relative humidity of the laboratory shall be not less than 50 %. The moist closet or moist room shall conform to the requirements of Specification C 511.

8. Test Specimens

8.1 Make two or three specimens from a batch of mortar for each period of test or test age.

9. Preparation of Specimen Molds

9.1 Apply a thin coating of release agent to the interior faces of the mold and non-absorptive base plates. Apply oils and greases using an impregnated cloth or other suitable means. Wipe the mold faces and the base plate with a cloth as necessary to remove any excess release agent and to achieve a thin, even coating on the interior surfaces. When using an aerosol lubricant, spray the release agent directly onto the mold faces and base plate from a distance of 6 to 8 in. or [150 to 200 mm] to achieve complete coverage. After spraying, wipe the surface with a cloth as necessary to remove any excess aerosol lubricant. The residue coating should be just sufficient to allow a distinct finger print to remain following light finger pressure (Note 5).

9.2 Seal the surfaces where the halves of the mold join by applying a coating of light cup grease such as petrolatum. The amount should be sufficient to extrude slightly when the two halves are tightened together. Remove any excess grease with a cloth.

9.3 Seal molds to their base plates with a watertight sealant. Use microcrystalline wax or a mixture of three parts paraffin to five parts rosin by mass. Paraffin wax is permitted as a sealant with molds that clamp to the base plate. Liquefy the wax by heating it to a temperature of between 230 and 248 °F or [110 and 120 °C]. Effect a watertight seal by applying the liquefied sealant at the outside contact lines between the mold and its base plate (Note 6).

9.4 Optionally, a watertight sealant of petroleum jelly is permitted for clamped molds. Apply a small amount of petroleum jelly to the entire surface of the face of the mold that will be contacting the base plate. Clamp the mold to the base plate and wipe any excess sealant from the interior of the mold and base plate.

NOTE 5—Because aerosol lubricants evaporate, molds should be checked for a sufficient coating of lubricant immediately prior to use. If an extended period of time has elapsed since treatment, retreatment may be necessary.

NOTE 6—*Watertight Molds*—The mixture of paraffin and rosin specified for sealing the joints between molds and base plates may be found difficult to remove when molds are being cleaned. Use of straight paraffin is permissible if a watertight joint is secured, but due to the low strength of paraffin it should be used only when the mold is not held to the base plate by the paraffin alone. When securing clamped molds with paraffin, an improved seal can be obtained by slightly warming the mold and base plate prior to applying the wax. Molds so treated should be allowed to return to room temperature before use.

10. Procedure

10.1 *Composition of Mortars*:

10.1.1 The proportions of materials for the standard mortar shall be one part of cement to 2.75 parts of graded standard sand by weight. Use a water-cement ratio of 0.485 for all portland cements and 0.460 for all air-entraining portland cements. The amount of mixing water for other than portland and air-entraining portland cements shall be such as to produce a flow of 110 ± 5 as determined in accordance with 10.3 and shall be expressed as weight percent of cement.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:11 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.1.2 The quantities of materials to be mixed at one time in the batch of mortar for making six and nine test specimens shall be as follows:

	Number of Specimens	
	6	9
Cement, g	500	740
Sand, g	1375	2035
Water, mL		
Portland (0.485)	242	359
Air-entraining portland (0.460)	230	340
Other (to flow of 110 ± 5)	...	...

10.2 *Preparation of Mortar*:

10.2.1 Mechanically mix in accordance with the procedure given in Practice C 305.

10.3 *Determination of Flow*:

10.3.1 Determine flow in accordance with procedure given in Test Method C 1437.

10.3.2 For portland and air-entraining portland cements, merely record the flow.

10.3.3 In the case of cements other than portland or air-entraining portland cements, make trial mortars with varying percentages of water until the specified flow is obtained. Make each trial with fresh mortar.

10.3.4 Immediately following completion of the flow test, return the mortar from the flow table to the mixing bowl. Quickly scrape the bowl sides and transfer into the batch the mortar that may have collected on the side of the bowl and then remix the entire batch 15 s at medium speed. Upon completion of mixing, the mixing paddle shall be shaken to remove excess mortar into the mixing bowl.

10.3.5 When a duplicate batch is to be made immediately for additional specimens, the flow test may be omitted and the mortar allowed to stand in the mixing bowl 90 s without covering. During the last 15 s of this interval, quickly scrape the bowl sides and transfer into the batch the mortar that may have collected on the side of the bowl. Then remix for 15 s at medium speed.

10.4 *Molding Test Specimens*:

10.4.1 Complete the consolidation of the mortar in the molds either by hand tamping or by a qualified alternative method. Alternative methods include but are not limited to the use of a vibrating table or mechanical devices.

10.4.2 *Hand Tamping*—Start molding the specimens within a total elapsed time of not more than 2 min and 30 s after completion of the original mixing of the mortar batch. Place a layer of mortar about 1 in. or [25 mm] (approximately one half of the depth of the mold) in all of the cube compartments. Tamp the mortar in each cube compartment 32 times in about 10 s in 4 rounds, each round to be at right angles to the other and consisting of eight adjoining strokes over the surface of the specimen, as illustrated in Fig. 1. The tamping pressure shall be just sufficient to ensure uniform filling of the molds. The 4 rounds of tamping (32 strokes) of the mortar shall be completed in one cube before going to the next. When the tamping of the first layer in all of the cube compartments is completed, fill the compartments with the remaining mortar and then tamp as specified for the first layer. During tamping of the second layer, bring in the mortar forced out onto the tops of the molds after each round of tamping by means of the gloved fingers and the tamper upon completion of each round and before starting the next round of tamping. On completion of the tamping, the tops of all cubes should extend slightly above the tops of the molds. Bring in the mortar that has been forced out onto the tops of the molds with a trowel and smooth off the cubes by drawing the flat side of the trowel (with the leading edge slightly raised) once across the top of each cube at right angles to the length of the mold. Then, for the purpose of leveling the mortar and making the mortar that protrudes above the top of the mold of more uniform thickness, draw the flat side of the trowel (with the leading edge slightly raised) lightly once along the length of the mold. Cut off the mortar to a plane surface flush with the top of the mold by drawing the straight edge of the trowel (held nearly perpendicular to the mold) with a sawing motion over the length of the mold.

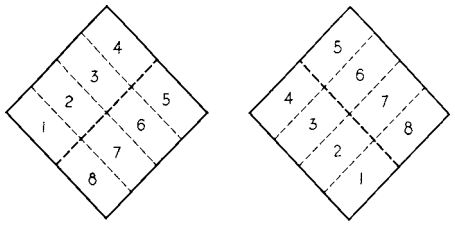

FIG. 1 Order of Tamping in Molding of Test Specimens

10.4.3 *Alternative Methods*—Any consolidation method may be used that meets the qualification requirements of this section. The consolidation method consists of a specific procedure, equipment and consolidation device, as selected and used in a consistent manner by a specific laboratory. The mortar batch size of the method may be modified to accommodate the apparatus, provided the proportions maintain the same ratios as given in 10.1.2.

10.4.3.1 Separate qualifications are required for the following classifications:

Class A, *Non-air entrained cements*—for use in concrete, such as sold under Specifications C 150, C 595, and C 1157.

Class B, *Air-entrained cements*—for use in concrete, such as sold under Specifications C 150, C 595, and C 1157.

Class C, *Masonry, Mortar and Stucco Cements*—such as sold under Specifications C 91, C 1328, and C 1329.

10.4.3.2 An alternative method may only be used to test the cement types as given in 10.4.3.1 above, for which it has been qualified.

10.4.3.3 It can also be used for Strength Activity Index determinations for fly ash and slag, such as sold under Specifications C 618 and C 989, provided the alternative method has qualified for both Class A and Class C cements.

10.4.4 *Qualification Procedure*—Contact CCRL to purchase cement samples that have been used in the Proficiency Sample Program (PSP). Four samples (5 Kg each) of the class to be qualified will be required to complete a single qualification (See Note 7).

10.4.4.1 In one day, prepare replicate 6-cube or 9-cube batches using one of the cements and cast a minimum of 36 cubes. Complete one round of tests on each cement on different days. Store and test all specimens as prescribed in the sections below. Test all cubes at the age of 7-days.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.4.4.2 Tabulate the compressive strength data and complete the mathematical analyses as instructed in Annex A1.

10.4.5 *Requalification of the Alternate Compaction Method*:

10.4.5.1 Requalification of the method shall be required if any of the following occur:

(1) Evidence that the method may not be providing data in accordance with the requirements of Table 2.

(2) Results that differ from the reported final average of a CCRL-PSP sample with a rating of 3 or less.

(3) Results that differ from the accepted value of a known reference sample with established strength values by more than twice the multi-laboratory 1s % values of Table 2.

Before starting the requalification procedure, evaluate all aspects of cube fabrication and testing process to determine if the offending result is due to some systematic error or just an occasional random event.

10.4.5.2 If the compaction equipment is replaced, significantly modified, repaired, or has been recalibrated, requalify the equipment in accordance with 10.4.4.

NOTE 7—It is recommended that a large homogenous sample of cement be prepared at the time of qualification for use as a secondary standard and for method evaluation. Frequent testing of this sample will give early warning of any changes in the performance of the apparatus.

10.5 *Storage of Test Specimens*—Immediately upon completion of molding, place the test specimens in the moist closet or moist room. Keep all test specimens, immediately after molding, in the molds on the base plates in the moist closet or moist room from 20 to 72 h with their upper surfaces exposed to the moist air but protected from dripping water. If the specimens are removed from the molds before 24 h, keep them on the shelves of the moist closet or moist room until they are 24-h old, and then immerse the specimens, except those for the 24-h test, in saturated lime water in storage tanks constructed of noncorroding materials. Keep the storage water clean by changing as required.

TABLE 2 Precision

		Test Age, Days	Coefficient of Variation 1s %[A]	Acceptable Range of Test Results d2s %[A]
Portland Cements				
Constant water-cement ratio:				
Single-lab		3	4.0	11.3
		7	3.6	10.2
	Av		3.8	10.7
Multi-lab		3	6.8	19.2
		7	6.4	18.1
	Av		6.6	18.7
Blended Cements				
Constant flow mortar:				
Single-lab		3	4.0	11.3
		7	3.8	10.7
		28	3.4	9.6
	Av		3.8	10.7

	Av		11.9	33.7

[A] These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

10.6 *Determination of Compressive Strength*:

10.6.1 Test the specimens immediately after their removal from the moist closet in the case of 24-h specimens, and from storage water in the case of all other specimens. All test specimens for a given test age shall be broken within the permissible tolerance prescribed as follows:

Test Age	Permissible Tolerance
24 h	±½ h
3 days	±1 h
7 days	±3 h
28 days	±12 h

If more than one specimen at a time is removed from the moist closet for the 24-h tests, keep these specimens covered with a damp cloth until time of testing. If more than one specimen at a time is removed from the storage water for testing, keep these specimens in water at a temperature of 73.5 ± 3.5 °F or [23 ± 2 °C] and of sufficient depth to completely immerse each specimen until time of testing.

10.6.2 Wipe each specimen to a surface-dry condition, and remove any loose sand grains or incrustations from the faces that will be in contact with the bearing blocks of the testing machine. Check these faces by applying a straightedge (Note 8). If there is appreciable curvature, grind the face or faces to plane surfaces or discard the specimen. A periodic check of the cross-sectional area of the specimens should be made.

NOTE 8—*Specimen Faces*—Results much lower than the true strength will be obtained by loading faces of the cube specimen that are not truly plane surfaces. Therefore, it is essential that specimen molds be kept scrupulously clean, as otherwise, large irregularities in the surfaces will occur. Instruments for cleaning molds should always be softer than the metal in the molds to prevent wear. In case grinding specimen faces is necessary, it can be accomplished best by rubbing the specimen on a sheet of fine emery paper or cloth glued to a plane surface, using only a moderate pressure. Such grinding is tedious for more than a few thousandths of an inch (hundredths of a millimetre); where more than this is found necessary, it is recommended that the specimen be discarded.

10.6.3 Apply the load to specimen faces that were in contact with the true plane surfaces of the mold. Carefully place the specimen in the testing machine below the center of the upper bearing block. Prior to the testing of each cube, it shall be ascertained that the spherically seated block is free to tilt. Use no cushioning or bedding materials. Bring the spherically seated block into uniform contact with the surface of the specimen. Apply the load rate at a relative rate of movement between the upper and lower platens corresponding to a loading on the specimen with the range of 200 to 400 lbs/s [900 to 1800 N/s]. Obtain this designated rate of movement of the platen during the first half of the anticipated maximum load and make no adjustment in the rate of movement of the platen in the latter half of the loading especially while the cube is yielding before failure.

NOTE 9—It is advisable to apply only a very light coating of a good quality, light mineral oil to the spherical seat of the upper platen.

www.technobetar.ir

11. Calculation

11.1 Record the total maximum load indicated by the testing machine, and calculate the compressive strength as follows:

$$fm = P/A \quad (1)$$

where:

fm = compressive strength in psi or [MPa],
P = total maximum load in lbf or [N], and
A = area of loaded surface in^2 or [mm^2].

Either 2-in. or [50-mm] cube specimens may be used for the determination of compressive strength, whether inch-pound or SI units are used. However, consistent units for load and area must be used to calculate strength in the units selected. If the cross-sectional area of a specimen varies more than 1.5 % from the nominal, use the actual area for the calculation of the compressive strength. The compressive strength of all acceptable test specimens (see Section 12) made from the same sample and tested at the same period shall be averaged and reported to the nearest 10 psi [0.1 MPa].

12. Report

12.1 Report the flow to the nearest 1 % and the water used to the nearest 0.1 %. Average compressive strength of all specimens from the same sample shall be reported to the nearest 10 psi [0.1 MPa].

13. Faulty Specimens and Retests

13.1 In determining the compressive strength, do not consider specimens that are manifestly faulty.

13.2 The maximum permissible range between specimens from the same mortar batch, at the same test age is 8.7 % of the average when three cubes represent a test age and 7.6 % when two cubes represent a test age (Note 10).

NOTE 10—The probability of exceeding these ranges is 1 in 100 when the within-batch coefficient of variation is 2.1 %. The 2.1 % is an average for laboratories participating in the portland cement and masonry cement reference sample programs of the Cement and Concrete Reference Laboratory.

13.3 If the range of three specimens exceeds the maximum in 13.2, discard the result which differs most from the average and check the range of the remaining two specimens. Make a retest of the sample if less than two specimens remain after disgarding faulty specimens or disgarding tests that fail to comply with the maximum permissible range of two specimens.

NOTE 11—Reliable strength results depend upon careful observance of all of the specified requirements and procedures. Erratic results at a given test period indicate that some of the requirements and procedures have not been carefully observed; for example, those covering the testing of the specimens as prescribed in 10.6.2 and 10.6.3. Improper centering of specimens resulting in oblique fractures or lateral movement of one of the heads of the testing machine during loading will cause lower strength results.

14. Precision and Bias

14.1 *Precision*—The precision statements for this test method are listed in Table 2 and are based on results from the Cement and Concrete Reference Laboratory Reference Sample Program. They are developed from data where a test result is the average of compressive strength tests of three cubes molded from a single batch of mortar and tested at the same age. A significant change in precision will not be noted when a test result is the average of two cubes rather than three.

14.2 These precision statements are applicable to mortars made with cements mixed, and tested at the ages as noted. The appropriate limits are likely, somewhat larger for tests at younger ages and slightly smaller for tests at older ages.

14.3 *Bias*—The procedure in this test method has no bias because the value of compressive strength is defined in terms of the test method.

15. Keywords

15.1 compressive strength; hydraulic cement mortar; hydraulic cement strength; mortar strength; strength

ANNEX

(Mandatory Information)

A1. ANALYSES OF TEST RESULTS FOR QUALIFICATION OF ALTERNATE COMPACTION METHODS

A1.1 *Calculation of Average Within-Batch Standard Deviation and Elimination of Outliers*—Tabulate the results for each cement sample (or round) in separate spreadsheets. In the spreadsheet, list results of each batch in columns and complete the calculations as shown in Table A1.1.

A1.1.1 Eliminate any outliers from the test data and repeat the calculations until none of the values lie outside the normal range.

A1.1.2 Tabulate the cube strengths with all the outliers eliminated and complete the calculations as shown in Table A1.2.

A1.2 *Summary of Results*—Compile the results of the four rounds and complete the calculations as shown in Table A1.3. The number of outliers shall not exceed 5 % of the total number of tests when rounded to the nearest whole number (for example, 4 rounds × 4 batches × 9 cubes = 144 tests × (5%/100) = 7.2 or 7).

A1.3 *Precision Qualification*—Calculate the relative within batch error (RWBE %) as shown in Table A1.3. This value must be less than 2.1 % to comply with the limit established in Note 10 of this specification.

A1.4 *Bias Qualification*—The test results compiled in Table A1.3 are evaluated against three limits to demonstrate an acceptable qualification. The limits have been established

TABLE A1.1 Example Using 9 Cube Batch

Round – 2
CCRL Sample # 140 Industry Average Strength, X_i = 32.923
Cast Date – 00/00/00

7-Day Strengths, MPa				
A	B	C	D	E
Batch No.	1	2	3	4
Cube 1	33.0	34.3	34.4	33.2
Cube 2	33.9	32.5	34.0	34.0
Cube 3	33.4	34.0	34.1	33.8
Cube 4	33.1	33.8	34.0	33.8
Cube 5	33.0	33.4	34.2	34.0
Cube 6	32.8	33.7	31.8	33.1
Cube 7	33.6	32.6	33.9	32.8
Cube 8	31.5	32.1	33.0	33.3
Cube 9	33.6	34.3	33.4	34.4
Average, X_b	33.10	33.42	33.65	33.60
SD_b	0.70	0.82	0.81	0.52
N_b	9	9	9	9
$(N_b–1)SD_b^2$	3.936	5.432	5.265	2.145
			N_r	36
			X_r	33.44
			SD_r	0.692
			MND	1.703
Normal Range				
Max	34.81	35.12	35.35	35.30
Min	31.40	31.71	32.95	31.89
Outliers	None	None	Cube 6	None

where:

X_i = industry average strength (CCRL),
X_b = average of tests values in a single batch,
SD_b = standard deviation of a single batch = $\sqrt{\frac{\sum_{Cube}(X - X_b)^2}{N_b - 1}}$
N_b = number of tests per batch,
$(N_b–1)SD_b^2$ = an intermediate calculation,
N_r = total number of tests per round,
X_r = grand average of tests values obtained per round, MPa,
SD_r = mean standard deviation of round = $\sqrt{\frac{\sum_{Batch}[(N_b - 1)SD_b^2]}{N_r - 1}}$
MND = maximum normal deviation: use Excel® function "=norminv(1–0.25/N_r,0,SD_r)" or equivalent, or use statistical tables to find the inverse integrated normal distribution for an integral value of (1–0.25/n_r) in a normal distribution with $\sigma = SD_r$.

Normal Range:
Maximum = (X_b + MND).
Minimum = (X_b – MND).
Outlier = any test value falling outside the calculated normal range.

statistically from analyses of historical CCRL data and are given in Table A1.4.

A1.5 *Rationale for the Limits Given in* A1.4:

A1.5.1 The multi-laboratory precision (1s%) for the average of *n* batches is given by:

$$s\%_{ML,n} = \sqrt{s\%_{ML}^2 - \left(1 - \frac{1}{n}\right)s\%_{SO}^2}$$

A1.5.2 The limit for deviation of the individual rounds (no failures being allowed when 4 rounds are performed) is 1.2 $s\%_{ML,n}$, as used in Test Methods C 114.

A1.5.3 The multi-laboratory precision (1s%) for the mean of 4 rounds is 0.5 $s\%_{ML,n}$.

TABLE A1.2 Test Data After the Elimination of Outliers (Example Using 9 Cube Batch)

Round – 2
CCRL Sample # 140 Industry Average Strength, X_i = 32.923
Cast Date – 00/00/00 Raw Cube Data:

7-Day Strengths, MPa				
A	B	C	D	E
Batch No.	1	2	3	4
Cube 1	33.0	34.3	34.4	33.2
Cube 2	33.9	32.5	34.0	34.0
Cube 3	33.4	34.0	34.1	33.8
Cube 4	33.1	33.8	34.0	33.8
Cube 5	33.0	33.4	34.2	34.0
Cube 6	32.8	33.7		33.1
Cube 7	33.6	32.6	33.9	32.8
Cube 8		32.1	33.0	33.3
Cube 9	33.6	34.3	33.4	34.4
Average, X_{bv}	33.29	33.42	33.89	33.60
SD_{bv}	0.39	0.82	0.46	0.52
N_{bv}	8	9	8	9
$(N_{bv}–1)SD_{bv}^2$	1.092	5.348	1.462	2.159
			N_{rv}	34
			X_{rv}	33.55
			X_i	32.92
			SD_{rv}	0.55
			E_r, MPa	0.63
			RE_r, %	1.91

where:

X_{bv} = average of valid test values obtained per batch, MPa,
X_i = industry average strength (CCRL), MPa,
SD_{bv} = $\sqrt{\frac{\sum_{ValidCube}(X - X_{bv})^2}{N_{bv} - 1}}$
N_{bv} = number of valid tests per batch,
$(N_{bv}\text{-}1)SD_{bv}^2$ = an intermediate calculation,
N_{rv} = total number of valid tests of the round,
X_{rv} = grand average of valid tests for the round, MPa,
SD_{rv} = mean standard deviation of the round = $\sqrt{\frac{\sum_{Batch}[(N_{bv} - 1)SD_{bv}^2]}{N_{rv} - 1}}$
E_r = error = (X_i – X_{rv}), MPa, and
RE_r = relative error for the round, % = 100(E_r/X_{rv}).

A1.5.4 The limit for deviation of the mean of 4 rounds (95 % confidence) is 1.96 times this, or 0.98 $s\%_{ML,n}$.

A1.5.5 The values for $s\%_{ML}$ and $s\%_{SO}$ for Cement Classes A and C (non-air-entrained cements for concrete and cements for mortar respectively) are the 7-day values in the current precision statement of Test Method C 109/C 109M. There appears to be no data for Cement Class B (air-entrained cements for concrete). Working on the assumption that the value of this quantity is related to the air content, the values adopted for Class B are the mean of the A- and C-values.

A1.5.6 For the applicable conditions, the equations above give the following:

Derivation of Limits for Table A1.4						
Cement Class	A	B	C	A	B	C
Batches per Round (n)	6	6	6	4	4	4
Single Operator s% (single batch)	3.6	5.75	7.9	3.6	5.75	7.9
Multi-Laboratory s% (single batch)	6.4	9.1	11.8	6.4	9.1	11.8
Multi-Laboratory s% (n batches)	5.5	7.4	9.3	5.6	7.6	9.6
Limit for deviation of a single round %	6.6	8.9	11.2	6.7	9.1	11.5
Limit for deviation of mean of four rounds %	5.4	7.3	9.2	5.5	7.5	9.4

						Max, RE_r, %		6.85
						Mean, RE_r, %		3.17
						GMWBE, MPa		0.65
						RWBE, %		2.01
						Max RWBE, %[A]		2.1
						Precision Test		Pass

where:

X_r = industry average strength, MPa,
X_{rv} = grand mean value of the valid tests of a round,
RE_{rv}, % = relative error = $100(X_i - X_{rv})$,
N_{rv} = total number of valid tests of the round,
SD_{rv} = mean standard deviation of a round =

$$\sqrt{\frac{\sum_{Batch}[(N_{bv}-1)SD_{rv}^2]}{N_{rv}-1}}$$

$(N_r-1)SD_r^2$ = intermediate calculation,
X_g = grand mean value of all valid tests (4 rounds),
N_g = total number of valid tests in 4 rounds,
$GMWBE$ = grand mean within-batch error, MPa =

$$\sqrt{\frac{\sum_{Round}[(N_{rv}-1)SD_{rv}^2]}{N_g-1}}$$

$RWBE$ = relative within batch error, % = $100(GMWBE / X_g)$, and
$Max\ RWBE$ = maximum allowed RWBE = 2.10 % (See Note 10).

[A] See Note 9.

TABLE A1.4 Bias Qualification Requirements

	6 Cube Batches (Min 6 Batches per Round)			9 Cube Batches (Min 4 Batches per Round)		
Cement Classification (see 10.4.3.1)	A	B	C	A	B	C
Max allowable relative error any 4 or 6 batches, MAREr %	6.6	8.9	11.2	6.7	9.1	11.5
Max allowable relative error mean of 4 rounds of 4 or 6 batches <5 % failures, GRE%	5.4	7.3	9.2	5.5	7.5	9.4
Minimum allowable confidence limit, % MACL %	95	95	95	95	95	95

www.technobetar.ir

TABLE A1.5 Bias Tests
(Example Using 9-Cube Batches, Class A Cement)

MREr %, the maximum relative error value of the four rounds	6.85
MAREr %, max allowable MREr from Table A1.4	6.7
	Fails
GRE %, the average REr % of the four rounds	3.13
Maximum limit of MGREg % from Table A1.4	5.5
	Pass
Bias confidence limit, CL %	96.99
Minimum allowable confidence limit, MACL % (from Table A1.4)	95
	Pass
The above results indicate the data fails to show compliance.	

where:

MREr, % = the maximum relative error, % obtained for any round (from values in column F, Table A1.3),

MAREr, % = the maximum allowable relative error, % of any Round (Table A1.4),

GRE, % = the grand average of the REr, % values of the four rounds,

MAREg, % = maximum allowed GRE, % value (average of column F, Table A1.3), and

CL, % = bias confidence limit, %, the confidence with which it can be stated that the error of the mean of 4 rounds is non-zero. Calculate this by use of Excel® function "=ttest(<range of industry means>,<range of values obtained>,1,1)" or equivalent, or use statistical tables to find the confidence in a one-tailed, paired-value t-test on the set of round errors.

NOTE—The qualification method fails for bias if *(1)* the MREr exceeds the MAREr, % limit; or if *(2)* the GRE, % exceeds the MGREg limit and the CL, % exceeds 95 %.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 109/C 109M – 07$^{\varepsilon 1}$, that may impact the use of this test method. (Approved December 1, 2008).

(*1*) Revised 5.1.

(*2*) Revised 9.3, added new 9.4, and revised Note 6.

Committee C01 has identified the location of selected changes to this test method since the last issue, C 109/C 109M – 05, that may impact the use of this test method. (Approved August 15, 2007).

(*1*) Revised 5.9.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 110 – 09a

Standard Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone[1]

This standard is issued under the fixed designation C 110; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 These test methods cover physical testing of quicklime and hydrated lime, and of limestone not otherwise covered in ASTM standards.[2]

NOTE 1—Quicklime and hydrated lime have a high affinity for moisture and carbon dioxide. Caution should be taken to protect both hydrated and quicklime during sampling, storage, and testing (see Practice C 50).

1.2 The test procedures appear in the following order:

	Section
Air Entrainment	8
Apparent Loose Density of Hydrated Lime, Pulverized Quicklime, and Limestone	20
Apparent Packed Density of Hydrated Lime, Pulverized Quicklime, and Limestone	21
Autoclave Expansion of Hydrated Lime	9
Dry Brightness of Pulverized Limestone	12
Dry Screening by Air Jet Sieve	18
Fineness of Pulverized Quicklime and Hydrated Lime by Air Permeability	16
Limestone Grindability	13
Particle Size of Pulverized Limestone	17
Plasticity of Lime Putty	6
Popping and Pitting of Hydrated Lime	10
Residue and Sieve Analysis	15
Settling Rate of Hydrated Lime	14
Slaking Rate of Quicklime	11
Specific Gravity of Hydrated Lime Products	22
Standard Consistency of Lime Putty	5
Water Retention of Hydrated Lime	7
Wet Sieve Analysis of Agricultural Liming Materials	19

1.3 The values stated in SI units are to be regarded as standard. The values given in parentheses are mathematical conversions to inch-pound units that are provided for information only and are not considered standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—Unless otherwise specified, for definitions of terms used in this standard see Terminology C 51.

4. General Procedures

4.1 *Sampling*—Samples of lime and limestone for physical analysis shall be taken and prepared in accordance with the requirements of Practice C 50 applicable to the material to be tested.

4.2 *Calculation*:

4.2.1 The calculations included in the individual procedures sometimes assume that the exact weight specified has been used. Accurately weighed samples which are approximately but not exactly equal to the weight specified may be used provided appropriate corrections are made in the calculation. Unless otherwise stated, weights of all samples and residues should be recorded to the nearest 0.0001 g.

4.2.2 In all mathematical operations on a set of observed values, the equivalent of two more places of figures than in the single observed values shall be retained. For example, if observed values are read or determined to the nearest 0.1 mg, carry numbers to the nearest 0.001 mg in calculation.

4.3 *Rounding Figures*—Rounding of figures to the nearest significant place required in the report should be done after the calculations are completed, in order to keep the final results free from calculation errors. The rounding procedure should follow the principle outlined in Practice E 29.

PLASTIC PROPERTY TESTING

5. Standard Consistency of Lime Putty

5.1 *Significance and Use*:

5.1.1 In order to measure certain physical properties of a lime putty, such as plasticity, it is necessary to have a uniform or standard consistency (viscosity), since the property measurement is affected by the consistency level.

5.2 *Apparatus*:

5.2.1 *Modified Vicat Apparatus*—The apparatus, constructed as shown in Fig. 1, shall consist of a bracket, *A*, bearing a movable brass rod, *B*, 6.3 mm in diameter and of suitable length to fit the Vicat bracket. A plunger, *C*, 12.5 mm in diameter, made of aluminum tubing, shall be attached to the lower end of the rod. The total weight of the rod with plunger shall be 30 g. The lower end of the plunger shall be closed without shoulders or curvature and the tube may be loaded with shot to the specified weight. The total weight required may also be obtained by means of a weight, *D*, screwed into the rod. The rod can be held in any position by means of a screw, *E*, and has a mark midway between the ends which moves under a scale, *F*, graduated in millimetres, attached to the bracket, *A*.

5.2.2 *Mold*—The conical ring mold shall be made of a noncorroding, nonabsorbent material, and shall have an inside diameter of 70 mm at the base and 60 mm at the top, and a height of 40 mm.

5.2.3 *Base Plate*—The base plate for supporting the ring mold shall be of plate glass and about 100 mm square.

5.2.4 *Mechanical Mixers*.

5.3 *Standard Consistency Determination*:

5.3.1 *Mechanical Mixing Procedure Using the Vac-U-Mixer*—To a measured amount of water contained in an 800-cm^3 Vac-U-Mix bowl, add 300 g of hydrated lime and hand mix for 10 s with a stiff spatula (Note 2). Cover putty to prevent evaporation of water. After the applicable soaking period, 30 min maximum for Type S, special hydrated lime, and not less than 16 h nor more than 24 h for Type N, normal hydrated lime, insert the paddle assembly and mix the putty for 30 s with the mechanical mixer. Remove the paddle assembly and scrape down any putty adhering to it and to the sides of the

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

mixing bowl. Remix for 30 s and determine the consistency as prescribed in 5.3. If the penetration is less than 15 mm, return all of the material to the mixer bowl, add additional water, and remix for 15 s. If the penetration is greater than 25 mm, repeat the test.

NOTE 2—Most lime hydrates will require 250 to 300 mL of water to produce a putty of proper consistency for this test if 300 g of lime are used.

5.3.2 *Mechanical Mixing Procedure Using the Hobart N-50 Mixer*—To a measured amount of water contained in the N-50 mixing bowl, add 600 g of hydrated lime and hand mix for 10 s with a stiff spatula (Note 3). Cover putty to prevent evaporation of water. After the applicable soaking period, 30 min maximum for Type S, special hydrated lime, and not less than 16 h nor more than 24 h for Type N, normal hydrated lime, insert the paddle assembly and mix the putty for 1 min at a slow speed. Stop the mixer and scrape down the paddle and the sides of the mixing bowl. Remix for 4 min at a slow speed. Determine the consistency as prescribed in 5.3.3. If the penetration is less than 15 mm, return all of the material to the mixing bowl, add additional water, and remix for 15 s. If the penetration is more than 25 mm, repeat the test.

NOTE 3—Most lime hydrates will require 500 to 600 mL of water to produce a putty of proper consistency for this test if 600 g of lime are used.

5.3.3 *Consistency Determination*—To determine consistency, place the mold with its larger end resting on the glass base plate and fill with the lime putty. Then strike off the putty flush with the top of the mold. Center the lime putty, confined in the ring mold resting on the plate, under the rod of the modified Vicat apparatus (Fig. 1). Bring the plunger end, *C*, in contact with the surface of the lime putty and take an initial reading. Release the rod and take the final reading 30 s after the plunger is released. The lime putty is of standard consistency when a penetration of 20 ± 5 mm is obtained. Record both the total amount of water required to bring the putty to standard consistency and the actual penetration. Proceed with the plasticity determination in accordance with 6.3.

5.4 *Precision and Bias*:

5.4.1 The precision and bias of this test method has not been determined.

6. Plasticity of Lime Putty

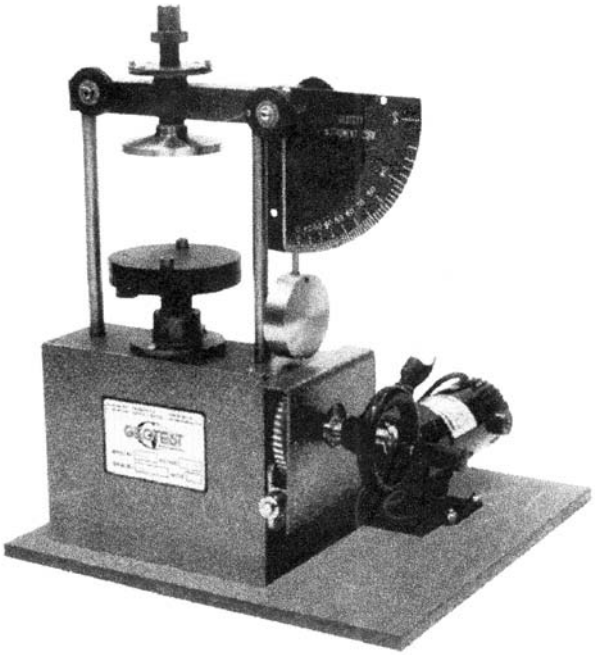
6.1 *Significance and Use*:

6.1.1 This test method provides a measure of the degree of stiffening of lime putty of standard consistency as water is withdrawn from it by a standard suction base plate.

6.1.2 Plasticity is an important property when applying mixtures containing lime putty to porous or absorptive surfaces such as in plastering, stuccoing, and masonry construction.

6.2 *Apparatus*:

6.2.1 Determine the plasticity of lime putty using the plasticimeter shown in Fig. 2.[4]



Constants of the Machine:

Absorption of Porcelain and Plaster Base Plate—minimum of 40 g in 24 h. For rate of absorption of base plates see 6.2.3.2.

Dimension of Base Plate—25 mm (1 in.) in thickness by 100 mm (4 in.) in diameter.

Dimensions of Disk—0.8 to 12.7 mm (1⁄32 to ½ in.) in thickness by 76 mm (3 in.) in diameter.

Speed of Vertical Shaft—1 revolution in 6 min, 40 s.

Torque on Disk when Bob Reading is 100—1.41 N·m.

FIG. 2 Emley Plasticimeter

6.2.2 *Cleaning and Care of Base Plates*—Base plates may be made of porcelain or plaster. In making the plasticity determinations, much of the success attainable depends upon the condition of the base plates. In the case of porcelain plates which are reused, improper cleaning results in clogging of the pores with reduction in the rate of absorption. After a porcelain plate has been used, wipe the excess lime off and immerse the plate in clear water for not less than 2 h, after which transfer it without drying to a dilute solution of hydrochloric acid (HCl, 1 + 9) where it shall be kept immersed for another 2 h. Then transfer to a receptacle containing running water for at least 1 h. The plate is then free of acid. After the removal of excess water, place the plate in an oven overnight at a temperature of between 100 and 110 °C (212 and 230 °F) for drying. Before using, cool the plate to room temperature. In the case of plaster base plates, dry the base plates prior to use in plasticity or absorption testing in an oven at a temperature between 37.8 and 48.9 °C (100 and 120 °F) until they achieve a constant weight. Before using, cool the plaster plate to room temperature in a dessicator charged with a drying agent. If the plate is not to be used immediately after reaching room temperature, continue to store the plate in the dessicator until such time that it is to be used. Plaster base plates shall not be reused after plasticity, total absorption or rate of absorption testing (see 6.2.3).

6.2.3 *Absorption of Plasticimeter Base Plates*:

[4] The sole source of supply of the Emley Plasticimeter known to the committee at this time is Geotest Instrument Corporation, 910 University Place, Evanston, IL 60201, USA. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee [1], which you may attend.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.2.3.1 *Total Absorption*—Plasticimeter base plates when immersed in water at room temperature for a period of 24 h shall absorb not less than 40 g of water. Before making the determination, dry the porcelain plates overnight in an oven at a temperature between 100 and 110 °C (212 and 230 °F) and permit to cool to room temperature. Dry the plaster plates in an oven at a temperature between 37.8 and 48.9 °C (100 and 120 °F) until they achieve a constant weight and permit to cool to room temperature in a dessicator charged with a drying agent. After immersion and before weighing either porcelain or plaster plates, wipe off the excess water with a damp cloth.

6.2.3.2 *Rate of Absorption (Note 4)*—When tested over an area 70 mm (2¾ in.) in diameter, the water absorbed by either porcelain or plaster base plates shall be in accordance with the following:

Time, min	Water Absorbed, mL
1	8 to 14
2	5 to 7½
3	4 to 6½
4	4 to 6
5	3½ to 5½

(1) Plaster plates designated for rate of absorption testing shall be statistically representative of all plates manufactured for that purpose and made from one manufacturing batch run. Plaster plates selected for rate of absorption testing may not be re-dried and used for plasticity testing. Porcelain plates designated for rate of absorption testing shall be individually tested and may be re-dried and used for plasticity testing (see 6.2.2).

NOTE 4—A convenient apparatus for determining the rate of absorption consists of a buret sealed onto an inverted glass funnel from which the stem has been removed. The diameter of the larger end of the funnel shall be ground so as to be 70 mm (2¾ in.) in internal diameter. The funnel may be attached to the plate on which the measurement is being made by melted paraffin. The paraffin should not be too hot. A little experience will indicate when it is of the proper consistency. Alternative apparati manufactured of polycarbonate, metal and other materials are acceptable.[5]

6.3 *Plasticity Determination*:

6.3.1 Lubricate a ring mold such as is described in 5.2.2 with a thin film of water, place on a porcelain base plate (see 6.2.2 and 6.2.3) or a disposable plaster base plate (see 6.2.3), fill with the paste which has been adjusted to standard consistency as described in 5.3.3, and strike off level. Remove the mold by raising it vertically without distorting the paste. Center the base plate and paste in the instrument and turn the carriage up by hand until the surface of the paste is in contact with the disk and the distance between the disk and the top of the base plate is 32 mm (1¼ in.). Throw the carriage into gear and start the motor. It is essential that the motor be started exactly 120 s after the first portion of the paste has been placed in the mold. Record the time when the first portion of paste is placed in the mold as zero time; the motor is therefore started at 2 min. Take care to protect the specimen from drafts during the test.

6.3.2 Record the scale reading at 1-min intervals until the test is completed. Consider the test complete when: *(1)* the scale reading reaches 100, *(2)* any reading is less than the one before, or *(3)* the scale reading remains constant for three consecutive readings (2 min) and the specimen has visibly ruptured or broken loose from the base plate. Note the time and the scale reading at the end of the test.

6.4 *Calculation*:

6.4.1 Calculate the plasticity figure as follows:

$$P = \sqrt{F^2 + (10T)^2} \quad (1)$$

where

P = plasticity figure,
F = scale reading at the end of the test, and
T = time in minutes from the time when the first portion of paste was put in the mold to the end of the test.

6.5 *Precision and Bias*:

6.5.1 The precision of this test method is based on interlaboratory studies conducted in March and October of 2007. To determine interlaboratory and intralaboratory precision, one operator from each of ten different laboratories tested three different dolomitic Type S hydrated lime samples and one dolomitic Type N hydrated lime sample made into lime putty of standard consistency for Final Vicat Penetration (mm) and Calculated Plasticity Figure (Emley Units). Each laboratory obtained three replicate test results for each of the supplied materials.[6] Statistical summaries of the testing results are shown in Tables 1 and 2.

6.5.1.1 *Repeatability*—Two test results obtained within one laboratory shall be judged not equivalent if they differ by more than the "r" value for that material; "r" is the interval representing the critical difference between two test results for

[5] Godbey, Richard J. and Thomson, Margaret L., "Standardized Laboratory Apparatus for Measuring Emley Baseplate Rate of Absorption," Rochell Jaffe, Ed., Proceedings: 2005--International Building Lime Symposium, Michael Tate, Chairperson, National Lime Association, Arlington, VA, ISBN 0-9767621-0-2.

[6] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C07–1005.

TABLE 1 Final Vicat Penetration (mm)

MATERIAL	Average	Repeatability Standard Deviation	Reproducibility Standard Deviation	Repeatability Limit	Reproducibility Limit
	$\bar{\chi}$	s_r	s_R	r	R
Type S Hydrated Lime Samples A, C, F	19.7	2.76	2.81	7.7	7.9
Type S Hydrated Lime Samples B, E, G	18.4	2.13	2.53	5.9	7.1
Type S Hydrated Lime Samples D H I	18.4	2.83	2.83	7.9	7.9
Type N Hydrated Lime	17.8	2.59	2.59	7.3	7.3

TABLE 2 Calculated Plasticity Figure (Emley Units)

MATERIAL	Average	Repeatability Standard Deviation	Reproducibility Standard Deviation	Repeatability Limit	Reproducibility Limit
	$\bar{\chi}$	s_r	s_R	r	R
Type S Hydrated Lime Samples A, C, F	502	22.70	41.62	64	117
Type S Hydrated Lime Samples B, E, G	480	42.93	66.77	120	187
Type S Hydrated Lime Samples D H I	381	40.52	49.11	114	138
Type N Hydrated Lime	438	25.06	53.51	70	150

the same material, obtained by the same operator using the same equipment on the same day in the same laboratory.

6.5.1.2 *Reproducibility*—Two test results should be judged not equivalent if they differ by more than the "R" value for that material; "R" is the interval representing the difference between two test results for the same material, obtained by different operators using different equipment in different laboratories.

6.5.1.3 Any judgment in accordance with statements 6.5.1.1 or 6.5.1.2 would have an approximate 95 % probability of being correct. To judge the equivalency of two test results, it is recommended to choose the material closest in characteristics to the test material (Type S or Type N hydrated lime).

6.5.2 *Bias*—At the time of the studies, there was no accepted reference material suitable for determining the bias for this test method, therefore no statement on bias can be made. To judge the equivalency of two test results, it is recommended to choose the material closest in characteristics to the test material (Type S or Type N hydrated lime).

7. Water Retention of Hydrated Lime

7.1 *Significance and Use*:

7.1.1 This test method measures the ability of the hydrated lime in a plastic mix with sand to retain water, and hence retain consistency of the mix, when subjected to an applied suction. This ability, measured as a percent of the original consistency, is indicative of the workability to be expected in a masonry mortar containing the lime.

7.2 *Proportioning and Mixing*:

7.2.1 *Apparatus*—The apparatus used shall conform to Practice C 305.

7.2.2 *Proportions*—The mortar tested shall be composed of 500 g of lime and 1500 g of standard sand conforming to 8.2.3. If hydrated lime putty is used, use that weight of putty that is equivalent to 500 g of dry hydrated lime.

7.2.3 *Mechanical Mixing*:

7.2.3.1 Place the dry paddle and the dry bowl in the mixing position in the mixer.

7.2.3.2 Place a measured quantity of water in the bowl.

7.2.3.3 Add the lime to the water, then start the mixer and mix at slow speed (140 ± 5 r/min) for 30 s.

7.2.4 Add the entire quantity of sand slowly over a 30-s period while mixing at slow speed.

7.2.5 Stop the mixer, change to medium speed (285 ± 10 rpm) and mix for 30 s.

7.2.6 Stop the mixer and let the mortar stand for 1½ min. (During the first 15 s of this interval, quickly scrape down into the batch any mortar that may have collected on the side of the bowl, then for the remainder of this interval cover the bowl with the lid.)

7.2.7 Finish the mixing for 1 min at medium speed.

7.2.8 In any case requiring a remixing interval, any mortar adhering to the side of the bowl shall be quickly scraped down into the batch prior to remixing.

7.3 *Consistency*:

7.3.1 *Apparatus*—The flow table and mold used for the measurement of consistency of the mortar shall conform to Specification C 230/C 230M.

7.3.2 *Procedure*—Carefully wipe dry the flow table top and place the flow mold at the center. Immediately after completing the mixing operation, fill the mold with mortar gently pressed into place by the finger tips to ensure uniform filling free of voids. Smooth off the mortar level with the top of the mold by aid of a trowel, and remove the mold. Immediately drop the table through a height of 13 mm (½ in.), 25 times in 15 s. The flow is the resulting increase in diameter of the mortar mass, expressed as the percentage of the original diameter. The mortar may be adjusted, if the flow is below 100 %, by additions of water until the flow is within the range from 100 to 115 %. Make each adjustment by returning the mortar to the original mixing bowl, add water, and then mix at medium speed (285 ± 10 r/min) for 30 s. If the flow of the original mortar is greater than 115 %, prepare a new batch.

7.4 *Water Retention Test*:

7.4.1 *Apparatus*—The equipment shall conform to the apparatus used for the water retention test in Specification C 91 (see Fig. 3).

7.4.2 *Procedure*:

7.4.2.1 Adjust the vacuum regulator to maintain a vacuum of 51 ± 3 mm as measured on the vacuum gauge. Seat the perforated dish on the greased gasket of the funnel. Place a wetted filter paper in the bottom of the dish. Turn the stopcock to apply the vacuum to the funnel and check the apparatus for leaks and to determine that the required vacuum is obtained. Then turn the stopcock to shut off the vacuum from the funnel.

7.4.2.2 Immediately after the final consistency test (7.3.2), return all of the mortar to the bowl and remix the entire batch for 15 s at medium speed. Immediately after remixing the mortar, fill the perforated dish with the mortar to slightly above the rim. Tamp the mortar 15 times with the tamper. Apply ten of the tamping strokes at approximately uniform spacing adjacent to the rim of the dish and with the long axis of the tamping face held at right angles, to the radius of the dish.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Apply the remaining five tamping strokes at random points distributed over the central area of the dish. The tamping pressure shall be just sufficient to ensure filling of the dish. On completion of the tamping, the top of the mortar should extend slightly above the rim of the dish. Smooth off the mortar by drawing the flat side of the straightedge (with the leading edge slightly raised) across the top of the dish. Then cut off the mortar to a plane surface flush with the rim of the dish by drawing the straightedge with a sawing motion across the top of the dish in two cutting strokes, starting each cut near the center of the dish. If the mortar is pulled away from the side of the dish during the process of cutting off the excess mortar, gently press the mortar back into contact with the side of the dish using the tamper.

7.4.2.3 Turn the stopcock to apply vacuum to the funnel. After suction for 60 s, quickly turn the stopcock to expose the funnel to atmospheric pressure. Immediately slide the perforated dish off the funnel, touch it momentarily on a damp cloth to remove droplets of water, and set the dish on the table. Then using the bowl scraper (rubber scraper as specified in Practice C 305), plow and mix the mortar in the dish for 15 s. Upon completion of mixing, place the mortar in the flow mold and determine the flow. Carry out the entire operation without interruption and as quickly as possible. Not more than 30 min should be required for completion, starting from the completion of the mixing of the mortar for the first flow determination.

7.4.3 *Calculation*:

7.4.3.1 Calculate the water retention value for the mortar as follows:

$$\textit{Water}\ \text{retention value} = (A/B) \times 100 \qquad (2)$$

where:

A = flow after suction, and

B = flow immediately after mixing.

7.5 *Precision and Bias*:

7.5.1 No precision data are available due to the limited use of this test method. Therefore, users are advised to develop their own laboratory precision.

8. Air Entrainment

8.1 *Significance and Use*:

8.1.1 Hydrated lime, particularly that containing an air-entraining additive, used in masonry mortar may contribute to the air content of the mortar. Certain specifications and applications of mortar place a limit on this air content.

8.2 *Apparatus*:

8.2.1 *Flow Table*, conforming to the requirements prescribed in Specification C 230/C 230M.

8.2.2 *Mixing Apparatus*, conforming to the requirements as prescribed in Practice C 305.

8.2.3 The sand shall be a blend of equal parts by weight of graded Ottawa sand and standard 20-30 Ottawa sand. The fineness of graded Ottawa sand and standard 20-30 sand may be checked by using the methods described in Specification C 778.

8.3 *Preparation of Mortar*:

8.3.1 *Proportions for Mortar*—Lime-based mortars for measurement of air entrainment shall be proportioned to conform, in batch size, to the unit weights by volume of cementitious material and aggregate as shown in Table 3. The cement shall conform to Specifications C 150, C 595, or C 1107, and the hydrated lime to Specification C 207. The quantity of water, measured in millilitres, shall be such as to produce a flow of 110 ± 5 % as determined by the flow table. Proportions for the generally used batch sizes based on Table 4 material unit weight shall contain the weights as prescribed in Table 5.

8.3.2 *Mixing of Mortars*—Mix the mortar in accordance with the procedure for mixing pastes in Practice C 305.

8.3.3 *Determination of Flow*—Determine the flow in accordance with the Procedure section of Test Method C 109/C 109M.

8.4 *Procedure*:

8.4.1 If the mortar has the correct flow, use a separate portion of the mortar for the determination of entrained air. The amount of air entrainment shall be determined by one of two methods. The density method determines air content from the measured density of the mortar, the known density of constituents, and the mixture properties. The air pail method measures air content using Test Method C 231.

8.4.2 Density Method:

8.4.2.1 *Apparatus*:

Scales, Sieves, Glass Graduates, Tamper, Measure, Straightedge, Spatula, Tapping Stick, and Spoon, conforming to the requirements given in Test Method C 185.

8.4.2.2 *Procedure*:

(1) Fill a 400 ml measure with the mortar sample in accordance with Test Method C 185.

(2) Determine the weight of mortar in the measure.

8.4.2.3 *Calculation*:

Calculate the air content of the mortar and report it to the nearest 0.1 % as follows:

$$D = (W_1 + W_2 + W_3 + V_w)/[(W_1/S_1) + (W_2/S_2) + (W_3/S_3) + V_w]A = 100 - (W_m/4D) \qquad (3)$$

where:

D = density of air-free mortar,

W_1 = weight of cement, g,

W_2 = weight of lime, g,

W_3 = weight of blended Ottawa sand, g,

V_w = water used, mL,

S_1 = specific gravity of portland cement,

S_2 = specific gravity of hydrated lime,

S_3 = specific gravity of blended Ottawa sand,

A = volume % of entrained air, and

W_m = weight of 400 mL of mortar, g.

TABLE 3 Unit Weights and Apparent Specific Gravities

Materials	Unit weight, kg/m³(lb/ft³)[A]	Specific Gravity
Portland Cement	1,504 (94)	3.15
Blended Cement	obtain from purchaser	
Hydraulic Cement	obtain from purchaser	
Hydrated Lime	640 (40)	2.30
Blended Ottawa Silica Sand	1,280 (80)	2.65

[A] The unit weight values listed for cementitious materials are assumed values commonly used in construction practice.

TABLE 4 Precision Data

Material	Labs	Results in °C Rise		*r*	*R*
		Time	Range Tested		
High Calcium	12	30 s	12.3–44.4	1.56	4.21
High Calcium	11	3 min	32.1–56.1	1.72	4.72
Dolomitic	10	30 s	3.6–12.0	1.38	2.84
Dolomitic	9	3 min	21.2–36.4	1.62	3.72

TABLE 5 Weight of Materials for Mortar Batch

Mortar Type	Proportions by Volume	Portland Cement (g)	Hydrated Lime (g)	Blended Ottawa Silica Sand (g)
M	1:¼ :3¾	470.0	62.5	1,500
S	1:½ :4½	376.0	100.0	1,440
N	1:1:6	282.0	150.0	1,440
O	1:2:9	188.0	200.0	1,440
Lime/Sand	1:3		300.0	1,440

NOTE 5—For lime/sand mortars, W_1 and S_1 should be dropped from the calculation.

8.4.2.4 *Precision and Bias*:

(1) The single operator within laboratory standard deviation has been found to be 0.56 % air content throughout the range of 8 % to 19 % air content. Therefore results of two properly conducted tests by the same operator on similar batches of mortar should not differ by more than 1.6 % air content.

(2) The multilaboratory standard deviation has been found to be 1.0 % air content throughout the range of 8 % to 19 % air content. Therefore, results of two different laboratories on similar batches of mortar should not differ from each other by more than 2.8 % air content (see Test Method C 185).

8.4.3 Air Pail Method

8.4.3.1 *Apparatus*:

(1) Air Meters—There are two basic operational designs employing the principle of Boyle's law. Both types of units are detailed in Test Method C 231.

(2) Calibration Vessel, Spray Tube, Tamping Rod, Mallet, Strike-Off Bar, Funnel, and Water Measure, conforming to the requirements given in Test Method C 231.

8.4.3.2 *Procedure*:

(1) Calibrate the air meter using procedures described in Test Method C 231 Section 5.

(2) Fill the air meter and determine air content by using the method detailed in Test Method C 231 Section 8, except that for Type B meters with a volume of 1 L or less, there shall be no use of an internal vibrator as required in Test Method C 231 and described in Practice C 192.

(3) When using Type B meters with a volume of 1 L or less, compact the mortar into the bowl by tamping the mortar 15 times with a tamper meeting the requirements of Test Method C 185 Section 5. Apply 10 of the tamping strokes near the outside circumference of the mortar bowl evenly spaced at right angles to the radius of the bowl and five of the tamping strokes at random points distributed in the center of the bowl. Apply the tamping strokes in such a manner as to only settle and consolidate the mortar into the bowl without the addition of voids left by the insertion and removal of the tamper at each stroke.

8.4.3.3 *Precision and Bias*:

Although precision for the test method for air content of freshly mixed concrete has been reported in Test Method C 231, the precision of this test method has not been determined for lime-based mortars. When sufficient data has been obtained and analyzed, a statement of precision will be provided. In the meantime users of the test method are advised to develop their own.

SOUNDNESS TESTING

9. Autoclave Expansion of Hydrated Lime

9.1 *Significance and Use*:

9.1.1 Expansion of pressed tablets of hydrated lime generally indicates the presence of unhydrated oxides of magnesium and calcium. The relation of the degree of expansion in this test method to field performance has not been determined.

9.2 *Apparatus*:

9.2.1 *Mold and Press*—A steel mold capable of producing a press tablet at least 0.032 m (1.25 in.) in diameter and 0.006 m (0.25 in.) thick, and able to sustain at least 88.9 kN (20 000 lbf) pressure from a suitable press. It should be provided with a release jig also.

9.2.2 *Autoclave*, capable of holding 1034 kPa (150 psi) for 2 h.

9.2.3 *Micrometer*, dial-type, capable of measuring 2.54 µm (0.0001 in.).

9.2.4 *Microscope*, with graduated lens for measuring 0.10 mm.

9.3 *Procedure*:

9.3.1 Weigh out 15 g of hydrated sample, place in the mold, and press into a tablet. Press to 33.4 kN (7500 lbf) for 10 s, then increase pressure to 88.9 kN (20 000 lbf) or more. Hold for 10 s before releasing. Press tablet from mold with jig and draw three diameter lines across the surface of the tablet using a lead pencil. Draw two diameter lines normal to each other and draw the third bisecting the 90° angles of the other two. Measure the diameters with a dial micrometer and place the tablet on the autoclave rack. Use aluminum foil to protect the tablets from water dripping. Autoclave at 862 to 1034 kPa (125 to 150 psi) for 2 h. Begin timing when the pressure reaches 345 kPa (50 psi). After the autoclaving interval, allow the autoclave to cool, remove the tablet, and remeasure the diameters. Calculate the average percent expansion of the tablet from the before and after measurements.

9.4 *Expansion of Hydrated Lime-Portland Cement-Aggregate*:

9.4.1 *Materials*:

9.4.1.1 *Standard Cement*—Type I or Type II portland cement.

9.4.1.2 *Standard Aggregate*—Pulverized limestone, minus 212-µm (No. 70) sieve, having less than 0.5 % silicon dioxide (SiO_2).

9.4.2 *Procedure*:

9.4.2.1 *Test Tablet*—Make up a pressed tablet in accordance with the procedure outlined in 9.3.1 using the following mixture for the sample:

Standard portland cement	14 g
Hydrated lime	8 g

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Standard aggregate (pulverized limestone)	72 g

Blend the mix until homogeneous.

9.4.2.2 *Standard Tablet*—Make up a pressed tablet in accordance with the procedure outlined in 9.3.1 using the following mixture for the sample:

Standard portland cement	7 g
Standard aggregate (pulverized limestone)	16 g

Blend the mix until homogeneous.

9.4.2.3 Autoclave and calculate expansions of the test tablet and the standard tablet in accordance with 9.3.1.

9.4.2.4 Determine the autoclave expansion of hydrated lime for masonry purposes by subtracting the average percent expansion of the standard tablet from the sample tablet.

9.5 *Precision and Bias*:

9.5.1 No precision data are available due to the limited use of this test method. Therefore, users are advised to develop their own laboratory precision. No statement is being made about the bias of this test method.

10. Popping and Pitting of Hydrated Lime

10.1 *Significance and Use*:

10.1.1 Pops and pits are caused by the hydration and expansion of coarse particles of unhydrated lime or lime-impurity reaction products present in the hydrated lime. The level of popping and pitting in the sample is indicative of the potential for the appearance of surface defects in plastering applications.

10.2 *Gauging Plaster*:

10.2.1 The gauging plaster used for the popping and pitting test shall conform to the Test Methods section of Specification C 28/C 28M and shall have a setting time of not more than 1 h when tested in accordance with Test Methods C 472. Test the gauging plaster without lime in the manner described in 10.3 to ensure its freedom from pops and pits. If any pops or pits are found, provide another lot of gauging plaster that is free of pops and pits when subjected to this test.

10.3 *Procedure*:

10.3.1 Mix 100 g of hydrated lime with sufficient water to bring to such a consistency as to give a penetration of 20 ± 5 mm when tested in accordance with 5.3.3. Mix into this putty, 25 g of gauging plaster (10.2.1), adding more water as required to maintain workable consistency. Spread on a glass plate to make a pat at least 150 by 200 mm (6 by 8 in.) by approximately 3 mm (⅛ in.) in thickness. Trowel to a smooth finish. Allow to stand overnight.

10.3.2 Place the specimen and plate on a rack in the steam bath so that water is not in contact with the specimen to be tested. Provide a sloping cover above the specimen to prevent condensed steam from dripping onto the surface of the specimen. Raise the temperature of the water in the steam bath to boiling and maintain at boiling for 5 h. Remove the specimens from the bath and examine for pops and pits.

10.3.3 The pitting potential of hydrated lime can be determined in conjunction with autoclave expansion as in 9.3.1. However, it is not necessary to measure diameter, if only the pitting potential is to be determined. After following the procedure for expansion in 9.3.1, examine the pressed tablet under the measuring microscope, and count and measure the pits in millimetres.

APPLICATION TESTING

11. Slaking Rate of Quicklime

11.1 Significance and Use:

11.1.1 The temperature rise in 30 s is a measure of the reactivity of the softer-burned portion of the quicklime. Total slaking time provides a measure of the overall degree of reactivity of the material. Total temperature rise is largely dependent on the available lime content of the sample.

11.1.2 These slaking parameters provide an indication of the performance of the quicklime to be expected in industrial slaking systems. Slaking characteristics have an effect on lime slurry properties such as settling characteristics, viscosity, particle size, and reaction rate.

11.2 *Apparatus*:

11.2.1 *Mechanical Stirrer*, speed 400 ± 50 r/min, fitted with a special stirring rod.

11.2.2 *Modified Dewar Flask*, 665-mL, fitted with special rubber gasket covers.

11.2.3 *Thermometer*, dial-type, 0 to 100 °C range in 1 °C increments or thermocouple with a response time equivalent to or faster than the dial thermometer.

11.2.4 *Torsion Balance*.

11.2.5 *Sieve*, 203-mm (8-in.), 3.35-mm (No. 6), conforming to Specification E 11.

11.2.6 An apparatus essentially the same as that illustrated in Fig. 4 and Fig. 5 shall be used. The apparatus consists of a covered reaction container fitted with a mechanical stirrer and thermometer. The quicklime charge shall be stirred with a mechanical stirrer fitted with a stainless steel rod, the end of which is formed into a loop to follow the contour of the reaction container. The vacuum reaction flask shall be provided with a cover consisting of two circular pieces of gasket rubber sheet, approximately 3 mm (⅛ in.) thick. The first piece is provided with a single radial slot that slides over the stirring rod and the thermometer. The second piece (top) has a similar slot plus a hole to provide for the dial thermometer. When the two cover pieces are in place, the slot on the lower piece is at right angles to the slot on the upper piece with the thermometer stem extending through the lower slot. The apparatus may be assembled by any convenient supporting equipment.

11.3 *Procedure*:

11.3.1 Prepare the sample of quicklime (as rapidly as possible to prevent sample deterioration) so that a majority of the material passes a 3.35 mm (No. 6) sieve. Place the sample in an airtight container and allow to come to room temperature before testing. The slaking rate of lime is significantly affected by the particle size of the sample and must be as close to a 3.35 mm (No. 6) sieve as possible. It is not necessary that 100 % of the sample pass a 3.35 mm (No. 6) sieve, but all of the sample, including the plus 3.35 mm (plus No. 6) fraction, must be used in the test.

11.3.2 *Slaking Rate*—Adjust the temperature of about 500 mL of distilled water in accordance with the schedule given in Table 6, and add the specified amount to the Dewar flask. Set

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

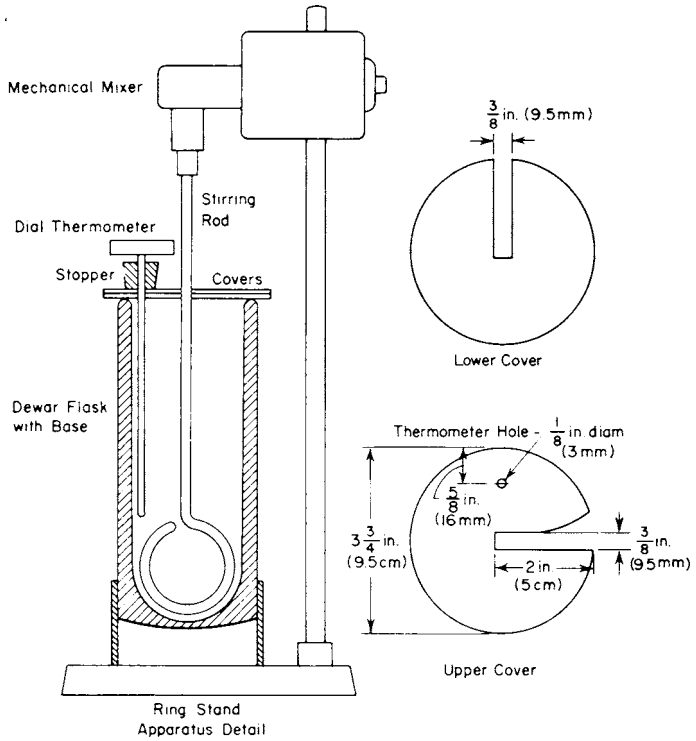

FIG. 4 Slaking Reactivity Apparatus

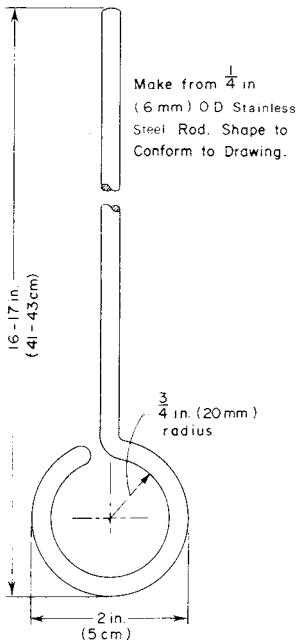

FIG. 5 Stirring Rod Detail

the agitator revolving at 400 ± 50 r/min. The temperature of the water in the flask must be ±0.5 °C of the desired temperature. Quarter and weigh out the required amount of the prepared quicklime sample. Add the quicklime to the water without delay and simultaneously begin timing. Put the covers in place immediately. Take a reading at each 30 s interval.

11.3.3 Continue readings until less than 0.5 °C temperature change is noted in each of three consecutive readings. The total active slaking time will then be the time at which the first of the three consecutive readings was taken. The temperature at this time will be considered the final reaction temperature. Subtract the initial temperature from the final temperature to obtain the total temperature rise. Subtract the initial temperature from the temperature at 30 s for the temperature rise in 30 s. Subtract the initial temperature from the temperature at 3 min for the temperature rise in 3 min.

TABLE 6 Schedule for Slaking Rate

	Material to Be Tested	
	Dolomitic	High Calcium
Temperature of water, °C	40	25[A]
Quantity of water, mL	400	400
Quantity of quicklime, g	120	100

[A] Initial temperature of 40 °C may be used, provided the report of results states the initial temperature.

11.3.4 *Residue of Quicklime*—Allow slurry from the slaking/reactivity test to continue slaking for a minimum of 15 min. Stop the stirrer and remove the Dewar flask, washing the slurry residue from the stirring rod into the flask. Carefully and slowly pour the residue through a No. 30 (600-µm) sieve (Note 6). Wash the slurry through the screen with a spray of tap water, being careful not to lose any residue over the top of the sieve. Continue washing until all slurry is through the sieve and all that remains are residue particles. Blot dry the bottom of the sieve with a paper towel and then place in a drying oven for 1 h at 105 ± 5 °C. Remove from the oven, cool, collect the dried residue, and weigh.

$$\textit{Calculation: } \frac{\textit{Grams of Residue}}{\textit{Weight of Sample}} \times 100 = \%\ \textit{Residue}$$

NOTE 6—The quicklime being slaked is very hot and highly basic. Caution must be taken not to let this material contact the eyes or skin as this may cause severe thermal and/or chemical burns.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11.4 *Report*:

11.4.1 Record the actual temperature rise and plot a suitable curve showing temperature rise as the ordinate and time as the abscissa. The results may also be reported as:

11.4.1.1 Temperature rise in 30 s (or at any other designated time) in degrees Celsius,

11.4.1.2 Total temperature rise in degrees Celsius, and

11.4.1.3 Total active slaking time in minutes.

11.5 *Precision and Bias*:

11.5.1 Twelve laboratories cooperated in the testing of five high calcium quicklimes and four dolomitic quicklimes thereby obtaining the repeatability (*r*) and reproducibility (*R*) (Practice E 691) data contained in Table 4.[7]

11.5.2 Due to the lack of a recognized industry standard, the bias of this test method has not been determined. The variety of reporting options also complicates obtaining a suitable bias statement.

12. Dry Brightness of Pulverized Limestone

12.1 *Summary of Test Method*:

12.1.1 A sample of the dry material is compressed and its reflectance measured on a reflectometer that has previously been standardized.

12.2 *Significance and Use*:

12.2.1 This test method provides a measure of the reflectance, or whiteness, or both of ground calcium carbonate products by comparison with a standard, using green and blue filters.

12.3 *Apparatus*:

12.3.1 *Reflectometer*:

12.3.2 *Dry Powder Press (See Fig. 6)*—Instructions, as supplied by the manufacturer, for preparation of the sample and use of the powder press shall be explicitly followed.

12.3.3 *White Porcelain Standard Plaque*, to be used as secondary standard.

12.4 *Reagent*:

12.4.1 *Barium Sulfate ($BaSO_4$)*—Use Eastman Kodak[8] Chemical No. 6091[9], white reflectance standard only.

12.5 *Calibration and Standardization*:

12.5.1 *Zero Scale Calibration (bottom of scale standardization)*:

12.5.1.1 Place the black glass provided with the instrument over the specimen port, so that the shiny side is towards the opening. The glass should be positioned so that no light escapes from the black glass-opening interface.

12.5.1.2 The processor is then adjusted to read *zero reflectance.*

12.5.2 *Standardizing of the White Standard (standardization of the upper part of the scale)*:

12.5.2.1 A primary standard pellet (barium sulfate) which is free from surface flaws should be positioned over the specimen port so that no light can escape at the pellet-opening interface.

12.5.2.2 The Eastman Kodak barium sulfate reflectance standard is provided with reflectance values at various wavelengths. Since some variation is possible between lots of $BaSO_4$, the values used to standardize the reflectometer must be calculated. A normal *Y* value will be between 99.0 and 98.5, depending on the lot number.

12.5.2.3 After this has been accomplished, a reading of the white standard plaque can be taken and the values of *X*, *Y*, and *Z* recorded. This plaque can then be used as a secondary standard for future standardizations. This reduces the necessity of making a barium sulfate pellet for every test series.

12.6 *Procedure*:

12.6.1 The reflectometer must be given ample warm-up time prior to the sample readings.

12.6.2 The reflectometer must first be standardized; this consists of standardization of the bottom of the scale and standardization of the upper part of the scale.

12.6.3 Sample pellets should then be pressed (Note 7) following manufacturer instructions explicitly (Note 8).

NOTE 7—Ground products with more than 0.5 % residue on a 45-μm (No. 325) screen will require special care in preparing the sample cup. The coarser the product, the harder to obtain a compact, smooth surface.

NOTE 8—Some reflectometers and spectrophotometers can measure reflectance with the powder sample in a horizontal position, thus eliminating the necessity to prepare a sample pellet. Also, coated ground limestones are difficult to pelletize. Loose powder samples should be smoothed in a convenient sized container until the surface is level and free from cracks and other surface defects.

12.6.4 After the reflectometer has been standardized, the sample pellets are centered beneath the opening and positioned so that no light escapes from the pellet-opening interface.

12.6.5 The samples are then read for *X*, *Y*, *Z*, *L*, *a*, and *b* values. These values are recorded.

12.6.6 To determine if the values of the reflectometer have drifted, the white standard (either the barium sulfate pellet or the porcelain plaque) is placed over the specimen port and read. Values should be the same as those placed in the processor during the standardization procedure.

12.7 *Report*:

12.7.1 The *Y* value is recorded as the dry brightness of that specific limestone.

12.8 *Precision and Bias*:

12.8.1 The same instrument, operator, and standard should reproduce ±0.2 %. Different instrument (Note 9), operators, and standard should agree ±1.0 %.

NOTE 9—It is recognized that there are various manufacturers of reflectometers, and testing has been undertaken to relate *X*, *Y*, and *Z* tristimulus color values from one instrument to another. If results of this comparison testing are desired, please contact the Pulverized Limestone Association.

13. Limestone Grindability Determination by the Laboratory Ball Mill Method

13.1 *Scope*:

[7] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C07–1003.

[8] Registered trademark.

[9] The sole source of supply of the apparatus known to the committee at this time is Eastman Kodak Co., 343 State St., Rochester, NY 14650. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

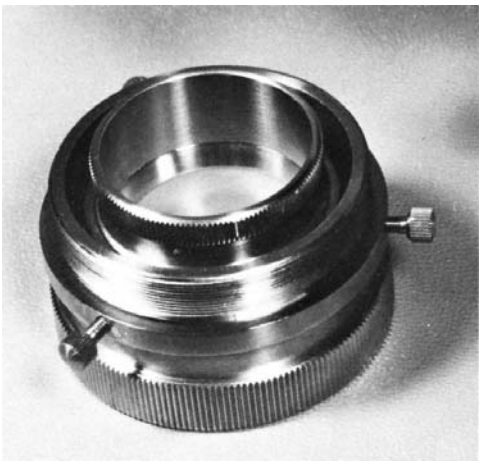

FIG. 6 Dry-Powder Press

13.1.1 This test method is used to determine the relative grindability or ease of pulverization of limestones of differing hardness and to report this as a grindability index.

13.1.2 This test method is applicable to all types of limestone.

13.2 *Summary of Test Method*:

13.2.1 Limestone of a specified size range is wet ground in a ball mill therein receiving a specified amount of grinding energy. The amount of minus 75-µm (200-mesh) limestone produced is measured by wet sieving and reported as the percent passing 75-µm (200-mesh) after 5000 revolutions. This is the grindability index.

13.3 *Significance and Use*:

13.3.1 This test method is useful for comparison and acceptance testing of limestone for applications where fine ground limestone is desired.

13.4 *Apparatus*:

13.4.1 *Jar Mill*, operated at 110 ± 10 r/min.

13.4.2 *Mill Jar*, ceramic 14 cm (5½ in.) diameter by 20.2 cm (6¾ in.) high.

13.4.3 *Grinding Media*, 160 ± 1 g total, consisting of seven ceramic 21 by 21 mm (13⁄16 by 13⁄16 in.) cylindrical grinding media (about 23 g each).

13.4.4 The sieves used shall conform to the requirements of Specification E 11.

13.4.5 Weights and weighing devices, shall conform to the requirements of Specification C 1005.

13.4.6 *Drying Oven*, capable of maintaining 100 °C.

13.4.7 *A Chipmunk Crusher*, capable of breaking large rocks to less than 6.35 mm (¼ in.).

13.4.8 *Riffle Sample Splitter*, open pan, 12.7 mm (½ in.) chute width.

13.4.9 *Stopwatch*.

13.5 *Reagents and Materials*:

13.5.1 *Milling Solution*, a 0.1 % solution of acrylate based dispersant. The dispersant chosen should not increase the solubility of limestone in water.[10]

13.6 *Sampling*:

13.6.1 Sample in accordance with Practice D 75.

13.6.2 Reduce the sample in accordance with Practice C 702 and prepare by sieving out the material that passes a 850-µm (No. 20) sieve[11] and is retained on a 425-µm (No. 40) sieve.[11]

13.7 *Procedure*:

13.7.1 Weigh seven grinding media, make adjustments (by substitutions or filing) to bring total weight to 160 g ± 1 g.

13.7.2 If the jar mill has provision for automatic shut-off, set it for 5000 revolutions, otherwise determine the mill r/min by counting the revolutions in an accurately timed period (using stopwatch) and then calculate the exact time required for 5000 revolutions.

13.7.3 Weigh out 20 ± 0.01 g of dried 20 by 40 mesh limestone. Record actual weight as *W*1.

13.7.4 Add 180 mL of milling solution to clean and empty mill jar.

13.7.5 Add the seven grinding media and quantitatively transfer the limestone sample to the mill jar and secure the top.

13.7.6 Place the mill jar on the mill rollers and operate the mill for the exact time required to make 5000 revolutions.

13.7.7 Quantitatively transfer the limestone slurry from the jar mill by rinsing the entire contents onto a coarse sieve (for example, 3.35 mm (No. 6)) and an underlying 75-µm (No. 200) sieve. Rinse the media and coarse sieve and separate the sieves.

13.7.8 Wet sieve the sample remaining on the 75-µm (No. 200) sieve to remove the finer material.

13.7.9 Dry and weigh the residue from the 75-µm (No. 200) sieve and record as *W*2 (to the nearest 0.01 g).

13.8 *Calculation*:

13.8.1 Calculate the grindability index (*GI*) as follows:

$$GI = (W1 - W2)/W1 \times 100 \quad (4)$$

13.9 *Precision and Bias*:

13.9.1 The precision and bias of this test method has not been determined at this time.

14. Settling Rate of Hydrated Lime

14.1 *Significance and Use*:

14.1.1 This test method provides a measure of the rate of settling of a hydrated lime slurry, a form in which this material is frequently used. In some applications a slow settling slurry is desirable; in others, fast settling is preferred.

14.2 *Procedure*:

14.2.1 Place 10.0 g of lime hydrate in a 100-mL glass-stoppered graduated cylinder (internal diameter about 24 mm). Wet with 50 mL of carbon dioxide (CO_2) free distilled water at 23 ± 1.7 °C (73.4± 3 °F) and mix thoroughly by alternately inverting and righting the cylinder slowly for a period of 2 min. Allow the graduate and contents to stand at 23 ± 1.7 °C for 30 min and then dilute to the 100-mL mark with CO_2-free distilled water at 23 ± 1.7 °C. Mix contents again thoroughly as before and allow to stand undisturbed at 23 ± 1.7 °C for 24 h.

14.3 *Report*:

[10] Distilled or deionized water should be used for milling solution or solubility tests.

[11] U.S. Standard Sieves 6, 20, 40 and 200 mesh sizes; 20.3 cm (8 in.) diameter by 5 cm (2 in.) depth with stainless steel wire cloth.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

14.3.1 Report the sedimentation height in millilitres after ¼ , ½ , ¾ , 1, 2, 4, and 24 h, reading the bottom of the meniscus.

NOTE 10—Slight variations in results of this test method on a sample run in different laboratories or by different operators are permissible. The test is not an absolute one, but is designed to distinguish between fast and slow settling hydrates.

14.4 *Precision and Bias*:

14.4.1 No precision data are available due to the limited use of this test method. Therefore, users are advised to develop their own laboratory precision.

PARTICLE SIZE ANALYSIS

15. Residue and Sieve Analysis

15.1 *Significance and Use*:

15.1.1 This test method determines the residue obtained from slaking quicklime. Residue, in this case, is largely unreacted material such as uncalcined limestone or dolomite, overburned quicklime, or gross impurities, or a combination of these.

15.2 *Apparatus*:

15.2.1 The sieves used shall conform to the requirements of Specification E 11. Preferably the sieves should have a 4-in. depth.

15.2.2 If sieve calibrations are required, follow the method as outlined in Test Method C 430.

15.2.3 *Spray Nozzle*, conforming to the requirements of Test Method C 430.

15.2.4 *Pressure Gage* shall be 3-in. (75-mm) minimum diameter, and shall be graduated in 1-psi (6.9 kPa) increments, and shall have a maximum capacity of 30-psi (207 kPa). The accuracy at 10 psi (69 kPa) shall be ±0.25 psi (±1.7 kPa).

15.2.5 Attach a pressure gage to the water faucet and a rubber tubing to the output side of the pressure gage. On the other end of the rubber tubing attach the spray nozzle (see 15.2.3).

15.3 *Residue of Quicklime*:

15.3.1 Select a representative 2.5-kg (5-lb) sample of the quicklime. Break lime selected for this test so as to entirely pass a 25.0-mm (1-in.) square mesh screen. Test the pulverized lime as received. Place the sample in a box of wood or of some material of similarly low thermal conductivity, and an experienced operator should slake it with sufficient water at 21 to 27 °C (70 to 80 °F) to produce the maximum quantity of lime putty, carefully avoiding "burning" or "drowning" the lime. Allow it to stand for 1 h and then wash through an 850-µm (No. 20) sieve by a stream of water having a moderate pressure. Do not rub any material through the sieve. Continue the washing until the residue on the screen appears to consist entirely of coarse particles, but in no case continue the washing for more than 30 min. Dry the residue to constant weight at a temperature of 100 to 107 °C (212 to 225 °F) and calculate the percentage residue, based on the original weight of the sample.

15.4 *Sieve Analysis of Hydrated Lime*:

15.4.1 Select a 100-g sample of the hydrated lime as received and place on a 600-µm (No. 30) sieve, which is nested above a 75-µm (No. 200) sieve. Wash the material through the sieves by means of a stream of water from the nozzle attached to a rubber tubing (see 15.2.5) after adjusting the water pressure to 10 psi (69 kPa) ±0.25 psi (±1.7 kPa). Carefully wash the sample through the sieves without allowing any splashing over the sides of the sieve. After the sample is washed through the top sieve, separate the two sieves and continue washing through the 75-µm (No. 200) sieve until the water coming through the sieve is clear, that is, no particles can be seen in a beaker of the rinse water, but in no case continue the washing longer than 30 min. Take care not to let water accumulate on the 75-µm (No. 200) sieve, because the openings will become clogged and the operation cannot be completed in 30 min.

15.4.2 Calculate the percentage residue retained on each sieve, based on the original weight of the sample. The weight of the material retained on the 600-µm (No. 30) sieve shall be added to the weight of the material retained on the 75-µm sieve to obtain the correct weight of the material retained on the 75-µm sieve.

15.5 *Sieve Analysis of Limestone and Dry Quicklime*:

15.5.1 Select the desired sieves and nest them with the coarsest sieves on top. Weigh a 100-g sample of the material to be tested and place it on the top sieve. Conduct the sieving operation by means of a lateral and vertical motion of the sieve accompanied by a jarring action to keep the sample moving continuously over the surface of the sieve. Continue sieving until not more than 1 % of the residue passes any sieve during 1 min. If mechanical sieving is used, the device shall be such as to impart the type of agitation described in the hand sieving operation. Continue the shaking for a period of 15 min.

15.5.2 Weigh the residue retained on each sieve to the nearest 0.1 g. Report the results of the sieve analysis as follows: (*1*) total percentages passing each sieve, (*2*) total percentages retained on each sieve, or (*3*) percentages retained between consecutive sieves, depending upon the form of the specification for the use of the material under test.

15.6 *Precision and Bias*:

15.6.1 No precision data are available due to the limited use of these test methods. Therefore, users are advised to develop their own laboratory precision. No statement is being made about the bias of these test methods.

16. Fineness of Pulverized Quicklime and Hydrated Lime by Air Permeability

16.1 *Significance and Use*:

16.1.1 This test method covers the determination of fineness of pulverized quicklime and hydrated lime using the Blaine air permeability apparatus described in Test Method C 204. Fineness in terms of surface area shall be expressed as total surface area in square centimetres per gram, or square metres per kilogram.

16.1.2 This test method provides, in general, relative rather than absolute fineness values. For the complete description of the apparatus and the procedures for use, refer to Test Method C 204.

16.2 *Precision and Bias*:

16.2.1 Although precision for the test method for fineness of portland cement by air permeability apparatus has been reported in Test Method C 204, the precision of this test method has not been determined for pulverized lime and hydrated lime.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

When sufficient data has been obtained and analyzed, a statement of precision will be provided. In the meantime users of this test method are advised to develop their own.

17. Particle Size of Pulverized Limestone

17.1 *Significance and Use*:

17.1.1 Particle size of pulverized limestone, as the word is used in these methods, is the percent distribution of the equivalent spherical diameter of the individual particles expressed in micrometres, using the principle of sedimentation and Stokes' law for particle size determination. It is intended for use with pulverized limestones with not more than 0.5 % residue on a 45-μm (No. 325) sieve.

17.2 *Apparatus*:

17.2.1 *Soil Hydrometer*, ASTM 152H.

17.2.2 *Sedimentation Cylinder*, ASTM, 1000-mL capacity.

17.2.3 *Rubber Stopper*, Size 12.

17.2.4 *Thermometer*, 0 to 105 °C.

17.2.5 *Stop Watch*.

17.2.6 *Regular Clock or Watch*.

17.2.7 *Mixer*.

17.2.8 *Water Bath*.

17.2.9 *Balance*.

17.2.10 *Watch Glass*.

17.2.11 *Graph Paper*, 3 cycles × 70 divisions.

17.2.12 *Sieve*, 45-μm (No. 325), stainless steel cloth, brass frame, 8-in. diameter.

17.2.13 *Sieve*, 500-mesh, stainless steel cloth, brass frame, 4-in. diameter, 5-in. tall frame.

17.3 *Reagents*:

17.3.1 *Particle-Dispersing Agent*, (30 mL of 25 % solution is diluted up to 400 mL with distilled water).

17.4 *Procedure*:

17.4.1 Determine meniscus correction by inserting the hydrometer in the sedimentation cylinder filled to mark with distilled water. Record the reading at the top of the meniscus and at the bottom of the meniscus. The difference between the two readings is the meniscus correction. For example, in Fig. 7, the correction for the hydrometer used is 1.2. This reading is *added* to each R to obtain R_r.

17.4.2 Calibrate the hydrometer by adding 30 mL of the particle-dispersing solution to the sedimentation cylinder, then bringing up to the mark with distilled water at 27 °C. Mix thoroughly and take a hydrometer reading (read at the top of the meniscus). Repeat after cooling the cylinder to 17 °C and adjusting the meniscus so it is on the mark. Assume a straight-line relationship and draw a line that gives the *composite correction factor.* This factor is the difference between the reading and zero. These are the corrections entered in Table 7 and should be determined for each hydrometer. Four factors are compensated for in the correction factor: (*1*) *Temperature:* Hydrometers and cylinders are calibrated at 20 °C; variations from this temperature produce inaccuracy in the hydrometer reading; (*2*) *Specific gravity:* Addition of dispersant changes the specific gravity of the solution; (*3*) *Meniscus correction:* Hydrometers are graduated to read at the bottom of the meniscus but opaque calcium carbonate solutions require readings at the top of the meniscus; and (*4*) *Hydrometers:* In spite of the supposed similarity in volume of the hydrometers (ASTM 152H), variations of as much as 1.0-scale divisions between two similar hydrometers have been noted. The correction factor brings all four into line with one another. It is not necessary to repeat this calibration unless changing to a different hydrometer.

17.4.3 Weigh 40 g of sample.

17.4.4 Add approximately 300 mL of distilled water to the mixer, 30 mL of the particle-dispersing solution, followed by 40 g of unknown sample. Cover. Agitate for exactly 2 min at high speed.

17.4.5 Transfer the slurry quantitatively to the 1000-mL sedimentation cylinder. Make up to approximately 3.2 mm (⅛ in.) above the mark since it must be read from the top (as the bottom of the meniscus is not visible) and this will approximate the 1000-mL calibration of the cylinder. Cylinder temperature can be adjusted to 20 °C by running cool water on the outside of the cylinder and stirring with a thermometer until 20 °C is reached. Cap with the rubber stopper. Mix well by inverting the cylinder 15 or more times. Remove the stopper and put the cylinder in a water bath that has been previously adjusted to as close to 20 °C as is possible. Start the stop watch and note the time on the clock. At exactly 4½ min after start, carefully insert the hydrometer to the approximate point where the reading is to be made. Take the reading at exactly 5 min. Record the reading and temperature (Note 11). Remove the hydrometer and wash clean of any slurry. Cover the cylinder with the watch glass.

NOTE 11—Temperature must be taken inside the cylinder and not in the water bath.

17.4.6 Take additional readings at 15, 30, 60, 120, *or* 180 min; 300 *or* 360 min; and 1200 *or* 1440 min after the start.

17.4.7 Take a 25-g sample and run a 500-mesh wet-sieve test. The opening of the 500-mesh sieve is approximately 25 μm. From this result calculate the percent finer than 25 μm. Do not discard the plus 500-mesh but use this with the 45-μm (No. 325) sieve to obtain the percent finer than 44 μm. The opening of the 45-μm sieve is 44 μm.

17.5 *Calculation*:

17.5.1 Arrange the data on a sample sheet.

17.5.2 Record the date and clock readings as readings are taken.

17.5.3 Readings are usually taken at 5, 15, 30, 60, 180, 360, and 1440 min. The 25-μm point is obtained from the 500-mesh sieve result and the 44-μm point is obtained from the 45-μm sieve result.

17.5.4 Record the temperature, T, and the hydrometer reading, R, for each reading.

17.5.5 Obtain R_r by *adding* the meniscus correction to each R value.

17.5.6 Obtain R_c, the corrected hydrometer reading, from Fig. 7. This value can be different for each hydrometer and must be individually determined.

17.5.7 Obtain L from Table 8 using R_r values.

17.5.8 $\sqrt{L/T}$ is found from Fig. 8 and the values for L and T (time). For times not in Fig. 8, calculate the $\sqrt{L/T}$ since the values for L and T (in minutes) are known.

17.5.9 Find D at 20 °C in terms of $\sqrt{L/T}$ using Table 9.

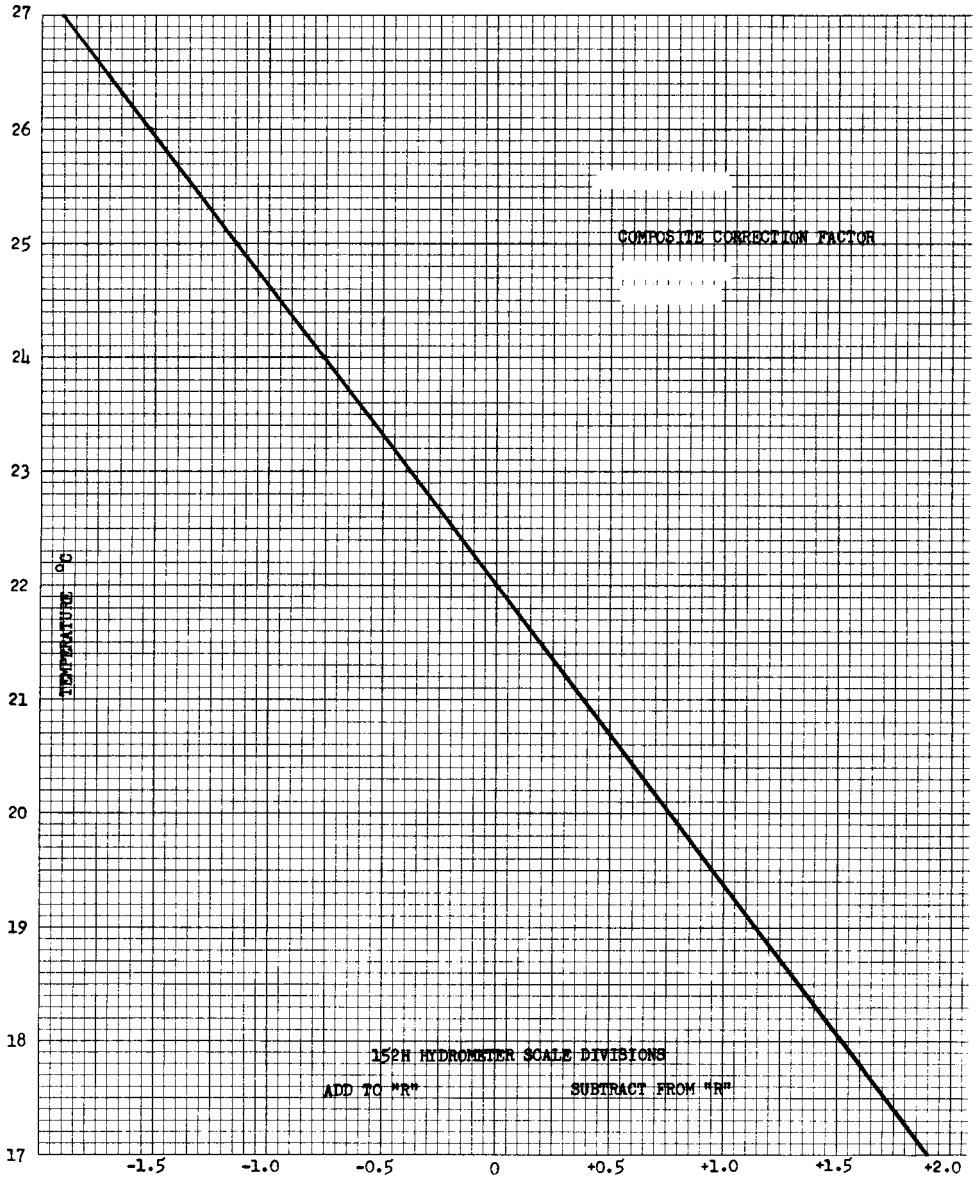

FIG. 7 Composite Correction Factor for Hydrometer

TABLE 7 Hydrometer Composite Correction Factor

Temperature, °C	Correction Factor
17	+1.90
18	+1.52
19	+1.14
20	+0.76
21	+0.39
22	0.00
23	−0.38
24	−0.76
25	−1.14
26	−1.52
27	−1.90

17.5.10 . To correct D for temperature, use Table 10 and find ΔD in terms of $\sqrt{L/T}$. Multiply by ΔT (ΔT is the difference in temperature between 20 °C and the actual temperature of the test). This will give a value to be subtracted from the D found in 17.5.9 if the temperature is above 20 °C. If the temperature is below 20 °C, this correction should be added.

17.5.11 Find P by using Table 10 and the value for R_c.

17.5.12 The values of D_c are now plotted against the values of P.

17.6 *Precision and Bias*:

17.6.1 The precision and bias of this test method has not been determined.

18. Dry Screening of Hydrated Lime, Pulverized Quicklime, and Limestone by Air Jet Sieving

18.1 *Significance and Use*:

18.1.1 This test method uses a rotating slit nozzle to supply a stream of air directed at the backside of a test sieve, keeping the screen from “blinding.” The aerated material is then pulled back through the sieve by a vacuum source.

28	11.7	59	6.6
29	11.5	60	6.5
30	11.4		

18.1.2 The advantages of dry screening by air jet sieving are twofold. The material being tested is less likely to "blind" the screen because of the recurring counterflow of an air stream to the back of the sieve. Also, dry screening avoids the error introduced by the interaction of the test material with soluble liquid media.

18.1.3 This test method is suitable for screening material from a nominal 300 µm (50 mesh) in size to 20 µm (635 mesh).

NOTE 12—Blinding of the sieves can occur at various sizes depending on the materials being sieved. Experience has shown 45 µm (325 mesh) to be the lower limit with some hydrates. Other hydrates and pulverized quicklime may be sieved to 32 µm (450 mesh). Limestone can be sieved to 20 µm (635 mesh).

18.2 *Apparatus*:

18.2.1 *An Enclosed Device*, capable of creating a vacuum on the backside of a sieve causing a rotating slit nozzle to supply an air stream perpendicular to the bottom of the sieve. The purpose is to suspend all material on the sieve by the air stream on a rotating basis.[12]

18.2.2 *Balance*, suitable for weighing accurately to 0.01 g.

NOTE 13—Selection of balance with regard to accuracy is dependent on the sample size chosen and residue retained and must be consistent with the accuracy required. Therefore, a balance weighing accurately to 0.001 g may be desired.

18.2.3 *Brush*, soft bristle.

18.2.4 *Sieve Cover*—A hard plastic transparent cover used to create a vacuum on the sieve.

18.2.5 *Test Sieves*—The sieves should be constructed using a woven wire, either brass or stainless steel, mounted on a substantial frame. Electroformed sieves are not recommended because of increased blinding and cleaning problems, making them impractical to use under most conditions. The sieves shall be approximately 8 in. in diameter and conform to Specification E 11. A flexible collar must be used to ensure an air tight fit between the sieve and the device.

18.3 *Procedure*:

18.3.1 After placing the appropriate sieve into position, weigh (to the nearest 0.01 g) a sample of the test material and place it on the sieve.

NOTE 14— The accuracy of sieve analysis with products with fine particle size distributions such as Type S hydrated lime can be improved by adding graphite powder (nominal 20 µm (625 mesh)) to the sample. For every 20 g of sample, 0.5 g of graphite should be added.

NOTE 15—The amount of sample and duration of sieving are dependent upon the type of material and gradation and therefore should be adapted to individual conditions. Generally, the larger the sample size, the more representative of the material tested and the less significant are errors of technique, therefore, the results are the more exact. Sample weights can vary from 20 g for material finer than 40 µm up to 50 g for larger, heavier materials.

18.3.2 Place cover on sieve, set timer to 6 min and start vacuum (maintain vacuum according to manufacturer's recommendation). Any material clinging to the cover or edge of the sieve can be removed by light tapping with a mallet or similar device (see Note 15). If agglomerations form, they can be broken apart with a soft bristle brush.

NOTE 16—Static electrical charges can often develop on the cover (if it is made of plastic) causing it to hold a heavy film of the material being sieved. If tapping will not loosen the material, a static face sheet[13] may be used to wipe the cover surface before starting the test.

18.3.3 After screening, clean the sieve with a fine bristle brush being careful not to damage the mesh and then weigh the residue to the nearest 0.01 g.

18.4 *Calculation*:

18.4.1 Calculate percent passing as follows:

$$[(S - R)/S] \times 100 = \text{percent passing} \quad (5)$$

where:

S = sample weight, g, and

R = weight of sieve residue, g.

18.5 *Precision and Bias*:

18.5.1 There are as yet insufficient analyzed data to permit preparation of a precision and bias statement for this test method.

19. Wet Sieve Analysis of Agricultural Liming Materials

19.1 *Scope*:

19.1.1 This test method covers the determination of gradation of an Agricultural Liming material by wash. Material finer

[12] The apparatus describes commercially available units sold by the Alpine American Corporation of Natick, Massachusetts. Although the description of the apparatus is directed toward this commercially available equipment, it does not restrict the use of other equivalent equipment which may be available or may be constructed, as long as it follows the general principles outlined under the summary of this test method.

[13] Commercially available.

than 75 micrometres (No. 200) sieve will be removed from the aggregate during the test, prior to dry sieving of the coarser fraction.

19.1.2 The results of this procedure can be used to determine compliance to a particle size distribution relative to applicable specifications for agricultural liming materials.

19.1.3 This method can **not** be used for the sieve analysis of quicklime or materials containing quicklime, because of the exothermic reaction with water.

19.2 *Significance and Use*:

19.2.1 Material finer than the 75 micrometres (No. 200) sieve can be separated from larger particles more efficiently

9.0	22.5	20.5	50.5	32.0	79.0		
9.5	23.5	21.0	52.0	32.5	80.0		
10.0	25.0	21.5	53.0	33.0	81.5		
10.5	26.0	22.0	54.5	33.5	82.5		
11.0	27.5	22.5	56.5	34.0	84.0		

and completely by wet sieving than through the use of dry sieving. In sieving fine aggregate, the finer fractions can adhere to the coarser fractions through a normal dry sieving operation. Further, due to electrostatic charges, fine material can also adhere to the coarser sieves. By removing the finer fractions through the wash test, these problems are avoided. Therefore, when an accurate determination of an agricultural liming material is desired, this test method should be used.

19.2.2 The results of this test method are included in the calculation of gradation, and the total amount of material finer than 75 micrometres by washing, plus that obtained by dry sieving the same sample, is reported with the results. Usually the additional amount of material finer than 75 micrometres obtained in the subsequent dry sieving process is a small amount. If it is large, the efficiency of the washing operation should be checked. It could, also, be an indication of degradation of the material.

19.3 *Apparatus and Materials*:

19.3.1 *Balance*—A balance or scale readable and accurate to 0.1 g or 0.1 % of the test load, whichever is greater, at any point within the range of use.

19.3.2 *Sieves*—The sieves shall be mounted on substantial frames, either full height or extended, and constructed in a manner that will prevent loss of material during sieving. The sieves shall be of equal diameter and shape to allow for nesting. The sieves shall conform to Specification E 11.

19.3.3 *Sieve Pan*—A pan of the same diameter as the sieves.

19.3.4 *Container*—A pan or vessel of a size sufficient to contain the sample covered with water and to permit vigorous agitation without loss of any part of the sample or water.

19.3.5 *Oven*—An oven of sufficient size, capable of maintaining a uniform temperature of 110 ± 5 °C.

NOTE 17—The use of a mechanical apparatus to perform the washing operation is not precluded, provided the results are consistent with those obtained using manual operations. The use of some mechanical washing equipment with some samples may cause degradation of the sample.

19.4 *Sampling*:

19.4.1 Since sampling is equally as important as testing, it is critical that samples be obtained that are representative of the materials being investigated. Therefore, sampling must be conducted in as conscientious a manner as possible. Incremental sampling should be employed, combining the increments into one bulk sample.

19.4.2 Use the procedures described in Practice C 50, or Practice D 75.

19.4.3 To reduce the bulk sample to the amount needed for testing, the use of mechanical splitters or the process of quartering must be used. At no time can a random lot be drawn from the bulk sample for testing.

19.5 *Procedure*:

19.5.1 Dry the test sample to constant mass at a temperature of 110 ± 5 °C. Determine the mass to the nearest 0.1 % of the mass of the test sample. The amount of sample required for this test shall be between 200 to 400 g. The test sample shall be the end result of the reduction. Reduction to an exact predetermined mass shall not be permitted.

19.5.2 After drying and determining the mass, place the test sample in the container and add sufficient water to cover it. Agitate the sample with sufficient vigor to result in complete separation from the coarser particles of all particles finer than the 75 micrometre sieve from the coarser particles, and to bring the fine material into suspension. Immediately pour the wash water containing the suspended and dissolved solids over the nested sieves (see Note 18), arranged with the coarser sieve on top. Take care to avoid, as much as feasible, the decantation of coarser particles of the sample.

NOTE 18—It is recommended that a #16 mesh sieve or one of approximate size be used to nest on top of the # 200 mesh sieve for protection from the sample.

19.5.3 Add a second charge of water to the sample in the container, agitate, and decant as before. Repeat this operation until the wash water is clear (see Note 19).

NOTE 19—If mechanical washing equipment is used, the charging of water, agitating, and decanting may be a continuous operation.

19.5.4 Return all material retained on the nested sieves by flushing to the washed sample. Dry the washed material to constant mass at a temperature of 110 ± 5 °C and determine the mass to the nearest 0.1 g. Calculate the amount of material passing a 75 micrometre sieve by washing according to 19.6.1.

19.5.5 Select the sieves of a suitable size as desired or required by specification and those sieves necessary to regulate the amount of material between the various screens. Nest the screens in order of decreasing size of opening, from top to bottom, on a sieve pan. Be sure to nest the 75 micrometre sieve just above the pan. Place the dried sample on the top sieve. Shake the nested sieves briskly or by use of a mechanical device for a sufficient period to assure that the sample has been adequately screened (see Note 20).

NOTE 20—To be adequately screened, no more than 1 % of the residue on any individual sieve will pass that sieve during 1 min. of continuous

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

sieving. For a more detailed explanation refer to C 136-84a, paragraph 7.4.

19.5.6 The amount of material on an eight inch sieve after shaking is limited to approximately 200 g, so that all particles during a test have access to the screen medium (see Note 21). If the amount remaining on a sieve is greater than 200 g, the sieve analysis must be repeated. Place an intermediate sieve between the overloaded sieve and the one nested above.

NOTE 21—A twelve inch screen can be used, but the amount of material retained on a sieve is limited to 6 kg/m^2.

19.5.7 Record the weight of material from each size increment and the sieve pan by weighing on a balance to the nearest 0.1 g (see Note 22). Total the retained masses of all the size increments and the sieve pan from the dry sieve test. If this amount differs from the dry mass of the sample after washing by more than 0.3 %, the results should not be used for acceptance purposes.

NOTE 22—A soft bristle can be used to help remove material from sieves, but at no time can material be forced through a sieve.

19.6 *Calculation*:

19.6.1 Calculate the amount of a material passing a 75 micrometre sieve by washing as follows:

$$A = [(B - C) / B] \times 100 \quad (6)$$

where:

A = percentage of material finer than a 75 micrometre sieve by washing,
B = original dry mass of sample, g, and
C = dry mass of sample after washing, g.

19.6.2 Calculation of amount of material passing individual sieves follows:

19.6.2.1 Add weight of material finer than a 75 micrometre sieve by washing (B – C, in 19.6.1) to the weight of material finer than a 75 micrometre sieve obtained in the dry screening, if washed.

19.6.2.2 Calculate the percent retained on each sieve and the pan as follows:

$$A = (B / C) \times 100 \quad (7)$$

where:

A = percentage of material retained on each sieve (pan),
B = dry mass of sample, g, retained on each sieve (pan), and
C = original dry mass of sample, g.

19.6.2.3 Calculate the cumulative percent retained for each screen by adding the percentage retained on that sieve and all sieves of larger diameter opening.

19.6.2.4 For each screen, subtract the cumulative percent retained from 100 to obtain the percent passing.

19.7 *Precision and Bias*:

19.7.1 The precision of this test method is based on an interlaboratory study of C 110 – 01 conducted in 2005. Each of the twelve laboratories tested five different materials. Each "test result" was an individual determination of the percent of material passing a particular mesh sieve. Participating laboratories obtained three replicate test results for each material and sieve combination.[14] See Tables 12-16.

19.7.1.1 *Repeatability*—Two test results obtained within one laboratory shall be judged not equivalent if they differ by more than the "*r*" value for that material; "*r*" is the interval representing the critical difference between two test results for the same material, obtained by the same operator using the same equipment on the same day in the same laboratory.

19.7.1.2 *Reproducibility*—Two test results should be judged not equivalent if they differ by more than the "*R*" value for that material; "*R*" is the interval representing the difference between two test results for the same material, obtained by different operators using different equipment in different laboratories.

19.7.1.3 Any judgment in accordance with these two statements would have an approximate 95 % probability of being correct.

19.7.2 *Bias*—At the time of the study, there was no accepted reference material suitable for determining the bias for this test method, therefore no statement on bias is being made.

19.7.3 The precision and bias statements were determined through statistical examination of 1440 test results, from a total of twelve laboratories, analyzing five materials.

DENSITY MEASUREMENT

20. Apparent Loose Density of Hydrated Lime, Pulverized Quicklime, and Limestone

20.1 *Significance and Use*:

20.1.1 This test method determines the loose or unsettled density of hydrated lime, pulverized quicklime, and limestone. It provides for an approximate measure of the maximum volume occupied by a given weight of hydrated lime, pulverized quicklime, or limestone.

20.2 *Apparatus*:

20.2.1 *Flour Sifter*—A 114 to 127 mm (4½ to 5 in.) kitchen-type flour sifter of either the squeeze handle type or the hand crank type. It shall be able to hold at least 300 g of hydrated lime or 500 g of limestone or quicklime. The wire mesh openings should be between 0.8 and 1.5 mm.

20.2.2 *Density Cup*, 400 mL cylindrical cup as described in the Apparatus Section of Test Method C 185.

[14] Supporting data pending being filed at ASTM International Headquarters.

20.2.3 *Balance*, suitable for weighing at least 800 g accurately to 0.1 g.

20.2.4 *Clock or Watch*.

20.2.5 *Straight Edge*.

20.3 *Procedure*:

20.3.1 Weigh the empty density cup to the nearest 0.1 g on a balance. Place the tared cup on a solid table with a suitable mat inserted underneath the cup to collect excess sample spilling over the cup. Fill the flour sifter with more than enough material to fill the density cup. Start the clock and the sifting device to facilitate the flow of powder into the cup. Overflow the cup until there is a cone of excess material.

20.3.2 After 3 min, carefully remove the excess powder by passing the edge of a spatula blade parallel with, and in contact with, the top of the cup. Move the spatula smoothly and keep it level at all times to prevent packing or pulling the sample out of the cup.

20.3.3 After the cup is level, lightly tap it with the edge of the spatula to settle the powder. Wipe the outside of the cup with a lintless cloth or paper towel. Avoid spilling the sample while transferring the cup to the balance for weighing.

20.3.4 Weigh the cup and sample to the nearest 0.1 g and determine the weight of the sample by difference.

20.3.5 The loose density of the material is calculated and reported as grams per cubic centimetre, or as pounds per cubic foot.

20.4 *Calculation*:

20.4.1 Calculate the loose density as follows:

$$D = W/V \tag{8}$$

where:

D = loose density,
W = weight of sample, g, and
V = volume of cup, cm^3.

20.4.2 For reporting as pounds per cubic foot, multiply grams per cubic centimetre by 62.43.

20.5 *Precision and Bias*:

20.5.1 *Single Operator Precision*—The single operator standard deviation has been found to be 0.4 lb/ft^3(Note 9). Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 1.13 lb/ft^3.

20.5.2 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 1.26 lb/ft^3(Note 23). Therefore, results of two properly conducted tests from two different laboratories on samples of the same material should not differ by more than 3.6 lb/ft^3.

NOTE 23—These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

20.5.3 The above precision statements are based on a multilaboratory testing program for determination of the loose bulk density of hydrated lime. No statement is made regarding the precision of this method as it relates to other materials. Due to a lack of a recognized industry standard, the bias of this test method has not been determined.

21. Apparent Packed Density of Hydrated Lime, Pulverized Quicklime, and Limestone

21.1 Significance and Use:

21.1.1 This test method determines the packed or settled density of hydrated lime, pulverized quicklime, and limestone. It provides for determining the minimum volume occupied by a given weight of hydrated lime, pulverized quicklime or limestone.

21.2 *Apparatus*:

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

21.2.1 *Graduated Cylinder*, 100 mL capacity.

21.2.2 *Balance*, accurate to 0.1 g.

21.3 *Procedure*:

21.3.1 Weigh to within 0.1 g a 25 g sample of powdered material and transfer it to the graduated cylinder.

21.3.2 Allow powder to settle by gently tapping the cylinder on a desk top cushioned with a thick magazine or writing tablet so that compaction occurs without fluffing.

21.3.3 Record the volume of the lime after each 100 taps and continue tapping until compaction volume change is less than 0.5 mL/100 taps.

21.3.4 Calculate the density in grams per cubic centimetre or in pounds per cubic foot to the nearest pound.

21.4 *Calculation*:

21.4.1 Calculate the packed density as follows:

$$D = W/V \tag{9}$$

where:

D = packed density,
W = weight of sample, g, and
V = final volume of sample, cm^3.

21.4.2 For reporting as pounds per cubic foot, multiply grams per cubic centimetre by 62.43.

21.5 *Precision and Bias*:

21.5.1 *Single Operator Precision*—The single operator standard deviation has been found to be 0.5 lb/ft^3(Note 23). Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 1.4 lb/ft^3.

21.5.2 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 1.7 lb/ft^3(Note 23). Therefore, results of two properly conducted tests from two different laboratories on samples of the same material should not differ by more than 4.8 lb/ft^3.

21.5.3 The above precision statements are based on a multilaboratory testing program for determination of the packed bulk density of hydrated lime. No statement is made regarding the precision of this method as it relates to other materials. Due to a lack of a recognized industry standard, the bias of this test method has not been determined.

22. Relative Density (Specific Gravity) of Hydrated Lime Products

22.1 *Significance and Use*:

22.1.1 This test method covers two methods for the determination of the relative density (specific gravity) of hydrated lime.

22.1.2 Relative density (specific gravity) of hydrated lime is defined as the ratio of the density of the material to the density of water at a stated temperature; the values are dimensionless.

22.2 *Le Chatelier Flask Method*:

22.2.1 The standard flask, which is circular in cross section with shape and dimensions conforming essentially to Fig. 1 of Test Method C 188 (Note 24). The requirements in regard to tolerance, inscription and length, spacing, and uniformity of graduation shall be rigidly observed. There shall be a space of at least 10 mm between the highest graduation mark and the lowest point of grinding for the glass stopper.

22.2.1.1 The material of construction shall be best quality glass, transparent and free of striae. The glass shall be chemically resistant and shall have small thermal hysteresis. The flasks shall be thoroughly annealed before being graduated. They shall be of sufficient thickness to ensure reasonable resistance to breakage.

22.2.1.2 The neck shall be graduated from 0 to 1 mL and from 18 to 24 mL in 0.1 mL graduations. The error of any indicated capacity shall not be greater than 0.05 mL.

22.2.1.3 Each flask shall bear a permanent identification number and the stopper, if not interchangeable ground, shall bear the same number. Interchangeable ground-glass parts shall be marked on both members with the standard-taper symbol followed by the size designation. The standard temperature shall be indicated, and the unit of capacity shall be shown by the letters "mL" placed above the highest graduation mark.

NOTE 24—The design is intended to ensure complete drainage of the flask when emptied, and stability of standing on a level surface, as well as accuracy and precision of reading.

22.3 *Reagents*:

22.3.1 *Ethyl Alcohol (Absolute)*, free of water, shall be used in the density determination. The ethanol used should not have been denatured with methanol.

22.4 *Procedure*:

22.4.1 Determine the specific gravity of hydrated lime on the material as received, unless otherwise specified.

22.4.2 Fill the flask (Note 25) with denatured ethyl alcohol to a point on the stem between the 0 and 1-mL mark. Dry the inside of the flask above the level of the liquid, if necessary, after pouring. Record the first reading after the flask has been immersed in the water bath (Note 26) in accordance with 19.3.4.

NOTE 25—It is advisable to use a rubber pad on the table top when filling or rolling the flask.

NOTE 26—Before the hydrated lime has been added to the flask, a loose fitting lead-ring weight around the stem of the flask will be helpful in holding the flask in an upright position in the water bath, or the flask may be held in the water bath by a buret clamp.

22.4.3 Introduce a quantity of hydrated lime, weighed to the nearest 0.05 g, (about 50 g for hydrated lime) in small increments at the same temperature as the liquid (Note 25). Take care to avoid splashing and see that the hydrated lime does not adhere to the inside of the flask above the liquid. A vibrating apparatus may be used to accelerate the introduction of the hydrated lime into the flask and to prevent the lime from sticking to the neck. After all the hydrated lime has been introduced, place the stopper in the flask and roll the flask in an inclined position (Note 25), or gently whirl it in a horizontal circle as to free the lime from air until no further air bubbles rise to the surface of the liquid. If a proper amount of hydrated lime has been added, the level of the liquid will be in its final position at some point of the upper series of graduations. Take the final reading after the flask has been immersed in the water bath in accordance with 22.3.4.

22.4.4 Immerse the flask in a constant-temperature water bath for sufficient periods of time in order to avoid flask temperature variations greater than 0.2 °C between the initial and final readings.

www.technobetar.ir

22.5 *Calculation:*

22.5.1 The difference between the first and the final readings represents the volume of liquid displaced by the mass of hydrated lime used in the test.

22.5.2 Calculate the hydrated lime density, *p*, as follows:

$$p(\mathrm{Mg/m^3}) = p(\mathrm{g/cm^3}) = \frac{\text{mass of hydrated lime (g)}}{\text{displaced volume (cm}^3\text{)}} \quad (10)$$

NOTE 27—The displaced volume in milliliters is numerically equal to the displaced volume in cubic centimeters.

22.6 *Precision and Bias*:

22.6.1 *Round Robin*—An interlaboratory study, consistent with the guidelines of Practice E 691, was conducted in June 2000. The test for specific gravity was conducted in accordance with these test methods, Section 22. Four hydrated lime products, two dolomitic "S" samples and two Type "N" (one high calcium and one dolomitic) samples were tested by seven laboratories. Each laboratory performed three determinations, thus meeting the requirements of Practice E 691. The research report is on file with ASTM International.[15]

22.6.2 *Precision*—The relative precision of this test method, characterized by repeatability (s_r and r) and reproducibility (s_R and R) has been determined for the materials to be the following:

Hydrate Type	Average	s_r	s_R	r	R
High Calcium "N"	2.217	0.007	0.030	0.020	0.083
Dolomitic "S"	2.306	0.023	0.059	0.065	0.164
Dolomitic "N"	2.466	0.016	0.035	0.045	0.097

22.6.3 *Repeatability*—Examine the data in 22.6.2 as to hydrate type to determine the expected differences in absolute value of replicate determinations, carried out in the same laboratory, by the same operator using the same apparatus at a 95 % confidence level. The critical value for repeatability is r.

22.6.4 *Reproducibility*—Examine the data in 22.6.2 as to hydrate type to determine the expected differences in absolute value of replicate determinations, carried out in different laboratories using samples taken at random from the same bulk sample. The critical value, R, may be expected to occur at a 95 % confidence level, for reproducibility.

22.6.5 *Bias*—No bias is expected for the method.

22.7 *Helium Gas Pycnometry Method*:

22.7.1 Apparatus and Instrument Requirements:

22.7.1.1 Helium gas pychnometers are commercially available.

22.7.1.2 Laboratory air temperature 25 ± 10 °C (50 – 96 °F).

22.7.1.3 Laboratory relative humidity 50 ± 30 %, non-condensing.

22.7.1.4 Pychnometer must be located free from draft and direct sunlight.

22.7.1.5 Power cords and voltage/amperage requirements must meet the requirements of the manufacturer's requirements.

22.7.1.6 Prior to analysis, calibration following manufacturer's instructions.

22.7.1.7 Purge fill and run fill pressure to be maintained at the manufacturer's requirements.

22.7.1.8 Sample purging to be completed as required by manufacturer.

22.7.1.9 Chamber cap to remain in place at all times, except when inserting or removing sample.

22.7.1.10 Sample holder or cup to be clean and dry. Use only cups provided by the manufacturer. Clean only with lint-free cloth. Handle only gloved hand.

22.7.1.11 Enable run precision or deviation requested at the mid-range of the manufacturer's offering.

22.7.1.12 Run equilibration rate at the manufacturer's requirements.

22.7.1.13 Percent of Nominal Cell Volume is entered at manufacturer's recommended value.

22.7.1.14 Precision reproducibility to be within ± 0.03 % of full scale cell chambers sample capacity; accuracy to within ± 0.02 of nominal full scale cell chamber volume sample capacity.

22.7.1.15 Mass balance shall be calibrated and capable of recording mass in grams to 4 decimal places with a tolerance of ± 0.01 mg.

22.7.2 *Reagents*:

22.7.2.1 Helium gas of research grade (99.995 % pure) or helium gas with dewpoint of –67 °C or less.

22.7.3 *Procedure*:

22.7.3.1 Warm up pycnometer for a least two hours prior to testing.

22.7.3.2 Ensure cell chamber, cap, and sample cup are clean and dry; wear gloves when handling; helium gas tank pressure within manufacturer's parameters; complete cell purges prior to analysis.

22.7.3.3 Weigh cup with lid (four decimal places), fill sample cup to ¾ full, and weigh cup-lid + sample. Record data.

22.7.3.4 Remove cell cap and insert cup, lid, and sample into the pycnometer cell chamber, replace cap and perform analysis following manufacturer's recommendations. Record results.

22.7.4 *Precision and Bias*:

22.7.4.1 The precision of this test method is based on an interlaboratory study of Test Methods C 110 conducted in 2007. Seven laboratories tested three different types of hydrated lime. Every "test result" represents an individual determination. Each laboratory was asked to report triplicate test results in order to permit the estimation of Intralaboratory precision. Practice E 691 was followed for the design and analysis of the data.[16]

22.7.4.2 *Repeatability limit (r)*—Two test results obtained within one laboratory shall be judged not equivalent if they differ by more than the "r" value for that material; "r" is the interval representing the critical difference between two test results for the same material, obtained by the same operator using the same equipment on the same day in the same laboratory.

[15] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C07-1004.

[16] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C07–ILS0238..

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:13 EDT 2010

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Repeatability limits are listed in Table 17.

22.7.4.3 *Reproducibility limit (R)*—Two test results shall be judged not equivalent if they differ by more than the "R" value for that material; "R" is the interval representing the critical difference between two test results for the same material, obtained by different operators using different equipment in different laboratories.

Reproducibility limits are listed in Table 17.

22.7.4.4 The above terms (repeatability limit and reproducibility limit) are used as specified in Practice E 177.

TABLE 17 Relative Density (Specific Gravity)

Material	Average[A]	Repeatability Standard Deviation	Reproducibility Standard Deviation	Repeatability Limit	Reproducibility Limit
	$\bar{X}$	s_r	s_R	r	R
1	2.3186	0.0076	0.0141	0.0212	0.0395
2	2.2978	0.0103	0.0236	0.0288	0.0660
3	2.5267	0.0088	0.0144	0.0246	0.0402

[A]The average of the laboratories' calculated averages.

22.7.4.5 Any judgment in accordance with statements 22.7.4.2 and 22.7.4.3 would have an approximate 95% probability of being correct.

22.8 *Bias*—At the time of the study, there was no accepted reference material suitable for determining the bias for this test method, therefore no statement on bias is being made.

22.9 The precision statement was determined through statistical examination of 63 results, from seven laboratories, on three materials. The materials were described as the following:

Material 1: Type S (Dolomitic) Hydrated Lime

Material 2: High Calcium Hydrated Lime

Material 3: Type N (Dolomitic) Hydrated Lime

23. Keywords

23.1 accepted reference value; accuracy; apparent density; bias; dry brightness; dry screening; fineness; interlaboratory study; lime putty; limestone grindability; particle size; precision; precision conditions; repeatability; reproducibility; slaking rate; standard deviation

SUMMARY OF CHANGES

Committee C07 has identified the location of selected changes to these test methods since the last issue, C 110 – 09, that may impact the use of these test methods. (Approved June 15, 2009)

(*1*) Heavily revised Section 22, including the addition of Table 17.

Committee C07 has identified the location of selected changes to these test methods since the last issue, C 110 – 08a, that may impact the use of these test methods. (Approved March 1, 2009)

(*1*) Revised Table 3.

(*2*) Revised Note 14.

Committee C07 has identified the location of selected changes to these test methods since the last issue, C 110 – 08, that may impact the use of these test methods. (Approved December 1, 2008)

(*1*) Revised 7.4.1 and 7.4.2.1.

(*2*) Moved old Section 22 Wet Sieve Analysis of Agricultural Liming Materials to Section 19 and renumbered subsequent sections. Added a precision and bias statement to Section 19.

Committee C07 has identified the location of selected changes to these test methods since the last issue, C 110 – 06, that may impact the use of these test methods. (Approved June 1, 2008)

(*1*) Revised the precision and bias statement in 6.5. Added new Tables 1 and 2 and renumbered subsequent tables. Added new Footnote 6 and renumbered subsequent footnotes.

(*2*) Revised 7.1.1.

(*3*) Added new Footnote 7 and renumbered subsequent footnotes.

Designation: C114 – 09b

Standard Test Methods for Chemical Analysis of Hydraulic Cement[1]

This standard is issued under the fixed designation C114; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 These test methods cover the chemical analyses of hydraulic cements. Any test methods of demonstrated acceptable precision and bias may be used for analysis of hydraulic cements, including analyses for referee and certification purposes, as explained in Section 3. Specific chemical test methods are provided for ease of reference for those desiring to use them. They are grouped as Reference Test Methods and Alternative Test Methods. The reference test methods are long accepted classical chemical test methods which provide a reasonably well-integrated basic scheme of analysis for hydraulic cements. The alternative test methods generally provide individual determination of specific components and may be used alone or as alternates and determinations within the basic scheme at the option of the analyst and as indicated in the individual method.

3. Description of Referee Analyses

3.1 *Referee Analyses*—When conformance to chemical specification requirements is questioned, perform referee analyses as described in 3.1.1. The reference test methods that follow in Sections 6-21, or other test methods qualified according to 4.4, the *Performance Requirements for Rapid Test Methods* Section, are required for referee analysis. A cement shall not be rejected for failure to conform to chemical requirements unless all determinations of constituents involved and all necessary separations prior to the determination of any one constituent are made entirely by these methods. When reporting the results of referee analyses, specify which test methods were used.

3.1.1 Referee analyses shall be made in duplicate and the analyses shall be made on different days. If the two results do not agree within the permissible variation given in Table 1, the determination shall be repeated until two or three results agree within the permissible variation. When two or three results do agree within the permissible variation, their average shall be accepted as the correct value. When an average of either two or three results can be calculated, the calculation shall be based on the three results. For the purpose of comparing analyses and calculating the average of acceptable results, the percentages shall be calculated to the nearest 0.01 (or 0.001 in the case of chloroform-soluble organic substances), although some of the average values are reported to 0.1 as indicated in the test methods. When a blank determination (See Note 1) is specified, one shall be made with each individual analysis or with each group of two or more samples analyzed on the same day for a given component.

NOTE 1—A blank determination is a procedure which follows all steps of analysis but in the absence of a sample. It is used for detection and compensation of systematic bias.

4. Qualification for Different Analyses

4.1 *Certified Reference Materials*—A Certified Reference Material (CRM) must be used in the qualification of test methods and analysts. Acceptable reference cements are NIST CRMs, or other reference cements traceable to the NIST CRMs. The reference cement must have an assigned value for the analyte being determined. Traceability consists of documentary evidence that the assigned values of the reference cement are compatible with the certified values of NIST CRMs. To demonstrate traceability for a given analyte, perform a referee analysis (as defined in 3.1) on the proposed reference cement, using a NIST CRM for demonstration of precision and accuracy. The reference cement is acceptable if its assigned value agrees with the average referee value within the limits given in column 3 of Table 1. If the reference cement, as supplied, has no documented guarantee of homogeneity, establish its homogeneity by analyzing at least six randomly selected samples. No result shall deviate from the assigned value by more than the limits given in column 2 of Table 1. An acceptable reference cement must be accompanied by a document showing the data produced in demonstrating traceability and homogeneity.

4.2 *Requirements for Qualification Testing*—Referee analyses or analyses intended for use as a basis for acceptance or rejection of a cement or for manufacturer's certification shall be made only after demonstration of precise and accurate analyses by the test methods in use by meeting the requirements of 4.2.1, except when demonstrated under 4.4, the *Performance Requirements for Rapid Test Methods* Section. Such demonstration may be made concurrently with analysis of the cement being tested and must have been made within the preceding two years. The requirements for verification of equipment and personnel are summarized in Table 2. The demonstration is required only for those constituents being used as a basis for acceptance, rejection, or certification of a cement, but may be made for any constituent of cement for which a standard exists.

4.2.1 Initial qualification of the analyst shall be demonstrated by analysis of each constituent of concern in at least one CRM cement no matter what test method is used (for example, gravimetric or instrumental). Duplicate samples shall be run on different days. The same test methods to be used for analysis of cement being tested shall be used for analysis of the CRM cement. If the duplicate results do not agree within the permissible variation given in Table 1, the determinations shall be repeated, following identification and correction of problems or errors, until a set of duplicate results do agree within the permissible variation.

4.2.2 The average of the results of acceptable duplicate determinations for each constituent may differ from the CRM assigned value by no more than the value shown in column 2 of Table 1 after correction for minor components when needed.

4.2.3 Qualification data demonstrating that the same operator or analyst making the acceptance determination obtained precise and accurate results with CRM cements as per 4.2.1 shall be made available on request to all parties concerned when there is a question of acceptance of a cement. If the CRM used is not a NIST cement, the traceability documentation of the CRM used shall also be made available on request.

4.3 *Alternative Analyses*—The alternative test methods provide, in some cases, procedures that are shorter or more convenient to use for routine determination of certain constituents than are the reference test methods (Note 2). Longer, more complex procedures, in some instances, have been retained as

TABLE 1 Maximum Permissible Variations in Results[A]

(Column 1) Component	(Column 2) Maximum Difference Between Duplicates[B]	(Column 3) Maximum Difference of the Average of Duplicates from SRM Certificate Values[C,D,B]
SiO_2(silicon dioxide)	0.16	±0.2
Al_2O_3(aluminum oxide)	0.20	±0.2
Fe_2O_3(ferric oxide)	0.10	±0.10
CaO (calcium oxide)	0.20	±0.3
MgO (magnesium oxide)	0.16	±0.2
SO_3(sulfur trioxide)	0.10	±0.1
LOI (loss on ignition)	0.10	±0.10
Na_2O (sodium oxide)	0.03	±0.05
K_2O (potassium oxide)	0.03	±0.05
TiO_2(titanium dioxide)	0.02	±0.03
P_2O_5(phosphorus pentoxide)	0.03	±0.03
ZnO (zinc oxide)	0.03	±0.03
Mn_2O_3(manganic oxide)	0.03	±0.03
S (sulfide sulfur)	0.01	*E*
Cl (chloride)	0.003	*E*
IR (insoluble residue)	0.10	*E*
Cx (free calcium oxide)	0.20	*E*
CO_2(carbon dioxide)	0.12	*E,F*
Alk_{sol}(water-soluble alkali)[G]	0.75/*w*	*E*
Chl_{sol}(chloroform-soluble organic substances)	0.004	*E*

[A] When seven CRM cements are required, as for demonstrating the performance of rapid test methods, at least six of the seven shall be within the prescribed limits and the seventh shall differ by no more than twice that value. When more than seven CRMs are used, as for demonstrating the performance of rapid test methods, at least 77 % shall be within the prescribed limits, and the remainder by no more than twice the value. When a lesser number of CRM cements are required, all of the values shall be within the prescribed limits.

[B] Where no value appears in Column 3, CRM certificate values do not exist. In such cases, only the requirement for differences between duplicates shall apply.

[C] Interelement corrections may be used for any oxide standardization provided improved accuracy can be demonstrated when the correction is applied to all seven CRM cements.

[D] Where an CRM certificate value includes a subscript number, that subscript number shall be treated as a valid significant figure.

[E] Not applicable. No certificate value given.

[F] Demonstrate performance by analysis, in duplicate, of at least one Portland cement. Prepare three standards, each in duplicate: Standard A shall be selected Portland cement; Standard B shall be Standard A containing 2.00 % Certified $CaCO_3$ (such as NIST 915a); Standard C shall be Standard A containing 5.00 % Certified $CaCO_3$. Weigh and prepare two separate specimens of each standard. Assign the CO_2 content of Standard A as the average of the two values determined, provided they agree within the required limit of Column 2. Assign CO_2 values to Standards B and C as follows: Multiply the Certified $CaCO_3$ value (Y) for CO_2 (from the certificate value) by the mass fraction of Certified $CaCO_3$ added to that standard (percentage added divided by 100); multiply the value determined for Standard A by the mass fraction of Standard A in each of the other standards (that is, 0.98 and 0.95 for Standards B and C, respectively); add the two values for Standard A and for Standard B, respectively; call these values B and C.

Example:

B = 0.98A + 0.02Y.

C = 0.95A + 0.05Y.

Where for Certified $CaCO_3$, if Y = 39.9 %

B = 0.98A + 0.80 % by mass.

C = 0.95A + 2.00 % by mass.

Maximum difference between the duplicate CO_2 values for Standards B and C, respectively, shall be 0.17 and 0.24 % by mass. Averages of the duplicate values for Standards B and C shall differ from their assigned values (B and C) by no more than 10 % of those respective assigned values.

[G] *w* = weight, in grams, of samples used for the test.

alternative test methods to permit comparison of results by different procedures or for use when unusual materials are being examined, where unusual interferences may be suspected, or when unusual preparation for analysis is required. Test results from alternative test methods may be used as a basis for acceptance or rejection when it is clear that a cement does or does not meet the specification requirement. Any change in test method procedures from those procedures listed in Sections 6-29 requires method qualification in accordance with 4.4, the *Performance Requirements for Rapid Test Methods* Section.

TABLE 2 Minimum Number of CRMs Required for Qualification of Chemical Testing

	Method Type	
	Reference[A]	Other[B]
Equipment Qualification	None	7
Analyst Qualification[C]	1	1

[A] Reference Methods are those outlined in Sections 6-21.

[B] These may be any test method as described in 4.3, the *Alternative Analyses* Section, or any instrumental or rapid test method, which must be qualified in accordance with 4.4, the *Performance Requirements for Rapid Test Methods* Section.

[C] Each analyst performing acceptance or reference analyses must be qualified in accordance with 4.2.1, the *Performance Requirements for Rapid Test Methods* Section, at a frequency of two years. If qualification of the instrument is completed by a single analyst, the analyst has demonstrated individual qualifications per 4.2.1.

NOTE 2—It is not intended that the use of reference test methods be confined to referee analysis. A reference test method may be used in preference to an alternative test method when so desired. A reference test method must be used where an alternative test method is not provided.

4.3.1 Duplicate analyses and blank determinations are not required when using the alternative test methods. If, however, a blank determination is desired for an alternative test method, one may be used and it need not have been obtained concurrently with the analysis. The final results, when corrected for blank values, should, in either case, be so designated.

4.4 *Performance Requirements for Rapid Test Methods:*[3]

4.4.1 *Definition and Scope*—Where analytical data obtained in accordance with this test method are required, any test method may be used that meets the requirements of 4.4.2, the *Qualification of a Test Method Section*. A test method is considered to consist of the specific procedures, reagents, supplies, equipment, instrument, etc. selected and used in a consistent manner by a specific laboratory. See Note 3 for examples of procedures.

NOTE 3—Examples of test methods used successfully by their authors for analysis of hydraulic cement are given in the list of references. Included are test methods using atomic absorption X-ray spectrometry, and spectrophotometry-EDTA.

4.4.1.1 If more than one instrument, even though substantially identical, is used in a specific laboratory for the same analyses, use of each instrument shall constitute a separate test method and each must be qualified separately.

4.4.2 *Qualification of a Test Method*—Prior to use for analysis of hydraulic cement, each test method (see 4.4.1) must be qualified individually for such analysis. Qualification data, or if applicable, requalification data, shall be made available pursuant to the Manufacturer's Certification Section of the appropriate hydraulic cement specification.

4.4.2.1 Using the test method chosen, make single determinations for each oxide under consideration on at least seven

[3] Gebhardt, R. F., "Rapid Methods for Chemical Analysis of Hydraulic Cement," ASTM STP 985, 1988.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

CRM samples. Requirements for a CRM are listed in 4.1, the *Certified Reference Material* Section. Complete two rounds of tests on different days repeating all steps of sample preparations. Calculate the differences between values and averages of the values from the two rounds of tests.

4.4.2.2 When seven CRMs are used in the qualification procedure, at least six of the seven differences between duplicates obtained of any single component shall not exceed the limits shown in Column 2 of Table 1 and the remaining differences by no more than twice that value. When more than seven CRMs are used, the values for at least 77 % of the samples shall be within the prescribed limits, while the values for the remainder shall differ by no more than twice that value.

4.4.2.3 For each component and each CRM, the average obtained shall be compared to the certified concentrations. Where a certificate value includes a subscript number, that subscript shall be assumed to be a significant number. When seven CRMs are used in the qualification procedure, at least six of the seven averages for each component (oxide) shall not differ from the certified concentrations by more than the value shown in Column 3 of Table 1, and the remaining average by more than twice that value. When more than seven CRMs are used in the qualification procedure, at least 77 % of the averages for each component (oxide) shall not differ from the certified concentrations by more than the value shown in Column 3 of Table 1, and the remaining average(s) by more than twice that value.

4.4.2.4 The standardization, if needed, used for qualification and for analysis of each constituent shall be determined by valid curve-fitting procedures. A point-to-point, saw-tooth curve that is artificially made to fit a set of data points does not constitute a valid curve-fitting procedure. A complex polynomial drawn through the points is similarly not valid. For the same reason, empirical inter-element corrections may be used, only if $\leq (N - 3)/2$ are employed, where N is the number of different standards used. The qualification testing shall be conducted with specimens newly prepared from scratch, including all the preparation stages applicable for analysis of an unknown sample, and employing the reagents currently in use for unknown analyses.

4.4.3 *Partial Results*—Test Methods that provide acceptable results for some components but not for others may be used only for those components for which acceptable results are obtained.

4.4.4 *Report of Results*—When performing chemical analysis and reporting results for Manufacturer's Certification, the type of method (Reference or Rapid) and the test method used along with any supporting qualification testing shall be available on request.

4.4.5 *Rejection of Material*—See 3.1, the *Referee Analyses* Section, and 4.3, the *Alternative Analyses* Section.

4.4.6 *Requalification of a Test Method*:

4.4.6.1 Requalification of a test method shall be required upon receipt of substantial evidence that the test method may not be providing data in accordance with Table 1 for one or more constituents. Such requalification may be limited to those constituents indicated to be in error and shall be carried out prior to further use of the method for analysis of those constituents.

4.4.6.2 Substantial evidence that a test method may not be providing data in accordance with Table 1 shall be considered to have been received when a laboratory is informed that analysis of the same material by Reference Test Methods run in accordance with 3.1.1, the final average of a CCRL sample, a certificate value of an NIST CRM, the assigned value of an alternate CRM, or an accepted value of a known secondary standard differs from the value obtained by the test method in question by more than twice the value shown in Column 2 of Table 1 for one or more constituents. When indirect test methods are involved, as when a value is obtained by difference, corrections shall be made for minor constituents in order to put analyses on a comparable basis prior to determining the differences. For any constituents affected, a test method also shall be requalified after any substantial repair or replacement of one or more critical components of an instrument essential to the test method.

4.4.6.3 If an instrument or piece of equipment is replaced, even if by one of identical make or model, or is significantly modified, a previously qualified test method using such new or modified instrument or equipment shall be considered a new method and must be qualified in accordance with 4.4.2.

4.4.7 *Precision and Bias*—Different analytical test methods are subject to individual limits of precision and bias. It is the responsibility of the user to demonstrate that the test methods used at least meet the limits of precision and bias shown in Table 1.

5. General

5.1 *Interferences and Limitations*:

5.1.1 These test methods were developed primarily for the analysis of portland cements. However, except for limitations noted in the procedure for specific constituents, the reference test methods provide for accurate analyses of other hydraulic cements that are completely decomposed by hydrochloric acid, or where a preliminary sodium carbonate fusion is made to ensure complete solubility. Some of the alternative test methods may not always provide accurate results because of interferences from elements which are not removed during the procedure.

5.1.2 When using a test method that determines total sulfur, such as most instrumental test methods, sulfide sulfur will be determined with sulfate and included as such. In most hydraulic cements, the difference resulting from such inclusion will be insignificant, less than 0.05 weight %. In some cases, notably slags and slag-containing cements but sometimes other cements as well, significant levels of sulfide may be present. In such cases, especially if there is a question of meeting or not meeting a specification limit or when the most accurate results are desired, analytical test methods shall be chosen so that sulfate and sulfide can be reported separately.

5.2 *Apparatus and Materials*:

5.2.1 *Balance*—The analytical balance used in the chemical determinations shall conform to the following requirements:

5.2.1.1 The balance shall be capable of reproducing results within 0.0002 g with an accuracy of ±0.0002 g. Direct-reading

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

balances shall have a sensitivity not exceeding 0.0001 g (Note 4). Conventional two-pan balances shall have a maximum sensibility reciprocal of 0.0003 g. Any rapid weighing device that may be provided, such as a chain, damped motion, or heavy riders, shall not increase the basic inaccuracy by more than 0.0001 g at any reading and with any load within the rated capacity of the balance.

NOTE 4—The sensitivity of a direct-reading balance is the weight required to change the reading one graduation. The sensibility reciprocal for a conventional balance is defined as the change in weight required on either pan to change the position of equilibrium one division on the pointer scale at capacity or at any lesser load.

5.2.2 *Weights*—Weights used for analysis shall conform to Types I or II, Grades S or O, Classes 1, 2, or 3 as described in Specification E617. They shall be checked at least once a year, or when questioned, and adjusted at least to within allowable tolerances for Class 3 weights (Note 5). For this purpose each laboratory shall also maintain, or have available for use, a reference set of standard weights from 50 g to 10 mg, which shall conform at least to Class 3 requirements and be calibrated at intervals not exceeding five years by the National Institute of Standards and Technology (NIST). After initial calibration, recalibration by the NIST may be waived provided it can be shown by documented data obtained within the time interval specified that a weight comparison between summations of smaller weights and a single larger weight nominally equal to that summation, establishes that the allowable tolerances have not been exceeded. All new sets of weights purchased shall have the weights of 1 g and larger made of stainless steel or other corrosion-resisting alloy not requiring protective coating, and shall meet the density requirements for Grades S or O.

NOTE 5—The scientific supply houses do not presently list weights as meeting Specification E617. They list weights as meeting NIST or OIML standards. The situation with regard to weights is in a state of flux because of the trend toward internationalization. Hopefully this will soon be resolved.

NIST Classes S and S-1 and OIML Class F_1 weights meet the requirements of this standard.

5.2.3 *Glassware and Laboratory Containers*—Standard volumetric flasks, burets, and pipets should be of precision grade or better. Standard-taper, interchangeable, ground-glass joints are recommended for all volumetric glassware and distilling apparatus, when available. Wherever applicable, the use of special types of glassware, such as colored glass for the protection of solutions against light, alkali-resistant glass, and high-silica glass having exceptional resistance to thermal shock is recommended. Polyethylene containers are recommended for all aqueous solutions of alkalies and for standard solutions where the presence of dissolved silica or alkali from the glass would be objectionable. Such containers shall be made of high-density polyethylene having a wall thickness of at least 1 mm.

5.2.4 *Desiccators*— Desiccators shall be provided with a good desiccant, such as magnesium perchlorate, activated alumina, or sulfuric acid. Anhydrous calcium sulfate may also be used provided it has been treated with a color-change indicator to show when it has lost its effectiveness. Calcium chloride is not a satisfactory desiccant for this type of analysis.

5.2.5 *Filter Paper*— Filter paper shall conform to the requirements of Specification E832, Type II, Quantitative. When coarse-textured paper is required, Class E paper shall be used, when medium-textured paper is required, Class F paper shall be used, and when retentive paper is required, Class G shall be used.

5.2.6 *Crucibles*—Platinum crucibles for ordinary chemical analysis should preferably be made of pure unalloyed platinum and be of 15 to 30-mL capacity. Where alloyed platinum is used for greater stiffness or to obviate sticking of crucible and lid, the alloyed platinum should not decrease in weight by more than 0.2 mg when heated at 1200 °C for 1 h.

5.2.7 *Muffle Furnace*— The muffle furnace shall be capable of operation at the temperatures required and shall have an indicating pyrometer accurate within ±25 °C, as corrected, if necessary, by calibration. More than one furnace may be used provided each is used within its proper operating temperature range.

5.3 *Reagents*:

5.3.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.[4] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.3.2 Unless otherwise indicated, references to water shall mean water conforming to the numerical limits for Type II reagent water described in Specification D1193.

5.3.3 *Concentration of Reagents*:

5.3.3.1 *Prepackaged Reagents*—Commercial prepackaged standard solutions or diluted prepackaged concentrations of a reagent may be used whenever that reagent is called for in the procedures provided that the purity and concentrations are as specified. Verify purity and concentration of such reagents by suitable tests.

5.3.3.2 *Concentrated Acids and Ammonium Hydroxide*—When acids and ammonium hydroxide are specified by name or chemical formula only, it shall be understood that concentrated reagents of the following specific gravities or concentrations by weight are intended:

Acetic acid ($HC_2H_3O_2$)	99.5 %
Hydrochloric acid (HCl)	sp gr 1.19
Hydrofluoric acid (HF)	48 %
Nitric acid (HNO_3)	sp gr 1.42
Phosphoric acid (H_3PO_4)	85 %
Sulfuric acid (H_2SO_4)	sp gr 1.84
Ammonium hydroxide (NH_4OH)	sp gr 0.90

5.3.3.3 The desired specific gravities or concentrations of all other concentrated acids shall be stated whenever they are specified.

[4] *Reagent Chemicals, American Chemical Society Specifications,* American Chemical Society, Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see *Analar Standards for Laboratory Chemicals,* BDH Ltd., Poole, Dorset, U.K., and the *United States Pharmacopeia and National Formulary,* U.S. Pharmacopeia Convention, Inc. (USPC), Rockville, MD.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

5.3.4 *Diluted Acids and Ammonium Hydroxide*—Concentrations of diluted acids and ammonium hydroxide, except when standardized, are specified as a ratio stating the number of volumes of the concentrated reagent to be added to a given number of volumes of water, for example: HCl (1+99) means 1 volume of concentrated HCl (sp gr 1.19) added to 99 volumes of water.

5.3.5 *Standard Solutions*—Concentrations of standard solutions shall be expressed as normalities (*N*) or as equivalents in grams per millilitre of the component to be determined, for example: 0.1 *N* $Na_2S_2O_3$ solution or $K_2Cr_2O_7$(1 mL = 0.004 g Fe_2O_3). The average of at least three determinations shall be used for all standardizations. When a material is used as a primary standard, reference has generally been made to the standard furnished by NIST. However, when primary standard grade materials are otherwise available they may be used or the purity of a salt may be determined by suitable tests.

5.3.6 *Nonstandardized Solutions*—Concentrations of nonstandardized solutions prepared by dissolving a given weight of the solid reagent in a solvent shall be specified in grams of the reagent per litre of solution, and it shall be understood that water is the solvent unless otherwise specified, for example: NaOH solution (10 g/L) means 10 g of NaOH dissolved in water and diluted with water to 1 L. Other nonstandardized solutions may be specified by name only, and the concentration of such solutions will be governed by the instructions for their preparation.

5.3.7 *Indicator Solutions*:

5.3.7.1 *Methyl Red*—Prepare the solution on the basis of 2 g of methyl red/L of 95 % ethyl alcohol.

5.3.7.2 *Phenolphthalein*— Prepare the solution on the basis of 1 g of phenolphthalein/L of 95 % ethyl alcohol.

5.4 *Sample Preparation*:

5.4.1 Before testing, pass representative portions of each sample through a No. 20 (850-µm) sieve, or any other sieve having approximately 20 openings/1 in., in order to mix the sample, break up lumps, and remove foreign materials. Discard the foreign materials and hardened lumps that do not break up on sieving or brushing.

TABLE 3 Rounding of Reported Results

Component	Decimal Places
SiO_2 (silicon dioxide)	1
Al_2O_3 (aluminum oxide)	1
Fe_2O_3 (ferric oxide)	2
CaO (calcium oxide)	1
MgO (magnesium oxide)	1
SO_3 (sulfur trioxide)	2
LoI (loss on ignition)	1
Na_2O (sodium oxide)	2
K_2O (potassium oxide)	2
SrO (strontium oxide)	2
TiO_2 (titanium dioxide)	2
P_2O_5 (phosphorous pentoxide)	2
ZnO (zinc oxide)	2
Mn_2O_3 (manganic oxide)	3
S (sulfide sulfur)	2
Cl (chloride)	3
IR (insoluble residue	2
FL (free calcium oxide)	1
CO_2 (carbon dioxide)	1
Water-soluble Alkali	2
Chloroform-soluble Organic Substances	3

5.4.2 By means of a sample splitter or by quartering, the representative sample shall be reduced to a laboratory sample of at least 50 g. Where larger quantities are required for additional determinations such as water-soluble alkali, chloride, duplicate testing, etc., prepare a sample of at least 100 g.

5.4.3 Pass the laboratory sample through a U.S. No. 100 sieve (sieve opening of 150 µm). Further grind the sieve residue so that it also passes the No. 100 sieve. Homogenize the entire sample by again passing it through the sieve.

5.4.4 Transfer the sample to a clean, dry, glass container with an airtight lid and further mix the sample thoroughly.

5.4.5 Expedite the above procedure so that the sample is exposed to the atmosphere for a minimum time.

5.5 *General Procedures*:

5.5.1 *Weighing*—The calculations included in the individual test methods assume that the exact weight specified has been used. Accurately weighed samples, that are approximately but not exactly equal to the weight specified, may be used provided appropriate corrections are made in the calculations. Unless otherwise stated, weights of all samples and residues should be recorded to the nearest 0.0001 g.

5.5.2 *Tared or Weighed Crucibles*—The tare weight of crucibles shall be determined by preheating the empty crucible to constant weight at the same temperature and under the same conditions as shall be used for the final ignition of a residue and cooling in a desiccator for the same period of time used for the crucible containing the residue.

5.5.3 *Constancy of Weight of Ignited Residues*—To definitely establish the constancy of weight of an ignited residue for referee purposes, the residue shall be ignited at the specified temperature and for the specified time, cooled to room temperature in a desiccator, and weighed. The residue shall then be reheated for at least 30 min, cooled to room temperature in a desiccator, and reweighed. If the two weights do not differ by more than 0.2 mg, constant weight is considered to have been attained. If the difference in weights is greater than 0.2 mg, additional ignition periods are required until two consecutive weights agree within the specified limits. For ignition loss, each reheating period shall be 5 min.

5.5.4 *Volatilization of Platinum*—The possibility of volatilization of platinum or alloying constituents from the crucibles must be considered. On reheating, if the crucible and residue lose the same weight (within 0.2 mg) as the crucible containing the blank, constant weight can be assumed. Crucibles of the same size, composition, and history shall be used for both the sample and the blank.

5.5.5 *Calculation*— In all operations on a set of observed values such as manual multiplication or division, retain the equivalent of at least two more places of figures than in the single observed values. For example, if observed values are read or determined to the nearest 0.1 mg, carry numbers to the nearest 0.001 mg in calculation. When using electronic calculators or computers for calculations, perform no rounding, except in the final reported value.

5.5.6 *Rounding Figures*— Rounding of figures to the number of significant places required in the report should be done after calculations are completed, in order to keep the final results substantially free of calculation errors. The rounding

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

procedure should follow the principle outlined in Practice E29.[5] In assessing analyst- and method-qualification in accordance with Section 3, the individual duplicate results, the difference between them, the average of duplicates on CRMs, and the difference of this average from the certificate value shall be left un-rounded for comparison with the required limits. Round results for reporting as shown in Table 3.

NOTE 6—The rounding procedure referred to in 5.5.6, in effect, drops all digits beyond the number of places to be retained if the next figure is less than 5. If it is more than 5, or equal to 5 and subsequent places contain a digit other than 0, then the last retained digit is increased by one. When the next digit is equal to 5 and all other subsequent digits are 0, the last digit to be retained is unchanged when it is even and increased by one when it is odd. For example 3.96 (50) remains 3.96 but 3.95 (50) becomes 3.96.

5.6 *Recommended Order for Reporting Analyses*—The following order is recommended for reporting the results of chemical analysis of portland cement:

Major Components:
SiO_2(silicon dioxide)
Al_2O_3(aluminum oxide)
Fe_2O_3(ferric oxide)
CaO (calcium oxide)
MgO (magnesium oxide)
SO_3(sulfur trioxide)
Loss on ignition
Minor Components:
Na_2O (sodium oxide)
K_2O (potassium oxide)
TiO_2(titanium dioxide)
P_2O_5(phosphorus pentoxide)
ZnO (zinc oxide)
Mn_2O_3(manganic oxide)
Sulfide sulfur
Separate Determinations:
Insoluble residue
Free calcium oxide
CO_2(Carbon Dioxide)
Water-soluble alkali
Chloroform—soluble organic substances

REFERENCE TEST METHODS

6. Insoluble Residue (*Reference Test Method*)

6.1 *Summary of Test Method*:

6.1.1 In this test method, insoluble residue of a cement is determined by digestion of the sample in hydrochloric acid followed, after filtration, by further digestion in sodium hydroxide. The resulting residue is ignited and weighed (Note 7).

NOTE 7—This test method, or any other test method designed for the estimation of an acid-insoluble substance in any type of cement, is empirical because the amount obtained depends on the reagents and the time and temperature of digestion. If the amount is large, there may be a little variation in duplicate determinations. The procedure should be followed closely in order to reduce the variation to a minimum.

6.1.2 When this test method is used on blended cement, the decomposition in acid is considered to be complete when the portland-cement clinker is decomposed completely. An ammonium nitrate solution is used in the final washing to prevent finely-ground insoluble material from passing through the filter paper.

6.2 *Reagents*:

6.2.1 *Ammonium Nitrate Solution* (20 g NH_4NO_3/L).

6.2.2 *Sodium Hydroxide Solution* (10 g NaOH/L).

6.3 *Procedure*:

6.3.1 To 1 g of the sample (Note 8) add 25 mL of cold water. Disperse the cement in the water and while swirling the mixture, quickly add 5 mL of HCl. If necessary, warm the solution gently, and grind the material with the flattened end of a glass rod for a few minutes until it is evident that decomposition of the cement is complete (Note 9). Dilute the solution to 50 mL with hot water (nearly boiling) and heat the covered mixture rapidly to near boiling by means of a high-temperature hot plate. Then digest the covered mixture for 15 min at a temperature just below boiling (Note 10). Filter the solution through a medium-textured paper into a 400-mL beaker, wash the beaker, paper, and residue thoroughly with hot water, and reserve the filtrate for the sulfur trioxide determination, if desired (Note 11). Transfer the filter paper and contents to the original beaker, add 100 mL of hot (near boiling) NaOH solution (10 g/L), and digest at a temperature just below boiling for 15 min. During the digestion, occasionally stir the mixture and macerate the filter paper. Acidify the solution with HCl using methyl red as the indicator and add an excess of 4 or 5 drops of HCl. Filter through medium-textured paper and wash the residue at least 14 times with hot NH_4 NO_3 solution (20 g/L) making certain to wash the entire filter paper and contents during each washing. Ignite the residue in a weighed platinum crucible at 900 to 1000 °C, cool in a desiccator, and weigh.

NOTE 8—If sulfur trioxide is to be determined by turbidimetry it is permissible to determine the insoluble residue on a 0.5-g sample. In this event, the percentage of insoluble residue should be calculated to the nearest 0.01 by multiplying the weight of residue obtained by 200. However, the cement should not be rejected for failure to meet the insoluble residue requirement unless a 1-g sample has been used.

NOTE 9—If a sample of portland cement contains an appreciable amount of manganic oxide, there may be brown compounds of manganese which dissolve slowly in cold diluted HCl but rapidly in hot HCl in the specified strength. In all cases, dilute the solution as soon as decomposition is complete.

NOTE 10—In order to keep the solutions closer to the boiling temperature, it is recommended that these digestions be carried out on an electric hot plate rather than in a steam bath.

NOTE 11—Continue with the sulfur trioxide determination (16.1.2.1-16.1.3) by diluting to 250 or 200 mL as required by the appropriate section.

6.3.2 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

6.4 *Calculation*— Calculate the percentage of the insoluble residue to the nearest 0.01 by multiplying the weight in grams of the residue (corrected for the blank) by 100.

7. Silicon Dioxide (*Reference Test Method*)

7.1 *Selection of Test Method*—For cements other than portland and for which the insoluble residue is unknown, determine the insoluble residue in accordance with Section 6 of

[5] See also the *ASTM Manual on Presentation of Data and Control Chart Analysis, STP 15D,* 1976.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

these test methods. For portland cements and other cements having an insoluble residue less than 1 %, proceed in accordance with 7.2. For cements having an insoluble residue greater than 1 % proceed in accordance with 7.3.

7.2 *Silicon Dioxide in Portland Cements and Cements with Low Insoluble Residue*:

7.2.1 *Summary of Test Method*—In this test method silicon dioxide (SiO_2) is determined gravimetrically. Ammonium chloride is added and the solution is not evaporated to dryness. This test method was developed primarily for hydraulic cements that are almost completely decomposed by hydrochloric acid and should not be used for hydraulic cements that contain large amounts of acid-insoluble material and require a preliminary sodium carbonate fusion. For such cements, or if prescribed in the standard specification for the cement being analyzed, the more lengthy procedure in 7.3 shall be used.

7.2.2 *Reagent*—Ammonium chloride (NH_4Cl).

7.2.3 *Procedure*:

7.2.3.1 Mix thoroughly 0.5 g of the sample and about 0.5 g of NH_4Cl in a 50-mL beaker, cover the beaker with a watch glass, and add cautiously 5 mL of HCl, allowing the acid to run down the lip of the covered beaker. After the chemical action has subsided, lift the cover, add 1 or 2 drops of HNO_3, stir the mixture with a glass rod, replace the cover, and set the beaker on a steam bath for 30 min (Note 12). During this time of digestion, stir the contents occasionally and break up any remaining lumps to facilitate the complete decomposition of the cement. Fit a medium-textured filter paper to a funnel, transfer the jelly-like mass of silicic acid to the filter as completely as possible without dilution, and allow the solution to drain through. Scrub the beaker with a policeman and rinse the beaker and policeman with hot HCl (1+99). Wash the filter two or three times with hot HCl (1+99) and then with ten or twelve small portions of hot water, allowing each portion to drain through completely. Reserve the filtrate and washings for the determination of the ammonium hydroxide group (Note 13).

NOTE 12—A hot plate may be used instead of a steam bath if the heat is so regulated as to approximate that of a steam bath.

Under conditions where water boils at a lower temperature than at sea level: such as at higher elevations, 30 min may not be sufficient to recover all of the silica. In such cases, increase the time of digestion as necessary to get complete recovery of the silica. In no case should this time exceed 60 min.

NOTE 13—Determine the ammonium hydroxide group in accordance with the procedure described in 8.1-8.3.

7.2.3.2 Transfer the filter paper and residue to a weighed platinum crucible, dry, and ignite, at first slowly until the carbon of the paper is completely consumed without inflaming, and finally at 1100 to 1200 °C for 1 h. Cool in a desiccator and weigh. Reignite to constant weight. Treat the SiO_2 thus obtained, which will contain small amounts of impurities, in the crucible with 1 or 2 mL of water, 2 drops of H_2SO_4 (1+1), and about 10 mL of HF, and evaporate cautiously to dryness. Finally, heat the small residue at 1050 to 1100 °C for 5 min, cool in a desiccator, and weigh. The difference between this weight and the weight previously obtained represents the weight of SiO_2. Consider the weighed residue remaining after the volatilization of SiO_2 as combined aluminum and ferric oxides and add it to the result obtained in the determination of the ammonium hydroxide group.

7.2.3.3 If the HF residue exceeds 0.0020 g, the silica determination shall be repeated, steps should be taken to ensure complete decomposition of the sample before a silica separation is attempted, and the balance of the analysis (ammonium hydroxide group, CaO, and MgO) determined on the new silica filtrate provided the new silica determination has a HF residue of 0.0020 g or less except as provided in 7.2.3.4 and 7.2.3.5.

7.2.3.4 If two or three repeated determinations of a sample of portland cement consistently show HF residues higher than 0.0020 g, this is evidence that contamination has occurred in sampling or the cement has not been burned properly during manufacture. In such a case, do not fuse the large HF residue with pyrosulfate for subsequent addition to the filtrate from the silica separation. Instead, report the value obtained for the HF residue. Do not ignite the ammonium hydroxide group in the crucible containing this abnormally large HF residue.

7.2.3.5 In the analysis of cements other than portland, it may not always be possible to obtain HF residues under 0.0020 g. In such cases, add 0.5 g of sodium or potassium pyrosulfate ($Na_2S_2O_7$ or $K_2S_2O_7$) to the crucible and heat below red heat until the small residue of impurities is dissolved in the melt (Note 14). Cool, dissolve the fused mass in water, and add it to the filtrate and washings reserved for the determination of the ammonium hydroxide group.

NOTE 14—A supply of nonspattering pyrosulfate may be prepared by heating some pyrosulfate in a platinum vessel below red heat until the foaming and spattering cease, cooling, and crushing the fused mass.

7.2.3.6 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

7.2.4 *Calculation*— Calculate the percentage of SiO_2 by multiplying the mass in grams of SiO_2 by 200 (100 divided by the mass (see 7.2.3.1) or equivalent mass (see 7.3.2.1) of the sample used (0.5 g)). Round in accordance with Table 3.

7.3 *Silicon Dioxide in Cements with Insoluble Residue Greater Than 1 %*:

7.3.1 *Summary of Test Method*—This test method is based on the sodium carbonate fusion followed by double evaporation to dryness of the hydrochloric acid solution of the fusion product to convert silicon dioxide (SiO_2) to the insoluble form. The solution is filtered and the insoluble siliceous residue is ignited and weighed. Silicon dioxide is volatilized by hydrofluoric acid and the loss of weight is reported as pure SiO_2.

7.3.2 *Procedure*:

7.3.2.1 Weigh a quantity of the ignited sample equivalent to 0.5 g of the as-received sample calculated as follows:

$$W = [(0.5\ (100.00 - I)]/100 \quad (1)$$

where:

W = weight of ignited sample, g, and
I = loss of ignition, %.

The ignited material from the loss on ignition determination may be used for the sample. Thoroughly mix the sample with 4 to 6 g of Na_2CO_3 by grinding in an agate mortar. Place a thin layer of Na_2CO_3 on the bottom of a platinum crucible of 20 to 30-mL capacity, add the cement-Na_2CO_3 mixture, and cover

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the mixture with a thin layer of Na_2CO_3. Place the covered crucible over a moderately low flame and increase the flame gradually to a maximum (approximately 1100 °C) and maintain this temperature until the mass is quiescent (about 45 min). Remove the burner, lay aside the cover of the crucible, grasp the crucible with tongs, and slowly rotate the crucible so that the molten contents spread over the sides and solidify as a thin shell on the interior. Set the crucible and cover aside to cool. Rinse off the outside of the crucible and place the crucible on its side in a 300-mL casserole about one third full of water. Warm the casserole and stir until the cake in the crucible disintegrates and can be removed easily. By means of a glass rod, lift the crucible out of the liquid, rinsing it thoroughly with water. Rinse the cover and crucible with HCl (1+3); then add the rinse to the casserole. Very slowly and cautiously add 20 mL of HCl (sp gr 1.19) to the covered casserole. Remove the cover and rinse. If any gritty particles are present, the fusion is incomplete and the test must be repeated, using a new sample. **Warning**—Subsequent steps of the test method must be followed exactly for accurate results.

7.3.2.2 Evaporate the solution to dryness on a steam bath (there is no longer a gelatinous appearance). Without heating the residue any further, treat it with 5 to 10 mL of HCl, wait at least 2 min, and then add an equal amount of water. Cover the dish and digest for 10 min on the steam bath or a hot plate. Dilute the solution with an equal volume of hot water, immediately filter through medium-textured paper and wash the separated SiO_2 thoroughly with hot HCl (1+99), then with hot water. Reserve the residue.

7.3.2.3 Again evaporate the filtrate to dryness, and bake the residue in an oven for 1 h at 105 to 110 °C. Cool, add 10 to 15 mL of HCl (1+1), and digest on the steam bath or hot plate for 10 min. Dilute with an equal volume of water, filter immediately on a fresh filter paper, and wash the small SiO_2 residue thoroughly as described in 7.3.2.2. Stir the filtrate and washings and reserve for the determination of the ammonium hydroxide group in accordance with 8.1-8.3.

7.3.2.4 Continue the determination of silicon dioxide in accordance with 7.2.3.2.

8. Ammonium Hydroxide Group (*Reference Test Method*)

8.1 *Summary of Test Method*—In this test method aluminum, iron, titanium, and phosphorus are precipitated from the filtrate, after SiO_2 removal, by means of ammonium hydroxide. With care, little if any manganese will be precipitated. The precipitate is ignited and weighed as the oxides.

8.2 *Procedure*:

8.2.1 To the filtrate reserved in accordance with 7.2.3.1 (Note 15) which should have a volume of about 200 mL, add HCl if necessary to ensure a total of 10 to 15 mL of the acid. Add a few drops of methyl red indicator and heat to boiling. Then treat with NH_4OH (1+1) (Note 16), dropwise until the color of the solution becomes distinctly yellow, and add one drop in excess (Note 17). Heat the solution containing the precipitate to boiling and boil for 50 to 60 s. In the event difficulty from bumping is experienced while boiling the ammoniacal solution, a digestion period of 10 min on a steam bath, or on a hot plate having the approximate temperature of a steam bath, may be substituted for the 50 to 60-s boiling period. Allow the precipitate to settle (not more than 5 min) and filter using medium-textured paper (Note 18). Wash, with hot ammonium nitrate (NH_4NO_3, 20 g/L) (Note 19), twice for a small precipitate to about four times for a large one.

NOTE 15—If a platinum evaporating dish has been used for the dehydration of SiO_2, iron may have been partially reduced. At this stage, add about 3 mL of saturated bromine water to the filtrate and boil the filtrate to eliminate the excess bromine before adding the methyl red indicator. If difficulty from bumping is experienced during the boiling, the following alternate techniques may be helpful: (*1*) a piece of filter paper, approximately 1 cm^2 in area, positioned where the bottom and side of the beaker merge and held down by the end of a stirring rod may solve the difficulty, and (*2*) use of 400-mL beakers supported inside a cast aluminum cup has also been found effective.

NOTE 16—The NH_4OH used to precipitate the hydroxides must be free of contamination with carbon dioxide (CO_2).

NOTE 17—It usually takes 1 drop of NH_4OH (1+1) to change the color of the solution from red to orange and another drop to change the color from orange to yellow. If desired, the addition of the indicator may be delayed until ferric hydroxide ($Fe(OH)_3$) is precipitated without aluminum hydroxide ($Al(OH)_3$) being completely precipitated. In such a case, the color changes may be better observed. However, if the content of Fe_2O_3 is unusually great, it may be necessary to occasionally let the precipitate settle slightly so that the color of the supernatant liquid can be observed. If the color fades during the precipitation, add more of the indicator. Observation of the color where a drop of the indicator strikes the solution may be an aid in the control of the acidity. The boiling should not be prolonged as the color may reverse and the precipitate may be difficult to retain on the filter. The solution should be distinctly yellow when it is ready to filter. If it is not, restore the yellow color with more NH_4OH (1+1) or repeat the precipitation.

NOTE 18—To avoid drying of the precipitate with resultant slow filtration, channeling, or poor washing, the filter paper should be kept nearly full during the filtration and should be washed without delay.

NOTE 19—Two drops of methyl red indicator solution should be added to the NH_4NO_3 solution in the wash bottle, followed by NH_4OH (1+1) added dropwise until the color just changes to yellow. If the color reverts to red at any time due to heating, it should be brought back to yellow by the addition of a drop of NH_4OH (1+1).

8.2.2 Set aside the filtrate and transfer the precipitate and filter paper to the same beaker in which the first precipitation was effected. Dissolve the precipitate with hot HCl (1+2). Stir to thoroughly macerate the paper and then dilute the solution to about 100 mL. Reprecipitate the hydroxides as described in 8.2.1. If difficulty from bumping is experienced while boiling the acid solution containing the filter paper, it may be obviated by diluting the hot 1+2 solution of the mixed oxides with 100 mL of boiling water and thus eliminate the need for boiling. Filter the solution and wash the precipitate with about four 10-mL portions of hot NH_4NO_3 solution (20 g/L) (Note 19). Combine the filtrate and washings with the filtrate set aside and reserve for the determination of CaO in accordance with 14.3.1.

8.2.3 Place the precipitate in a weighed platinum crucible, heat slowly until the papers are charred, and finally ignite to constant weight at 1050 to 1100 °C taking care to prevent reduction, and weigh as the ammonium hydroxide group.

8.2.4 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

8.3 *Calculation*— Calculate the percentage of ammonium hydroxide group by multiplying the weight in grams of

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

ammonium hydroxide group by 200 (100 divided by the weight of sample used (0.5 g)).

9. Ferric Oxide (*Reference Test Method*)

9.1 *Summary of Test Method*—In this test method, the Fe_2O_3 content of the cement is determined on a separate portion of the cement by reducing the iron to the ferrous state with stannous chloride ($SnCl_2$) and titrating with a standard solution of potassium dichromate ($K_2Cr_2O_7$). This determination is not affected by any titanium or vanadium that may be present in the cement.

9.2 *Reagents*:

9.2.1 *Barium Diphenylamine Sulfonate Indicator Solution*—Dissolve 0.3 g of barium diphenylamine sulfonate in 100 mL of water.

9.2.2 *Potassium Dichromate, Standard Solution* (1 mL = 0.004 g Fe_2O_3)—Pulverize and dry primary standard potassium dichromate ($K_2Cr_2O_7$) reagent, the current lot of NIST 136, at 180 to 200 °C to constant weight. Weigh accurately an amount of dried reagent equal to 2.45700 g times the number of litres of solution to be prepared. Dissolve in water and dilute to exactly the required volume in a single volumetric flask of the proper size. This solution is a primary standard and requires no further standardization.

NOTE 20—Where large quantities of standard solution are required, it may be desirable for certain laboratories to use commercially-produced primary standard potassium dichromate for most determinations. Such a material may be used provided that the first solution made from the container is checked, as follows: Using a standard solution of NIST 136, prepared as described in 9.2.2, analyze, in duplicate, samples of a NIST CRM cement, by the procedure given in 8.3.1.3 and 8.3.1.4. Repeat using a similar solution prepared from the commercial primary standard dichromate. The average percentages of Fe_2O_3 found by each method should not differ by more than 0.06 %.

9.2.3 *Stannous Chloride Solution*—Dissolve 5 g of stannous chloride ($SnCl_2 \cdot 2H_2O$) in 10 mL of HCl and dilute to 100 mL. Add scraps of iron-free granulated tin and boil until the solution is clear. Keep the solution in a closed dropping bottle containing metallic tin.

9.3 *Procedure*—For cements other than portland and for which the insoluble residue is unknown, determine the insoluble residue in accordance with the appropriate sections of these test methods. When insoluble residue is known, proceed in accordance with 9.3.1 or 9.3.2 as is appropriate for the cement being analyzed.

9.3.1 For portland cements and cements having insoluble residue lower than 1 %, weigh 1 g of the sample into a 500-mL Phillips beaker or other suitable container. Add 40 mL of cold water and, while the beaker is being swirled, add 10 mL of HCl. If necessary, heat the solution and grind the cement with the flattened end of a glass rod until it is evident that the cement is completely decomposed. Continue the analysis in accordance with 9.3.3.

9.3.2 For cements with insoluble residue greater than 1 %, weigh a 0.500 g sample, blend with 1 g $LiBO_2$ using a mortar and pestle, and transfer to a previously fired 8-mL carbon crucible that has 0.1 g $LiBO_2$ sprinkled in the bottom (Note 21). Cover with 0.1 g $LiBO_2$ that was used to chemically wash the mortar and pestle (Note 22). Place the uncovered crucible in a furnace set at 1100 °C for 15 min. Remove the crucible from the furnace and check for complete fusion (Note 23). If the fusion is incomplete, return the crucible to the furnace for another 30 min. Again, check for complete fusion. If the fusion is still incomplete, discard the sample and repeat the fusion procedure using 0.250 g sample or a smaller quantity with the same amount of $LiBO_2$. When the fusion is complete, gently swirl the melt and pour into a 150-mL glass beaker containing 10 mL concentrated HCl and 50 mL water. Stir continuously until the fusion product is dissolved, usually 10 min or less (Note 24). If a stirring bar is used, remove and rinse the bar. Continue the analysis in accordance with 9.3.3.

NOTE 21—The firing loosens the carbon on the surface, reducing the possibility of the fusion product sticking to the crucible.

NOTE 22—A chemical wash is a dry rinse of the equipment in which the blending was done so that any sample adhering to this equipment will be loosened and transferred to the crucible.

NOTE 23—When fusion is incomplete, the sample may not be completely melted or there may be particles on top of the bead. Usually, if the bead forms a small smooth spherical ball when taken from the furnace and before it is swirled, the sample is completely fused.

NOTE 24—There are usually some carbon particles that are in suspension, undissolved in the solution, but they will not interfere with the completion of the analysis.

9.3.3 Heat the solution to boiling and treat it with the $SnCl_2$ solution, added dropwise while stirring and boiling, until the solution is decolorized. Add 1 drop in excess and cool the solution to room temperature by placing the beaker in a pan of cool water. After cooling and without delay, rinse the inside of the vessel with water, and add all at once 10 mL of a cool, saturated mercuric chloride ($HgCl_2$) solution. Stir the solution vigorously for 1 min by swirling the beaker and add 10 mL of H_3PO_4 (1+1) and 2 drops of barium diphenylamine sulfonate indicator. Add sufficient water so that the volume after titration will be between 75 and 100 mL. Titrate with the standard $K_2Cr_2O_7$ solution. The end point shall be taken as the point at which a single drop causes an intense purple coloration that remains unchanged on further addition of standard $K_2Cr_2O_7$ solution.

9.3.4 *Blank*—Make a blank determination following the same procedure and using the same amounts of reagents. Record the volume of $K_2Cr_2O_7$ solution required to establish the end point as described in 9.3.3. As some iron must be present to obtain the normal end point, if no definite purple color is obtained after the addition of 4 drops of the standard $K_2Cr_2O_7$ solution, record the blank as zero.

9.4 *Calculation*:

9.4.1 Calculate the percentage of Fe_2O_3 as follows:

$$Fe_2O_3, \% = E(V - B) \times 100/W \quad (2)$$

where:

E = Fe_2O_3 equivalent of the $K_2Cr_2O_7$ solution, g/mL,
V = millilitres of $K_2Cr_2O_7$ solution required by the sample determination,
B = millilitres of $K_2Cr_2O_7$ solution required by the blank determination, and
W = mass of sample within 0.1 mg.

Round in accordance with Table 3.

10. Phosphorus Pentoxide (*Reference Test Method*)

10.1 *Summary of Test Method*—This colorimetric test method is applicable to the determination of P_2O_5 in portland cement. Under the conditions of the test, no constituent normally present in portland cement will interfere.

10.2 *Apparatus*:

10.2.1 *Spectrophotometer* (Note 25):

10.2.1.1 The instrument shall be equipped to measure absorbance of solutions at a spectral wavelength of 725 nm.

10.2.1.2 Wavelength measurements shall be repeatable within ±1 nm or less.

10.2.1.3 In the absorbance range from 0.1 to 1.0, the absorbance measurements shall be repeatable within ±1 % or less.

10.2.1.4 To establish that the spectrophotometer will permit a satisfactory degree of accuracy, qualify the instrument in accordance with 4.4.2 using the procedure in 10.4.1-10.4.9.

NOTE 25—For the measurement of the performance of the spectrophotometer, refer to Practice E275.

10.3 *Reagents*:

10.3.1 *Ammonium Molybdate Solution*—Into a 1-L volumetric flask introduce 500.0 mL of 10.6 *N* H_2SO_4 (10.3.7). Dissolve 25.0 g of ammonium molybdate ($(NH_4)_6MO_7O_{24} \cdot 4H_2O$) in about 250 mL of warm water and transfer to the flask containing the H_2SO_4, while swirling the flask. Cool, dilute to 1 L with water, and store in a plastic bottle.

10.3.2 *Ascorbic Acid Powder*—For ease in dissolving, the finest mesh available should be used.

10.3.3 *Hydrochloric Acid, Standard* (6.5 ± 0.1 *N*)—Dilute 540 mL of concentrated HCl (sp gr 1.19) to 1 L with water. Standardize against standard NaOH solution (10.3.6) using phenolphthalein as indicator. Determine the exact normality and adjust to 6.5 ± 0.1 *N* by dilution with water. Restandardize to ensure that the proper normality has been achieved.

10.3.4 *Phosphate, Standard Solution A*—Dissolve 0.1917 g of oven-dried potassium dihydrogen phosphate (KH_2PO_4) in water and dilute to 1 L in a volumetric flask.

10.3.5 *Phosphate, Standard Solution B*—Dilute 50.0 mL of phosphate solution A to 500 mL with water.

10.3.6 *Sodium Hydroxide, Standard Solution* (1 *N*)—Dissolve 40.0 g of sodium hydroxide (NaOH) in water, add 10 mL of a freshly filtered saturated solution of barium hydroxide ($Ba(OH)_2$), and dilute to 1 L with water that has been recently boiled and cooled. Shake the solution from time to time during a several-hour period, and filter into a plastic bottle. Keep the bottle tightly closed to protect the solution from CO_2 in the air. Standardize against acid potassium phthalate or benzoic acid acidimetric standards furnished by NIST (standard samples 84f and 350), using the test methods in the certificates accompanying the standard samples. Determine the exact normality of the solution.

10.3.7 *Sulfuric Acid, Standard* (10.6 ± 0.1 *N*)—To a 1-L volumetric flask cooled in water add about 600 mL of water and then, slowly, with *caution,* 300 mL of concentrated H_2SO_4 (sp gr 1.84). After cooling to room temperature, dilute to 1 L with water. Standardize against the standard NaOH solution (10.3.6) using phenolphthalein as indicator. Determine the normality and adjust to 10.6 ± 0.1 *N* by dilution with water. Restandardize to ensure that the proper normality has been achieved.

10.4 *Procedure*:

10.4.1 Prepare a series of phosphate solutions to cover the range from 0 to 0.5 % P_2O_5. Prepare each solution by adding a suitable volume of standard phosphate solution B and 25.0 mL of the 6.5 *N* hydrochloric acid to a 250-mL volumetric flask (Note 26). Dilute to the mark with water.

NOTE 26—One millilitre of standard phosphate solution B/250 mL of solution is equivalent to 0.004 % P_2O_5 for a 0.25-g cement sample. Aliquots of 0, 12.5, 25, 50, 74, 100, and 125 mL are equivalent to P_2O_5 contents in the sample of 0, 0.05, 0.10, 0.20, 0.30, 0.40, and 0.50 %.

10.4.2 Prepare a blank by adding 25.0 mL of the standard HCl to a 250-mL volumetric flask and diluting to 250 mL with water.

10.4.3 Develop colors in the series of phosphate solutions, and in the blank, in accordance with 10.4.6-10.4.8.

10.4.4 Plot the net absorbance (absorbance of standard minus that of the blank) values obtained as ordinates and the corresponding P_2O_5 concentrations as abscissas. Draw a smooth curve through the points.

NOTE 27—A suitable paper for plotting the calibration curve is a 10 by 15-in. (254 by 381-mm) linear cross section paper having 20 by 20 divisions to the inch. The percentage of P_2O_5 can then be plotted on the long dimension using five divisions equal to 0.01 % P_2O_5. A scale of one division equal to 0.005 absorbance units is suitable as the ordinate (short dimension of the paper). Scales other than this may be used but under no circumstances should a scale division less than 1/20 in. (1.3 mm) be used for 0.005 units of absorbance or for 0.005 % P_2O_5. A separate calibration curve should be made for each spectrophotometer used, and the calibration curve checked against standard phosphate solution whenever a new batch of ammonium molybdate reagent is used.

10.4.5 Transfer 0.250 g of the sample to a 250-mL beaker and moisten with 10 mL of cold water to prevent lumping. Add 25.0 mL of the standard HCl and digest with the aid of gentle heat and agitation until solution is complete. Filter into a 250-mL volumetric flask and wash the paper and the separated silica thoroughly with hot water. Allow the solution to cool and then dilute with water to 250 mL.

10.4.6 Transfer a 50.0-mL aliquot (Note 28) of the sample solution to a 250-mL beaker, add 5.0 mL of ammonium molybdate solution and 0.1 g of ascorbic acid powder. Mix the contents of the beaker by swirling until the ascorbic acid has dissolved completely. Heat the solution to vigorous boiling and then boil, uncovered, for 1.5 ± 0.5 min. Cool to room temperature and transfer to a 50-mL volumetric flask. Rinse the beaker with one small portion of water and add the rinse water to the flask. Dilute to 50 mL with water.

NOTE 28—The range of the test can be extended by taking a smaller aliquot of the sample solution. In such instances the decrease in the aliquot volume must be made up by the blank solution (10.4.5) to maintain the proper acidity of the final solution. Thus, if a 25-mL aliquot of the sample solution is taken (instead of the usual 50 mL), a 25-mL aliquot of the blank solution should be added before proceeding with the test. The result of the test must then be calculated accordingly.

10.4.7 Measure the absorbance of the solution against water as the reference at 725.0 nm.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.4.8 Develop on a 50.0-mL aliquot of the blank solution prepared in 10.4.2 in the same manner as was used in 10.4.6 for the sample solution. Measure the absorbance in accordance with 10.4.7 and subtract this absorbance value from that obtained for the sample solution in 10.4.6 in order to obtain the net absorbance for the sample solution.

10.4.9 Using the net absorbance value found in 10.4.8, record the percentage of P_2O_5 in the cement sample as indicated by the calibration curve. Report the percentage of P_2O_5 rounded in accordance with Table 3

11. Titanium Dioxide (*Reference Test Method*)

11.1 *Summary of Test Method*—In this test method titanium dioxide (TiO_2) in portland cement is determined colorimetrically using Tiron reagent. Under the conditions of the test iron is the only constituent of portland cement causing a very slight interference equivalent to 0.01 % for each 1 % of Fe_2O_3 present in the sample.

11.2 *Apparatus*:

11.2.1 *Spectrophotometer* (Note 29):

11.2.1.1 The instrument shall be equipped to measure absorbance of solutions at a spectral wavelength of 410 nm.

11.2.1.2 Wavelength measurements shall be repeatable within ±1 nm or less.

11.2.1.3 In the absorbance range from 0.1 to 1.0, the absorbance measurements shall be repeatable within ±1 % or less.

11.2.1.4 To establish that the spectrophotometer will permit a satisfactory degree of accuracy, qualify the instrument in accordance with 4.4.2 using the procedure in 11.4.1-11.4.6 of this test method.

NOTE 29—For the measurement of the performance of the spectrophotometer, refer to Practice E275.

11.3 *Reagents*:

11.3.1 *Buffer* (pH 4.7)—68 g of $NaC_2H_3O_2 \cdot 3H_2O$, plus 380 mL of water, plus 100 mL of 5.0 *N* CH_3COOH.

11.3.2 *Ethylenedinitrilo Tetraacetic Acid Disodium Salt, Dihydrate* (0.2 *M* EDTA)—Dissolve 37.5 g of EDTA in 350 mL of warm water, and filter. Add 0.25 g of $FeCl_3 \cdot 6H_2O$ and dilute to 500 mL.

11.3.3 *Hydrochloric Acid* (1+6).

11.3.4 *Hydrochloric Acid, Standard* (6.5 *N*)—Dilute 540 mL of concentrated HCl (sp gr 1.19) to 1 L with water.

11.3.5 *Ammonium Hydroxide* (NH_4OH, 1+1).

11.3.6 *Potassium Pyrosulfate* ($K_2S_2O_7$).

11.3.7 *Titanium Dioxide, Stock Solution A*—Fuse slowly in a platinum crucible over a very small flame 0.0314 g of NIST SRM 154b (TiO_2 = 99.74 %) or its replacements with about 2 or 3 g of $K_2S_2O_7$. Allow to cool, and place the crucible in a beaker containing 125 mL of H_2SO_4 (1+1). Heat and stir until the melt is completely dissolved. Cool, transfer to a 250-mL volumetric flask, and dilute the solution to volume.

11.3.7.1 *Titanium Dioxide, Dilute Standard Solution B* (1 mL = 0.0125 mg TiO_2)—Pipet 50 mL of stock TiO_2 solution into a 500-mL volumetric flask, and dilute to volume. One millilitre of this solution is equal to 0.0125 mg of TiO_2, which is equivalent to 0.05 % TiO_2 when used as outlined in 11.4.4-11.4.6.

11.3.8 *Sulfuric Acid* (1+1).

11.3.9 *Tiron* (disodium-1,2-dihydroxybenzene-3,5 disulfonate).

11.4 *Procedure*:

11.4.1 Prepare a series of TiO_2 solutions to cover the range from 0 to 1.0 % TiO_2. Prepare each solution in a 50-mL volumetric flask.

NOTE 30—One millilitre of dilute TiO_2 standard solution B per 50 mL (11.3.7.1) is equivalent to 0.05 % TiO_2 for a 0.2500-g cement sample. Aliquots of 0, 5, 10, 15, and 20 mL of dilute TiO_2 standard solution are equivalent to TiO_2 contents in the sample of 0, 0.25, 0.50, 0.75, and 1.0 %. Dilute each to 25 mL with water.

11.4.2 Develop color in accordance with 11.4.4 starting with second sentence. Measure absorbance in accordance with 11.4.5.

11.4.3 Plot absorbance values obtained as ordinates and the corresponding TiO_2 concentrations as abscissas. Draw a smooth curve through the points.

NOTE 31—A suitable paper for plotting the calibration curve is a linear cross section paper having 10 × 10 divisions to 1 cm. A scale division equivalent to 0.002 absorbance and 0.002 % TiO_2 should be used. A separate calibration curve should be made for each spectrophotometer used.

11.4.4 Transfer a 25.0-mL aliquot of the sample solution prepared in 10.4.5 into a 50-mL volumetric flask (Note 32). Add 5 mL tiron and 5 mL EDTA, mix, and then add NH_4OH (1+1) dropwise, mixing thoroughly after each drop, until the color changes through yellow to green, blue, or ruby red. Then, just restore the yellow color with HCl (1+6) added dropwise and mixing after each drop. Add 5 mL buffer, dilute to volume and mix.

11.4.5 Measure the absorbance of the solution against water as the reference at 410 nm.

NOTE 32—The range of the test can be extended by taking a smaller aliquot. The results of the test must then be calculated accordingly.

11.4.6 Using the absorbance value determined in 11.4.5, record the percentage of TiO_2 in the cement sample as indicated by the calibration curve. Correct for the iron present in the sample to obtain the true TiO_2 as follows: True TiO_2 = measured % TiO_2 – (0.01 × % Fe_2O_3). Report the percent of TiO_2 rounded in accordance with Table 3.

12. Zinc Oxide (*Reference Test Method*)[6]

12.1 Any test method may be used that meets the requirements of Section 4.4 and Table 1.

12.2 Report the result rounded in accordance with Table 3.

13. Aluminum Oxide (*Reference Test Method*)

NOTE 33—In the reference test method, Al_2O_3 is calculated from the ammonium hydroxide group by subtracting the separately determined constituents that usually are present in significant amounts in the ammonium hydroxide precipitate. These are Fe_2O_3, TiO_2 and P_2O_5. Most instrumental test methods for Al_2O_3 analysis give Al_2O_3 alone if standardized and calibrated properly.

[6] The 1988 revision of these test methods deleted the colorimetric method for determination of ZnO using an extraction with CCl_4. Those interested in this test method should refer to the *1987 Annual Book of ASTM Standards,* Volume 04.01.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

13.1 *Calculation*:

13.1.1 Calculate the percentage of Al_2O_3 by deducting the percentage of the sum of the Fe_2O_3, TiO_2, and P_2O_5 from the percentage of ammonium hydroxide group, using un-rounded values of all four quantities. All determinations shall be by referee test methods described in the appropriate sections herein. Report the Al_2O_3 rounded in accordance with Table 3. For nonreferee analyses, the percentages of Fe_2O_3, TiO_2, and P_2O_5 can be determined by any procedure for which qualification has been shown.

14. Calcium Oxide (*Reference Test Method*)

14.1 *Summary of Test Method*:

14.1.1 In this test method, manganese is removed from the filtrate after the determination of SiO_2 and the ammonium hydroxide group. Calcium is then precipitated as the oxalate. After filtering, the oxalate is redissolved and titrated with potassium permanganate ($KMnO_4$).

NOTE 34—For referee analysis or for the most accurate determinations, removal of manganese in accordance with 14.3.2 must be made. For less accurate determinations, and when only insignificant amounts of manganese oxides are believed present, 13.3.2 may be omitted.

14.1.2 Strontium, usually present in portland cement as a minor constituent, is precipitated with calcium as the oxalate and is subsequently titrated and calculated as CaO. If the SrO content is known and correction of CaO for SrO is desired as, for example, for research purposes or to compare results with CRM certificate values, the CaO obtained by this method may be corrected for SrO. In determining conformance of a cement to specifications, the correction of CaO for SrO should not be made.

14.2 *Reagents*:

14.2.1 *Ammonium Oxalate Solution* (50 g/L).

14.2.2 *Potassium Permanganate, Standard Solution* (0.18 *N*)—Prepare a solution of potassium permanganate ($KMnO_4$) containing 5.69 g/L. Let this solution stand at room temperature for at least 1 week, or boil and cool to room temperature. Siphon off the clear solution without disturbing the sediment on the bottom of the bottle; then filter the siphoned solution through a bed of glass wool in a funnel or through a suitable sintered glass filter. Do not filter through materials containing organic matter. Store in a dark bottle, preferably one that has been painted black on the outside. Standardize the solution against 0.7000 to 0.8000 g of primary standard sodium oxalate, according to the directions furnished with the sodium oxalate and record the temperature at which the standardization was made (Note 35).

14.2.2.1 Calculate the CaO equivalent of the solution as follows:

1 mL of 1 *N* $KMnO_4$ solution is equivalent to 0.06701 g of pure sodium oxalate.

$$\text{Normality of } KmnO_4 = \frac{\text{weight of sodium oxalate} \times \text{fraction of its purity}}{\text{mL of } KMnO_4 \text{ solution} \times 0.06701} \quad (3)$$

1 mL of 1 *N* $KMnO_4$ solution is equivalent to 0.02804 g of CaO.

$$F = \frac{\text{normality of } KMnO_4 \text{ solution} \times 0.02804 \times 100}{0.5}$$

where F = CaO equivalent of the $KMnO_4$ solution in % CaO/mL based on a 0.5-g sample of cement.

NOTE 35—Because of the instability of the $KMnO_4$ solution, it is recommended that it be restandardized at least bimonthly.

14.3 *Procedure*:

14.3.1 Acidify the combined filtrates obtained in the precipitations of the ammonium hydroxide group (8.2.2). Neutralize with HCl to the methyl red end point, make just acid, and add 6 drops of HCl in excess.

14.3.2 *Removal of Manganese*—Evaporate to a volume of about 100 mL. Add 40 mL of saturated bromine water to the hot solution and immediately add NH_4OH until the solution is distinctly alkaline. Addition of 10 mL of NH_4OH is generally sufficient. A piece of filter paper, about 1 cm^2 in area, placed in the heel of the beaker and held down by the end of a stirring rod aids in preventing bumping and initiating precipitation of hydrated manganese oxides (MnO). Boil the solution for 5 min or more, making certain that the solution is distinctly alkaline at all times. Allow the precipitate to settle, filter using medium-textured paper, and wash with hot water. If a precipitate does not appear immediately, allow a settling period of up to 1 h before filtration. Discard any manganese dioxide that may have been precipitated. Acidify the filtrate with HCl using litmus paper as an indicator, and boil until all the bromine is expelled (Note 36).

14.3.3 Add 5 mL of HCl, dilute to 200 mL, and add a few drops of methyl red indicator and 30 mL of warm ammonium oxalate solution (50 g/L) (Note 37). Heat the solution to 70 to 80 °C, and add NH_4OH (1+1) dropwise, while stirring until the color changes from red to yellow (Note 38). Allow the solution to stand without further heating for 60 ± 5 min (no longer), with occasional stirring during the first 30 min.

14.3.4 Filter, using retentive paper, and wash the precipitate 8 to 10 times with hot water, the total amount of water used in rinsing the beaker and washing not to exceed 75 mL. During this washing, water from the wash bottle should be directed around the inside of the filter paper to wash the precipitate down, then a jet of water should be gently directed towards the center of the paper in order to agitate and thoroughly wash the precipitate. Acidify the filtrate with HCl and reserve for the determination of MgO.

14.3.5 Place the beaker in which the precipitation was made under the funnel, pierce the apex of the filter paper with the stirring rod, place the rod in the beaker, and wash the precipitate into the beaker by using a jet of hot water. Drop about 10 drops of H_2SO_4 (1+1) around the top edge of the filter paper. Wash the paper five more times with hot water. Dilute to 200 mL, and add 10 mL of H_2SO_4 (1+1). Heat the solution to a temperature just below boiling, and titrate it immediately with the 0.18 *N* $KMnO_4$ solution (Note 39). Continue the titration slowly until the pink color persists for at least 10 s. Add the filter paper that contained the original precipitate and macerate it. If the pink color disappears continue the titration until it again persists for at least 10 s.

NOTE 36—Potassium iodide starch paper may be used to indicate the complete volatilization of the excess bromine. Expose a strip of moistened paper to the fumes from the boiling solution. The paper should remain colorless. If it turns blue bromine is still present.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 37—If the ammonium oxalate solution is not perfectly clear, it should be filtered before use.

NOTE 38—This neutralization must be made slowly, otherwise precipitated calcium oxalate may have a tendency to run through the filter paper. When a number of these determinations are being made simultaneously, the following technique will assist in ensuring slow neutralization. Add two or three drops of NH_4OH to the first beaker while stirring, then 2 or 3 drops to the second, and so on, returning to the first beaker to add 2 or 3 more drops, etc., until the indicator color has changed in each beaker.

NOTE 39—The temperature of the 0.18 *N* $KMnO_4$ solution at time of use should not vary from its standardization temperature by more than 10 °F (5.5 °C). Larger deviations could cause serious error in the determination of CaO.

14.3.6 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents (Note 40), and record the millilitres of $KMnO_4$ solution required to establish the end point.

NOTE 40—When the amount of calcium oxalate is very small, its oxidation by $KMnO_4$ is slow to start. Before the titration, add a little $MnSO_4$ to the solution to catalyze the reaction.

14.4 *Calculation*:

14.4.1 Calculate the percentage of CaO as follows:

$$\text{CaO, \%} = E(V - B) \quad (4)$$

where:

E = CaO equivalent of the $KMnO_4$ solution in % CaO/mL based on a 0.5-g sample,

V = millilitres of $KMnO_4$ solution required by the sample, and

B = millititres of $KMnO_4$ solution required by the blank.

Report the result rounded in accordance with Table 3.

14.4.2 If desired calculate the percentage of CaO corrected for SrO as follows:

$$\text{CaO}_c\ \% = \text{CaO}_i\ \% - 0.54\ \text{SrO}\ \% \quad (5)$$

where:

CaO_c = CaO corrected for SrO, and

CaO_i = initial CaO as determined in 14.4.1

$0.54 = \frac{56.08}{103.62}$ = molecular weight ratio $\frac{\text{CaO}}{\text{SrO}}$

15. Magnesium Oxide (*Reference Test Method*)

15.1 *Summary of Test Method*—In this test method, magnesium is precipitated as magnesium ammonium phosphate from the filtrate after removal of calcium. The precipitate is ignited and weighed as magnesium pyrophosphate ($Mg_2P_2O_7$). The MgO equivalent is then calculated.

15.2 *Reagent*—Ammonium phosphate, dibasic (100 g/L) $(NH_4)_2HPO_4$.

15.3 *Procedure*:

15.3.1 Acidify the filtrate from the determination of CaO (14.3.4) with HCl and evaporate by boiling to about 250 mL. Cool the solution to room temperature, add 10 mL of ammonium phosphate, dibasic, $(NH_4)_2HPO_4$ (100 g/L), and 30 mL of NH_4OH. Stir the solution vigorously during the addition of NH_4OH and then for 10 to 15 min longer. Let the solution stand for at least 8 h in a cool atmosphere and filter. Wash the residue five or six times with NH_4OH (1+20) and ignite in a weighed platinum or porcelain crucible, at first slowly until the filter paper is charred and then burn off (see 15.4.1), and finally at 1100 °C for 30 to 45 min. Weigh the residue as magnesium pyrophosphate ($Mg_2P_2O_7$).

15.3.2 *Blank*—Make a blank determination following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

15.4 *Calculation*:

15.4.1 Calculate the percentage of MgO to the nearest 0.1 as follows:

$$\text{MgO, \%} = W \times 72.4 \quad (6)$$

where:

W = grams of $Mg_2P_2O_7$, and

72.4 = molecular ratio of 2MgO to $Mg_2P_2O_7$(0.362) divided by the weight of sample used (0.5 g) and multiplied by 100.

Report the result rounded in accordance with Table 3.

Warning—Extreme caution should be exercised during this ignition. Reduction of the phosphate precipitate can result if carbon is in contact with it at high temperatures. There is also danger of occluding carbon in the precipitate if ignition is too rapid.

16. Sulfur (See Note 41)

16.1 *Sulfur Trioxide: (Reference Test Method)*:

16.1.1 *Summary of Test Method*—In this test method, sulfate is precipitated from an acid solution of the cement with barium chloride ($BaCl_2$). The precipitate is ignited and weighed as barium sulfate ($BaSO_4$) and the SO_3 equivalent is calculated.

16.1.2 *Procedure*:

16.1.2.1 To 1 g of the sample add 25 mL of cold water and, while the mixture is stirred vigorously, add 5 mL of HCl (Note 42). If necessary, heat the solution and grind the material with the flattened end of a glass rod until it is evident that decomposition of the cement is complete (Note 43). Dilute the solution to 50 mL and digest for 15 min at a temperature just below boiling. Filter through a medium-textured paper and wash the residue thoroughly with hot water. Dilute the filtrate to 250 mL and heat to boiling. Add slowly, dropwise, 10 mL of hot $BaCl_2$(100 g/L) and continue the boiling until the precipitate is well formed. Digest the solution for 12 to 24 h at a temperature just below boiling (Note 44). Take care to keep the volume of solution between 225 and 260 mL and add water for this purpose if necessary. Filter through a retentive paper, wash the precipitate thoroughly with hot water, place the paper and contents in a weighed platinum crucible, and slowly char and consume the paper without inflaming. Ignite at 800 to 900 °C, cool in a desiccator, and weigh.

NOTE 41—When an instrumental test method is used for sulfur or when comparing results of classical wet and instrumental test methods, consult 5.1.2 of these test methods.

NOTE 42—The acid filtrate obtained in the determination of the insoluble residue (6.3.1) may be used for the determination of SO_3 instead of using a separate sample.

NOTE 43—A brown residue due to compounds of manganese may be disregarded (see Note 9).

NOTE 44—If a rapid determination is desired, immediately after adding the $BaCl_2$, place the beaker with the solution in an ultrasonic bath for 5 min, and then continue the determination starting with "Filter through a

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

retentive paper. . .". Qualify the method in accordance with the Performance Requirements for Rapid Test Methods.

16.1.2.2 *Blank*—Make a blank determination following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

16.1.3 *Calculation*— Calculate the percentage of SO_3 to the nearest 0.01 as follows:

$$SO_3, \% = W \times 34.3 \quad (7)$$

where:

W = grams of $BaSO_4$, and
34.3 = molecular ratio of SO_3 to $BaSO_4$(0.343) multiplied by 100.

Report the result rounded in accordance with Table 3.

16.2 *Sulfide: (Reference Test Method)*

16.2.1 *Summary of Test Method*—In this test method sulfide sulfur is determined by evolution as hydrogen sulfide (H_2S) from an acid solution of the cement into a solution of ammoniacal zinc sulfate ($ZnSO_4$) or cadmium chloride (CdCl 2). The sulfide sulfur is then titrated with a standard solution of potassium iodate (KIO_3). Sulfites, thiosulfates, and other compounds intermediate between sulfides and sulfates are assumed to be absent. If such compounds are present, they may cause an error in the determination.

16.2.2 *Apparatus*:

16.2.2.1 *Gas-Generating Flask*—Connect a dry 500-mL boiling flask with a long-stem separatory funnel and a small connecting bulb by means of a rubber stopper. Bend the stem of the funnel so that it will not interfere with the connecting bulb, adjust the stem so that the lower end is close to the bottom of the flask, and connect the opening of the funnel with a source of compressed air. Connect the bulb with an L-shaped glass tube and a straight glass tube about 200 mm in length. Insert the straight glass tube in a tall-form, 400-mL beaker. A three-neck distilling flask with a long glass tubing in the middle opening, placed between the source of compressed air and the funnel, is a convenient aid in the regulation of the airflow. Rubber used in the apparatus shall be pure gum grade, low in sulfur, and shall be cleaned with warm HCl.

16.2.3 *Reagents*:

16.2.3.1 *Ammoniacal Cadmium Chloride Solution*—Dissolve 15 g of cadmium chloride ($CdCl_2 \cdot 2H_2O$) in 150 mL of water and 350 mL of NH_4OH. Filter the solution after allowing it to stand at least 24 h.

16.2.3.2 *Ammoniacal Zinc Sulfate Solution*—Dissolve 50 g of zinc sulfate ($ZnSO_4 \cdot 7H_2O$) in 150 mL of water and 350 mL of NH_4OH. Filter the solution after allowing it to stand at least 24 h.

16.2.3.3 *Potassium Iodate, Standard Solution* (0.03 *N*)—Prepare a solution of potassium iodate (KIO_3) and potassium iodide (KI) as follows: Dry KIO_3 at 180 °C to constant weight. Weigh 1.0701 g of the KIO_3 and 12 g of KI. Dissolve and dilute to 1 L in a volumetric flask. This is a primary standard and requires no standardization (Note 45). One millilitre of this solution is equivalent to 0.0004809 g of sulfur.

NOTE 45—The solution is very stable, but may not maintain its titer indefinitely. Whenever such a solution is over 1 year old it should be discarded or its concentration checked by standardization.

16.2.3.4 *Stannous Chloride Solution*—To 10 g of stannous chloride ($SnCl_2 \cdot 2H_2O$) in a small flask, add 7 mL of HCl (1+1), warm the mixture gently until the salt is dissolved, cool the solution, and add 95 mL of water. This solution should be prepared as needed, as the salt tends to hydrolyze.

16.2.3.5 *Starch Solution*— To 100 mL of boiling water, add a cool suspension of 1 g of soluble starch in 5 mL of water and cool. Add a cool solution of 1 g of sodium hydroxide (NaOH) in 10 mL of water, then 3 g of potassium iodide (KI), and mix thoroughly.

16.2.4 *Procedure*:

16.2.4.1 Place 15 mL of the ammoniacal $ZnSO_4$ or $CdCl_2$ solution (Note 46) and 285 mL of water in a beaker. Put 5 g of the sample (Note 47) and 10 mL of water in the flask and shake the flask gently to wet and disperse the cement completely. This step and the addition of $SnCl_2$ should be performed rapidly to prevent the setting of the cement. Connect the flask with the funnel and bulb. Add 25 mL of the $SnCl_2$ solution through the funnel and shake the flask. Add 100 mL of HCl (1+3) through the funnel and shake the flask. During these shakings keep the funnel closed and the delivery tube in the ammoniacal $ZnSO_4$ or $CdCl_2$ solution. Connect the funnel with the source of compressed air, open the funnel, start a slow stream of air, and heat the flask and contents slowly to boiling. Continue the boiling gently for 5 or 6 min. Cut off the heat, and continue the passage of air for 3 or 4 min. Disconnect the delivery tube and leave it in the solution for use as a stirrer. Cool the solution to 20 to 30 °C (Note 48), add 2 mL of the starch solution and 40 mL of HCl (1+1) and titrate immediately with the 0.03 *N* KIO_3 solution until a persistent blue color is obtained (Note 49).

NOTE 46—In general, the $ZnSO_4$ is preferable to the $CdCl_2$ solution because $ZnSO_4$ is more soluble in NH_2OH than is $CdCl_2$. The $CdCl_2$ solution may be used when there is doubt as to the presence of a trace of sulfide sulfur, as the yellow cadmium sulfide (CdS) facilitates the detection of a trace.

NOTE 47—If the content of sulfur exceeds 0.20 or 0.25 %, a smaller sample should be used so that the titration with the KIO_3 solution will not exceed 25 mL.

NOTE 48—The cooling is important as the end point is indistinct in a warm solution.

NOTE 49—If the content of sulfur is appreciable but not approximately known in advance, the result may be low due to the loss of H_2S during a slow titration. In such a case the determination should be repeated with the titration carried out more rapidly.

16.2.4.2 Make a blank determination, following the same procedure and using the same amounts of reagents. Record the volume of KIO 3 solution necessary to establish the end point as described in 16.2.4.1.

16.2.5 *Calculation*— Calculate the percentage of sulfide sulfur (see 16.2.1) as follows:

$$\text{Sulfide}, \% = E(V - B) \times 20 \quad (8)$$

where:

E = sulfide equivalent of the KIO_3 solution, g/mL,
V = millilitres of KIO_3 solution required by the sample,
B = millilitres of KIO_3 solution required by the blank, and
20 = 100 divided by the weight of sample used (5 g).

Report the result rounded in accordance with Table 3.

17. Loss on Ignition (*Reference Test Methods*)

17.1 *Portland Cement*:

17.1.1 *Summary of Test Method*—In this test method, the cement is ignited in a muffle furnace at a controlled temperature. The loss is assumed to represent the total moisture and CO_2 in the cement. This procedure is not suitable for the determination of the loss on ignition of portland blast-furnace slag cement and of slag cement. A test method suitable for such cements is described in 17.2.1 through 17.2.3.

17.1.2 *Procedure*—Weigh 1 g of the sample in a tared platinum crucible. Cover and ignite the crucible and its contents to constant weight in a muffle furnace at a temperature of 950 ± 50 °C. Allow a minimum of 15 min for the initial heating period and at least 5 min for all subsequent periods.

17.1.3 *Calculation*— Calculate the percentage of loss on ignition to the nearest 0.1 by multiplying the loss of weight in grams by 100. Report the result rounded in accordance with Table 3.

17.2 *Portland Blast-Furnace Slag Cement and Slag Cement*:

17.2.1 *Summary of Test Method*—Since it is desired that the reported loss on ignition represent moisture and CO_2, this test method provides a correction for the gain in weight due to oxidation of sulfides usually present in portland blast-furnace slag cement and slag cement by determining the increase in SO_3 content during ignition. An optional test method providing for a correction based on the decrease in sulfide sulfur during ignition is given in 25.1.1 through 23.1.3.1.

17.2.2 *Procedure*:

17.2.2.1 Weigh 1 g of cement into a tared platinum crucible and ignite in a muffle furnace at a temperature of 950 ± 50 °C for 15 min. Cool to room temperature in a desiccator and weigh. Without checking for constant weight, carefully transfer the ignited material to a 400-mL beaker. Break up any lumps in the ignited cement with the flattened end of a glass rod.

17.2.2.2 Determine the SO_3 content by the test method given in 15.1.1.1 through 15.1.3.1 (Note 50). Also determine the SO_3 content of a portion of the same cement that has not been ignited, using the same procedure.

NOTE 50—Some of the acid used for dissolving the sample may first be warmed in the platinum crucible to dissolve any adhering material.

17.2.3 *Calculation*— Calculate the percentage loss of weight occurring during ignition and add 0.8 times the difference between the percentages of SO_3 in the ignited sample and the original cement (Note 51). Report the corrected percentage, rounded in accordance with Table 3, as loss on ignition.

NOTE 51—If a gain in weight is obtained during ignition, subtract the percentage gain from the correction for SO_3.

18. Sodium and Potassium Oxides (*Reference Test Methods*)

18.1 *Total Alkalies*:

18.1.1 *Summary of Test Method*—This test method[7] covers the determination of sodium oxide (Na_2O) and potassium oxide (K_2O) by flame photometry or atomic absorption.

NOTE 52—This test method is suitable for hydraulic cements that are completely decomposed by hydrochloric acid and should not be used for determination of total alkalies in hydraulic cements that contain large amounts of acid-insoluble material, for example, pozzolan cements. It may be used to determine acid-soluble alkalies for such cements. An alternate test method of sample dissolution for such cements is in preparation.

18.1.2 *Apparatus*:

18.1.2.1 *Instrument*—Any type flame photometer or atomic absorption unit may be used provided it can be demonstrated that the required degree of accuracy and precision is as indicated in 18.1.3.

NOTE 53—After such accuracy is established, for a specific instrument, further tests of instrument accuracy are not required except when it must be demonstrated that the instrument gives results within the prescribed degree of accuracy by a single series of tests using the designated standard samples.

NOTE 54—For normal laboratory testing, it is recommended that the accuracy of the instrument be routinely checked by the use of either a National Institute of Standards and Technology cement or cement of known alkali content.

18.1.2.2 The instrument shall consist at least of an atomizer and burner; suitable pressure-regulating devices and gages for fuel and oxidant gas; an optical system, capable of preventing excessive interference from wavelengths of light other than that being measured; and a photosensitive indicating device.

18.1.3 *Initial Qualification of Instrument*—Qualify the instrument in accordance with 4.4.2 to establish that an instrument provides the desired degree of precision and accuracy.

18.1.4 *Reagents and Materials*:

18.1.4.1 *Laboratory Containers*—All glassware shall be made of borosilicate glass and all polyethylene shall comply with the requirements of 5.2.3.

18.1.4.2 *Calcium Carbonate*—The calcium carbonate ($CaCO_3$) used in the preparation of the calcium chloride stock solution (18.1.5.1) shall contain not more than 0.020 % total alkalies as sulfate.

NOTE 55—Materials sold as a primary standard or ACS "low alkali" grade normally meet this requirement. However, the purchaser should assure himself that the actual material used conforms with this requirement.

18.1.4.3 *Potassium Chloride* (KCl).

18.1.4.4 *Sodium Chloride* (NaCl).

18.1.4.5 Commercially available solutions may be used in place of those specified in 18.1.5.

18.1.5 *Preparation of Solutions*:

[7] The 1963 revision of these test methods deleted the classical (J. L. Smith) gravimetric method for the determination of Na_2O and K_2O in cements. Those interested in this method should refer to the *1961 Book of ASTM Standards,* Part 4. The 1983 revision of these test methods deleted the details of the flame photometric procedure for the determination of Na_2O and K_2O. Those interested in this method should refer to the *1982 Annual Book of ASTM Standards,* Part 13.

www.technobetar.ir

18.1.5.1 *Calcium Chloride Stock Solution*—Add 300 mL of water to 112.5 g of $CaCO_3$ in a 1500-mL beaker. While stirring, slowly add 500 mL of HCl. Cool the solution to room temperature, filter into a 1-L volumetric flask, dilute to 1 L, and mix thoroughly. This solution contains the equivalent of 63 000 ppm (6.30 %) CaO.

18.1.5.2 *Sodium-Potassium Chloride Stock Solution*—Dissolve 1.8858 g of sodium chloride (NaCl) and 1.583 g of potassium chloride (KCl) (both dried at 105 to 110 °C for several hours prior to weighing) in water. Dilute to 1 L in a volumetric flask and mix thoroughly. This solution contains the equivalent of 1000 ppm (0.10 %) each of Na_2O and K_2O. Separate solutions of Na_2O and of K_2O may be used provided that the same concentration solutions are used for calibration for cement analysis as were used for the calibration when qualifying the instrument in accordance with 18.1.3.

18.1.5.3 *Standard Solutions*—Prepare the standard solutions prescribed for the instrument and method used. Measure the required volume of NaCl-KCl stock solutions in calibrated pipets or burets. The calcium chloride stock solutions, if needed, may be measured in appropriate graduated cylinders. If the instrument being used requires an internal standard, measure the internal standard solution with a pipet or buret. Place each solution in a volumetric flask, dilute to the indicated volume, and mix thoroughly.

18.1.5.4 If more dilute solutions are required by the method in use, pipet the required aliquot to the proper sized volumetric flask, add any necessary internal standard, dilute to the mark, and mix thoroughly.

18.1.6 *Calibration of Apparatus*:

NOTE 56—No attempt is made in this section to describe in detail the steps for putting the instrument into operation since this will vary considerably with different instruments. The manufacturer's instructions should be consulted for special techniques or precautions to be employed in the operation, maintenance, or cleaning of the apparatus.

18.1.6.1 Turn on the instrument and allow it to warm up in accordance with the manufacturer's instructions. (A minimum of 30 min is required for most instruments.) Adjust the fuel and oxidant gas pressures as required by the instrument being used. Light and adjust the burner for optimum operation. Make any other adjustments that may be necessary to establish the proper operating conditions for the instrument.

18.1.7 *Procedure*:

18.1.7.1 *Solution of the Cement*—Prepare the solution of the cement in accordance with the procedure specified by the instrument manufacturer. If no procedure is specified, or if desired, proceed as specified in 17.1.7.1.1 or 17.1.7.1.2 (Note 56).

NOTE 57—The presence of SiO_2 in solution affects the accuracy of some flame photometers. In cases where an instrument fails to provide results within the prescribed degree of accuracy outlined in 4.4.2.1-4.4.3 tests should be made on solutions from which the SiO_2 has been removed. For this removal proceed as in .

18.1.7.1.1 Place 1.000 ± 0.001 g of the cement in a 150-mL beaker and disperse with 20 mL of water using a swirling motion of the beaker. While still swirling add 5.0 mL of HCl all at once. Dilute immediately to 50 mL with water. Break up any lumps of cement remaining undispersed with a flat-end stirring rod. Digest on a steam bath or hot plate for 15 min, then filter through a medium-textured filter paper into a 100-mL volumetric flask. Wash beaker and paper thoroughly with hot-water, cool contents of the flask to room temperature, dilute to 100 mL, and mix the solution thoroughly. Continue as given in 18.1.7.2.

18.1.7.1.2 Place 1.000 ± 0.001 g of cement into a platinum evaporating dish and disperse with 10 mL of water using a swirling motion. While still swirling, add 5.0 mL of HCl all at once. Break up any lumps with a flat-end stirring rod and evaporate to dryness on a steam bath. Make certain that the gelatinous appearance is no longer evident. Treat the residue with 2.5 mL of HCl and about 20 mL of water. Digest on a steam bath for 5 to 10 min and filter immediately through a 9-cm medium-textured filter paper into a 100-mL volumetric flask. Wash thoroughly with repeated small amounts of hot water until the total volume of solution is 80 to 95 mL. Cool to room temperature, dilute to the mark, and mix thoroughly.

When it has been demonstrated that the removal of SiO_2 is necessary to obtain the required accuracy described in 4.4.2.1-4.4.3 for a specific flame photometer, SiO_2 must always be removed when making analyses that are used as the basis for rejection of a cement for failure to comply with specifications or where specification compliance may be in question. Where there is no question as to specification compliance, analyses may be made by such instruments without SiO_2 removal provided the deviations from certificate values obtained by the tests prescribed in 4.4.2.1-4.4.3 are not more than twice the indicated limits.

18.1.7.2 If the test method in use requires more dilute solutions, an internal standard, or both, carry out the same dilutions as in 18.1.5.4 as needed. The standard and the sample solutions to be analyzed must be prepared in the same way and to the same dilution as the solutions of standard cements analyzed for the qualification of the instrument.

18.1.7.3 *Procedure for Na_2O (Note 59)*—Warm up and adjust the instrument for the determination of Na_2O as described in 18.1.6.1. Immediately following the adjustment and without changing any instrumental settings, atomize the cement solution and note the scale reading (Note 58). Select the standard solutions which immediately bracket the cement solution in Na_2O content and observe their readings. Their values should agree with the values previously established during calibration of the apparatus. If not, recalibrate the apparatus for that constituent. Finally, alternate the use of the unknown solution and the bracketing standard solutions until readings of the unknown agree within one division on the transmission or meter scale, or within 0.01 weight percent for instruments with digital readout, and readings for the standards similarly agree with the calibration values. Record the average of the last two readings obtained for the unknown solution.

NOTE 58—The order in determining Na_2O or K_2O is optional. In all cases, however, the determination should immediately follow the adjustment of the instrument for that particular constituent.

18.1.7.4 If the reading exceeds the scale maximum, either transfer a 50-mL aliquot of the solution prepared in 18.1.7.1 to a 100-mL volumetric flask or, if desired, prepare a new solution by using 0.500 g of cement and 2.5 mL of HCl (instead of 5.0

www.technobetar.ir

mL) in the initial addition of acid. In the event silica has to be removed from the 0.5-g sample of cement, treat the dehydrated material with 1.25 mL of HCl and about 20 mL of water, then digest, filter, and wash. In either case, add 5.0 mL of calcium chloride stock solution (18.1.5.1) before diluting to mark with water. Dilute to the mark. Proceed as in 18.1.5.4 if more dilute solutions are required by the test method in use. Determine the alkali content of this solution as described in (18.1.7.3) and multiply by a factor of 2 the percentage of alkali oxide.

18.1.7.5 *Procedure for* K_2O—Repeat the procedure described in 18.1.7.3 except that the instrument shall be adjusted for the determination of K_2O. For instruments that read both Na_2O and K_2O simultaneously, determine K_2O at the same time as determining Na_2O.

18.1.8 *Calculation and Report*—From the recorded averages for Na_2O and K_2O in the unknown sample, report each oxide rounded in accordance with Table 3.

18.2 *Water-Soluble Alkalies*:

NOTE 59—The determination of water-soluble alkali should not be considered as a substitute for the determination of total alkali according to 18.1.2.1 to 18.1.8. Moreover, it is not to be assumed that in this method all water-soluble alkali in the cement will be dissolved. Strict adherence to the procedure described is essential where there is a specified limit on the content of water-soluble alkali or where several lots of cement are compared on the basis of water-soluble alkali.

18.2.1 *Procedure*:

18.2.1.1 Weigh 25.0 g of sample into a 500-mL Erlenmeyer flask and add 250 mL of water. Stopper the flask with a rubber stopper and shake continuously for 10 min at room temperature. Filter through a Büchner funnel which contains a well-seated retentive, dry filter paper, into a 500-mL filtering flask, using a weak vacuum. Do not wash.

18.2.1.2 Transfer a 50-mL aliquot (Note 60) of the filtrate to a 100-mL volumetric flask and acidify with 0.5 mL of concentrated HCl (sp gr 1.19). Add 9.0 mL of stock $CaCl_2$ solution (63 000 ppm CaO), described in 18.1.5.1, to the 100-mL flask, and dilute the solution to 100 mL. If the test method in use requires more dilute solutions, an internal standard, or both, carry out the same dilutions as in 18.1.5.4, as needed. Determine the Na_2O and K_2O contents of this solution as described in 18.1.7.3 and 18.1.7.5. Record the parts per million of each alkali in the solution in the 100-mL flask.

NOTE 60—The aliquot of the filtrate taken for the analysis should be based on the expected water-soluble alkali content. If the expected level of either K_2O or Na_2O is more than 0.08 weight % of cement, or if the water soluble alkali level is unknown, a 50-mL aliquot as given in 18.2.1.2 should be used to make up the initial test solution. If either the Na_2O or K_2O exceeds 0.16 %, place a 50-mL aliquot of the solution from 18.2.1.2 in a 100-mL volumetric flask, add 5 mL of $CaCl_2$ stock solution, and dilute to 100 mL. When the level of either K_2O or Na_2O is less than 0.08 %, take a 100-mL aliquot from the original filtrate (obtained by 18.2.1.1), add 1 mL of HCl, and evaporate on a hot plate in a 250-mL beaker to about 70 mL. Add 8 mL of stock $CaCl_2$ solution and transfer the sample to a 100-mL volumetric flask, rinsing the beaker with a small portion of distilled water. Cool the solution to room temperature and dilute to 100 mL.

18.2.2 *Calculations*—Calculate the percentage of the water-soluble alkali, expressed as Na_2O, as follows:

$$\text{Total water-soluble alkali, as } Na_2O = A + E \quad (9)$$

$$A = B/(V \times 10)$$

$$C = D/(V \times 10)$$

$$E = C \times 0.658$$

where:

- A = percentage of water-soluble sodium oxide (Na_2O),
- V = millilitres of original filtrate in the 100-mL flask,
- B = parts per million of Na_2O in the solution in the 100-mL flask,
- C = percent of water-soluble potassium oxide (K_2O),
- D = parts per million of K_2O in the 100-mL flask,
- E = percentage Na_2O equivalent to K_2O determined, and
- *0.658* = molecular ratio of Na_2O to K_2O.

Report the result rounded in accordance with Table 3.

19. Manganic Oxide (*Reference Method*)

19.1 *Summary of Method*—In this procedure, manganic oxide is determined volumetrically by titration with sodium arsenite solution after oxidizing the manganese in the cement with sodium metabismuthate ($NaBiO_3$).

19.2 *Reagents*:

19.2.1 *Sodium Arsenite, Standard Solution* (1 mL = 0.0003 g Mn_2O_3)—Dissolve in 100 mL of water 3.0 g of sodium carbonate (Na_2CO_3) and then 0.90 g of arsenic trioxide (As_2O_3), heating the mixture until the solution is as complete as possible. If the solution is not clear or contains a residue, filter the solution. Cool it to room temperature, transfer to a volumetric flask, and dilute to 1 L.

19.2.1.1 Dissolve 0.58 g of potassium permanganate ($KMnO_4$) in 1 L of water and standardize it against about 0.03 g of sodium oxalate ($Na_2C_2O_4$) oxidimetric standard furnished by NIST (Standard Sample No. 40 or its replacement) according to the directions furnished with the sodium oxalate. Put 30.0 mL of the $KMnO_4$ solution in a 250-mL Erlenmeyer flask. Add 60 mL of HNO_3 (1+4) and 10 mL of sodium nitrite ($NaNO_2$, 50 g/L) to the flask. Boil the solution until the HNO_2 is completely expelled. Cool the solution, add $NaBiO_3$, and finish by titrating with the standard sodium arsenite ($NaAsO_2$) solution as described in 19.3.2. Calculate the manganic oxide (Mn_2O_3) equivalent of the $NaAsO_2$ solution, g/mL, as follows:

$$E = (A \times 7.08)/BC \quad (10)$$

where:

- E = Mn_2O_3 equivalent of the $NaAsO_2$ solution, g/mL,
- A = grams of $Na_2C_2O_4$ used,
- B = millilitres of $KMnO_4$ solution required by the $Na_2C_2O_4$,
- C = millilitres of $NaAsO_2$ solution required by 30.0 mL of $KMnO_4$ solution, and
- *7.08* = molecular ratio of Mn_2O_3 to 5 $Na_2C_2O_4$(0.236) multiplied by 30.0 (millilitres of $KMnO_4$ solution).

19.2.2 *Sodium Metabismuthate* ($NaBiO_3$).

19.2.3 *Sodium Nitrite Solution* (50 g $NaNO_2$/L).

19.3 *Procedure*:

19.3.1 Weigh 1.0 to 3.0 g of the sample (Note 61) into a 250-mL beaker and treat it with 5 to 10 mL of water and then with 60 to 75 mL of HNO_3 (1+4). Boil the mixture until the solution is as complete as possible. Add 10 mL of $NaNO_2$

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

solution (50 g/L) to the solution and boil it until the nitrous acid is completely expelled (Note 62), taking care not to allow the volume of the solution to become so small as to cause the precipitation of gelatinous SiO_2. There may be some separated SiO_2, which may be ignored, but if there is still a red or brown residue, use more $NaNO_2$ solution (50 g/L) to effect a complete decomposition, and then boil again to expel the nitrous acid. Filter the solution through a medium-textured paper into a 250-mL Erlenmeyer flask and wash the filter paper with water.

NOTE 61—The amount of cement taken for analysis depends on the content of manganese, varying from 1 g for about 1 % of Mn_2O_3 to 3 g for 0.25 % or less of Mn_2O_3.

NOTE 62—When $NaNO_2$ is added, the expulsion of HNO_2 by boiling must be complete. If any HNO_2 remains in the solution, it will react with the added $NaBiO_3$ and decrease its oxidizing value. If there is any manganese in the cement, the first small quantity of $NaBiO_3$ should bring out a purple color.

19.3.2 The solution should have a volume of 100 to 125 mL. Cool it to room temperature. To the solution add a total of 0.5 g of $NaBiO_3$ in small quantities, while shaking intermittently. After the addition is completed, shake the solution occasionally for 5 min and then add to it 50 mL of cool HNO_3 (1+33) which has been previously boiled to expel nitrous acid. Filter the solution through a pad of ignited asbestos in a Gooch crucible or a carbon or fritted-glass filter with the aid of suction. Wash the residue four times with the cool HNO_3 (1+33). Titrate the filtrate immediately with the standard solution of $NaAsO_2$. The end point is reached when a yellow color is obtained free of brown or purple tints and does not change upon further addition of $NaAsO_2$ solution.

19.3.3 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

19.4 Calculate the percentage of Mn_2O_3 to the nearest 0.01 as follows:

$$Mn_2O_3, \% = (EV/S) \times 100 \quad (11)$$

where:

E = Mn_2O_3 equivalent of the $NaAsO_2$ solution, g/mL,
V = millilitres of $NaAsO_2$ solution required by the sample, and
S = grams of sample used.

Report the result rounded in accordance with Table 3.

20. Chloride (*Reference Test Method*)

20.1 *Summary of Test Method*—In this test method acid-soluble chloride content of cement is determined by the potentiometric titration of chloride with silver nitrate (See Note 63). The procedure is also applicable to clinker and portland cement raw mix. Under the conditions of the test, no constituent normally present in these materials will interfere (See Note 64).

NOTE 63—In most cases acid-soluble chloride content of a portland cement is total chloride content.

NOTE 64—Species that form insoluble silver salts or stable silver complexes in acid solution interfere with potentiometric measurements. Thus, iodides and bromides interfere while fluorides will not. Sulfide salts in concentrations typical of these materials should not interfere because they are decomposed by acid treatment.

20.2 *Apparatus*:

20.2.1 *Chloride, Silver/Sulfide Ion Selective Electrode,* or a silver billet electrode coated with silver chloride (Note 65), with an appropriate reference electrode.

20.2.2 *Potentiometer,* with millivolt scale readable to 1 mV or better. A digital read-out is preferred but not required.

20.2.3 *Buret,* Class A, 10-mL capacity with 0.05-mL divisions. A buret of the potentiometric type, having a displaced delivery tip, is convenient, but not required.

NOTE 65—Suitable electrodes are available from Orion, Beckman Instruments, and Leeds and Northrup. Carefully following the manufacturer's instructions, add filling solution to the electrodes. The silver billet electrodes must be coated electrolytically with a thin, even layer of silver chloride. To coat the electrode, dip the clean silver billet of the electrode into a saturated solution of potassium chloride (about 40 g/L) in water and pass an electric current through the electrode from a 1½ to 6-V dry cell with the silver billet electrode connected to the positive terminal of the battery. A carbon rod from an all-dry cell or other suitable electrode is connected to the negative terminal and immersed in the solution to complete the electrical circuit. When the silver chloride coating wears off, it is necessary to rejuvenate the electrode by repeating the above procedure. All of the old silver chloride should first be removed from the silver billet by rubbing it gently with fine emery paper followed by water rinsing of the billet.

20.3 *Reagents*:

20.3.1 *Sodium Chloride* (NaCl), primary standard grade.

20.3.2 *Silver Nitrate* ($AgNO_3$), reagent grade.

20.3.3 *Potassium Chloride* (KCl), reagent grade (required for silver billet electrode only).

20.3.4 *Reagent Water* conforming to the requirements of Specification D1193 for Type III reagent water.

20.4 *Preparation of Solutions*:

20.4.1 *Sodium Chloride, Standard Solution* (0.05 *N* NaCl)—Dry sodium chloride (NaCl) at 105 to 110 °C to a constant weight. Weigh 2.9222 g of dried reagent. Dissolve in water and dilute to exactly 1 L in a volumetric flask and mix thoroughly. This solution is the standard and requires no further standardization.

20.4.2 *Silver Nitrate, Standard Solution* (0.05 *N* $AgNO_3$)—Dissolve 8.4938 g of silver nitrate ($AgNO_3$) in water. Dilute to 1 L in a volumetric flask and mix thoroughly. Standardize against 5.00 mL of standard 0.05 *N* sodium chloride solution diluted to 150 mL with water following the titration test method given in 20.5.4 beginning with the second sentence. The exact normality shall be calculated from the average of three determinations as follows:

$$N = 0.25/V \quad (12)$$

where:

N = normality of $AgNO_3$ solution,
0.25 = milliequivalents NaCl (5.0 mL × 0.05 *N*), and
V = volume of $AgNO_3$ solution, mL.

Commercially available standard solutions may be used provided the normality is checked according to the standardization procedure.

20.4.3 *Methyl Orange Indicator*—Prepare a solution containing 2 g of methyl orange per litre of 95 % ethyl alcohol.

20.5 *Procedure*:

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

20.5.1 Weigh a 5.0-g sample of the cement into a 250-mL beaker (Note 66). Disperse the sample with 75-mL of water. Without delay slowly add 25 mL of dilute (1+1) nitric acid, breaking up any lumps with a glass rod. If the smell of hydrogen sulfide is strongly evident at this point, add 3 mL of hydrogen peroxide (30 % solution) (Note 67). Add 3 drops of methyl orange indicator and stir. Cover the beaker with a watch glass and allow to stand for 1 to 2 min. If a yellow to yellow-orange color appears on top of the settled solids, the solution is not sufficiently acidic. Add additional dilute nitric acid (1+1) dropwise while stirring until a faint pink or red color persists. Then add 10 drops in excess. Heat the covered beaker rapidly to boiling. Do not allow to boil for more than a few seconds. Remove from the hot plate (Note 68).

NOTE 66—Use a 5-g sample for cement and other materials having an expected chloride content of less than about 0.15 % Cl. Use proportionally smaller samples for materials with higher chloride concentrations. Use cement and other powdered materials as is without grinding. Coarse samples require grinding to pass a 20-mesh sieve. If a sample is too fine, excessive silica gel may form during digestion with nitric acid, thereby slowing subsequent filtration.

NOTE 67—Slags and slag cements contain sulfide sulfur in concentrations that can interfere with the determination.

NOTE 68—It is important to keep the beaker covered during heating and digestion to prevent the loss of chloride by volatilization. Excessive amounts of acid should not be used since this results in early removal of the silver chloride coating from the silver billet electrode. A slurry that is only slightly acidic is sufficient.

20.5.2 Wash a 9-cm coarse-textured filter paper with four 25-mL increments of water using suction filtering provided by a 250-mL or 500-mL Büchner funnel and filtration flask. Discard the washings and rinse the flask once with a small portion of water. Reassemble the suction apparatus and filter the sample solution. Rinse the beaker and the filter paper twice with small portions of water. Transfer the filtrate from the flask to a 250-mL beaker and rinse the flask once with water. The original beaker may be used (Note 69). Cool the filtrate to room temperature. The volume should not exceed 175 mL.

NOTE 69—It is not necessary to clean all the slurry residue from the sides of the beaker nor is it necessary that the filter remove all of the fine material. The titration may take place in a solution containing a small amount of solid matter.

20.5.3 For instruments equipped with dial readout it is necessary to establish an approximate "equivalence point" by immersing the electrodes in a beaker of water and adjusting the instrument to read about 20 mV lower than mid-scale. Record the approximate millivoltmeter reading. Remove the beaker and wipe the electrodes with absorbent paper.

20.5.4 To the cooled sample (Note 70) beaker from 20.5.2, carefully pipet 2.00 mL of standard 0.05 *N* NaCl solution. Place the beaker on a magnetic stirrer and add a TFE-fluorocarbon-coated magnetic stirring bar. Immerse the electrodes into the solution taking care that the stirring bar does not strike the electrodes; begin stirring gently. Place the delivery tip of the 10-mL buret, filled to the mark with standard 0.05 *N* silver nitrate solution, in (preferably) or above the solution (Note 71).

NOTE 70—It is advisable to maintain constant temperature during measurement, for the solubility relationship of silver chloride varies markedly with temperature at low concentrations.

NOTE 71—If the tip of the buret is out of the solution, any adhering droplet should be rinsed onto the beaker with a few millilitres of water following each titration increment.

20.5.5 Gradually titrate, record the amount of standard 0.05 *N* silver nitrate solution required to bring the millivoltmeter reading to −60.0 mV of the equivalence point determined in the water.

20.5.6 Continue the titration with 0.20-mL increments. Record the buret reading and the corresponding millivoltmeter reading in columns 1 and 2 of a four-column recording form like that shown in Appendix X1. Allow sufficient time between each addition for the electrodes to reach equilibrium with the sample solution. Experience has shown that acceptable readings are obtained when the minimum scale reading does not change within a 5-s period (usually within 2 min).

20.5.7 As the equivalence point is approached, the equal additions of $AgNO_3$ solution will cause larger and larger changes in the millivoltmeter readings. Past the equivalence point the change per increment will again decrease. Continue to titrate until three readings past the approximate equivalence point have been recorded.

20.5.8 Calculate the difference in millivolt readings between successive additions of titrant and enter the values in Column 3 of the recording form. Calculate the difference between consecutive values in Column 3 and enter the results in Column 4. The equivalence point of the titration will be within the maximum Δ mV interval recorded in Column 3. The precise equivalence point can be interpolated from the data listed in Column 4 as shown in the Appendix X1.

20.5.9 *Blank*—Make a blank determination using 75 mL of water in place of the sample, following the same procedure starting with the third sentence of 20.5.1 without delay. Correct the results obtained in the analysis accordingly (Note 72) by subtracting the blank.

20.6 *Calculation*— Calculate the percent chloride to the nearest 0.001 % as follows:

$$\text{Cl, \%} = \frac{3.545\,[(V_1 - V_2)N - 0.10]}{W} \qquad (13)$$

where:

V_1 = millilitres of 0.05 *N* $AgNO_3$ solution used for sample titration (equivalence point),
V_2 = millilitres of 0.05 *N* $AgNO_3$ solution used for blank titration (equivalence point),
N = exact normality of 0.05 *N* $AgNO_3$ solution, and
W = weight of sample, g.

Report the result rounded in accordance with Table 3.

NOTE 72—For nonreferee analysis the blank may be omitted.

21. Chloroform-Soluble Organic Substances (*Reference Test Method*)

21.1 *Summary of Test Method*—This test method[8] was specially designed for the determination of Vinsol resin and

[8] The 1965 revision of these test methods deleted the methoxyl test method for determining Vinsol resin. Those interested in this test method should refer to the *1966 Book of ASTM Standards,* Part 9.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

tallow in portland cement, although mineral oil, common rosin, calcium stearate, and other fatty acid compounds, and probably some other substances, if present, will be included in the determination. Extreme care is necessary in the entire procedure. The test method may be applied to types of cement other than portland cement, although if the cement contains a large amount of acid-insoluble matter, the emulsions may separate slowly, and less vigorous shaking, more chloroform, and more washing may be necessary.

21.2 *Reagents*:

21.2.1 *Chloroform*—If the blank determination as described in 21.3.5 exceeds 0.0015 g, the chloroform should be distilled before use. Chloroform recovered in the procedure may be slightly acid but can be reused for the portions to be shaken with the aqueous acid solution of the sample in the 1-L funnel. Chloroform used for washing the filter and transferring the extract should be fresh or distilled from fresh chloroform.

21.2.2 *Stannous Chloride* ($SnCl_2$).

21.3 *Procedure*:

21.3.1 Place 40 g of cement in a 1-L Squibb separatory funnel (Note 73) and mix it with 520 mL of water added in two approximately equal portions. Shake vigorously immediately after the addition of the first portion to effect complete dispersion. Then add the second portion and shake again. At once add rapidly 185 mL of HCl in which 10 g of $SnCl_2$ (Note 74) have been dissolved, rapidly insert the stopper in the funnel, invert, and shake with a swirling motion for a few seconds to loosen and disperse all the cement, taking care to avoid the development of great internal pressure due to unnecessarily violent shaking. Release internal pressure immediately by opening and closing the stopcock. Repeat the shaking and release the pressure until the decomposition of the cement is complete. If necessary, break up persistent lumps with a long glass rod. Cool to room temperature rapidly by allowing tap water to run on the flask.

NOTE 73—The use of grease to lubricate the stopcocks and glass stoppers of the separatory funnels should be avoided. Wetting the stopcocks with water before using will assist in their easy operation.

NOTE 74—The purpose of the $SnCl_2$ is to prevent the oxidation of sulfide sulfur to elemental sulfur, which is soluble in chloroform.

21.3.2 Add 75 mL of chloroform to the solution, stopper the funnel, shake it vigorously for 5 min, and allow the water and chloroform to stand 15 min to separate. Draw off the lower chloroform layer into a 125-mL Squibb separatory funnel, including the scum (Note 75) and a few millilitres of the aqueous layer, making certain that all the scum is transferred. Keep the amount of the aqueous layer transferred to an absolute minimum, since excessive water in the 125-mL funnel may result in incomplete extraction of the scum and may cause an emulsion which does not separate readily. Shake the funnel vigorously to ensure the complete extraction of the scum. Allow the chloroform to separate, and draw it into a 250-mL Squibb separatory funnel which contains 50 mL of water and a few drops of HCl, making sure to keep the scum behind in the 125-mL funnel. Shake the 250-mL funnel, and draw the chloroform into another 250-mL funnel that contains 50 mL of water and a few drops of HCl. Shake this funnel as in the case of the first 250-mL funnel. When the chloroform separates, draw it into a standard-taper flat-bottom boiling flask (Note 76), taking care not to allow any water to enter the flask.

NOTE 75—There is usually a dark colored scum at the liquid interface. It may contain chloroform-soluble organic substance after shaking in the funnel, where the proportion of water to chloroform is great. It may be concentrated and confined to a small volume by gently twirling the funnel after the scum has been drawn into the narrower part of the funnel.

NOTE 76—The liquid is later distilled. No cork or rubber stoppers should be used. A250 or 300-mL soil analysis flask, fitted with a condenser tube by means of a ground joint, is satisfactory. The tube may be bent near the neck and the remaining part fitted with a water-cooling jacket. Chloroform thus recovered may be reused as described in 21.2.1.

21.3.3 Add 25 mL of chloroform to the solution in the original 1-L separatory funnel, and carry out the operations as described in 21.3.2, retaining the original wash water in the 250-mL funnels. Repeat, using another 25-mL portion of chloroform.

21.3.4 Distill the combined chloroform extracts in the boiling flask until their volume is reduced to 10 to 15 mL. Filter the remaining liquid into a weighed 100-mL glass beaker or platinum dish (Note 77) through a small medium-textured filter paper that has been washed with fresh chloroform. Rinse the flask and wash the paper with several small portions of fresh chloroform. Evaporate the extracts at a low temperature (not over 63 °C) to dryness (Note 78) and heat it in an oven at 57 to 63 °C for 3 min. Pass dry air into the vessel for 15 s, cool, and weigh. Repeat the heating and weighing until two successive weighings do not differ by more than 0.0010 g. The higher of the last two weights shall be taken as the true weight.

NOTE 77—A platinum dish is preferable, as it quickly attains the temperature of the balance. If a glass beaker is used, it should be allowed to stand in the case of the balance for at least 20 min before weighing.

NOTE 78—Care should be taken in drying the extract, as many of the chloroform-soluble organic substances are somewhat volatile when heated for a long time at even moderate temperatures. With protection from the accumulation of dust, the solution may be evaporated at room temperature overnight.

When a quick evaporation is desired, the solution may be evaporated on a hot plate at low heat under a stream of dry air through a glass tube (about 10 mm in inside diameter) until it is about 3 mm in depth. Then remove the vessel from the hot plate and continue a slow stream of dry air until the residue appears dry. Then continue with a more rapid stream of dry air for 5 min at room temperature before placing the vessel in the oven at 57 to 63 °C. After each 3-min heating period in the oven, pass dry air into the vessel for about 15 s before weighing. The air may be dried by passing it through a cheap desiccant, such as calcium chloride or sulfuric acid, followed by a desiccant of high efficiency, such as magnesium perchlorate or anhydrous calcium sulfate, with care taken to avoid the carrying of dust from the desiccant by the air. Instead of using compressed air, which is often contaminated with oil, dirt, and moisture, one can place the chloroform solution under a bell glass and induce a stream of air through the desiccants by means of an aspirator or vacuum pump.

When Vinsol resin is known to be the only substance present, the residue is more stable and may be heated at 100 to 105 °C, instead of 57 to 63 °C, in order to expel all possible traces of chloroform.

21.3.5 *Blank*—Make a blank determination. Ignite a 40-g sample of the cement at 950 to 1000 °C for 1 h (Note 79) and regrind. Treat this ignited sample by the same procedure and using the same reagents as in the analysis and correct the results accordingly.

NOTE 79—Care should be taken to completely burn off the organic

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

substance. A 100-mL flat platinum dish, in which the sample is well spread out, and a muffle furnace are advised for this purpose. If such a furnace is not available, a large high-temperature burner of the Meker type may be used. Thorough stirring of the sample should be done frequently—every 5 min when a burner is used.

21.4 *Calculation*— Calculate the percentage of chloroform-soluble organic substances to the nearest 0.001 by multiplying the weight in grams of residue (Note 80) by 2.5 (100 divided by the weight of the sample used (40 g)). Report the result rounded in accordance with Table 3.

NOTE 80—If the organic substance in the cement is tallow, the residue is the fatty acids resulting from the hydrolysis of the tallow in the hot acid solution, and its weight should be multiplied by 1.05 to give the weight of the original glycerides in the tallow. If the original substance is calcium stearate, the residue is stearic acid, and its weight multiplied by 1.07 gives the weight of calcium stearate.

ALTERNATIVE TEST METHODS

22. Calcium Oxide (*Alternative Test Method*)

22.1 *Summary of Test Method*:

22.1.1 This test method covers the gravimetric determination of CaO after removal of SiO_2 and the ammonium hydroxide groups and double precipitation of calcium as the oxalate. The precipitate is converted to CaO by ignition and is weighed.

22.1.2 Strontium, usually present in portland cement as a minor constituent, is precipitated with calcium as the oxalate and is subsequently calculated as CaO. If the SrO content is known and correction of CaO for SrO is desired as, for example, for research purposes or to compare results with CRM certificate values, the CaO obtained by this test method may be corrected by subtracting percent SrO. In determining conformance of a cement to specifications the correction of CaO for SrO should not be made.

22.2 *Procedure* (Note 81):

22.2.1 Acidify the combined filtrates obtained in the determination of the ammonium hydroxide group (8.1-8.3) and, if necessary, evaporate to a volume of about 200 mL. Add 5 mL of HCl, a few drops of methyl red indicator solution, and 30 mL of warm ammonium oxalate solution (50 g/L) (Note 37). Heat the solution to 70 to 80 °C and add NH_4OH (1+1) dropwise with stirring until the color changes from red to yellow (see Note 38). Allow the solution to stand without further heating for 1 h (not longer), with occasional stirring during the first 30 min. Filter using a retentive paper and wash moderately with cold ammonium oxalate solution (1 g/L). Reserve the filtrate and washings.

NOTE 81—When analyses are being made for determining conformity to specifications and there is a possibility that sufficient manganese will be present to cause the percentage of magnesium determined by alternate test methods to exceed the specification limit, manganese may be removed as directed in 14.3.2 before CaO is determined by this alternative test method.

22.2.2 Transfer the precipitate and filter paper to the beaker in which the precipitation was made. Dissolve the oxalate in 50 mL of hot HCl (1+4) and macerate the filter paper. Dilute to 200 mL with water, add a few drops of methyl red indicator and 20 mL of ammonium oxalate solution, heat the solution nearly to boiling, and precipitate calcium oxalate again by neutralizing the acid solution with NH_4OH as described in 14.3.1. Allow the solution to stand 1 to 2 h (standing for 2 h at this point does no harm), filter, and wash as before. Combine the filtrate with that already obtained and reserve for the determination of MgO (15.3.1).

22.2.3 Dry the precipitate in a weighed covered platinum crucible. Char the paper without inflaming, burn the carbon at as low a temperature as possible, and, finally, heat with the crucible tightly covered in an electric furnace or over a blast lamp at a temperature of 1100 to 1200 °C. Cool in a desiccator and weigh as CaO. Repeat the ignition to constant weight.

22.2.4 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

22.3 *Calculation*:

22.3.1 Calculate the percentage of CaO to the nearest 0.1 by multiplying the weight in grams of CaO by 200 (100 divided by the weight of sample used (0.5 g)).

22.3.2 Correct the percent CaO for SrO, if desired, by subtracting the percent SrO.

23. Carbon Dioxide (*Reference Test Method*)

23.1 Any test method may be used, provided that acceptable performance has been demonstrated in accordance with 23.2. See Appendix Appendix X2 for guidance on methods.

23.2 Demonstrate performance by analysis, in duplicate, of at least one Portland cement. Prepare three standards, each in duplicate: Standard A shall be the selected Portland cement; Standard B shall be Standard A containing 2.00 % Certified $CaCO_3$(such as NIST 915a); Standard C shall be Standard A containing 5.00 % Certified $CaCO_3$. Prepare duplicate specimens of each standard. Assign the CO_2 content of Standard A as the average of the two values determined, provided they agree within the required limit of Table 1, Column 2. Assign CO_2 values to Standards B and C as follows: multiply the Certified $CaCO_3$ value (Y) for CO_2(from the certificate value) by the mass fraction of Certified $CaCO_3$ added to that standard (percentage added divided by 100); multiply the value determined for Standard A by the mass fraction of Standard A in each of the other standards (that is, 0.98 and 0.95 for Standards B and C, respectively); add the two values for Standard A and for Standard B, respectively; call these values B and C.

Example:

$B = 0.98A + 0.02Y$

$C = 0.95A + 0.05Y$

Where for Certified $CaCO_3$, if Y = 44.01 %

B = 0.98A + 0.88 % by mass

C = 0.95A + 2.20 % by mass

The difference between the duplicate CO_2 values for Standards B and C, respectively, shall not exceed 0.17 and 0.24 % by mass. The difference between the average of the duplicate values for Standards B and C and their assigned values (B and C) shall not exceed 0.13 and 0.26 % by mass respectively.

23.3 Report the result rounded in accordance with Table 3.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

24. Magnesium Oxide (*Alternative Test Method*)

24.1 *Summary of Test Method*—This alternative test method is a volumetric procedure suitable for use when the determinations of silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), ferric oxide (Fe_2O_3), and calcium oxide (CaO) are omitted.

24.2 *Rapid Volumetric Test Method (Titration of Magnesium Oxyquinolate)*:

24.3 *Reagents*:

24.3.1 *Ammonium Nitrate Solution* (20 g NH_4NO_3/L).

24.3.2 *Ammonium Oxalate Solution* (50 g/L).

24.3.3 *Hydroxyquinoline Solution*—Dissolve 25 g of 8-hydroxyquinoline in 60 mL of acetic acid. When the solution is complete, dilute to 2 L with cold water. One millilitre of this solution is equivalent to 0.0016 g of MgO.

24.3.4 *Potassium Bromate-Potassium Bromide, Standard Solution* (0.2 *N*)—Dissolve 20 g of potassium bromide (KBr) and 5.57 g of potassium bromate ($KBrO_3$) in 200 mL of water and dilute to 1 L. Obtain the ratio of the strength of this solution to that of the 0.1 *N* $Na_2S_2O_3$ solution (22.2.6) as follows: To 200 mL of water in a 500-mL Erlenmeyer flask add 25.0 mL of the 0.2 *N* $KBrO_3$-KBr solution, measured from a pipet or buret. Add 20 mL of HCl, stir, and add immediately 10 mL of potassium iodide (KI) (250 g/L). Mix well and titrate at once with the $Na_2S_2O_3$ solution until nearly colorless. Add 2 mL of starch solution and titrate to the disappearance of the blue color. Calculate the ratio in strength of the $KBrO_3$-KBr solution to the $Na_2S_2O_3$ solution by dividing the volume of $Na_2S_2O_3$ solution by the volume of $KBrO_3$-KBr solution used in the titration.

24.3.5 *Potassium Iodide Solution* (250 g KI/L).

24.3.6 *Sodium Thiosulfate, Standard Solution* (0.1 *N*)—Dissolve 25 g of sodium thiosulfate ($Na_2S_2O_3 \cdot 5H_2O$) in 200 mL of water, add 0.1 g of sodium carbonate (Na_2CO_3), and dilute to 1 L. Let stand at least 1 week. Standardize this solution directly against primary standard potassium dichromate ($K_2Cr_2O_7$). One millilitre of 0.10 *N* $Na_2S_2O_3$ solution is equivalent to 0.000504 g of MgO.

24.3.7 *Starch Solution*— To 500 mL of boiling water add a cold suspension of 5 g of soluble starch in 25 mL of water, cool to room temperature, add a cool solution of 5 g of sodium hydroxide (NaOH) in 50 mL of water, add 15 g of KI, and mix thoroughly.

24.4 *Procedure*:

24.4.1 Disperse 0.5 g (Note 82) of the sample of cement in a 400-mL beaker with 10 mL of water, using a swirling motion. While still swirling, add 10 mL of HCl all at once. Dilute immediately to 100 mL. Heat gently and grind any coarse particles with the flattened end of a glass rod until decomposition is complete, add 2 or 3 drops of HNO_3 and heat to boiling (Note 83).

NOTE 82—If SiO_2, ammonium hydroxide group, and CaO are separated and determined in accordance with the appropriate sections for either the reference or alternative test methods, the remaining filtrate may be used for the determination of MgO as described in 24.4.1, starting with the third from the last sentence of 24.4.2, "Add 5 mL of HCl. . .".

NOTE 83—In the case of cements containing blast-furnace slag or a significant quantity of sulfide sulfur, add 12 drops of HNO_3 and boil for 20 min to oxidize iron and remove sulfide.

24.4.2 Add 3 drops of methyl red indicator to the solution and then add NH_4OH until the solution is distinctly yellow. Heat this solution to boiling and boil for 50 to 60 s. In the event difficulty from bumping is experienced while boiling the ammoniacal solution, a digestion period of 10 min on a steam bath, or a hot plate having the approximate temperature of a steam bath, may be substituted for the 50 to 60-s boiling period. Remove from the burner, steam bath, or hot plate and allow to stand until the precipitate has settled. Using medium-textured paper, filter the solution without delay, wash the precipitate twice with hot NH_4NO_3(20 g/L), and reserve the filtrate. Transfer the precipitate with the filter paper to the beaker and dissolve in 10 mL of HCl (1+1). Macerate the filter paper. Dilute to about 100 mL and heat to boiling. Reprecipitate, filter, and wash the hydroxides as above. Combine this filtrate and washings with those from the first precipitation taking care that the volume does not exceed 300 mL (Note 84). Add 5 mL of HCl, a few drops of methyl red indicator solution and 30 mL of warm ammonium oxalate solution (50 g/L). Heat the solution to 70 to 80 °C and add NH_4OH (1+1) dropwise, while stirring, until the color changes from red to yellow (see Note 38). Allow the solution to stand without further heating for 15 min on a steam bath.

NOTE 84—In the case of cements containing blast-furnace slag, or which are believed to contain a significant quantity of manganese, acidify with HCl, evaporate to about 100 mL, and remove the manganese, using the procedure described in 14.3.1.

24.4.3 Add 10 to 25 mL of the 8-hydroxyquinoline reagent (Note 85) and then 4 mL of NH_4OH/100 mL of solution. Stir the solution on a mechanical stirring machine for 15 min and set aside until the precipitate has settled (Note 86). Filter the solution using medium-textured paper and wash the precipitate with hot NH_4OH (1+40). Dissolve the precipitate in 50 to 75 mL of hot HCl (1+9) in a 500-mL Erlenmeyer flask. Dilute the resulting solution to 200 mL and add 15 mL of HCl. Cool the solution to 25 °C and add 10 to 35 mL of the 0.2 *N* $KBrO_3$-KBr solution (Note 87) from a pipet or buret. Stir the solution and allow to stand for about 30 s to ensure complete bromination. Add 10 mL of KI (250 g/L). Stir the resulting solution well and then titrate with the 0.1 *N* $Na_2S_2O_3$ solution until the color of the iodine becomes faintly yellow. At this point add 2 mL of the starch solution and titrate the solution to the disappearance of the blue color.

NOTE 85—An excess of the 8-hydroxyquinoline reagent is needed to avoid a low result for MgO, but too great an excess will yield high results. The following guide should be used to determine the amount of reagent added:

Approximate Content of MgO, %	Approximate Amount of Reagent Required, mL
0 to 1.5	10
1.5 to 3.0	15
3.0 to 4.5	20
4.5 to 6.0	25

NOTE 86—The precipitate should be filtered within an hour. Prolonged standing may cause high results.

NOTE 87—The amount of the standard $KBrO_3$–KBr solution used should be as follows:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Approximate Content of MgO, %	Amounts of Standard $KBrO_3$–KBr Solution, mL
0 to 1	10
1 to 2	15
2 to 3	20
3 to 4	25
4 to 5	30
5 to 6	35

24.4.4 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

24.5 *Calculation*— Calculate the percentage of MgO to the nearest 0.1 as follows: (Note 88)

$$\text{MgO, \%} = E(V_1R - V_2) \times 200 \quad (14)$$

where:

E = MgO equivalent of the $Na_2S_2O_3$ solution, g/mL,
V_1 = millilitres of $KBrO_3$–KBr solution used,
R = ratio in strength of the $KBrO_3$–KBr solution to the $Na_2S_2O_3$ solution,
V_2 = millilitres of $Na_2S_2O_3$ solution used, and
200 = 100 divided by the weight of sample used (0.5 g).

Report the result rounded in accordance with Table 3.

NOTE 88—V_1R represents the volume of $Na_2S_2O_3$ solution equivalent to the volume of $KBrO_3$–KBr solution used. V_2 represents the amount of $Na_2S_2O_3$ required by the excess $KBrO_3$–KBr which is not reduced by magnesium oxyquinolate.

25. Loss on Ignition

25.1 *Portland Blast-Furnace Slag Cement and Slag Cement (Alternative Test Method)*:

25.1.1 *Summary of Test Method*—This test method covers a correction for the gain in weight due to oxidation of sulfides usually present in such cement by determining the decrease in the sulfide sulfur content during ignition. It gives essentially the same result as the reference test method (17.2.1 through 17.2.3) which provides for applying a correction based on the increase in SO_3 content.

25.1.2 *Procedure*:

25.1.2.1 Weigh 1 g of cement in a tared platinum crucible, cover, and ignite in a muffle furnace at a temperature of 950 ± 50 °C for 15 min. Cool to room temperature in a desiccator and weigh. After weighing carefully transfer the ignited material to a 500-mL boiling flask. Break up any lumps in the ignited cement with the flattened end of a glass rod.

25.1.2.2 Determine the sulfide sulfur content of the ignited sample using the procedure described in 16.2.1 through 16.2.5. Using the same procedure, also determine the sulfide sulfur content of a portion of the cement that has not been ignited.

25.1.3 *Calculation*—Calculate the percentage loss of weight occurring during ignition (25.1.2.1) and add twice the difference between the percentages of sulfide sulfur in the original sample and ignited sample as determined in 25.1.2.2. Report this value as the loss on ignition, rounded in accordance with Table 3.

NOTE 89—If a gain of weight is obtained during the ignition, subtract the percentage of gain from the correction for sulfide oxidation.

26. Titanium Dioxide (*Alternative Test Method*)

26.1 *Summary of Test Method*—In this test method, titanium dioxide (TiO_2) is determined colorimetrically by comparing the color intensity of the peroxidized solution of the titanium in the sample with the color intensity of a peroxidized standard solution of titanic sulfate.

26.2 *Interferences*— Interfering elements in the peroxide method for TiO_2 are vanadium, molybdenum, and chromium. In very small quantities the interference of the last two is negligible. However, vanadium in very small quantities causes interference and, as some cements contain this element, the Na_2CO_3 fusion (26.5.4) and extraction with water are necessary.

26.3 *Apparatus*:

26.3.1 *Colorimeter*— The apparatus shall consist of a colorimeter of the Kennicott or Duboscq type, or other colorimeter or spectrophotometer designed to measure light transmittancy, and suitable for measurements at wavelengths between 400 and 450 nm.

26.4 *Reagents*:

26.4.1 *Ammonium Chloride* (NH_4Cl).

26.4.2 *Ammonium Nitrate* (20 g NH_4NO_3/L).

26.4.3 *Ferrous Sulfate Solution* (1 mL = 0.005 g Fe_2O_3)—Dissolve 17.4 g of ferrous sulfate ($FeSO_4 \cdot 7H_2O$) in water containing 50 mL of H_2SO_4 and dilute to 1 L. One millilitre is equivalent to 1 % of Fe_2O_3 in 0.5 g of sample.

26.4.4 *Hydrogen Peroxide* (30 %)—Concentrated hydrogen peroxide (H_2O_2).

26.4.5 *Sodium Carbonate* (20 g Na_2CO_3/L).

26.4.6 *Sodium or Potassium Pyrosulfate* ($Na_2S_2O_7$ or $K_2S_2O_7$).

26.4.7 *Titanic Sulfate, Standard Solution* (1 mL = 0.0002 g TiO_2)—Use standard TiO_2 furnished by NIST (Standard Sample 154 or its replacements). Dry for 2 h at 105 to 110 °C. Transfer a weighed amount, from 0.20 to 0.21 g of the TiO_2 to a 125-mL Phillips beaker. Add 5 g of ammonium sulfate ($(NH_4)_2SO_4$) and 10 mL of H_2SO_4 to the beaker and insert a short-stem glass funnel in the mouth of the beaker. Heat the mixture cautiously to incipient boiling while rotating the flask over a free flame. Continue the heating until complete solution has been effected and no unattacked material remains on the wall of the flask (Note 90). Cool and rapidly pour the solution into 200 mL of cold water while stirring vigorously. Rinse the flask and funnel with H_2SO_4(1+19), stir, and let the solution and washings stand for at least 24 h. Filter into a 1-L volumetric flask, wash the filter thoroughly with H_2SO_4 (1+19), dilute to the mark with H_2SO_4 (1+19), and mix.

NOTE 90—There may be a small residue, but it should not contain more than a trace of TiO_2 if the operations have been properly performed.

26.4.8 Calculate the TiO_2 equivalent of the titanic sulfate solution, g/mL, as follows:

$$E = AB/1000 \quad (15)$$

where:

E = TiO_2 equivalent of the $Ti(SO_4)_2$ solution, g/mL,
A = grams of standard TiO_2 used (corrected for loss on drying),

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

B = percentage of TiO_2 in the standard TiO_2 as certified by the National Institute of Standards and Technology, divided by 100, and

1000 = Number of millilitres in the volumetric flask.

26.5 *Procedure*:

26.5.1 Mix thoroughly 0.5 g of the sample of cement and about 0.5 g of NH_4Cl in a 50-mL beaker, cover the beaker with a watch glass, and add cautiously 5 mL of HCl, allowing the acid to run down the lip of the covered beaker. After the chemical action has subsided, lift the cover, stir the mixture with a glass rod, replace the cover, and set the beaker on a steam bath for 30 min (Note 91). During this time of digestion, stir the contents occasionally and break up any remaining lumps to facilitate the complete decomposition of the cement. Fit a medium-textured filter paper to a funnel and transfer the precipitate to the filter. Scrub the beaker with a rubber policeman and rinse the beaker and policeman. Wash the filter two or three times with hot HCl (1+99) and then with ten or twelve small portions of hot water, allowing each portion to drain through completely.

NOTE 91—A hot plate may be used instead of a steam bath if the heat is so regulated as to approximate that of a steam bath.

26.5.2 Transfer the filter and residue to a platinum crucible (Note 92), dry, and ignite slowly until the carbon of the paper is completely consumed without inflaming. Treat the SiO_2 thus obtained with 0.5 to 1 mL of water, about 10 mL of HF, and 1 drop of H_2SO_4, and evaporate cautiously to dryness (Note 93).

NOTE 92—When it is desired to shorten the procedure for purposes other than referee analysis, usually with little sacrifice of accuracy, the procedure given in 26.5.2 may be omitted.

NOTE 93—When a determination of SiO_2 is desired in addition to one of TiO_2, the SiO_2 may be obtained and treated with HF as directed in 7.2.3.1 through 7.2.4.

26.5.3 Heat the filtrate to boiling and add NH_4OH until the solution becomes distinctly alkaline, as indicated by an ammoniacal odor. Add a small amount of filter paper pulp to the solution and boil for 50 to 60 s. Allow the precipitate to settle, filter through a medium-textured paper, and wash twice with hot NH_4NO_3 solution (20 g/L). Place the precipitate in the platinum crucible in which the SiO_2 has been treated with HF and ignite slowly until the carbon of the paper is consumed.

NOTE 94—When a determination of ammonium hydroxide group is desired in addition to one of TiO_2, the precipitation and ignition may be made as described in 8.2.1-8.2.4. However, the crucible must contain the residue from the treatment of the SiO_2 with HF unless circumstances permit its omission as indicated in Note 93.

26.5.4 Add 5 g of Na_2CO_3 to the crucible and fuse for 10 to 15 min (see 24.2.1). Cool, separate the melt from the crucible, and transfer to a small beaker. Wash the crucible with hot water, using a policeman. Digest the melt and washings until the melt is completely disintegrated, then filter through a 9-cm medium-textured filter paper and wash a few times with Na_2CO_3 (20 g/L). Discard the filtrate. Place the precipitate in the platinum crucible and ignite slowly until the carbon of the paper is consumed.

26.5.5 Add 3 g of $Na_2S_2O_7$ or $K_2S_2O_7$ to the crucible and heat below red heat until the residue is dissolved in the melt (Note 95). Cool and dissolve the fused mass in water containing 2.5 mL of H_2SO_4. If necessary, reduce the volume of the solution (Note 96), filter into a 100-mL volumetric flask through a 7-cm medium-textured filter paper, and wash with hot water. Add 5 mL of H_3PO_4, and cool the solution to room temperature. Add H_2O_2 (1.0 mL of 30 % strength or its equivalent) (Note 97), dilute to the mark with water, and mix thoroughly.

NOTE 95—Start the heating with caution because pyrosulfates (also known as fused bisulfates) as received often foam and spatter in the beginning due to an excess of H_2SO_4. Avoid an unnecessarily high temperature or unnecessarily prolonged heating, as fused pyrosulfates may attack platinum. A supply of nonspattering pyrosulfates may be prepared by heating some pyrosulfate in a platinum vessel to eliminate the excess H_2SO_4 and crushing the cool fused mass.

NOTE 96—If the solution is evaporated to too small a volume and allowed to cool, there may be a precipitate of sulfates difficult to redissolve. In case of over-evaporation, do not permit the contents to cool, but add hot water and digest on a steam bath or hot plate until the precipitate is redissolved, with the possible exception of a small amount of SiO_2.

NOTE 97—Hydrogen peroxide deteriorates on standing. Its strength may be determined by adding a measured volume of the solution to 200 mL of cold water and 10 mL of H_2SO_4 (1+1) and titrating with a standard solution of potassium permanganate ($KMnO_4$) prepared in accordance with 14.2.2. If the standard solution contains 0.0056357 g of $KMnO_4$/mL, 49.5 mL of it will be required by 0.50 mL of H_2O_2 (30 %).

26.5.6 Prepare from the standard $Ti(SO_4)_2$ solution a suitable reference standard solution or a series of reference standard solutions in 100-mL volumetric flasks, depending upon the type of colorimeter to be used. To each solution add 3 g of $Na_2S_2O_7$ or $K_2S_2O_7$ dissolved in water, an amount of $FeSO_4$ solution equivalent to the Fe_2O_3 content in 0.5 g of the cement under test, 2.5 mL of H_2SO_4, and 5 mL of H_3PO_4 (Note 98). When the solution is at room temperature, add H_2O_2(1.0 mL of 30 % strength or its equivalent), dilute to the mark with water, and mix thoroughly (Note 99).

NOTE 98—The color imparted to the solution by $Fe_2(SO_4)_2$ is partly offset by the bleaching effect of H_2SO_4, H_3PO_4, and alkali salts on ferric and peritanic ions. The directions should be followed closely for the highest degree of precision. However, when it is desired to shorten this procedure for purposes other than referee analysis, the addition of pyrosulfate, $FeSO_4$ solution and H_3PO_4 to the color comparison solutions may be omitted provided the Fe_2O_3 of the sample cement is less than 5 %. This usually leads to little sacrifice to accuracy.

NOTE 99—The color develops rapidly and is stable for a sufficient period of time, but if the peroxidized solution is allowed to stand a long time, bubbles of oxygen may appear and interfere with color comparison. When the contents of a tube are first mixed, there may be fine bubbles which should be allowed to clear up before the comparison is made. Comparison between the standard and unknown solution should be made not less than 30 min after addition of H_2O_2.

26.5.7 Compare the color, light transmittancy, or absorbance of the unknown solution with the reference standard solution. The technique of comparing colored solutions or measuring transmittancy or absorbance depends on the type of apparatus (see 26.5.8-26.5.10) and should be in accordance with standard practice appropriate to the particular type used or with instructions supplied by the manufacturer of the equipment. If the peroxidized solution of cement is compared with a single standard peroxidized solution, bear in mind that a single peroxidized solution cannot be used for the whole range in TiO

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

2 content that may be encountered. The difference in volume or depth for the two liquids should not exceed 50 % of the smaller value. All solutions should contain the prescribed concentrations of H_2SO_4, H_3PO_4, $Fe_2(SO_4)_3$, and persulfate except under the circumstances indicated in Note 99.

26.5.8 *Colorimeter of the Kennicott Type*—By means of a plunger in a reservoir of standard peroxidized solution, adjust the amount of solution through which light passes until it gives the same color intensity as the peroxidized solution of the sample.

26.5.9 *Colorimeter of the Duboscq Type*—Lower or raise the plungers in the cups until the two solutions give the same color intensity when viewed vertically. The color matching may be done either visually or photoelectrically.

26.5.10 *Colorimeter Designed to Measure Light Transmittancy*—The measurement should be made between 400 to 450 nm and may be made either visually or photoelectrically. In most colorimeters of this type, the instrument is calibrated with standard solutions and a calibration curve showing the relation of light transmittancy or absorbance to TiO_2 content is prepared in advance of the analysis of the sample for TiO_2.

26.5.11 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagent, and correct the results obtained in the analysis accordingly.

26.6 *Calculation*—Calculate the percentage of TiO_2, rounded in accordance with Table 3. When a colorimeter designed to measure light transmittancy is used, read the percentage of TiO_2 from a calibration curve showing the relation of light intensity to TiO_2 content. When the peroxidized solution of the sample is compared with a single reference standard solution, calculate the percentage of TiO_2 as follows (Note 100):

26.6.1 *For Colorimeters of the Kennicott Type*:

$$TiO_2, \% = (100\ VE/S) \times (D/C) \quad (16)$$

26.6.2 *For Colorimeters of the Duboscq Type*:

$$TiO_2, \% = (100\ VE/S) \times (F/G) \quad (17)$$

where:

- V = millilitres of standard $Ti(SO_4)_2$ solution in the peroxidized standard solution,
- E = tiO_2 equivalent of the standard $Ti(SO_4)_2$ solution, g/mL,
- S = Grams of sample used,
- C = total volume of the peroxidized reference standard solution, mL,
- D = Volume of peroxidized reference standard solution that matches the peroxidized solution of the sample, mL,
- F = Depth of peroxidized reference standard solution through which light passes, anD
- G = Depth of peroxidized solution of the sample through which light passes.

NOTE 100—The difference between D and C or between F and G should not exceed 50 % of the smaller value.

27. Phosphorus Pentoxide (*Alternative Test Method*)

27.1 *Summary of Test Method*—In this test method, phosphorus is determined volumetrically by precipitation of the phosphorus as ammonium phosphomolybdate and titration with NaOH and H_2SO_4.

27.2 *Reagents*:

27.2.1 *Ammonium Molybdate Solution*—Prepare the solution in accordance with 10.3.1.

27.2.2 *Ammonium Nitrate* (NH_4NO_3).

27.2.3 *Potassium Nitrate Solution* (10 g/L)—Dissolve 10 g of potassium nitrate (KNO_3) in water freshly boiled to expel CO_2 and cooled, and dilute to 1 L.

27.2.4 *Sodium Hydroxide, Standard Solution* (0.3 *N*)—Dissolve 12 g of sodium hydroxide (NaOH) in 1 L of water that has been freshly boiled to expel CO_2, and cooled. Add 10 mL of a freshly filtered, saturated solution of barium hydroxide ($Ba(OH)_2$). Shake the solution frequently for several hours, and filter it. Protect it from contamination by CO_2 in the air. Standardize the solution against standard acid potassium phthalate (Standard Sample No. 84) or benzoic acid (Standard Sample No. 39) furnished by the National Institute of Standards and Technology, according to the directions furnished with the standard. Calculate the phosphorus pentoxide (P_2O_5) equivalent (Note 103) of the solution, g/mL, as follows:

$$E = N \times 0.003086 \quad (18)$$

where:

- E = P_2O_5 equivalent of the NaOH solution, g/mL,
- N = normality of the NaOH solution, and
- *0.003086* = P_2O_5 equivalent of 1 *N* NaOH solution, g/mL.

NOTE 101—The value of the solution is based on the assumption that the phosphorus in cement is precipitated as ammonium phosphomolybdate ($2(NH_4)_3PO_4 \cdot 12MoO_3$) and that the precipitate reacts with the NaOH solution thus:

$$2(NH_4)_3PO_4 \cdot 12MoO_3 + 46NaOH = 2(NH_4)_2HPO_4 + (NH_4)_2MoO_4 + 23Na_2MoO_4 + 22H_2O \quad (19)$$

The number of 0.003086 is obtained by dividing the molecular weight of P_2O_5 (141.96) by 46 (for 46 NaOH in the equation) and by 1000 (number of millilitres in 1 L).

As the actual composition of the precipitate is influenced by the conditions under which the precipitation is made, it is essential that all the details of the procedure are followed closely as prescribed.

27.2.5 *Sodium Nitrite* (50 g $NaNO_2$/L).

27.2.6 *Sulfuric Acid, Standard Solution* (0.15 *N*)—Dilute 4.0 mL of H_2SO_4 to 1 L with water that has been freshly boiled and cooled. Standardize against the standard NaOH solution. Determine the ratio in strength of the standard H_2SO_4 solution to the standard NaOH solution by dividing the volume of NaOH solution by the volume of H_2SO_4 solution used in the titration.

27.3 *Procedure*:

27.3.1 Weigh 1 to 3 g of the sample (Note 102) and 10 g of NH_4NO_3 into a 150-mL beaker. Mix the contents, add 10 mL of HNO_3, and stir quickly, using the flattened end of a glass rod to crush lumps of cement, until the cement is completely decomposed and the thick gel of silica (SiO_2) is broken up. Cover the beaker with a watch glass, place it on a water bath or a hot plate at approximately 100 °C for 15 to 20 min, and stir the contents occasionally during the heating. Add 20 mL of hot water to the beaker and stir the contents. If the cement contains an appreciable amount of manganese, as shown by the presence of a red or brown residue, add a few millilitres of

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$NaNO_2$(50 g/L) to dissolve this residue. Boil the contents of the beaker until all nitrous fumes are completely expelled. This procedure should not take more than 5 min, and water should be added to replace any lost by evaporation. Filter, using medium-textured paper, into a 400-mL beaker under suction and with a platinum cone to support the filter paper. Wash the residue of SiO_2 with hot water until the volume of filtrate and washings is about 150 mL.

NOTE 102—The amounts of sample and reagents used depend on the content of phosphorus in the cement. The minimum requirements are sufficient if the cement contains 0.5 % P_2O_5 or more. The maximum amounts are required if the content of P_2O_5 is 0.1 % or less.

27.3.2 Heat the solution to 69 to 71 °C, remove it from the heat source, and immediately add 50 to 100 mL of the ammonium molybdate solution. Stir the solution vigorously for 5 min, wash down the sides of the beaker with cool KNO_3 solution (10 g/L), cover the beaker with a watch glass, and allow to stand 2 h. Using suction, filter the precipitate (Note 103), decanting the solution with as little disturbance to the precipitate as possible. Stir the precipitate in the beaker with a stream of the cool KNO_3 solution, decant the liquid, then wash the precipitate onto the filter. Scrub the stirring rod and beaker with a policeman and wash the contents onto the filter. Wash and precipitate until it is acid-free (Note 104), allowing each portion of wash solution to be sucked completely through before adding the next.

NOTE 103—The filter may be a small medium-textured filter paper supported by a platinum cone, or a small Hirsch funnel may be used with filter paper cut to fit and a thin mat of paper pulp or acid-washed asbestos pulp. The filtration should be carried out with care to avoid any loss of the precipitate. The filter should fit well, and the suction should be started before filtration and maintained until the end of the washing.

NOTE 104—About ten washings are usually required. Test the tenth washing with one drop of neutral phenolphthalein indicator and half a drop of the standard NaOH solution. If a definite pink color lasts at least 5 min, the precipitate is considered to be acid-free; otherwise, continue the washing.

27.3.3 Transfer the filter and precipitate to the beaker in which the precipitation took place, using small damp pieces of paper to wipe out the funnel and to pick up portions of the precipitate that may remain on it. Add 20 mL of cool CO_2-free water to the beaker, and break up the filter by stirring rapidly with the policeman that was used to scrub the beaker. Add an excess of the 0.3 *N* NaOH solution, stir the contents until all trace of yellow has disappeared, wash down the policeman and sides of the beaker with 50 mL of cool, CO_2-free water, and add 2 drops of neutral phenolphthalein indicator solution. Treat the solution with a measured quantity of the 0.15 *N* H_2SO_4 solution, sufficient to destroy completely the pink color. Complete the titration with the NaOH solution until there is a definite faint pink color that lasts at least 5 min.

27.3.4 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

27.4 *Calculation*—Calculate the percentage of P_2O_5 to the nearest 0.01 as follows:

$$P_2O_5, \% = [E(V_1 - V_2R)/S] \times 100 \quad (20)$$

where:

E = P_2O_5 equivalent of the NaOH solution, g/mL,
V_1 = millilitres of NaOH solution used,
V_2 = millilitres of H_2SO_4 solution used,
R = ratio in strength of the H_2SO_4 solution to the NaOH solution, and
S = grams of sample used.

Report the result rounded in accordance with Table 3.

28. Manganic Oxide (*Alternative Test Method*)

28.1 *Summary of Test Method*—In this test method manganic oxide is determined volumetrically by titration with potassium permanganate solution.

28.2 *Reagents*:

28.2.1 *Potassium Permanganate, Standard Solution* (0.18 *N*)—Prepare a solution of potassium permanganate ($KMnO_4$) and standardize as described in 14.2.2, except that the manganic oxide (Mn_2O_3) equivalent of the solution is calculated instead of the calcium oxide (CaO) equivalent. Calculate the Mn_2O_3 equivalent of the solution as follows:

$$E = (B \times 0.3534)/A \quad (21)$$

where:

E = Mn_2O_3 equivalent of the $KMnO_4$ solution, g/mL,
B = grams of $Na_2C_2O_4$ used,
A = millilitres of $KMnO_4$ solution required by the $Na_2C_2O_4$, and
0.3534 = mole ratio of 3 Mn_2O_3 to 10 $Na_2C_2O_4$.

28.2.2 *Zinc Oxide* (ZnO), powder.

28.3 *Procedure*:

28.3.1 Place 2 g of the sample in a 250-mL beaker and add about 50 mL of water to the cement. Stir the mixture until it is in suspension and then add about 15 mL of HCl. Heat the mixture gently until the solution is as complete as possible. Add 5 mL of HNO_3 and 50 mL of water to the solution and boil it until most of the chlorine has been expelled. If necessary, add hot water to maintain the solution at a volume of about 100 mL. Stop the boiling and add ZnO powder to the solution until the acid is neutralized. Add an excess of 3 to 5 g of ZnO powder to the solution and boil it for a few minutes.

28.3.2 Without filtering, and while keeping the solution hot (90 to 100 °C) by intermittent or continuous heating, titrate the solution with the 0.18 *N* $KMnO_4$ solution until a drop of it gives a permanent pink color (Note 105). When the end point is approached, add the standard solution dropwise. After each drop, stir the solution, allow the precipitate to settle a little, and observe the color of the stratum of the solution by looking through the side of the beaker.

NOTE 105—In the case of a cement in which the approximate content of Mn_2O_3 is unknown, a preliminary determination may be made with rapid titration, 0.5 to 1 mL of the standard solution being added at a time, and without an attempt to keep the solution close to the boiling point.

28.3.3 *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

28.4 *Calculation*— Calculate the percentage of Mn_2O_3 to the nearest 0.01 as follows:

$$Mn_2O_3, \% = EV \times 50 \quad (22)$$

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

where:
E = Mn_2O_3 equivalent of the $KMnO_4$ solution, g/mL,
V = millilitres of $KMnO_4$ solution used, and
50 = 100 divided by the weight of sample used (2 g).

Report the result rounded in accordance with Table 3.

29. Free Calcium Oxide (*Alternative Test Methods*)

29.1 *Summary of Test Methods*—These are rapid test methods for the determination of free calcium oxide in fresh clinker. When applied to cement or aged clinker, the possibility of the presence of calcium hydroxide should be kept in mind since these methods do not distinguish before free CaO and free $Ca(OH)_2$. Two test methods are provided. Alternate Test Method A is a modified Franke procedure in which uncombined lime is titrated with dilute perchloric acid after solution in an ethylacetoacetate-isobutylalcohol solvent. Alternate Test Method B is an ammonium acetate titration of the alcohol–glycerin solution of uncombined lime with $Sr(NO_3)_2$ as an accelerator.

29.2 *Modified Franke Test Method (Alternative Test Method A)*:

29.2.1 *Apparatus*:

29.2.1.1 *Refluxing Assembly,* consisting of a flask with flat-bottom short neck Erlenmeyer flask with 250-mL capacity. The water-cooled refluxing condenser should have a minimum length of 300 mm. The flask and reflux condenser shall be connected with standard tapered ground glass joints. The reflux condenser shall be fitted with an absorption tube containing a desiccant, such as indicating silica gel, and a material for the removal of CO_2, such as Ascarite. The absorption tube shall be inserted with a rubber stopper in the upper end of the reflux column.

29.2.1.2 *Buret,* having a 10-mL capacity and graduated in units not more than 0.05 mL.

29.2.1.3 *Vacuum Filtration Assembly,* consisting of a Gooch crucible size No. 3, 25-mL capacity in which is placed a suitable filter paper, 21-mm size, a Walter crucible holder, a 500-mL vacuum flask, and vacuum source. The crucible is half filled with compressed filter pulp.

29.2.1.4 *Glass Boiling Beads*:

29.2.2 *Solutions Required*:

29.2.2.1 *Ethyl Acetoacetate–Isobutyl Alcohol Solvent*—3 parts of volume of ethyl acetoacetate and 20 parts by volume of isobutyl alcohol.

29.2.2.2 *Thymol Blue Indicator*—Dissolve 0.1 g of thymol blue indicator powder in 100 mL of isobutyl alcohol.

29.2.2.3 *Perchloric Acid, Standard Solution* (0.2 *N*)—Dilute 22 mL of 70 to 72 % perchloric acid to 1 L with isobutyl alcohol. Standardize this solution as follows: Ignite 0.1000 g of primary standard calcium carbonate in a platinum crucible at 900 to 1000 °C. Cool the crucible and contents in a desiccator and weigh to the nearest 0.0001 g to constant weight. Perform the weighings quickly to prevent absorption of water and CO_2. Immediately transfer the CaO without grinding to a clean, dry Erlenmeyer flask and reweigh the empty crucible to the nearest 0.0001 g to determine the amount of CaO added. Then follow procedure beginning with "Add 70 mL of the ethyl acetoacetate–isobutyl alcohol. . ." in 29.2.3.1. Calculate the CaO equivalents of the standard perchloric acid solution in grams per millilitre by dividing the weight of CaO used by the volume of perchloric acid required for the titration.

29.2.3 *Procedure*:

29.2.3.1 Weigh 1.0000 g of ground sample (Note 106) and transfer it into a clean, dry 250-mL Erlenmeyer flask. Add four to five glass boiling beads. Add 70 mL of prepared ethyl acetoacetate–isobutyl alcohol solvent. Agitate the flask to disperse the sample.

NOTE 106—Thorough grinding of the sample is essential for proper exposure of the free lime grains that often are occluded in crystals of tricalcium silicate in the cement. However, exposure of the sample to the air must be kept at a minimum to prevent carbonation of the free lime. In particular, direct breathing into the sample must be avoided. The sample should be sufficiently fine to easily pass a No. 200 (75-μm) sieve but actual sieving is not recommended. If the sample is not to be immediately tested, it must be kept in an airtight container to avoid unnecessary exposure to the atmosphere.

29.2.3.2 Attach the flask to a reflux condenser and bring the material to a boil. Reflux for 15 min.

29.2.3.3 Remove flask from condenser, stopper, and cool rapidly to room temperature.

29.2.3.4 Filter the sample and solution using the vacuum assembly. Wash the flask and residue with small increments (10 to 15 mL) of isobutyl alcohol until a total of 50 mL has been used for wash solution.

29.2.3.5 Add 12 drops of the thymol blue indicator to the filtrate and immediately titrate with 0.2 *N* perchloride acid to the first distinct color change.

29.2.4 *Calculation*— Calculate the percent free calcium oxide to the nearest 0.1 % as follows:

$$\text{free CaO, \%} = \frac{EV \times 100}{W} \tag{23}$$

where:
E = CaO equivalent of the perchloric acid, g/mL,
V = millilitres of perchloric acid solution required by sample, and
W = weight of the sample, g.

Report the result rounded in accordance with Table 3.

29.3 *Rapid $Sr(NO_3)_2$* Method (Alternative Test Method B):

29.3.1 *Reagents*:

29.3.1.1 *Ammonium Acetate, Standard Solution* (1 mL = 0.005 g CaO)—Prepare a standard solution of ammonium acetate ($NH_4C_2H_3O_2$) by dissolving 16 g of desiccated ammonium acetate in 1 L of ethanol in a dry, clean, stoppered bottle. Standardize this solution by the same procedure as described in 29.3.2.1, except use the following in place of the sample: ignite to constant weight approximately 0.1 g of calcium carbonate ($CaCO_3$) in a platinum crucible at 900 to 1000 °C, cool the contents in a desiccator, and weigh to the nearest 0.0001 g. Perform the weighings quickly to prevent absorption of water and CO_2. Immediately transfer the CaO without grinding to a 250-mL boiling flask (containing glycerin–ethanol solvent and $Sr(NO_3)_2$), and reweigh the empty crucible to determine the weight of CaO to the nearest 0.0001 g. Continue as described in 29.3.2.1 and 29.3.2.2. Calculate the CaO equivalent of the ammonium acetate in grams per millilitre by dividing the weight of CaO used by the volume of solution required.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

29.3.1.2 *Phenolphthalein Indicator*—Dissolve 1.0 g of phenolphthalein in 100 mL of ethanol (Formula 2B) (Note 107).

29.3.1.3 *Glycerin-Ethanol Solvent* (1+2)—Mix 1 volume of glycerin with 2 volumes of ethanol (Formula 2B). To each litre of this solution, add 2.0 mL of phenolphthalein indicator solution.

NOTE 107—Ethanol denatured in accordance with Formula 2B (99.5 % ethanol and 0.5 % benzol) is preferred but may be replaced by isopropyl alcohol, A.R.

29.3.1.4 *Strontium Nitrate* ($Sr(NO_3)_2$), reagent grade.

29.3.2 *Procedure*:

29.3.2.1 Transfer 60 mL of the glycerin–ethanol solvent into a clean, dry, 250-mL standard-taper flat-bottom boiling flask. Add 2 g of anhydrous strontium nitrate ($Sr(NO_3)_2$), and adjust the solvent to slightly alkaline with a dropwise addition of a freshly prepared dilute solution of NaOH in ethanol until a faint pink color is formed. Weigh 1.000 g of the finely ground sample (Note 107) into the flask, add encapsulated stirring bar, and immediately attach a water-cooled condenser (with a standard 24/40 glass joint). Boil the solution in the flask on a magnetic stirrer hot plate for 20 min with mild stirring.

29.3.2.2 Remove the condenser and filter the contents of the flask on a small polypropylene Büchner funnel under vacuum, using a 250-mL filtering flask with side tube. Bring the filtrate to a boil and immediately titrate with standard ammonium acetate solution to a colorless end point.

29.3.3 *Calculation*— Calculate the percent free CaO to the nearest 0.1 % as follows:

$$\text{free CaO, \%} = EV \times 100 \quad (24)$$

where:

E = CaO equivalent of the ammonium acetate solution, g/mL, and

V = millilitres of ammonium acetate solution required by the sample.

Report the result rounded in accordance with Table 3.

30. Keywords

30.1 chemical analysis; compositional analysis; hydraulic cements

APPENDIXES

(Nonmandatory Information)

X1. EXAMPLE OF DETERMINATION OF EQUIVALENCE POINT FOR THE CHLORIDE DETERMINATION

(Column 1) $AgNO_3$, mL	(Column 2) Potential, mV	(Column 3) Δ mV[A]	(Column 4) Δ^2 mV[B]
1.60	125.3		
		5.8	
1.80	119.5		1.4
		7.2	
2.00	112.3		1.3
		8.5	
2.20	103.8		1.3
		9.8	
2.40	94.0		0.6
		9.2	
2.60	84.8		2.3
		6.9	
2.80	77.9		0.8
		6.1	
3.00	71.8		1.3
		4.8	
3.20	67.0		

The equivalence point is in the maximum Δ mV interval (Column 3) and thus between 2.20 and 2.40 mL. The exact equivalence point in this 0.20 increment is calculated from the Δ^2 mV (Column 4) data as follows:

$$E = 2.20 + \left(1.3/(1.3 + 0.6)\right) \times 0.20 = 2.337 \text{ mL. Round to } 2.34.$$

[A] Differences between successive readings in Column 2.

[B] Differences between successive Δ readings in Column 3 "second differentials".

X2. CO_2 DETERMINATIONS IN HYDRAULIC CEMENTS

X2.1 Scope

X2.1.1 This appendix contains information about methods for determination of carbon dioxide (CO_2) in hydraulic cement. The methods listed received a favorable evaluation by Task Group C01.23.04.

X2.1.2 Section X2.2 lists the analytical methods that received a favorable evaluation, briefly describes each method, suggests analytical techniques or cautions that may be useful, and indicates limitations to some of the methods.

X2.1.3 The methods listed as X2.2.1, X2.2.4, X2.2.5, and X2.2.6 determine total carbon calculated as CO_2. For that reason, they are not appropriate for determination of carbon dioxide in fly ash, limestones containing carbon in the form of graphite or kerogen, in other carbon bearing materials, or in blended cements produced from these materials.

X2.1.4 The methods listed in X2.2.2 and X2.2.3 can determine actual CO_2 directly rather than by calculation from total carbon. They are suggested for analysis of blended cements and blended cement ingredients which are likely to contain non-carbonate carbon.

X2.1.5 The split loss on ignition method in X2.2.1 can give misleading results when used with materials containing $Ca(OH)_2$ (calcium hydroxide). This can occur with aged cement, cement made from aged clinker, or high free lime clinker, in addition to cements with a lime or hydrated lime ingredient.

X2.2 Analytical Methods

X2.2.1 *Split Loss on Ignition*—This procedure is comparable to the analytical method described in Test Methods C114, Section 17.1.1, with the following modifications:

1. A crucible of known mass and containing a sample of known mass is initially heated at 550 °C for 2 h.
2. After being cooled to room temperature in a desiccator, and its mass determined, the crucible with sample is then heated at 950 °C for 2 h.
3. Finally, the crucible with sample is cooled and its mass is determined as per Step No. 2.
4. The difference in residue masses after the respective heat treatments is assumed to be carbon dioxide.

TGA results indicated that $Ca(OH)_2$ can lose a significant portion of its mass above 500 °C. Thus, the Split Loss on Ignition procedure should not be used when situations described in X2.1.5 exist.

X2.2.2 *Thermogravimetric Analysis (TGA)*—This method involves the determination of sample mass loss at various temperatures. The heating of a sample through a temperature range allows for mass loss differentiation based on mineral form (for example, $CaCO_3$, $MgCO_3$, $Ca(OH)_2$, etc.). Specific operational information is provided by the equipment manufacturers. If free carbon is present, an inert atmosphere (for example, nitrogen) should be used for sample analysis.

X2.2.3 *Test Methods C25, Section 22*—"Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime." This method involves decomposition of the sample with HCl. The liberated CO_2 is then passed through a series of scrubbers to remove water and sulfides. The CO_2 is absorbed with special Sodium Hydroxide Absorbent (Ascarite). The gain in mass of the absorption tube is determined and calculated as percent CO_2. Calcium carbonate, for instance, can be calculated by multiplying the determined CO_2 content by a conversion factor (for example, $CO_2 \times 2.2742 = CaCO_3$).

X2.2.4 *X-ray Fluorescence Spectroscopy*—In this method the sample is ground to a fine particle size, pressed into a flat pellet and irradiated with the chosen instrument. Carbon content is determined by comparing the collected carbon emissions to calibration standards.

X2.2.5 *Combustion by Induction Furnace/IR*—This method involves volatilization by induction furnace and detection by infrared absorption. Suitable calibration standards (for example, calcium carbonate and synthetic carbon) are available from some instrument manufacturers. NIST cement SRMs with known additions of NIST argillaceous limestone (or other suitable standards) should also be considered to check instrument calibration.

X2.2.6 *"Test Methods E350*—This method, Total Carbon by the Combustion Gravimetric Method from Test Methods for Chemical Analysis of Carbon Steel, Low-Alloy Steel, Silicon Electrical Steel, Ingot Iron, and Wrought Iron," is suitable for the determination of carbon in concentrations from 0.05 to 1.80 % (as carbon dioxide 0.18 to 6.60 %). The test method involves burning the sample in a stream of oxygen; the carbon dioxide in the evolved gases is then collected in a suitable absorbent and its mass determined. Time of analysis is less than 10 min.

X2.3 Cooperative Test Results

X2.3.1 Tables X2.1 and X2.2 list results from two series of cooperative tests using several of the analytical methods evaluated by the Task Group. In all, five of the six methods receiving favorable ratings were included. The sixth method, Test Methods C25, was specifically not tested in these cooperative series, but was rated favorably because of long history of use with related materials.

X2.3.2 Table X2.1 includes results of single determinations using three of the different analytical methods. The methods used were Split Loss on Ignition, Test Methods E350, and Combustion by Induction Furnace with Infra-Red Detection.

X2.3.3 Table X2.2 includes results based on average of three determinations. Results from four of the different analytical methods are included. Methods used were Split Loss on Ignition, X-Ray Fluorescence Analysis, Induction furnace with Infra-Red Detection, and Thermo-Gravimetric Analysis. Test Methods E350 was not used in this series of tests.

TABLE X2.1 Cooperative Test Series No. 1

	Single Determinations			
	Carbon Dioxide Unknown[A]	Determinations Base Cement[B]	Added CO_2, c% Determined[C]	Added CO_2, % Known[D]
Split LOI	2.40	0.45	1.97	2.00
	2.52	0.56	1.99	
	2.41	0.36	2.07	
	2.39	0.32	2.09	
	2.41	0.36	2.07	
	2.28	0.27	2.02	
Test Methods E350	2.00	0.02	1.98	
	2.00	0.02	1.98	
Induction Furnace/IR	2.46	0.40	2.07	
	2.53	0.48	2.08	
	2.38	0.40	2.00	
	2.42	0.48	1.97	
Average Standard Deviation			2.02	
			0.05	

[A] The Unknown was prepared by blending/grinding a mixture of 5.00 % NIST SRM 1C Argillaceous Limestone and 95.00 % CCRL Portland Cement Reference Sample No. 85. According to the Certificate of Analysis, the SRM 1C had a loss on ignition of 39.9 %. For the purpose of the cooperative test series, the loss on ignition was assumed to be CO_2 only.

[B] The Base Cement was CCRL Portland Cement Reference Sample No. 85.

[C] The Determined % Added CO_2 was obtained by subtracting the Base Cement % CO_2 from the Unknown % CO_2.

[D] The addition of 5.00 % NIST SRM 1C (with a loss on ignition value of 39.9 %) would provide 2.00 % Added CO_2. (Again, it was assumed that the SRM 1C loss on ignition was only carbon dioxide.)

TABLE X2.2 Cooperative Test Series No. 2

	Averages from Three Determinations			
	Carbon Dioxide Unknown[A]	Determinations Base Cement[B]	Added CO_2, % Determined[C]	Added CO_2 % Known[D]

	1.96	0.28	1.68	
	1.95	0.40	1.55	
TGA	1.77	0.20	1.57	
	1.87	0.25	1.62	
Average Standard Deviation			1.60	
			0.14	

[A] The Unknown was prepared by blending/grinding a mixture of 4.00 % NIST SRM 1C Argillaceous Limestone and 96.00 % CCRL Portland Cement Reference Sample No. 85. According to the Certificate of Analysis, the SRM 1C had a loss on ignition of 39.9 %. For the purpose of the cooperative test series, the loss on ignition was assumed to be CO_2 only.

[B] The Base Cement was CCRL Portland Cement Reference Sample No. 85.

[C] The Determined % Added CO_2 was obtained by subtracting the Base Cement % CO_2 from the Unknown % CO_2.

[D] The addition of 4.00 % NIST SRM 1C (with a loss on ignition value of 39.9 %) would provide 1.60 % Added CO_2. (Again, it was assumed that the SRM 1C loss on ignition was only carbon dioxide.)

[E] The XRF instrument was calibrated using standards composed of the Base Cement (that is, CCRL No. 85) and NIST SRM 1C. It was assumed that the Base Cement contained 0 % CO_2.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to these test methods since the last issue, C114 – 09a, that may impact the use of these test methods. (Approved December 15, 2009)

(*1*) Reordered sections in the standard and renumbered subsequent sections throughout.

Committee C01 has identified the location of selected changes to these test methods since the last issue, C114 – 09, that may impact the use of these test methods. (Approved December 1, 2009)

(*1*) Revised 4.2.1, 4.4.4, and Table 2.

(*2*) Deleted Note 5 and renumbered subsequent notes.

Committee C01 has identified the location of selected changes to these test methods since the last issue, C114 – 07, that may impact the use of these test methods. (Approved February 1, 2009)

(*1*) Revised Section 3.

(*2*) Added new Note 1 and renumbered subsequent notes.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org). Permission rights to photocopy the standard may also be secured from the ASTM website (www.astm.org/COPYRIGHT/).

Designation: C 115 – 96a (Reapproved 2003)

Standard Test Method for Fineness of Portland Cement by the Turbidimeter[1]

This standard is issued under the fixed designation C 115; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers determination of the fineness of portland cement as represented by a calculated measure of specific surface, expressed as square centimetres of total surface area per gram, or square metres of total surface area per kilogram, of cement, using the Wagner turbidimeter.[2]

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in SI units are to regarded as the standard. The inch-pound equivalents may be approximate.

2. Referenced Documents

2.1 *ASTM Standards:*

C 114 Test Methods for Chemical Analysis of Hydraulic Cement[3]

C 430 Test Method for Fineness of Hydraulic Cement by the 45-μm (No. 325) Sieve[3]

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials[4]

3. Significance and Use

3.1 The purpose of this test method is to determine whether or not the hydraulic cement under test meets the Wagner turbidimetric fineness requirements of the applicable hydraulic cement specification for which the test is being made. Fineness of the cement component is only one of the many characteristics that influence the strength capabilities of concrete.

4. Apparatus

4.1 *Nature of Apparatus*—The Wagner turbidimeter consists essentially of a source of light maintained at constant intensity and adjusted so that approximately parallel rays of light pass through a suspension of the cement to be tested and impinge upon the sensitive plate of a photoelectric cell. The current generated in the cell is measured by means of a microammeter and the indicated reading is a measure of the turbidity of the suspension. General considerations indicate that turbidity is in turn a measure of the surface area of the suspended sample of cement. The apparatus shall consist specifically of the parts described in 4.2-4.7 and shall be constructed in accordance with the detailed design and dimensional requirements shown in Fig. 1 and Table 1, except that the case may be either of wood or of metal.

4.2 *Turbidimeter*, mounted in a suitable wood or metal case including the following features:

4.2.1 *Source of Light*—The source of light (Fig. 1) shall consist of a concentrated-filament electric lamp of between 3 and 6 cd operated by a source of constant emf. The lamp shall be mounted rigidly in the socket. A clean, bright parabolic metallic reflector shall be rigidly mounted behind the lamp, focused so that approximately parallel rays of light will pass through the sedimentation tank and impinge upon the photoelectric cell. The light intensity shall be regulated by two rheostats of approximately 6 and 30 Ω, respectively, and they shall possess such characteristics that uniform changes in light intensity may be obtained over the full range of resistance. The rheostats shall be mounted in parallel with each other and in series with the lamp.

4.2.2 *Heat-Absorbing Device*—The light shall pass through a suitable heat absorbing device before entering the sedimentation tank in order that radiant heat from the beam shall be absorbed, the device being either (*1*) a water cell or (*2*) a special heat-absorbing glass filter. The water cell shall be made from 76-mm (3-in.) outside diameter seamless brass tubing, 3-mm (⅛-in.) thick wall, 102-mm (4 in.) in length with glass windows sealed in the ends. The cell shall contain a hole for filling with distilled water. The hole shall be sealed with a metal plug. The cell, when mounted on the movable shelf, may have the plug in either the top or bottom position. The heat-absorbing device shall be so arranged that essentially all

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.25 on Fineness.

Current edition approved July 10, 2003. Published September 2003. Originally approved in 1934. Last previous edition approved in 1996 as C 115 – 96a.

[2] This turbidimeter was developed by L. A. Wagner, Research Associate of the Cement Reference Laboratory, National Institute of Standards and Technology, Washington, DC. A description of the apparatus and the original mathematical derivations of formulas used are given in the paper: Wagner, L. A., "A Rapid Method for the Determination of the Specific Surface of Portland Cement," *Proceedings*, ASTM, ASTEA, Vol 33, Part II, 1933, p. 553.

Microammeter Internal Resistance = 90 Ω
Shunt Equivalent Resistance:

$$470\ \Omega \text{ in parallel with } 100\ \Omega = \frac{470 \times 100}{470 + 100} = 82\ \Omega$$

Meter & Shunt Equivalent + Resistance:

$$90\ \Omega \text{ in parallel with } 82\ \Omega = \frac{90 \times 82}{90 + 82} = 43\ \Omega$$

Series Resistance = 90 − 43 = 47 Ω

FIG. 1 Illustrated Example of D'Arsonval Meter Circuit for I_r Determination

rays of light entering the sedimentation tank shall first pass through the heat-absorbing device.

4.2.3 *Retarding Filter*—A light-retarding glass or other device shall be provided that will reduce the intensity of light from that corresponding to 100 µA to a reading of 20 to 30 µA. The light intensity shall be uniformly retarded over the entire area of that portion of the cell which is exposed to light during a test. The retarding filter shall be mounted in a carrier on the shield and shall be capable of being swung out of the light path by means of a handle.

4.2.4 *Sedimentation Tank*—The sedimentation tank shall be either (*1*) constructed of 5 to 6-mm (3⁄16 to 1⁄4-in.) plate glass or borosilicate glass cemented or sealed together to form a rectangular tank, or (*2*) a molded glass tank having walls approximately 5-mm (3⁄16 in.) thick with plane surfaces. The inside dimensions of the rectangular tank shall be 51 mm by 38 mm by 203 mm (2 in. by 1½ in. by 8 in.) in height. The permissible variation on the inside dimensions of the tank shall be ±2.5 mm (0.1 in.) in length and ±0.76 mm (0.03 in.) in width. The 51-mm faces of the tank shall be equidistant within 0.25 mm (0.1 in.) at all points. A mark shall be placed on the side of the tank to indicate a volumetric content of 335 mL, which is the level to which the tank will be filled in a test. A tank filled to the mark with clear kerosine and placed in the turbidimeter light beam shall yield uniform microammeter readings, within ±0.1 µA, for the entire usable portion of the tank.

4.2.5 *Photoelectric Cell*—The means of measuring the light intensity shall be a sensitive photoelectric cell[5] connected directly to a microammeter. A hood with a horizontal slot 13 mm (½ in.) in height by 35 mm (1 3⁄8 in.) in width shall be mounted over the photoelectric cell. The front of the hood shall be 25 ± 1 mm (1 ± 1⁄16 in.) in front of the face of the cell. The face of the photocell shall be parallel to the tank faces within 0.5 mm (0.02 in.).

4.2.6 *Shield*—A metallic shield having a slot 16 mm (5⁄8 in.) in height by 38 mm (1½ in.) in width, as indicated in Fig. 1, shall be placed between the heat absorbing device and the sedimentation tank.

4.2.7 *Elevating Device*—The source of the light, the heat-absorbing device, the photoelectric cell, the retarding filter, and the shield shall be mounted on a movable shelf which may be raised or lowered by two connected lead screws, and which may be readily and accurately adjusted so that the turbidity of the suspension may be determined at any desired depth. The center of the light source, the heat absorbing device, the photocell, the center of the slots of the metal shield, and the hood shall be on a straight line which is parallel to the shelf. The sedimentation tank shall be mounted on a base which is independent of the rest of the apparatus so that the tank shall be free from vibration caused by moving the shelf. Care shall be taken that the shelf shall be level at all points of elevation and that the tank shall be normal to the shelf. The distance between the tank and the edges of the opening in the shelf shall vary not more than 1⁄64 in. (0.4 mm) between the "30–50" and "0" positions. The level of the light beam with reference to the surface of the suspension shall be indicated by a pointer which will travel along a scale mounted on the cabinet. The zero of the scale shall indicate that position at which the center lines of the slots for the light beam are at the same elevation as the surface of the liquid in the tank when filled to the 335-mL level. The lines on the scale to be marked 7.5, 10, 15, 20, 25, and 30–50, shall be located at distances from the zero mark equal to suspension depth values, *h*, in Table 2. The scale, when compared with a standard scale accurate to within 0.1 mm at all points, shall not show a deviation at any point greater than 0.25 mm and shall indicate the positions at which the pointer should be located when turbidity readings for these values of *h* are taken. The interior of the turbidimeter cabinet and the exterior surfaces of the shelf, the parabolic reflector, the heat absorbing device, the shield, and the photoelectric cell hood shall be painted with a dull flat black paint.

NOTE 1—The requirement of the 0 to 50 markings on the scale shall apply only to new Wagner Turbidimeters and not to equipment in use which meets the other requirements of this method.

4.3 *Microammeters*:

4.3.1 *D'Arsonval-Type Microammeters* shall have a range from 0 to 50 µA and shall be readable to 0.1 µA. New microammeters shall be accurate to ±0.5 % of full scale value at any part of the scale value at any part of the scale at 77°F (25°C). For microammeters, in use, the accuracy shall be the same as for new instruments except that the accuracy at 40 and 50 µA shall be ±1 % of full scale. The internal resistance of the microammeter shall be between 50 and 150 Ω . The microammeter shall not be mounted upon a working surface containing or consisting of iron or steel, or near other magnetic influence.

4.3.2 *Digital Microammeter*:

NOTE 2—A meter with a range of 199.9 µA is satisfactory for use and enables the operator to read the theoretical I_0 directly without supplementary devices. The high internal resistance of the digital microammeter does not affect the linearity of readings at the light intensity levels encountered in a Wagner turbidimetric determination of fineness.

4.4 *Source of Current*—A 6-V automobile starting and lighting storage battery or a source of constant emf shall be used for supplying current to the lamp.

4.5 *Sieve*—The sieve shall conform to the requirements of Test Method C 430.

[5] Weston Photronic type, Model 594YY is acceptable.

S	69.8	2¾			

[A] These are pure numbers such as parts of a thread designation and numbers of links per unit; consequently, they do not correspond with the column titles.

4.6 *Stirring Apparatus*—The stirring apparatus shall consist of either (*1*) a cylindrical brush, 19 mm (¾ in.) in diameter and about 45 mm (1¾ in.) in length, with an end approximately fitting the contour of the bottom of a 22-mm (⅞-in.) diameter test tube, or (*2*) any other stirring device that will be equally efficient in dispersion as measured by specific surface determinations on a standard sample. The stirring apparatus shall rotate at a speed of approximately 3500 r/min.

4.7 *Timing Buret*—The time of settling for the different-sized particles shall be obtained by use of a buret from which kerosine is allowed to flow. The buret shall consist of a glass tube having a capillary tube fused into the lower end. The

TABLE 2 Values of *h*, *d*, and h/d^2 to be Used in Calibration of the Turbidimeter Apparatus

Particle Diameter, *d*, μm	Depth of Suspension, *h*, cm	h/d^2
50	15	0.00600
45	15	0.00741
40	15	0.00938
35	15	0.01224
30	15	0.01667
25	13.1	0.0210
20	10	0.0250
15	6.6	0.0293
10	3.3	0.0330
7.5	2.1	0.0373

upper end of the large tube shall be flared to serve as a funnel for introducing kerosine into the tube. The buret shall conform to the limiting dimensions given in Table 3. The graduation lines on the buret shall be complete circles. A filter made of No. 325 (45-μm) wire cloth shall be used with the timing buret and a cover shall be placed over the top of the buret when it is not in use.

4.8 *Weights and Weighing Devices*, shall conform to the requirements of Methods C 114.

5. Materials

5.1 *Suspending Liquid*—Clear white kerosine shall be used with the turbidimeter apparatus. The kerosine shall not be reused.

6. Test Specimen or Sample

6.1 *Size of Test Sample*—Select the size of the sample of cement for test so that the initial microammeter reading is between 12 and 20 μA.

NOTE 3—The following approximations will be helpful in many instances in selecting the size of sample: 0.25 g for normal fineness cements and 0.20 g for high fineness cements.

7. Calibration

7.1 *Calibration of Turbidimeter*—Calibrate the turbidimeter apparatus in accordance with the following procedure:

7.1.1 *Calibration of Buret Scale*:

7.1.1.1 For calibration of the buret scale use a kerosine having a known viscosity and density for the temperature at which the calibration is to be made. Density and viscosity of the kerosine should be determined. Calculate the times of flow from the buret that correspond to the times of settling for the different sized particles, from the following equation:

TABLE 3 Buret Dimensions[A]

	Dimension, cm	Permissible Variation, cm
Length of large tube	38	±4
Inside diameter of large tube	1.9	±0.2
Length of capillary	17.5	±2.5
Diameter of capillary	0.09	±0.005
Top of buret to zero line	7	±1

[A] Since glass tubing of desired dimensions is not always obtainable, the wide permissible variations listed above allow selection of dimensions to produce a buret having a duration of flow which will permit calibration as described in 7.1.1.

$$t = [1{,}837{,}000\eta/(\rho_1 - \rho_2)] \times (h/d^2) \quad (1)$$

where:

- t = time of settling, or time of flow, s,
- η = viscosity of kerosine at the temperature of calibration, P,
- ρ_1 = density of cement particles, Mg/m^3 (g/cm^3) = 3.15 for portland cement (Note 4),
- ρ_2 = density of kerosine, Mg/m^3 at the temperature of calibration,
- h = depth of suspension to level of light, cm, and
- d = diameter of particle, μm.

Values of h/d^2 are given in Table 2.

7.1.1.2 Fill the buret with kerosine at the calibrating temperature, start a timing clock at the instant the kerosine in the buret drains past the zero line, and mark on the buret the levels reached by the draining kerosine for each of the time intervals, *t*, calculated as described above. At these marks, etch permanent lines and numbers on the buret indicating the corresponding diameters (Note 5). The construction and the graduation of the buret shall be such that at the temperature of calibration the time required for the kerosine to pass the permanent lines of the buret agrees with the calculated time of settling within 1 percent, except that the permissible variation shall be not less than 1 s.

NOTE 4—The density of portland cement does not vary greatly and in this work it is considered constant at 3.15. A variation of 0.15 from this value when substituted in Stokes' law gives a variation of 2.5 % in the diameter of the particle measured.

NOTE 5—By using the calibrated buret the apparatus may be used within the normal range of room temperatures without further correction, the change in rate of flow of the kerosine from the buret automatically compensating for change in viscosity of the suspension due to temperature. The temperature of the kerosine in the buret and that of the suspension should be kept the same within 0.5°C (1°F). This condition will ordinarily exist if the supply of kerosine is kept in the same room as the apparatus.

Care must be taken to ascertain that only clean kerosine is used in the buret, and, in addition, the capillary should be examined frequently to make sure that no small pieces of lint or other foreign material have become lodged in it.

7.1.2 *Calibration of No. 325 (45-μm) Sieve*—Calibration shall be made in accordance with Method C 430, basing the percentage sieve correction on the difference between the test residue obtained and the assigned residue value indicated by the electroformed sheet sieve fineness specified for the standard sample, expressed as a percentage of the test residue.

7.1.3 *Determination of the Proper Light Intensity, I_r*:

7.1.3.1 Fill the sedimentation tank to the mark with clear kerosine.

7.1.3.2 For a turbidimeter equipped with a digital-type microammeter with a range of 199.9 μA, place the sedimentation tank containing clear kerosine against the guides of the tank support in the turbidimeter. Set the light intensity so that the microammeter reads 100.0 μA. Readjust the light intensity until equilibrium is established at this reading. Place the light retarding filter in the path of the light beam. When equilibrium is established, record this meter reading as I_r. This meter reading becomes the reference value for the intensity of the light. Meter readings are also taken at the beginning and end of

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:17 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

each test through the light retarding filter alone to check the requirements of 8.3.8.

7.1.3.3 For a turbidimeter equipped with a D'Arsonval-type microammeter, place the sedimentation tank containing clear kerosine against the guides of the turbidimeter. Set the light intensity so that the microammeter reads 50.0 μA with the light retarding filter removed from the light path. Readjust the light intensity until equilibrium is established at this reading. Connect resistors or resistor combinations as indicated in Fig. 1 so that the meter reading is reduced to an equilibrium value between 23.0 and 25.0 μA. Increase the light intensity until the equilibrium light reading obtained between 23.0 and 25.0 μA is exactly doubled. Readjust the light intensity until the equilibrium is established at this doubled meter reading level. Place the light-retarding filter in the path of the light beam. Remove the resistors from the meter circuit. When equilibrium is established, record this meter reading as I_r. This becomes the reference value for the intensity of the light. Adjust the rheostats at the beginning of each test to give this meter reading through the filter plus the tank of clear kerosine. This meter reading corresponds to a meter reading of 100.0 μA through the tank containing clear kerosine with the light filter removed from the light path. Meter readings are also taken at the beginning and at the end of each test through the light retarding filter alone to check the requirements of 8.3.8.

NOTE 6—A half-watt carbon resistor preferably with 5 % tolerance limits can be used to obtain the desired meter readings. The shunt resistor or resistor combination as shown in Fig. 1 shall have a resistance value between 85 and 100 % of the value of the internal resistance of the meter as printed on the card in the meter cover. The series resistor shall have a resistance value equal to the difference between the internal resistance of the meter and the calculated resistance of the meter and shunt combination.

NOTE 7—A less exact but still acceptable procedure for determining a meter setting that corresponds to a current of 100.0 μA through the meter with the light filter removed from the light path can be achieved by eliminating the series resistor in the meter circuit. The internal resistance of the photocell is sufficiently large to cause only a minor error of approximately 0.5 % in the desired setting when the series resistor is omitted from the circuit.

7.1.3.4 *Example*—If the internal resistance of the meter is 90 Ω, and the meter is shunted with a 470-Ω resistor in parallel with a 100 Ω resistor, the combined resistance of the meter and shunts would be reduced to 43 Ω. This would reduce the meter reading from 50.0 μA to a calculated value of 23.9 μA.

7.1.4 *Determination of the Value of K in the Specific Surface Equation*—Using the regular procedure in 8.1-8.3; and with the light adjusted in accordance with the appropriate procedure in 7.1.3, make a specific surface determination on the current lot of National Institute of Standards and Technology's Reference Material No. 114.[6] Determine the value of *K* in the specific surface equation in 10.1.1 by dividing the assigned specific surface of the standard sample by the value obtained for the expression in brackets [ ]. Repeat this calibration procedure twice more. Use the average of the three results (Note 8) obtained for the value of *K* during calibration in specific surface equation in 10.1.1.

7.1.5 *Frequency of Calibration*—The turbidimeter apparatus shall have been calibrated within 6 months prior to testing a cement sample.

NOTE 8—The three individual values of *K* determined during calibration should not vary from the average value by more than 1.5 %.

8. Procedure

8.1 *Sieve Determination*—Make a No. 325 (45-μm) sieve determination on a 1-g sample of cement in accordance with the procedure stated in Test Method C 430. Record the percentage (corrected) of cement passing the sieve as *r*.

8.2 *Preparation of the Suspension*:

8.2.1 *Dispersion of the Sample*—Place the cement sample in a test tube together with 10 to 15 mL of kerosine and 5 drops of dispersing agent—oleic acid or aged linseed oil (Note 9). Stir the mixture for 1 min, using the apparatus described in 4.6, and then transfer to the sedimentation tank. Wash the stirring apparatus and the tube with clear kerosine, which is then added together with additional clear kerosine until the total volume of the suspension in the tank is 335 mL (Note 10).

NOTE 9—The oleic acid, if used, shall be of USP grade. The aged linseed oil, if used, shall have a density in the range from 0.948 to 0.953 Mg/m^3 (g/cm^3). These dispersing agents have slight or no effect on the viscosity of the kerosine. Each of these dispersing agents changes with age or with exposure to heat and light—hence should be kept in well-stoppered, dark-glass bottles. Dropping bottles should be emptied, thoroughly cleaned, dried, and refilled periodically. Where conditions are such that poor dispersion is obtained with oleic acid or when foaming of the suspension occurs (possibly due to traces of water in the kerosine) aged linseed oil shall be used as the dispersing agent. The same dispersing agent shall be used for both the instrument calibration and the fineness determination.

NOTE 10—Since it is important that the level of the liquid in the tank coincide with the zero mark on the scale of the instrument (see 4.2.7), it is correspondingly important that the volume of the suspension be close to 335 mL, as specified. This may be accomplished by the use of a flask, calibrated to deliver 335 mL, from which all the kerosine used in making up a suspension is taken; or a point gage may be used, consisting essentially of a flat plate approximately 50 by 63 mm (2 by 2½ in.), to the center of which is attached vertically a metal pin of such length that, when the plate is placed in position on top of the tank, the point of the pin is at the 335-mL level. Either of these methods should ensure the position of the liquid level within a few tenths of a millimetre.

8.2.2 *Agitation of the Suspension*—Just before placing the tank in the path of the light beam, agitate the contents to effect a uniformity of the suspension. Cover the tank with a ground-glass cover and oscillate 180° about a horizontal axis through the center of the tank, turning the tank upside down and back again to its original upright position approximately once each second for about 1 min (Note 11). Take care to prevent loss of kerosine (Note 12). The suspension is then ready to place in its proper position in the path of the light beam.

NOTE 11—The procedure described for oscillating the suspension shall be carefully followed. The procedure used in shaking a cocktail shall not be employed.

NOTE 12—The lid to the tank shall fit so that no kerosine drains down the outside faces of the tank. The faces of the glass tank shall be clean when the suspension is added, and care shall be taken to avoid the necessity of cleaning the faces until the determination is complete.

www.technobetar.ir

8.3 *Operation of Turbidimeter*—Operate the turbidimeter apparatus in accordance with the following procedure:

8.3.1 With retarding filter and sedimentation tank containing approximately 100 mL of clear kerosine in the light path, adjust the light to the intensity, I_r, as determined in 7.1.3 by taking repeated readings at 1-min intervals until an unchanging value indicates that the lamp and the photoelectric cell are in equilibrium. Remove the tank, check, and record the intensity of the lamp.

NOTE 13—To protect the microammeter, the lamp shall be turned on only with a suspension or the retarding filter in position to reduce the light intensity to a value within the range of the microammeter. A freshly charged storage battery should be momentarily short-circuited to reduce the voltage to constant value. If the microammeter indication continues to fluctuate, look for loose connections in the lamp and photoelectric cell circuits, see that the rheostat contacts are clean, and make certain that the lamp, socket, and reflector are rigidly fixed in their mounting.

8.3.2 Weigh the sample of cement in the appropriate amount and record the weight to the nearest 0.0002 g. Prepare a suspension in accordance with 8.2.

8.3.3 Place the shelf level pointer at the 30–50 µm position.

8.3.4 Fill the buret to the predetermined height with kerosine from the same lot and at the same temperature as the kerosine used in the suspension, and start oscillation of the tank containing the suspension in accordance with 8.2.2. Continue the oscillation until the kerosine drains to the zero line on the buret; then stop the agitation. Immediately place the tank in position in the path of the light beam.

8.3.5 Immediately remove the retarding filter from the light path and close the cabinet door.

8.3.6 Read the microammeter to the nearest 0.1 µA at the instant the kerosine in the buret drains past marks 50, 45, 40, 35, and 30.

8.3.7 Raise the shelf successively to the marks 25, 20, 15, 10, and 7.5 on the pointer scale, reading the microammeter at each position as the kerosine drains past the corresponding mark on the buret.

8.3.8 Lower the shelf to the 30–50 µm position. Replace the filter in the path of the light beam, remove the tank, and check the intensity of the lamp. If the microammeter indication has shifted more than 0.3 µA from the initial setting through the filter alone, the test must be repeated.

9. Data Recording

9.1 The form shown in Table 4 is suggested for the recording of turbidimeter data and for the calculation of specific surface.

10. Calculation

10.1 *Calculation of Specific Surface*:

10.1.1 Calculate the turbimetric specific surface as follows:

$$S = K\left[\frac{r(2 - \log I_{50})}{1.5 + 0.75 \log I_{7.5} + \log I_{10} + \log I_{15} \ldots + \log I_{45} - 9.5 \log I_{50}}\right] \quad (2)$$

TABLE 4 Illustrative Form for Recording Turbidimeter Test Data and Calculation of Specific Surface

NOTE—Values shown are for purpose of illustration only.

Sample identification	sample X
Passing 45-µm (No. 325) sieve, *r*, corrected, *T*	90.4
Calibration factor, *K*	33.9
Meter reading through filter alone, µA:	
Before test	17.5
After test	17.5
Weight of sample tested, g	0.25

Particle Size, µm	*I*, µA		log *I*	
50	17.3		...	1.238[A]
45	17.4		1.241	
40	17.6		1.246	
35	17.9		1.253	
30	18.4		1.265	
25	19.1		1.281	
20	20.1		1.303	
15	21.6		1.334	
10	23.9		1.378	
7.5	25.6		...	1.408[A]
	0.75	× 1.408 =	1.056	
			1.500	
		Sum =	12.857	
		9.5 × 1.238 =	11.761	
		Difference =	1.096	
$S = (33.9 \times 90.4 \times 0.762)/1.096 = 2131$ cm²/g (Round to 2130 cm²/g or 213 m²/kg)				

[A] For convenience in calculation, log I_{50} and log $I_{7.5}$ are recorded in a separate column.

where:

S = specific surface of the sample, m²/kg,
K = calibration factor as determined in 7.1.4
r = corrected weight percent of sample passing the 45-µm (No. 325) sieve (Note 14), and $I_{7.5}$, I_{10}, I_{15}..., I_{50} = microammeter readings, µA, that correspond to the particle diameters 7.5, 10, 15 ⋯, 50 µm.

NOTE 14—The value of K as determined in 7.1.3 applies only to a material having the density of portland cement (approximately 3.15 Mg/m³ or g/cm³). For any other material, the corresponding value must be calculated for this factor which, in the derivation of the formula, varies inversely as the density of the particles (g/cm³).

10.1.2 To calculate the specific surface values in square metres per kilogram, multiply the surface area in cm²/g by the factor of 0.1.

10.1.3 Round values in cm²/g to the nearest 10 units (in m²/kg to the nearest unit).

10.2 *Specific Surface From First Turbidity Reading I_{50}*—This test method may be used for successive determinations from the same plant, provided that the same size test samples are used and that there is no great change in fineness, color, or other properties of the cement. Under these conditions the specific surface of a sample may be calculated from the first turbidity reading, I_{50}, by using the following equation:

$$S = c(2 - \log I_{50}) \quad (3)$$

where:

S = specific surface of the sample, m²/kg,
I_{50} = microammeter reading corresponding to particle diameter of 50 µm, and
c = transmittancy constant for the particular plant.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:17 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 15—The transmittancy constant, *c*, may be evaluated by substituting in the above equation known values of *S* and $2 - \log I_{50}$ as determined from a complete turbidimeter test. The average of not less than five values of *c*, as determined from complete tests, should be used in the above equation.

10.3 If fineness of a sample as determined in accordance with 10.2 fails to conform with the specification requirements for fineness, a retest shall be made using the complete procedure in 8.3, 9.1, and 10.1.

11. Precision and Bias

11.1 *Single-Operator Precision*—The single-operator coefficient of variation has been found to be 2.6 % (Note 16). Therefore, results of two properly conducted tests by the same operator, on the same sample should not differ by more than 7.3 % (Note 13) of their average.

11.2 *Multilaboratory Precision*—The multilaboratory coefficient of variation has been found to be 3.8 % (Note 16). Therefore, results of two different laboratories on identical samples of a material should not differ from each other by more than 10.6 % (Note 16) of their average.

NOTE 16—These numbers represent, respectively, the (D1S %) and (D2S %) limits as described in Practice C 670.

11.3 Since there is no accepted reference material suitable for determining any bias that may be associated with this test method, no statement on bias is being made.

Designation: C 117 – 04

Standard Test Method for Materials Finer than 75-μm (No. 200) Sieve in Mineral Aggregates by Washing[1]

This standard is issued under the fixed designation C 117; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the determination of the amount of material finer than a 75-μm (No. 200) sieve in aggregate by washing. Clay particles and other aggregate particles that are dispersed by the wash water, as well as water-soluble materials, will be removed from the aggregate during the test.

1.2 Two procedures are included, one using only water for the washing operation, and the other including a wetting agent to assist the loosening of the material finer than the 75-μm (No. 200) sieve from the coarser material. Unless otherwise specified, Procedure A (water only) shall be used.

1.3 The values stated in SI units are to be regarded as the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 702 Practice for Reducing Field Samples of Aggregate to Testing Size

D 75 Practice for Sampling Aggregates

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

2.2 *AASHTO Standard:*

T11 Method of Test for Amount of Material Finer than 0.075-mm Sieve in Aggregate[3]

3. Summary of Test Method

3.1 A sample of the aggregate is washed in a prescribed manner, using either plain water or water containing a wetting agent, as specified. The decanted wash water, containing suspended and dissolved material, is passed through a 75-μm (No. 200) sieve. The loss in mass resulting from the wash treatment is calculated as mass percent of the original sample and is reported as the percentage of material finer than a 75-μm (No. 200) sieve by washing.

4. Significance and Use

4.1 Material finer than the 75-μm (No. 200) sieve can be separated from larger particles much more efficiently and completely by wet sieving than through the use of dry sieving. Therefore, when accurate determinations of material finer than 75 μm in fine or coarse aggregate are desired, this test method is used on the sample prior to dry sieving in accordance with Test Method C 136. The results of this test method are included in the calculation in Test Method C 136, and the total amount of material finer than 75 μm by washing, plus that obtained by dry sieving the same sample, is reported with the results of Test Method C 136. Usually, the additional amount of material finer than 75 μm obtained in the dry sieving process is a small amount. If it is large, the efficiency of the washing operation should be checked. It could also be an indication of degradation of the aggregate.

4.2 Plain water is adequate to separate the material finer than 75 μm from the coarser material with most aggregates. In some cases, the finer material is adhering to the larger particles, such as some clay coatings and coatings on aggregates that have been extracted from bituminous mixtures. In these cases, the fine material will be separated more readily with a wetting agent in the water.

5. Apparatus and Materials

5.1 *Balance*—A balance or scale readable and accurate to 0.1 g or 0.1 % of the test load, whichever is greater, at any point within the range of use.

5.2 *Sieves*—A nest of two sieves, the lower being a 75-µm (No. 200) sieve and the upper a 1.18-mm (No. 16) sieve, both conforming to the requirements of Specification E 11.

5.3 *Container*—A pan or vessel of a size sufficient to contain the sample covered with water and to permit vigorous agitation without loss of any part of the sample or water.

5.4 *Oven*—An oven of sufficient size, capable of maintaining a uniform temperature of 110 ± 5 °C (230 ± 9 °F).

5.5 *Wetting Agent*—Any dispersing agent, such as liquid dishwashing detergents, that will promote separation of the fine materials.

NOTE 1—The use of a mechanical apparatus to perform the washing operation is not precluded, provided the results are consistent with those obtained using manual operations. The use of some mechanical washing equipment with some samples may cause degradation of the sample.

6. Sampling

6.1 Sample the aggregate in accordance with Practice D 75. If the same test sample is to be tested for sieve analysis according to Test Method C 136, comply with the applicable requirements of that test method.

6.2 Thoroughly mix the sample of aggregate to be tested and reduce the quantity to an amount suitable for testing using the applicable methods described in Practice C 702. If the same test sample is to be tested according to Test Method C 136, the minimum mass shall be as described in the applicable sections of that method. Otherwise, the mass of the test sample, after drying, shall conform with the following:

Nominal Maximum Size	Minimum Mass, g
4.75 mm (No. 4) or smaller	300
Greater than 4.75 mm (No. 4) to 9.5 mm (⅜ in.)	1000
Greater than 9.5 mm (⅜ in.) to 19.0 mm (¾ in.)	2500
Greater than 19.0 mm (¾ in.)	5000

7. Selection of Procedure

7.1 Procedure A shall be used, unless otherwise specified by the Specification with which the test results are to be compared, or when directed by the agency for which the work is performed.

8. Procedure A—Washing with Plain Water

8.1 Dry the test sample in the oven to constant mass at a temperature of 110 ± 5 °C (230 ± 9 °F). Determine the mass to the nearest 0.1 % of the mass of the test sample.

8.2 If the applicable specification requires that the amount passing the 75-µm (No. 200) sieve shall be determined on a portion of the sample passing a sieve smaller than the nominal maximum size of the aggregate, separate the sample on the designated sieve and determine the mass of the material passing the designated sieve to 0.1 % of the mass of this portion of the test sample. Use this mass as the original dry mass of the test sample in 10.1.

NOTE 2—Some specifications for aggregates with a nominal maximum size of 50 mm or greater, for example, provide a limit for material passing the 75-µm (No. 200) sieve determined on that portion of the sample passing the 25.0-mm sieve. Such procedures are necessary since it is impractical to wash samples of the size required when the same test sample is to be used for sieve analysis by Test Method C 136.

8.3 After drying and determining the mass, place the test sample in the container and add sufficient water to cover it. No detergent, dispersing agent, or other substance shall be added to the water. Agitate the sample with sufficient vigor to result in complete separation of all particles finer than the 75-µm (No. 200) sieve from the coarser particles, and to bring the fine material into suspension. Immediately pour the wash water containing the suspended and dissolved solids over the nested sieves, arranged with the coarser sieve on top. Take care to avoid, as much as feasible, the decantation of coarser particles of the sample.

8.4 Add a second charge of water to the sample in the container, agitate, and decant as before. Repeat this operation until the wash water is clear.

NOTE 3—If mechanical washing equipment is used, the charging of water, agitating, and decanting may be a continuous operation.

8.5 Return all material retained on the nested sieves by flushing to the washed sample. Dry the washed aggregate in the oven to constant mass at a temperature of 110 ± 5 °C (230 ± 9 °F) and determine the mass to the nearest 0.1 % of the original mass of the sample.

NOTE 4—Following the washing of the sample and flushing any material retained on the 75-µm (No. 200) sieve back into the container, no water should be decanted from the container except through the 75-µm sieve, to avoid loss of material. Excess water from flushing should be evaporated from the sample in the drying process.

9. Procedure B—Washing Using a Wetting Agent

9.1 Prepare the sample in the same manner as for Procedure A.

9.2 After drying and determining the mass, place the test sample in the container. Add sufficient water to cover the sample, and add wetting agent to the water (Note 5). Agitate the sample with sufficient vigor to result in complete separation of all particles finer than the 75-µm (No. 200) sieve from the coarser particles, and to bring the fine material into suspension. Immediately pour the wash water containing the suspended and dissolved solids over the nested sieves, arranged with the coarser sieve on top. Take care to avoid, as much as feasible, the decantation of coarser particles of the sample.

NOTE 5—There should be enough wetting agent to produce a small amount of suds when the sample is agitated. The quantity will depend on the hardness of the water and the quality of the detergent. Excessive suds may overflow the sieves and carry some material with them.

9.3 Add a second charge of water (without wetting agent) to the sample in the container, agitate, and decant as before. Repeat this operation until the wash water is clear.

9.4 Complete the test as for Procedure A.

10. Calculation

10.1 Calculate the amount of material passing a 75-µm (No. 200) sieve by washing as follows:

$$A = [(B - C)/B] \times 100 \quad (1)$$

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:20 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

where:

A = percentage of material finer than a 75-µm (No. 200) sieve by washing,
B = original dry mass of sample, g, and
C = dry mass of sample after washing, g.

11. Report

11.1 Report the following information:

11.1.1 Report the percentage of material finer than the 75-µm (No. 200) sieve by washing to the nearest 0.1 %, except if the result is 10 % or more, report the percentage to the nearest whole number.

11.1.2 Include a statement as to which procedure was used.

12. Precision and Bias

12.1 *Precision*—The estimates of precision of this test method listed in Table 1 are based on results from the AASHTO Materials Reference Laboratory Proficiency Sample Program, with testing conducted by this test method and AASHTO Method T 11. The significant differences between the methods at the time the data were acquired is that Method T 11 required, while Test Method C 117 prohibited, the use of a wetting agent. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories.

12.1.1 The precision values for fine aggregate in Table 1 are based on nominal 500-g test samples. Revision of this test method in 1994 permits the fine aggregate test sample size to be 300 g minimum. Analysis of results of testing of 300-g and 500-g test samples from Aggregate Proficiency Test Samples 99 and 100 (Samples 99 and 100 were essentially identical) produced the precision values in Table 2, which indicates only minor differences due to test sample size.

NOTE 6—The values for fine aggregate in Table 1 will be revised to reflect the 300-g test sample size when a sufficient number of Aggregate Proficiency Tests have been conducted using that sample size to provide reliable data.

12.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is made.

TABLE 1 Precision

	Standard Deviation (1s)[A], %	Acceptable Range of two Results (d2s)[A], %
Coarse Aggregate[B]		
Single-Operator Precision	0.10	0.28
Multilaboratory Precision	0.22	0.62
Fine Aggregate[C]		
Single-Operator Precision	0.15	0.43
Multilaboratory Precision	0.29	0.82

[A] These numbers represent the (1s) and (d2s) limits as described in Practice C 670.

[B] Precision estimates are based on aggregates having a nominal maximum size of 19.0 mm (¾ in.) with less than 1.5% finer than the 75-µm (No. 200) sieve.

[C] Precision estimates are based on fine aggregates having 1.0 to 3.0% finer than the 75-µm (No. 200) sieve.

13. Keywords

13.1 aggregate; coarse aggregate; fine aggregate; grading; loss by washing; 75 µm (No. 200) sieve; size analysis

TABLE 2 Precision Data for 300-g and 500-g Test Samples

Fine Aggregate Proficiency Sample				Within Laboratory		Between Laboratory	
Test Result	Sample Size	No. of Labs	Average	1s	d2s	1s	d2s
AASHTO T11/ASTM C117	500 g	270	1.23	0.08	0.24	0.23	0.66
Total material passing the No. 200 sieve by washing (%)	300 g	264	1.20	0.10	0.29	0.24	0.68

Designation: C 123 – 04

American Association State
Highway and Transportation Standard
AASHTO No.: T 113

Standard Test Method for Lightweight Particles in Aggregate[1]

This standard is issued under the fixed designation C 123; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the percentage of lightweight particles in aggregate by means of sink-float separation in a heavy liquid of suitable specific gravity.

1.2 The values given in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For a specific hazard statement, see 6.1.4.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 33 Specification for Concrete Aggregates

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 127 Test Method for Density, Relative Density (Specific Gravity), and Absorption of Coarse Aggregate

C 128 Test Method for Density, Relative Density (Specific Gravity), and Absorption of Fine Aggregate

C 702 Practice for Reducing Field Samples of Aggregate to Testing Size

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

D 75 Practice for Sampling Aggregates

D 3665 Practice for Random Sampling of Construction Materials

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

E 100 Specification for ASTM Hydrometers

3. Terminology

3.1 For definitions of terms used in this test method, refer to Terminology C 125.

4. Significance and Use

4.1 This test method is used to determine conformance with provisions of Specification C 33 pertaining to the amount of lightweight material in fine and coarse aggregates. A heavy liquid with a specific gravity of 2.0 is used to separate particles which may be classified as coal or lignite. Heavier liquids are to be used to check the percentages of other lightweight particles such as chert and shale having a specific gravity less than 2.40.

4.2 The test method is useful in identifying porous aggregate particles in research activities or in petrographic analyses.

5. Apparatus

5.1 *Balances*—For determining the mass of fine aggregates, a balance having a capacity of not less than 500 g, sensitive to at least 0.1 g: for determining the mass of coarse aggregate, a balance having a capacity of not less than 5000 g, sensitive to at least 1 g. Both balances shall conform to the accuracy criterion of the applicable sections of Specification C 1005.

5.2 *Containers* suitable for drying the aggregate sample, and containers suitable for holding the heavy liquid during the sink-float separation.

5.3 *Skimmer*—A piece of 300-μm (No. 50) sieve cloth, conforming to Specification E 11, of suitable size and shape for separating the floating particles from the heavy liquid.

5.4 *Hot Plate or Oven*.

5.5 *Sieves*, 300-μm (No. 50) and 4.75-mm (No. 4) conforming to Specification E 11.

5.6 *Specific Gravity Measurement*—A hydrometer conforming to the physical requirement sections for individual hydrometers of Specification E 100, or a suitable combination of graduated glassware and balance capable of measuring the liquid specific gravity within ±0.01.

6. Heavy Liquid

6.1 The heavy liquid shall consist of one of the following (see 6.1.4):

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved July 1, 2004. Published July 2004. Originally approved in 1936. Last previous edition approved in 2003 as C 123 – 03.

www.technobetar.ir

6.1.1 A solution of zinc chloride in water (for a specific gravity up to about 2.0).

6.1.2 A mixture of kerosene with 1,1,2,2-tetrabromoethane, proportioned to produce desired specific gravities. (1,1,2,2-tetrabromoethane has a specific gravity of about 2.95) (see Note 1).

6.1.3 A solution of zinc bromide in water (for a specific gravity up to about 2.4).

6.1.4 **Warning**—The chemicals listed in 6.1.2 are toxic, both by absorption through the skin and by inhalation. They shall be used only in a hood (preferably of the down-draft type) or out-of-doors, and care shall be taken to avoid inhalation or contact with the eyes or skin. There is no particular hazard from the fumes of zinc-chloride solution (6.1.1) or zinc-bromide solution (6.1.3) but goggles and gloves shall be worn to prevent contact with the eyes or skin.

6.2 The specific gravity of the heavy liquid shall be maintained within ±0.01 of the specified value at all times during the test.

NOTE 1—1,1,2,2-tetrabromoethane is highly toxic and extremely dangerous to use and when heated emits highly toxic fumes of bromine, hydrogen bromide, and carbonyl bromide. It should be handled only by personnel trained and qualified in its use. Its storage should be in a secured location.

7. Sampling

7.1 Secure a field sample of the aggregate in accordance with Practices D 75 and D 3665. Reduce the sample to test portion size in accordance with Practice C 702.

7.2 Dry the test portion to constant mass at a temperature of 110 ± 5 °C (230 ± 9 °F) before testing and sieve to remove the undersize material as specified in 8.1 and 8.2. The minimum size of the test specimen shall be as follows:

Nominal Maximum Size of Aggregate (square-opening sieves)		Minimum Mass of Sample, g
4.75 mm or smaller	(No. 4 or smaller)	200
9.5 mm	(⅜ in.)	1 500
12.5 to 19.0 mm	(½ to ¾ in.)	3 000
25 to 37.5 mm	(1 to 1½ in.)	5 000
50 mm or larger	(2 in. or larger)	10 000

8. Procedure

8.1 *Fine Aggregate*—Allow the dried test specimen of fine aggregate to cool to room temperature and then sieve over a 300-µm (No. 50) sieve until less than 1 % of the retained material passes the sieve in 1 min of continuous sieving. Determine the mass of the material coarser than the 300-µm (No. 50) sieve to the nearest 0.1 g, and bring this material to a saturated-surface-dry condition by means of the procedure specified in Test Method C 128 (see 8.1.1), then introduce it into the heavy liquid (see 6.1.4) in a suitable container. The volume of liquid shall be at least three times the absolute volume of the aggregate. Pour the liquid, including the floating particles, into a second container, passing it through the skimmer, taking care that only the floating particles are poured off with the liquid and that none of the fine aggregate that sinks is decanted onto the skimmer. Return to the first container the liquid that has been collected in the second container and, after further agitation of the sample by stirring, repeat the decanting process just described until the specimen is free of floating particles. Wash the decanted particles contained on the skimmer in an appropriate solvent to remove the heavy liquid. Alcohol is appropriate for 1,1,2,2-tetrabromoethane and water for the zinc-chloride and zinc-bromide solutions. After the decanted particles have been washed, allow them to dry (see 8.1.2). Brush the dry decanted particles from the skimmer onto the balance pan and determine the mass to the nearest 0.1 g. If more precise determination is required, the decanted particles shall be dried to constant mass at 110 ± 5 °C to determine the value of W_1 used for the calculation in 9.1 (see 8.1.3).

8.1.1 If the absorption as determined in accordance with Test Method C 128 is known, the fine aggregate is permitted to be prepared for test by adding to a known mass of dry sand the amount of water it will absorb, mixing thoroughly, and permitting the sand to stand in a covered pan for 30 min before use.

8.1.2 Drying shall take place in the hood or out-of-doors if other than zinc chloride or zinc bromide is used. An oven or hot plate is permitted to be used to accelerate the drying providing that it is done in the hood or that the oven is forced-air ventilated to the outside of the building and that a temperature of 115 °C is not exceeded.

8.1.3 Normally the discrepancy between oven-dry mass and saturated-surface-dry mass of the decanted particles will not significantly affect the calculated percentage of light-weight particles.

8.2 *Coarse Aggregate*—Allow the dried test specimen of coarse aggregate to cool to room temperature and sieve over a 4.75-mm (No. 4) sieve. Determine the mass of the material coarser than the 4.75-m (No. 4) sieve to the nearest 1 g, and bring to a saturated-surface-dry condition by means of the procedure specified in Test Method C 127; then introduce it into the heavy liquid in a suitable container. The volume of liquid shall be at least three times the absolute volume of the aggregate. Using the skimmer, remove the particles that float to the surface, and save them. Repeatedly agitate the remaining particles, and remove the floating particles until no additional particles rise to the surface. Wash the particles which are skimmed off in an appropriate solvent to remove the heavy liquid (see 8.1). After the heavy liquid has been removed, allow the particles to dry (see 8.1.2). Determine the mass of the decanted particles to the nearest 1 g. If a more precise determination is required, dry the particles to constant mass at 110 ± 5 °C to determine the value of W_1 used for the calculation in 9.1 (see 8.1.3).

9. Calculation

9.1 Calculate the percentage by mass of lightweight particles (particles floating on the heavy liquid) as follows:

For fine aggregate:

$$L = (W_1/W_2) \times 100 \quad (1)$$

For coarse aggregate:

$$L = (W_1/W_3) \times 100 \quad (2)$$

where:

L = percentage by mass of lightweight particles,
W_1 = dry mass of particles that float,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:02:22 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

W_2 = dry mass of portion of specimen coarser than 300-µm (No. 50) sieve, and

W_3 = dry mass of portion of specimen coarser than the 4.75-mm (No. 4) sieve.

10. Report

10.1 Report the following information:

10.1.1 Identification of the aggregate as to source, type and nominal maximum size,

10.1.2 The mass of the test sample used,

10.1.3 Type and specific gravity of heavy liquid used for the test, and

10.1.4 Percentage by mass of lightweight particles rounded to nearest 0.1 %.

11. Precision and Bias

11.1 *Precision*—No interlaboratory or intralaboratory studies have been conducted using this test method to determine precision indices. The committee is seeking pertinent data from users of the test method.

11.2 *Bias*—Bias of the test method may be estimated by running separate specific gravity and absorption determinations on individual particles of the separate sink, or float fractions, or both.

12. Keywords

12.1 aggregate; heavy liquid; lightweight particles

Designation: C125 – 09a

Standard Terminology Relating to Concrete and Concrete Aggregates[1]

This standard is issued under the fixed designation C125; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This standard is a compilation of general terminology related to hydraulic cement concrete, concrete aggregates, and other materials used in or with hydraulic cement concrete.

1.2 Other terminology under the jurisdiction of Committee C09 is included in two specialized standards. Terms relating to constituents of concrete aggregates are defined in Descriptive Nomenclature C294. Terms relating to constituents of aggregates for radiation-shielding concrete are defined in Descriptive Nomenclature C638.

1.3 Related terminology for hydraulic cement is included in Terminology C219. Additional related terminology can be found in ACI 116R.

1.4 When a term is used in an ASTM standard for which Committee C09 is responsible, it is included herein only if used in more than one Committee C09 standard.

1.5 Definitions that are adopted from those published by other ASTM committees or other standards organizations are identified with the ASTM designation (for example, Terminology C219) or with the abbreviation of the name of the other organization.

1.6 A definition in this standard is a statement of the meaning of a word or word group expressed in a single sentence with additional information included in notes or discussion.

NOTE 1—The subcommittee responsible for this standard will review definitions on a five-year basis to determine if the definition is still appropriate as stated. Revisions will be made when determined necessary. The year shown in parentheses at the end of a definition indicates the year the definition or revision to the definition was approved. A letter R and a year indicate when the definition was reviewed. No date indicates the term has not yet been reviewed.

308 Practice for Curing Concrete
116R Cement and Concrete Terminology

3. Terms and Their Definitions

absorption, *n*—the process by which a liquid is drawn into and tends to fill permeable pores in a porous solid body; also, the increase in mass of a porous solid body resulting from the penetration of a liquid into its permeable pores. (R 2008)

DISCUSSION—In the case of concrete and concrete aggregates, unless otherwise stated, the liquid involved is water, the increase in mass is that which does not include water adhering to the outside surface, the increase in mass is expressed as a percentage of the dry mass of the body and the body is considered to be "dry" when it has been treated by an appropriate process to remove uncombined water, such as drying to constant mass at a temperature between 100 and 110 °C.

admixture, *n*—a material other than water, aggregates, hydraulic cementitious material, and fiber reinforcement that is used as an ingredient of a cementitious mixture to modify its freshly mixed, setting, or hardened properties and that is added to the batch before or during its mixing. (R 2008)
accelerating admixture, n—admixture that accelerates the setting and early strength development of concrete. (C494/C494M)
air-entraining admixture, n—admixture that causes the development of a system of microscopic air bubbles in concrete or mortar during mixing.
chemical admixture, n—a nonpozzolanic admixture in the form of a liquid, suspension, or water-soluble solid.
mineral admixture, n—deprecated term.

DISCUSSION—This term has been used to refer to different types of water insoluble, finely divided materials such as pozzolanic materials, cementitious materials, and aggregate. These materials are not similar, and it is not useful to group them under a single term. The name of the specific material should be used, for example, use "pozzolan," "ground granulated blast-furnace slag," or "finely divided aggregate," as is appropriate.

retarding admixture, n—admixture that retards the setting of concrete. (C494/C494M)
water-reducing admixture, n—admixture that either increases the slump of freshly mixed mortar or concrete without increasing the water content or that maintains the slump with a reduced amount of water due to factors other than air entrainment.
water-reducing admixture, high-range, n—a water-reducing admixture capable of producing at least 12 % reduction of water content when tested in accordance with Specification C494/C494M and meeting the other relevant requirements of Specification C494/C494M.

aggregate, *n*—granular material, such as sand, gravel, crushed stone, or iron blast-furnace slag, used with a cementing medium to form hydraulic-cement concrete or mortar. (R 2008)
coarse aggregate, n—(1) aggregate predominantly retained on the 4.75-mm (No. 4) sieve; or *(2)* that portion of an aggregate retained on the 4.75-mm (No. 4) sieve.

DISCUSSION—The definitions are alternatives to be applied under differing circumstances. Definition *(1)* is applied to an entire aggregate either in a natural condition or after processing. Definition *(2)* is applied to a portion of an aggregate. Requirements for properties and grading should be stated in the specification.

fine aggregate, n—(1) aggregate passing the 9.5-mm (⅜-in.) sieve and almost entirely passing the 4.75-mm (No. 4) sieve and predominantly retained on the 75-μm (No. 200) sieve; or *(2)* that portion of an aggregate passing the 4.75-mm (No. 4) sieve and retained on the 75-μm (No. 200) sieve.

DISCUSSION—The definitions are alternatives to be applied under differing circumstances. Definition *(1)* is applied to an entire aggregate either in a natural condition or after processing. Definition *(2)* is applied to a portion of an aggregate. Requirements for properties and grading should be stated in the specifications.

heavyweight aggregate, n—see *high-density aggregate*.
high-density aggregate, n—aggregate with relative density greater than 3.3, such as: barite, magnetite, limonite, ilmenite, iron, or steel.
lightweight aggregate, n—see *low-density aggregate*.
low-density aggregate, n—aggregate with bulk density less than 1120 kg/m^3 (70 lb/ft^3), such as: pumice, scoria, volcanic cinders, tuff, and diatomite; expanded or sintered clay, shale, slate, diatomaceous shale, perlite, vermiculite, or slag; and end products of coal or coke combustion.
normal-density aggregate, n—aggregate that is neither high nor low density.

DISCUSSION—This term refers to aggregate with relative density typically ranging between 2.4 and 3.0, or with bulk density typically ranging between 1120 kg/m^3 (70 lb/ft^3) and 1920 kg/m^3 (120 lb/ft^3).

normalweight aggregate, n—see *normal-density aggregate*.

air content, *n*—the volume of air voids in cement paste, mortar, or concrete, exclusive of pore space in aggregate particles, usually expressed as a percentage of total volume of the paste, mortar, or concrete. (R 2008)

air-cooled blast-furnace slag—see **blast-furnace slag, air-cooled.**

air void—see **void, air.**

blast-furnace slag, *n*—the nonmetallic product, consisting essentially of silicates and aluminosilicates of calcium and other bases, that is developed in a molten condition simultaneously with iron in a blast furnace. (R 2008)

blast-furnace slag, air-cooled , *n*—the material resulting from solidification of molten blast-furnace slag under atmospheric conditions; subsequent cooling may be accelerated by application of water to the solidified surface. (R 2008)

blast-furnace slag, granulated, *n*—the glassy, granular material formed when molten blast-furnace slag is rapidly chilled, as by immersion in water. (R 2008)

bleeding, *n*—the autogenous flow of mixing water within, or its emergence from, newly placed concrete or mortar caused by the settlement of the solid materials within the mass, also called water gain. (R 2008)

bulk density, *n—of aggregate,* the mass of a unit volume of bulk aggregate material (the unit volume includes the volume of the individual particles and the volume of the

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

voids between the particles). (R 2008)

DISCUSSION—This term replaces the deprecated term **unit weight**—*of aggregate*.

bulk specific gravity, *n*—the ratio of the mass of a volume of a material (including the permeable and impermeable voids in the material, but excluding the voids between particles of the material) at a stated temperature to the mass of an equal volume of distilled water at a stated temperature. (R 2008)

bulk specific gravity *(saturated surface dry)***,** *n*—the ratio of the mass of a volume of a material including the mass of water within the pores in the material (but excluding the voids between particles) at a stated temperature, to the mass of an equal volume of distilled water at a stated temperature. (R 2008)

cellular concrete—see **concrete, cellular.**

cement, hydraulic, *n*—a cement that sets and hardens by chemical reaction with water and is capable of doing so under water. (R 2008)

cementitious material *(hydraulic)***,** *n*—an inorganic material or a mixture of inorganic materials that sets and develops strength by chemical reaction with water by formation of hydrates and is capable of doing so under water. (R 2008)

cementitious mixture, *n*—a mixture (mortar, concrete, or grout) containing hydraulic cement. (R 2008)

concrete, *n*—a composite material that consists essentially of a binding medium within which are embedded particles or fragments of aggregate; in hydraulic-cement concrete, the binder is formed from a mixture of hydraulic cement and water. (R 2008)

concrete, cellular, *n*—a lightweight hydraulic-cement concrete having a homogeneous void or cell structure attained using gas-forming chemicals or foaming agents. (R 2008)

concrete, fresh, *n*—concrete which possesses enough of its original workability so that it can be placed and consolidated by the intended methods. (R 2008)

concrete, hardened, *n*—concrete that has developed sufficient strength to serve some defined purpose or resist a stipulated loading without failure. (R 2008)

concrete, roller-compacted, RCC, *n*—concrete compacted while fresh by a roller, often a vibratory roller. (R 2008)

concrete, self-consolidating, SCC, *n*—concrete that can flow around reinforcement and consolidate under its own weight without additional effort and without exceeding specified limits of segregation. (R 2008)

DISCUSSION—Project specifications shall indicate the acceptable segregation based upon a specified test method. Although there currently are no ASTM test methods approved to define specified limits of segregation, they are under development; also, there are industry methods available to specifiers.

consistency, *n—of fresh concrete, mortar, or grout,* the relative mobility or ability to flow. (R 2008)

DISCUSSION—This characteristic of fresh cementitious mixtures is difficult to quantify and empirical test methods have been adopted to provide indicators of consistency. For example, the slump test described in Test Method C143/C143M is used for concrete, the flow table method described in Test Method C109/C109M is used for mortar, and the flow cone method described in Test Method C939 is used for grout.

consolidation, *n—of cementitious mixtures,* the process of increasing the density of a fresh cementitious mixture in a form, mold, or container by reducing the volume of voids. (2009)

DISCUSSION—Except for **self-consolidating concrete**, consolidation is accomplished by inputting mechanical energy, typically by rodding, tamping, tapping, vibration, or some combination of these actions. Specific apparatus and methods for consolidation are defined in the relevant C09 Standards.

crushed gravel—see **gravel, crushed.**

crushed stone—see **stone, crushed.**

curing, *n*—action taken to maintain moisture and temperature conditions in a freshly-placed cementitious mixture to allow hydraulic cement hydration and (if applicable) pozzolanic reactions to occur so that the potential properties of the mixture may develop (see ACI 308). (R 2008)

curing compound, *n*—a liquid that, when applied as a coating to the surface of newly-placed concrete, forms a membrane that retards the evaporation of water and, in the case of white pigmented compounds, reflects heat (see also **curing**). (R 2008)

D-cracking, *n—in concrete*, a series of cracks near to and roughly parallel to features such as joints, edges, and structural cracks.

density, *n*—mass per unit volume (preferred over deprecated term **unit weight**).

elongated piece *(of aggregate)***,** *n*—a particle of aggregate for which the ratio of the length to width of its circumscribing rectangular prism is greater than a specified value (see also **flat piece** (*of aggregate*)).

entrained air—see **void, air.**

entrapped air—see **void, air.**

expanded blast-furnace slag, *n*—the lightweight cellular material obtained by controlled processing of molten blast-furnace slag with water or water and other agents, such as steam or compressed air or both.

fibers, *n*—slender filaments, which may be discrete or in the form of bundles, networks, or strands of natural or manufactured materials, which can be distributed uniformly throughout a fresh cementitious mixture.

fineness modulus, *n—of aggregate*, a factor obtained by adding the percentages of material in the sample that is coarser than each of the following sieves (cumulative percentages retained), and dividing the sum by 100: 150-μm (No. 100), 300-μm (No. 50), 600-μm (No. 30), 1.18-mm (No. 16), 2.36-mm (No. 8), 4.75-mm (No. 4), 9.5-mm (⅜-in.), 19.0-mm (¾-in.), 37.5-mm (1½-in.), 75-mm (3-in.), 150-mm (6-in.).

flat piece *(of aggregate)***,** *n*—a particle of aggregate for which the ratio of the width to thickness of its circumscribing rectangular prism is greater than a specified value (see also **elongated piece** (*of aggregate*)).

fly ash, *n*—the finely divided residue that results from the combustion of ground or powdered coal and that is transported by flue gases from the combustion zone to the particle removal system.

fog room, *n*—a moist room in which the humidity is controlled by atomization of water. (see Specification C511)

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

fresh concrete—see **concrete, fresh.**

granulated blast-furnace slag—see **blast-furnace slag, granulated.**

gravel, *n*—coarse aggregate resulting from natural disintegration and abrasion of rock or processing of weakly bound conglomerate.

gravel, crushed, *n*—the product resulting from the artificial crushing of gravel with substantially all fragments having at least one face resulting from fracture.

grout, *n*—a cementitious mixture, with or without admixtures, that is used primarily to fill voids.

grout, hydraulic–cement, *n*—a grout made with hydraulic cement.

grout (nonshrink), hydraulic-cement, *n*—a hydraulic-cement grout that produces a volume that, when hardened under stipulated test conditions, is greater than or equal to the original installed volume, often used as a transfer medium between load-bearing members.

hardened concrete—see **concrete, hardened**.

hardening, *n*—gain of strength, and other properties, of a cementitious mixture as a result of hydration after final setting (for the definition of hydration, see Terminology C219).

hydraulic cement—see **cement, hydraulic**.

laitance, *n*—a layer of weak material derived from cementitious material and aggregate fines either: 1) carried by bleeding to the surface or to internal cavities of freshly placed concrete, or 2) separated from the concrete and deposited on the concrete surface or in internal cavities during placement of concrete under water.

lime-saturated water, *n—for curing test specimens*, water containing calcium hydroxide at saturation level and in contact with solid calcium hydroxide so that saturation is maintained.

manufactured sand—see **sand, manufactured**.

maturity, *n*—the extent of the development of a property of a cementitious mixture.

DISCUSSION—This term is usually used to describe the extent of relative strength development of concrete. However, the term can also be applied to the evolution of other properties which are dependent on the chemical reactions which occur in the cementitious materials. At any age, maturity is dependent on the curing history.

maturity function, *n*—a mathematical expression which uses the measured temperature history of a cementitious mixture during the curing period to calculate an index that is indicative of the maturity at the end of that period.

maturity index, *n*—an indicator of maturity which is calculated from the temperature history of the cementitious mixture by using a maturity function.

DISCUSSION—The calculated index is indicative of maturity provided there has been a sufficient supply of water for hydration or pozzolanic reaction of the cementitious materials during the time interval used in the calculation. Two widely used maturity indexes are the temperature-time factor and the equivalent age. See Practice C1074.

maximum size *(of aggregate)***,** *n*—in specifications for, or description of aggregate, the smallest sieve opening through which the entire amount of aggregate is required to pass.

moist room, *n*—an enclosed room for storage and curing of paste, mortar, and concrete specimens in which temperature and high relative humidity can be controlled within specified limits. (see Specification C511)

nominal maximum size *(of aggregate)***,** *n*—in specifications for, or description of aggregate, the smallest sieve opening through which the entire amount of the aggregate is permitted to pass.

DISCUSSION—Specifications on aggregates usually stipulate a sieve opening through which all of the aggregate may, but need not, pass so that a stated maximum proportion of the aggregate may be retained on that sieve. A sieve opening so designated is the *nominal maximum size* of the aggregate.

pozzolan, *n*—a siliceous or siliceous and aluminous material, which in itself possesses little or no cementitious value but will, in finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties.

*relative density***,** *n*—see **specific gravity**

rodding, *n*—consolidation of a fresh cementitious mixture by repeated insertion of a rod. (2009)

roller-compacted concrete, RCC—see **concrete, roller-compacted.**

sand, *n*—fine aggregate resulting from natural disintegration and abrasion of rock or processing of completely friable sandstone.

sand, manufactured, *n*—fine aggregate produced by crushing rock, gravel, iron blast-furnace slag, or hydraulic-cement concrete.

*saturated-lime water***,** *n*—see **lime-saturated water**.

segregation, *n*—the unintentional separation of the constituents of concrete or particles of an aggregate, causing a lack of uniformity in their distribution.

self-consolidating concrete, SCC—see **concrete, self-consolidating.**

setting, *n*—the process, due to chemical reactions, occurring after the addition of mixing water, that results in a gradual development of rigidity of a cementitious mixture.

shotcrete, *n*—a mortar or concrete that is projected pneumatically at high velocity onto a surface.

dry–mixture shotcrete, n—shotcrete in which most of the mixing water is added at the nozzle.

wet–mix shotcrete, n—shotcrete in which most of the ingredients, including water, are mixed prior to introduction into the delivery hose.

silica fume, *n*—very fine pozzolanic material, composed mostly of amorphous silica produced by electric arc furnaces as a by-product of the production of elemental silicon or ferro-silicon alloys (also known as condensed silica fume and microsilica). (C1240) (2009)

slump flow, *n*—the average diameter of the spread concrete mass, obtained from two measurements perpendicular to each other, after a self-consolidating concrete has ceased to flow during a slump-flow test.

DISCUSSION—Slump flow of self-consolidating concrete is measured using Test Method C1611/C1611M.

www.technobetar.ir

specific gravity, *n*—the ratio of mass of a volume of a material at a stated temperature to the mass of the same volume of distilled water at a stated temperature.

stability, *n—of self-consolidating concrete (SCC),* the ability of self-consolidating concrete to resist separation of the paste from the aggregates.

stone, crushed, *n*—the product resulting from the artificial crushing of rocks, boulders, or large cobblestones, substantially all faces of which have resulted from the crushing operation.

tamping, *n*—consolidation of a fresh cementitious mixture by repeated blows to the surface of the mixture. (2009)

tapping, *n*—striking the side of a mold to close voids in a fresh cementitious mixture created by rodding or an internal vibrator. (2009)

time of setting, *n*—the elapsed time from the addition of mixing water to a cementitious mixture until the mixture reaches a specified degree of rigidity as measured by a specific procedure.

DISCUSSION—Development of rigidity during setting is a gradual and continuous process, and the time of setting is defined arbitrarily in terms of a given test method. For cementitious mixtures, time of setting is usually defined as the elapsed time to attain a specified level of resistance to penetration by a probe. For example, the time of initial setting of concrete is determined by Test Method C403/C403M and is defined as the elapsed time, after initial contact of cement and water, for the mortar sieved from the concrete to reach a penetration resistance of 500 psi (3.5 MPa).

time of final setting (of concrete), n—the elapsed time, after initial contact of cement and water, required for the mortar sieved from the concrete to reach a penetration resistance of 4000 psi (27.6 MPa). (C403/C403M).

time of initial setting (of concrete), n—the elapsed time, after initial contact of cement and water, required for the mortar sieved from the concrete to reach a penetration resistance of 500 psi (3.5 MPa). (C403/C403M)

unit weight, *n—of aggregate*, mass per unit volume. (Deprecated term—use preferred term **bulk density**).

vibration, *n*—agitation of a fresh cementitious mixture by an internal or external vibrating device to assist in consolidating the mixture in a form, mold, or container. (2009)

void, air , *n*—a space in cement paste, mortar, or concrete filled with air; an entrapped air void is characteristically 1 mm or more in width and irregular in shape; an entrained air void is typically between 10 and 1000 μm in diameter and spherical or nearly so.

DISCUSSION—The content of the voids may include atmospheric air incorporated into the concrete during mixing of air or other gases released by chemical or other processes within the fresh concrete.

water-cement ratio, *n*—the ratio of the mass of water, exclusive only of that absorbed by the aggregates, to the mass of portland cement in concrete, mortar, or grout, stated as a decimal.

DISCUSSION—This term, abbreviated as *w/c*, is applicable only to cementitious mixtures in which the only cementitious material is portland cement. For cementitious mixtures containing blended hydraulic cement, or a combination of portland cement and separate addition of another cementitious material (such as a pozzolan), use the term **water-cementitious material ratio**.

water-cementitious material ratio, *n*—the ratio of the mass of water, exclusive only of that absorbed by the aggregates, to the mass of cementitious material (*hydraulic*) in concrete, mortar, or grout, stated as a decimal (see also **water-cement ratio**).

DISCUSSION—This term, abbreviated as *w/cm*, is applicable only to cementitious mixtures which contain cementitious material other than just portland cement, such as a blended hydraulic cement, or a combination of portland cement and separate addition of another cementitious material (such as a pozzolan). When portland cement is the only cementitious material contained in the cementitious mixture, use the term **water-cement ratio**.

workability, *n—of concrete*, that property determining the effort required to manipulate a freshly mixed quantity of concrete with minimum loss of homogeneity.

Designation: C 127 – 07

Standard Test Method for Density, Relative Density (Specific Gravity), and Absorption of Coarse Aggregate[1]

This standard is issued under the fixed designation C 127; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the average density of a quantity of coarse aggregate particles (not including the volume of voids between the particles), the relative density (specific gravity), and the absorption of the coarse aggregate. Depending on the procedure used, the density (kg/m^3 (lb/ft^3)) is expressed as oven-dry (OD), saturated-surface-dry (SSD), or as apparent density. Likewise, relative density (specific gravity), a dimensionless quantity, is expressed as OD, SSD, or as apparent relative density (apparent specific gravity). The OD density and OD relative density are determined after drying the aggregate. The SSD density, SSD relative density, and absorption are determined after soaking the aggregate in water for a prescribed duration.

1.2 This test method is used to determine the density of the essentially solid portion of a large number of aggregate particles and provides an average value representing the sample. Distinction is made between the density of aggregate particles as determined by this test method, and the bulk density of aggregates as determined by Test Method C 29/C 29M, which includes the volume of voids between the particles of aggregates.

1.3 This test method is not intended to be used with lightweight aggregates.

1.4 The values stated in SI units are to be regarded as the standard for conducting the tests. The test results for density shall be reported in either SI units or inch-pound units, as appropriate for the use to be made of the results.

1.5 The text of this test method references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this test method.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

prescribed period of time, but not including water adhering to the outside surface of the particles, expressed as a percentage of the dry mass.

3.1.2 *oven-dry (OD), adj—related to aggregate particles,* the condition in which the aggregates have been dried by heating in an oven at 110 ± 5 °C for sufficient time to reach a constant mass.

3.1.3 *saturated-surface-dry (SSD), adj—related to aggregate particles*, the condition in which the permeable pores of aggregate particle are filled with water to the extent achieved by submerging in water for the prescribed period of time, but without free water on the surface of the particles.

3.1.4 *density, n*—the mass per unit volume of a material, expressed as kilograms per cubic metre (pounds per cubic foot).

3.1.4.1 *density (OD), n*—the mass of oven dry aggregate per unit volume of aggregate particles, including the volume of permeable and impermeable pores within the particles, but not including the voids between the particles.

3.1.4.2 *density (SSD), n*—the mass of saturated-surface-dry aggregate per unit volume of the aggregate particles, including the volume of impermeable pores and permeable, water-filled pores within the particles, but not including the voids between the particles.

3.1.4.3 *apparent density, n*—the mass per unit volume of the impermeable portion of the aggregate particles.

3.1.5 *relative density (specific gravity), n*—the ratio of the density of a material to the density of distilled water at a stated temperature; the values are dimensionless.

3.1.5.1 *relative density (specific gravity) (OD), n*—the ratio of the density (OD) of the aggregate to the density of distilled water at a stated temperature.

3.1.5.2 *relative density (specific gravity) (SSD), n*—the ratio of the density (SSD) of the aggregate to the density of distilled water at a stated temperature.

3.1.5.3 *apparent relative density (apparent specific gravity), n*—the ratio of the apparent density of aggregate to the density of distilled water at a stated temperature.

3.1.6 For definitions of other terms related to aggregates, see Terminology C 125.

4. Summary of Test Method

4.1 A sample of aggregate is immersed in water for 24 ± 4 h to essentially fill the pores. It is then removed from the water, the water dried from the surface of the particles, and the mass determined. Subsequently, the volume of the sample is determined by the displacement of water method. Finally, the sample is oven-dried and the mass determined. Using the mass values thus obtained and formulas in this test method, it is possible to calculate density, relative density (specific gravity), and absorption.

5. Significance and Use

5.1 Relative density (specific gravity) is the characteristic generally used for calculation of the volume occupied by the aggregate in various mixtures containing aggregate, including portland cement concrete, bituminous concrete, and other mixtures that are proportioned or analyzed on an absolute volume basis. Relative density (specific gravity) is also used in the computation of voids in aggregate in Test Method C 29/C 29M. Relative density (specific gravity) (SSD) is used if the aggregate is wet, that is, if its absorption has been satisfied. Conversely, the relative density (specific gravity) (OD) is used for computations when the aggregate is dry or assumed to be dry.

5.2 Apparent density and apparent relative density (apparent specific gravity) pertain to the solid material making up the constituent particles not including the pore space within the particles which is accessible to water.

5.3 Absorption values are used to calculate the change in the mass of an aggregate due to water absorbed in the pore spaces within the constituent particles, compared to the dry condition, when it is deemed that the aggregate has been in contact with water long enough to satisfy most of the absorption potential. The laboratory standard for absorption is that obtained after submerging dry aggregate for a prescribed period of time. Aggregates mined from below the water table commonly have a moisture content greater than the absorption determined by this test method, if used without opportunity to dry prior to use. Conversely, some aggregates which have not been continuously maintained in a moist condition until used are likely to contain an amount of absorbed moisture less than the 24-h soaked condition. For an aggregate that has been in contact with water and that has free moisture on the particle surfaces, the percentage of free moisture is determined by deducting the absorption from the total moisture content determined by Test Method C 566.

5.4 The general procedures described in this test method are suitable for determining the absorption of aggregates that have had conditioning other than the 24-h soak, such as boiling water or vacuum saturation. The values obtained for absorption by other test methods will be different than the values obtained by the prescribed soaking, as will the relative density (specific gravity) (SSD).

5.5 The pores in lightweight aggregates are not necessarily filled with water after immersion for 24 h. In fact, the absorption potential for many such aggregates is not satisfied after several days' immersion in water. Therefore, this test method is not intended for use with lightweight aggregate.

6. Apparatus

6.1 *Balance*—A device for determining mass that is sensitive, readable, and accurate to 0.05 % of the sample mass at any point within the range used for this test, or 0.5 g, whichever is greater. The balance shall be equipped with suitable apparatus for suspending the sample container in water from the center of the platform or pan of the balance.

6.2 *Sample Container*—A wire basket of 3.35 mm (No. 6) or finer mesh, or a bucket of approximately equal breadth and height, with a capacity of 4 to 7 L for 37.5-mm (1½-in.) nominal maximum size aggregate or smaller, and a larger container as needed for testing larger maximum size aggregate. The container shall be constructed so as to prevent trapping air when the container is submerged.

6.3 *Water Tank*—A watertight tank into which the sample container is placed while suspended below the balance.

6.4 *Sieves*—A 4.75-mm (No. 4) sieve or other sizes as needed (see 7.2-7.4), conforming to Specification E 11.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:03:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.5 *Oven*—An oven of sufficient size, capable of maintaining a uniform temperature of 110 ± 5 °C (230 ± 9 °F).

7. Sampling

7.1 Sample the aggregate in accordance with Practice D 75.

7.2 Thoroughly mix the sample of aggregate and reduce it to the approximate quantity needed using the applicable procedures in Practice C 702. Reject all material passing a 4.75-mm (No. 4) sieve by dry sieving and thoroughly washing to remove dust or other coatings from the surface. If the coarse aggregate contains a substantial quantity of material finer than the 4.75-mm sieve (such as for Size No. 8 and 9 aggregates in Classification D 448), use the 2.36-mm (No. 8) sieve in place of the 4.75-mm sieve. Alternatively, separate the material finer than the 4.75-mm sieve and test the finer material according to Test Method C 128.

NOTE 1—If aggregates smaller than 4.75 mm (No. 4) are used in the sample, check to ensure that the size of the openings in the sample container is smaller than the minimum size aggregate.

7.3 The minimum mass of test sample to be used is given as follows. Testing the coarse aggregate in several size fractions is permitted. If the sample contains more than 15 % retained on the 37.5-mm (1½-in.) sieve, test the material larger than 37.5 mm in one or more size fractions separately from the smaller size fractions. When an aggregate is tested in separate size fractions, the minimum mass of test sample for each fraction shall be the difference between the masses prescribed for the maximum and minimum sizes of the fraction.

Nominal Maximum Size, mm (in.)	Minimum Mass of Test Sample, kg (lb)
12.5 (½) or less	2 (4.4)
19.0 (¾)	3 (6.6)
25.0 (1)	4 (8.8)
37.5 (1½)	5 (11)
50 (2)	8 (18)
63 (2½)	12 (26)
75 (3)	18 (40)
90 (3½)	25 (55)
100 (4)	40 (88)
125 (5)	75 (165)

7.4 If the sample is tested in two or more size fractions, determine the grading of the sample in accordance with Test Method C 136, including the sieves used for separating the size fractions for the determinations in this method. In calculating the percentage of material in each size fraction, ignore the quantity of material finer than the 4.75-mm (No. 4) sieve (or 2.36-mm (No. 8) sieve when that sieve is used in accordance with 7.2).

NOTE 2—When testing coarse aggregate of large nominal maximum size requiring large test samples, it may be more convenient to perform the test on two or more subsamples, and the values obtained combined for the computations described in Section 9.

8. Procedure

8.1 Dry the test sample in the oven to constant mass at a temperature of 110 ± 5 °C, cool in air at room temperature for 1 to 3 h for test samples of 37.5-mm (1½-in.) nominal maximum size, or longer for larger sizes until the aggregate has cooled to a temperature that is comfortable to handle (approximately 50 °C). Subsequently immerse the aggregate in water at room temperature for a period of 24 ± 4 h.

8.2 Where the absorption and relative density (specific gravity) values are to be used in proportioning concrete mixtures in which the aggregates will be in their naturally moist condition, the requirement in 8.1 for initial drying is optional, and, if the surfaces of the particles in the sample have been kept continuously wet until tested, the requirement in 8.1 for 24 ± 4 h soaking is also optional.

NOTE 3—Values for absorption and relative density (specific gravity) (SSD) may be significantly higher for aggregate not oven dried before soaking than for the same aggregate treated in accordance with 8.1. This is especially true of particles larger than 75 mm since the water may not be able to penetrate the pores to the center of the particle in the prescribed soaking period.

8.3 Remove the test sample from the water and roll it in a large absorbent cloth until all visible films of water are removed. Wipe the larger particles individually. A moving stream of air is permitted to assist in the drying operation. Take care to avoid evaporation of water from aggregate pores during the surface-drying operation. Determine the mass of the test sample in the saturated surface-dry condition. Record this and all subsequent masses to the nearest 0.5 g or 0.05 % of the sample mass, whichever is greater.

8.4 After determining the mass in air, immediately place the saturated-surface-dry test sample in the sample container and determine its apparent mass in water at 23 ± 2.0 °C. Take care to remove all entrapped air before determining its mass by shaking the container while immersed.

NOTE 4—The difference between the mass in air and the mass when the sample is submerged in water equals the mass of water displaced by the sample.

NOTE 5—The container should be immersed to a depth sufficient to cover it and the test sample while determining the apparent mass in water. Wire suspending the container should be of the smallest practical size to minimize any possible effects of a variable immersed length.

8.5 Dry the test sample in the oven to constant mass at a temperature of 110 ± 5 °C, cool in air at room temperature 1 to 3 h, or until the aggregate has cooled to a temperature that is comfortable to handle (approximately 50 °C), and determine the mass.

9. Calculations

9.1 *Relative Density (Specific Gravity)*:

9.1.1 *Relative Density (Specific Gravity) (OD)*—Calculate the relative density (specific gravity) on the basis of oven-dry aggregate as follows:

$$\text{Relative density (specific gravity) (OD)} = A/(B - C) \quad (1)$$

where:

A = mass of oven-dry test sample in air, g,
B = mass of saturated-surface-dry test sample in air, g, and
C = apparent mass of saturated test sample in water, g.

9.1.2 *Relative Density (Specific Gravity) (SSD)*—Calculate the relative density (specific gravity) on the basis of saturated-surface-dry aggregate as follows:

$$\text{Relative density (specific gravity) (SSD)} = B/(B - C) \quad (2)$$

9.1.3 *Apparent Relative Density (Apparent Specific Gravity)*—Calculate the apparent relative density (apparent specific gravity) as follows:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:03:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$$\text{Apparent relative density (apparent specific gravity)} = A/(A - C) \quad (3)$$

9.2 *Density*:

9.2.1 *Density (OD)*—Calculate the density on the basis of oven-dry aggregate as follows:

$$\text{Density (OD), kg/m}^3, = 997.5\ A/(B - C) \quad (4)$$

$$\text{Density (OD), lb/ft}^3, = 62.27\ A/(B - C) \quad (5)$$

NOTE 6—The constant values used in the calculations in 9.2.1-9.2.3 (997.5 kg/m^3 and 62.27 lb/ft^3) are the density of water at 23 °C.

9.2.2 *Density (SSD)*—Calculate the density on the basis of saturated-surface-dry aggregate as follows:

$$\text{Density (SSD), kg/m}^3, = 997.5\ B/(B - C) \quad (6)$$

$$\text{Density (SSD), lb/ft}^3, = 62.27\ B/(B - C) \quad (7)$$

9.2.3 *Apparent Density*—Calculate the apparent density as follows:

$$\text{Apparent density, kg/m}^3 = 997.5\ A/(A - C) \quad (8)$$

$$\text{Apparent density, lb/ft}^3 = 62.27\ A/(A - C) \quad (9)$$

9.3 *Average Density and Relative Density (Specific Gravity) Values*—When the sample is tested in separate size fractions, compute the average values for density or relative density (specific gravity) of the size fraction computed in accordance with 9.1 or 9.2 using the following equation:

$$G = \frac{1}{\frac{P_1}{100\,G_1} + \frac{P_2}{100\,G_2} + \cdots \frac{P_n}{100\,G_n}} \text{ (see AppendixX1)} \quad (10)$$

where:

G = average density or relative density (specific gravity). All forms of expression of density or relative density (specific gravity) can be averaged in this manner,

$G_1, G_2 \ldots G_n$ = appropriate average density or relative density (specific gravity) values for each size fraction depending on the type of density or relative density (specific gravity) being averaged, and

$P_1, P_2, \ldots P_n$ = mass percentages of each size fraction present in the original sample (not including finer material—see 7.4).

9.4 *Absorption*—Calculate the percentage of absorption, as follows:

$$\text{Absorption, \%} = [(B - A)/A] \times 100 \quad (11)$$

NOTE 7—Some authorities recommend using the density of water at 4 °C (1000 kg/m^3 or 1.000 Mg/m^3 or 62.43 lb/ft ^{3}) as being sufficiently accurate.

9.5 *Average Absorption Value*—When the sample is tested in separate size fractions, the average absorption value is the average of the values as computed in 9.4, weighted in proportion to the mass percentages of each size fraction present in the original sample (not including finer material—see 7.4) as follows:

$$A = (P_1A_1/100) + (P_2A_2/100) + \ldots\ (P_nA_n/100) \quad (12)$$

where:

A = average absorption, %,

$A_1, A_2 \ldots A_n$ = absorption percentages for each size fraction, and

$P_1, P_2, \ldots P_n$ = mass percentages of each size fraction present in the original sample.

10. Report

10.1 Report density results to the nearest 10 kg/m^3, or 0.5 lb/ft^3, relative density (specific gravity) results to the nearest 0.01, and indicate the basis for density or relative density (specific gravity), as either (OD), (SSD), or apparent.

10.2 Report the absorption result to the nearest 0.1 %.

10.3 If the density, relative density (specific gravity) and absorption values were determined without first drying the aggregate, as permitted in 8.2, note that fact in the report.

11. Precision and Bias

11.1 The estimates of precision of this test method listed in Table 1 are based on results from the AASHTO Materials Reference Laboratory Proficiency Sample Program, with testing conducted by this test method and AASHTO Method T 85. The significant difference between the methods is that Test Method C 127 requires a saturation period of 24 ± 4 h, while AASHTO Method T 85 requires a saturation period of 15 h minimum. This difference has been found to have an insignificant effect on the precision indices. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories. The precision estimates for density were calculated from values determined for relative density (specific gravity), using the density of water at 23 °C for the conversion.

11.2 *Bias*—Since there is no accepted reference material for determining the bias for the procedure in this test method, no statement on bias is being made.

TABLE 1 Precision

	Standard Deviation (1s)[A]	Acceptable Range of Two Results (d2s)[A]
Single-Operator Precision:		
Density (OD), kg/m^3	9	25
Density (SSD), kg/m^3	7	20
Apparent density, kg/m^3	7	20
Relative density (specific gravity) (OD)	0.009	0.025
Relative density (specific gravity) (SSD)	0.007	0.020
Apparent relative density (apparent specific gravity)	0.007	0.020
Multilaboratory Precision:		
Density (OD), kg/m^3	13	38
Density (SSD), kg/m^3	11	32
Apparent density, kg/m^3	11	32
Relative density (specific gravity) (OD)	0.013	0.038
Relative density (specific gravity) (SSD)	0.011	0.032
Apparent relative density (apparent specific gravity)	0.011	0.032

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670. The precision estimates were obtained from the analysis of combined AASHTO Materials Reference Laboratory proficiency sample data from laboratories using 15 h minimum saturation times and other laboratories using 24 ± 4 h saturation times. Testing was performed on normal-weight aggregates, and started with aggregates in the oven-dry condition.

12. Keywords

12.1 absorption; aggregate; apparent density; apparent relative density; coarse aggregate; density; relative density; specific gravity

APPENDIXES

(Nonmandatory Information)

X1. DEVELOPMENT OF EQUATIONS

X1.1 The derivation of the equation is from the following simplified cases using two solids. Solid 1 has a mass M_1 in grams and a volume V_1 in millilitres; its relative density (specific gravity) (G_1) is therefore M_1/V_1. Solid 2 has a mass M_2 and volume V_2, and $G_2 = M_2/V_2$. If the two solids are considered together, the relative density (specific gravity) of the combination is the total mass in grams divided by the total volume in millilitres:

$$G = (M_1 + M_2) / (V_1 + V_2) \tag{X1.1}$$

Manipulation of this equation yields the following:

$$G = \frac{1}{\frac{V_1 + V_2}{M_1 + M_2}} = \frac{1}{\frac{V_1}{M_1 + M_2} + \frac{V_2}{M_1 + M_2}} \tag{X1.2}$$

$$G = \frac{1}{\frac{M_1}{M_1 + M_2}\left(\frac{V_1}{M_1}\right) + \frac{M_2}{M_1 + M_2}\left(\frac{V_2}{M_2}\right)} \tag{X1.3}$$

However, the mass fractions of the two solids are:

$$M_1/(M_1 + M_2) = P_1/100 \text{ and } M_2/(M_1 + M_2) = P_2/100 \tag{X1.4}$$

and,

$$1/G_1 = V_1/M_1 \text{ and } 1/G_2 = V_2/M_2 \tag{X1.5}$$

Therefore,

$$G = \frac{1}{\frac{P_1}{100}\frac{1}{G_1} + \frac{P_2}{100}\frac{1}{G_2}} \tag{X1.6}$$

An example of the computation is given in Table X1.1.

TABLE X1.1 Example of Calculation of Weighted Values of Relative Density (Specific Gravity) and Absorption for a Coarse Aggregate Tested in Separate Sizes

Size Fraction, mm (in.)	% in Original Sample	Sample Mass Used in Test, g	Relative Density (Specific Gravity) (SSD)	Absorption, %
4.75 to 12.5 (No. 4 to ½)	44	2213.0	2.72	0.4
12.5 to 37.5 (½ to 1½)	35	5462.5	2.56	2.5
37.5 to 63 (1½ to 2½)	21	12593.0	2.54	3.0

Average Relative Density (Specific Gravity) (SSD)

$$G_{SSD} = \frac{1}{\frac{0.44}{2.72} + \frac{0.35}{2.56} + \frac{0.21}{2.54}} = 2.62$$

Average Absorption

$$A = (0.44)\,(0.4) + (0.35)\,(2.5) + (0.21)\,(3.0) = 1.7\ \%$$

X2. INTERRELATIONSHIPS BETWEEN RELATIVE DENSITIES (SPECIFIC GRAVITIES) AND ABSORPTION AS DEFINED IN TEST METHODS C 127 AND C 128

X2.1 Where:

S_d = relative density (specific gravity) (OD),
S_s = relative density (specific gravity) (SSD),
S_a = apparent relative density (apparent specific gravity), and
A = absorption in %.

X2.2 Calculate the values of each as follows:

$$S_s = (1 + A/100)S_d \tag{X2.1}$$

$$S_a = \frac{1}{\frac{1}{S_d} - \frac{A}{100}} = \frac{S_d}{1 - \frac{AS_d}{100}} \tag{X2.2}$$

$$S_a = \frac{1}{\frac{1 + A/100}{S_s} - \frac{A}{100}} = \frac{S_s}{1 - \left[\frac{A}{100}(S_s - 1)\right]} \tag{X2.3}$$

$$A = \left(\frac{S_s}{S_d} - 1\right) 100 \tag{X2.4}$$

$$A = \left(\frac{S_a - S_s}{S_a(S_s - 1)}\right) 100 \tag{X2.5}$$

Designation: C 128 – 07a

Standard Test Method for Density, Relative Density (Specific Gravity), and Absorption of Fine Aggregate[1]

This standard is issued under the fixed designation C 128; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the average density of a quantity of fine aggregate particles (not including the volume of voids between the particles), the relative density (specific gravity), and the absorption of the fine aggregate. Depending on the procedure used, the density, in kg/m^3(lb/ft^3) is expressed as oven-dry (OD), saturated-surface-dry (SSD), or as apparent density. Likewise, relative density (specific gravity), a dimensionless quality, is expressed as OD, SSD, or as apparent relative density (apparent specific gravity). The OD density and OD relative density are determined after drying the aggregate. The SSD density, SSD relative density, and absorption are determined after soaking the aggregate in water for a prescribed duration.

1.2 This test method is used to determine the density of the essentially solid portion of a large number of aggregate particles and provides an average value representing the sample. Distinction is made between the density of aggregate particles as determined by this test method, and the bulk density of aggregates as determined by Test Method C 29/C 29M, which includes the volume of voids between the particles of aggregates.

1.3 This test method is not intended to be used for lightweight aggregates.

1.4 The values stated in SI units are to be regarded as the standard for conducting the tests. The test results for density shall be reported in either SI units or inch-pound units, as appropriate for the use to be made of the results.

1.5 The text of this test method references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this test method.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

prescribed period of time but not including water adhering to the outside surface of the particles, expressed as percentage of the dry mass.

3.1.2 *density*, *n*—the mass per unit volume of a material, expressed as kilograms per cubic metre (pounds per cubic foot).

3.1.2.1 *density (OD), n*—the mass of oven-dry aggregate particles per unit volume of aggregate particles, including the volume of permeable and impermeable pores within particles, but not including the voids between the particles.

3.1.2.2 *density (SSD), n*—the mass of saturated-surface-dry aggregate per unit volume of the aggregate particles, including the volume of impermeable pores and permeable, water-filled pores within the particles, but not including the voids between the particles.

3.1.2.3 *apparent density, n*—the mass per unit volume of the impermeable portion of the aggregate particles.

3.1.3 *oven-dry (OD), adj—related to aggregate particles,* the condition in which the aggregates have been dried by heating in an oven at 110 ± 5 °C for sufficient time to reach a constant mass.

3.1.4 *relative density (specific gravity), n*—the ratio of the density of a material to the density of water at a stated temperature; the values are dimensionless.

3.1.4.1 *relative density (specific gravity), (OD), n*—the ratio of the density (OD) of the aggregate to the density of water at a stated temperature.

3.1.4.2 *relative density (specific gravity), (SSD), n*—The ratio of the density (SSD) of the aggregate to the density of water at a stated temperature.

3.1.4.3 *apparent relative density (apparent specific gravity), n*—the ratio of the apparent density of aggregate to the density of water at a stated temperature.

3.1.5 *saturated-surface-dry (SSD), adj—related to aggregate particles,* the condition in which the permeable pores of aggregate particles are filled with water to the extent achieved by submerging in water for the prescribed period of time, but without free water on the surface of the particles.

3.1.6 For definitions of other terms related to aggregates see Terminology C 125.

4. Summary of Test Method

4.1 A sample of aggregate is immersed in water for 24 ± 4 h to essentially fill the pores. It is then removed from the water, the water is dried from the surface of the particles, and the mass determined. Subsequently, the sample (or a portion of it) is placed in a graduated container and the volume of the sample is determined by the gravimetric or volumetric method. Finally, the sample is oven-dried and the mass determined again. Using the mass values thus obtained and formulas in this test method, it is possible to calculate density, relative density (specific gravity), and absorption.

5. Significance and Use

5.1 Relative density (specific gravity) is the characteristic generally used for calculation of the volume occupied by the aggregate in various mixtures containing aggregate including portland cement concrete, bituminous concrete, and other mixtures that are proportioned or analyzed on an absolute volume basis. Relative density (specific gravity) is also used in the computation of voids in aggregate in Test Method C 29/C 29M. Relative density (specific gravity) (SSD) is used in the determination of surface moisture on fine aggregate by displacement of water in Test Method C 70. Relative density (specific gravity) (SSD) is used if the aggregate is wet, that is, if its absorption has been satisfied. Conversely, the density or relative density (specific gravity) (OD) is used for computations when the aggregate is dry or assumed to be dry.

5.2 Apparent density and apparent relative density (apparent specific gravity) pertain to the solid material making up the constituent particles not including the pore space within the particles that is accessible to water. This value is not widely used in construction aggregate technology.

5.3 Absorption values are used to calculate the change in the mass of an aggregate material due to water absorbed in the pore spaces within the constituent particles, compared to the dry condition, when it is deemed that the aggregate has been in contact with water long enough to satisfy most of the absorption potential. The laboratory standard for absorption is that obtained after submerging dry aggregate for a prescribed period of time. Aggregates mined from below the water table commonly have a moisture content greater than the absorption determined by this test method, if used without opportunity to dry prior to use. Conversely, some aggregates which have not been continuously maintained in a moist condition until used are likely to contain an amount of absorbed moisture less than the 24-h soaked condition. For an aggregate that has been in contact with water and that has free moisture on the particle surfaces, the percentage of free moisture is determined by deducting the absorption from the total moisture content determined by Test Method C 566 by drying.

5.4 The general procedures described in this test method are suitable for determining the absorption of aggregates that have had conditioning other than the 24-h soak, such as boiling water or vacuum saturation. The values obtained for absorption by other test methods will be different than the values obtained by the prescribed 24-h soak, as will the density (SSD) or relative density (specific gravity (SSD).

5.5 The pores in lightweight aggregates are not necessarily filled with water after immersion for 24 h. In fact, the absorption potential for many such aggregates is not satisfied after several days immersion in water. Therefore, this test method is not intended for use with lightweight aggregate.

6. Apparatus

6.1 *Balance*—A balance or scale having a capacity of 1 kg or more, sensitive to 0.1 g or less, and accurate within 0.1 % of the test load at any point within the range of use for this test method. Within any 100-g range of test load, a difference between readings shall be accurate within 0.1 g.

6.2 *Pycnometer (for Use with Gravimetric Procedure)*—A flask or other suitable container into which the fine aggregate test sample can be readily introduced and in which the volume content can be reproduced within ± 0.1 cm^3. The volume of the container filled to mark shall be at least 50 % greater than

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:03:30 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the space required to accommodate the test sample. A volumetric flask of 500-cm^3 capacity or a fruit jar fitted with a pycnometer top is satisfactory for a 500-g test sample of most fine aggregates.

6.3 *Flask (for Use with Volumetric Procedure)*—A Le Chatelier flask as described in Test Method C 188 is satisfactory for an approximately 55-g test sample.

6.4 *Mold and Tamper for Surface Moisture Test*—The metal mold shall be in the form of a frustum of a cone with dimensions as follows: 40 ± 3-mm inside diameter at the top, 90± 3-mm inside diameter at the bottom, and 75 ± 3 mm in height, with the metal having a minimum thickness of 0.8 mm. The metal tamper shall have a mass of 340 ± 15 g and a flat circular tamping face 25 ± 3 mm in diameter.

6.5 *Oven*—An oven of sufficient size, capable of maintaining a uniform temperature of 110 ± 5 °C (230 ± 9 °F).

7. Sampling

7.1 Sample the aggregate in accordance with Practice D 75. Thoroughly mix the sample and reduce it to obtain a test specimen of approximately 1 kg using the applicable procedures described in Practice C 702.

8. Preparation of Test Specimen

8.1 Place the test specimen in a suitable pan or vessel and dry in the oven to constant mass at a temperature of 110 ± 5 °C (230 ± 9 °F). Allow it to cool to comfortable handling temperature (approximately 50 °C), cover with water, either by immersion or by the addition of at least 6 % moisture to the fine aggregate, and permit to stand for 24 ± 4 h.

8.1.1 Where the absorption and relative density (specific gravity) values are to be used in proportioning concrete mixtures in which the aggregates will be in their naturally moist condition, the requirement in 8.1 for initial drying is optional, and, if the surfaces of the particles in the sample have been kept continuously wet until tested, the requirement in 8.1 for 24 ± 4 h soaking is also optional.

NOTE 1—Values for absorption and for relative density (specific gravity) (SSD) may be significantly higher for aggregate not oven dried before soaking than for the same aggregate treated in accordance with 8.1.

8.2 Decant excess water with care to avoid loss of fines (see also Appendix X1), spread the sample on a flat nonabsorbent surface exposed to a gently moving current of warm air, and stir frequently to secure homogeneous drying. Employ mechanical aids such as tumbling or stirring to assist in achieving the saturated surface-dry condition, if desired. Continue this operation until the test specimen approaches a free-flowing condition. Follow the procedure in 8.3 to determine if surface moisture is still present on the constituent fine aggregate particles. Make the first trial for surface moisture when there is still some surface water in the test specimen. Continue drying with constant stirring and test at frequent intervals until the test indicates that the specimen has reached a surface-dry condition. If the first trial of the surface moisture test indicates that moisture is not present on the surface, it has been dried past the saturated surface-dry condition. In this case, thoroughly mix a few millilitres of water with the fine aggregate and permit the specimen to stand in a covered container for 30 min. Then resume the process of drying and testing at frequent intervals for the onset of the surface-dry condition.

8.3 *Test for Surface Moisture*—Hold the mold firmly on a smooth nonabsorbent surface with the large diameter down. Place a portion of the partially dried fine aggregate loosely in the mold by filling it to overflowing and heaping additional material above the top of the mold by holding it with the cupped fingers of the hand holding the mold. Lightly tamp the fine aggregate into the mold with 25 light drops of the tamper. Start each drop approximately 5 mm above the top surface of the fine aggregate. Permit the tamper to fall freely under gravitational attraction on each drop. Adjust the starting height to the new surface elevation after each drop and distribute the drops over the surface. Remove loose sand from the base and lift the mold vertically. If surface moisture is still present, the fine aggregate will retain the molded shape. Slight slumping of the molded fine aggregate indicates that it has reached a surface-dry condition.

8.3.1 Some fine aggregate with predominately angular-shaped particles or with a high proportion of fines does not slump in the cone test upon reaching the surface-dry condition. Test by dropping a handful of the fine aggregate from the cone test onto a surface from a height of 100 to 150 mm, and observe for fines becoming airborne; presence of airborne fines indicates this problem. For these materials, consider the saturated surface-dry condition as the point that one side of the fine aggregate slumps slightly upon removing the mold.

NOTE 2—The following criteria have also been used on materials that do not readily slump:

(1) Provisional Cone Test—Fill the cone mold as described in 8.3 except only use 10 drops of the tamper. Add more fine aggregate and use 10 drops of the tamper again. Then add material two more times using 3 and 2 drops of the tamper, respectively. Level off the material even with the top of the mold, remove loose material from the base; and lift the mold vertically.

(2) Provisional Surface Test—If airborne fines are noted when the fine aggregate is such that it will not slump when it is at a moisture condition, add more moisture to the sand, and at the onset of the surface-dry condition, with the hand lightly pat approximately 100 g of the material on a flat, dry, clean, dark or dull nonabsorbent surface such as a sheet of rubber, a worn oxidized, galvanized, or steel surface, or a black-painted metal surface. After 1 to 3 s, remove the fine aggregate. If noticeable moisture shows on the test surface for more than 1 to 2 s then surface moisture is considered to be present on the fine aggregate.

(3) Colorimetric procedures described by Kandhal and Lee, Highway Research Record No. 307, p. 44.

(4) For reaching the saturated surface-dry condition on a single size material that slumps when wet, hard-finish paper towels can be used to surface dry the material until the point is just reached where the paper towel does not appear to be picking up moisture from the surfaces of the fine aggregate particles.

9. Procedure

9.1 Test by either the gravimetric procedure in 9.2 or the volumetric procedure in 9.3. Make all determinations of mass to 0.1 g.

9.2 *Gravimetric (Pycnometer) Procedure*:

9.2.1 Partially fill the pycnometer with water. Introduce into the pycnometer 500 ± 10 g of saturated surface-dry fine aggregate prepared as described in Section 8, and fill with additional water to approximately 90 % of capacity. Agitate the pycnometer as described in 9.2.1.1 (manually) or 9.2.1.2 (mechanically).

9.2.1.1 Manually roll, invert, or agitate the pycnometer (or use a combination of these actions) to eliminate visible air bubbles.

NOTE 3—About 15 to 20 min are normally required to eliminate the air bubbles by manual methods. Dipping the tip of a paper towel into the pycnometer has been found to be useful in dispersing the foam that sometimes builds up when eliminating the air bubbles. Optionally, a small amount of isopropyl alcohol may be used to disperse the foam.

9.2.1.2 Mechanically agitate the pycnometer by external vibration in a manner that will not degrade the sample. A level of agitation adjusted to just set individual particles in motion is sufficient to promote de-airing without degradation. A mechanical agitator shall be considered acceptable for use if comparison tests for each six-month period of use show variations less that the acceptable range of two results (d2s) indicated in Table 1 from the results of manual agitation on the same material.

9.2.2 After eliminating all air bubbles, adjust the temperature of the pycnometer and its contents to 23.0 ± 2.0 °C if necessary by partial immersion in circulating water, and bring the water level in the pycnometer to its calibrated capacity. Determine the total mass of the pycnometer, specimen, and water.

9.2.3 Remove the fine aggregate from the pycnometer, dry in the oven to constant mass at a temperature of 110 ± 5 °C (230 ± 9 °F), cool in air at room temperature for 1 ± ½ h, and determine the mass.

9.2.4 Determine the mass of the pycnometer filled to its calibrated capacity with water at 23.0 ± 2.0 °C.

9.3 *Volumetric (Le Chatelier Flask) Procedure*:

9.3.1 Fill the flask initially with water to a point on the stem between the 0 and the 1-mL mark. Record this initial reading with flask and contents within the temperature range of 23.0 ± 2.0 °C. Add 55 ± 5 g of fine aggregate in the saturated surface-dry condition (or other measured quantity as necessary). After all fine aggregate has been introduced, place the stopper in the flask and roll the flask in an inclined position, or gently whirl it in a horizontal circle so as to dislodge all entrapped air, continuing until no further bubbles rise to the surface (Note 4). Take a final reading with the flask and contents within 1 °C of the original temperature.

NOTE 4—A small measured amount (not to exceed 1 mL) of isopropyl alcohol may be used to eliminate foam appearing on the water surface. The volume of alcohol used must be subtracted from the final reading (R_2).

9.3.2 For determination of the absorption, use a separate 500 ± 10-g portion of the saturated surface-dry fine aggregate, dry to constant mass, and determine the dry mass.

TABLE 1 Precision

	Standard Deviation (1s)[A]	Acceptable Range of Two Results (d2s)[A]
Single-Operator Precision:		
Density (OD), kg/m^3	11	13
Density (SSD), kg/m^3 [B†]	9.5	27
Apparent density, kg/m^3	9.5	27
Relative density (specific gravity) (OD)	0.011	0.032
Relative density (specific gravity) (SSD)	0.0095	0.027
Apparent relative density (apparent specific gravity)	0.0095	0.027
Absorption[C], %	0.11	0.31
Multilaboratory Precision:		
Density (OD), kg/m^3	23	64
Density (SSD), kg/m^3	20	56
Apparent density, kg/m^3	20	56
Relative density (specific gravity) (OD)	0.023	0.066
Relative density (specific gravity) (SSD)	0.020	0.056
Apparent relative density (apparent specific gravity)	0.020	0.056
Absorption[C], %	0.23	0.66

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670. The precision estimates were obtained from the analysis of combined AASHTO Materials Reference Laboratory proficiency sample data from laboratories using 15 to 19-h saturation times and other laboratories using 24 ± 4-h saturation time. Testing was performed on normal weight aggregates, and started with aggregates in the oven-dry condition.

[B†] Revised editorially to correct a typographical error in August 2003.

[C] Precision estimates are based on aggregates with absorptions of less than 1 % and may differ for manufactured fine aggregates and the aggregates having absorption values greater than 1 %.

10. Calculations

10.1 *Symbols*:

A = mass of oven dry specimen, g

B = mass of pycnometer filled with water, to calibration mark, g

C = mass of pycnometer filled with specimen and water to calibration mark, g

R_1= initial reading of water level in Le Chatelier flask, mL

R_2= final reading of water in Le Chatelier flask, mL

S = mass of saturated surface-dry specimen (used in the gravimetric procedure for density and relative density (specific gravity), or for absorption with both procedures), g

S_1= mass of saturated surface-dry specimen (used in the volumetric procedure for density and relative density (specific gravity)), g

10.2 *Relative Density (Specific Gravity)*:

10.2.1 *Relative Density (Specific Gravity) (Oven dry)*—Calculate the relative density (specific gravity) on the basis of oven-dry aggregate as follows:

10.2.1.1 *Gravimetric Procedure*:

$$\text{Relative density (specific gravity) (OD)} = A/(B + S - C) \quad (1)$$

10.2.1.2 *Volumetric Procedure*:

$$\text{Relative density (specific gravity) (OD)} = [S_1\,(A/S)]/[0.9975\,(R_2 - R_1)] \quad (2)$$

10.2.2 *Relative Density (Specific Gravity) Saturated Surface-dry)*—Calculate the relative density (specific gravity) on the basis of saturated surface-dry aggregate as follows:

10.2.2.1 *Gravimetric Procedure*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:03:30 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$$\text{Relative density (specific gravity) (SSD)} = S/(B + S - C) \quad (3)$$

10.2.2.2 *Volumetric Procedure*:

$$\text{Relative density (specific gravity) (SSD)} = S_1/[0.9975\ (R_2 - R_1)] \quad (4)$$

10.2.3 *Apparent Relative Density (Apparent Specific Gravity)*—Calculate the apparent relative density (apparent specific gravity) as follows:

10.2.3.1 *Gravimetric Procedure*:

$$\text{Apparent relative density (apparent specific gravity)} = A/(B + A - C) \quad (5)$$

10.2.3.2 *Volumetric Procedure*:

$$\text{Apparent relative density (apparent specific gravity)} = \frac{S_1\ (A/S)}{0.9975\ (R_2 - R_1) - [(S_1/S)(S - A)]} \quad (6)$$

10.3 *Density*:

10.3.1 *Density (Oven-dry)*—Calculate the density on the basis of oven-dry aggregates as follows:

10.3.1.1 *Gravimetric Procedure*:

$$\text{Density (OD), kg/m}^3 = 997.5\ A/(B + S - C) \quad (7)$$

$$\text{Density (OD), lb/ft}^3 = 62.27\ A/(B + S - C) \quad (8)$$

10.3.1.2 *Volumetric Procedure*:

$$\text{Density (OD), kg/m}^3 = 997.5\ S_1\ (A/S)/[0.9975\ (R_2 - R_1)] \quad (9)$$

$$\text{Density (OD), lb/ft}^3 = 62.27\ S_1\ (A/S)/[0.9975\ (R_2 - R_1)] \quad (10)$$

NOTE 5—The constant values used in the calculations in 10.3.1-10.3.3 (997.5 kg/m^3 and 62.27 lb/ft^3) are the density of water at 23 °C. Some authorities recommend using the density of water at 4 °C (1000 kg/m^3 or 1000 Mg/m^3 or 62.43 lb/ft^3) as being sufficiently accurate.

10.3.2 *Density (Saturated surface-dry)*—Calculate the density on the basis of saturated surface-dry aggregate as follows:

10.3.2.1 *Gravimetric Procedure*:

$$\text{Density (SSD), kg/m}^3 = 997.5\ S/(B + S - C) \quad (11)$$

$$\text{Density (SSD), lb/ft}^3 = 62.27\ S/(B + S - C) \quad (12)$$

10.3.2.2 *Volumetric Procedure*:

$$\text{Density (SSD), kg/m}^3 = 997.5\ S_1/[0.9975\ (R_2 - R_1)] \quad (13)$$

$$\text{Density (SSD), lb/ft}^3 = 62.27\ S_1/[0.9975\ (R_2 - R_1)] \quad (14)$$

10.3.3 *Apparent Density*—Calculate the apparent density as follows:

10.3.3.1 *Gravimetric Procedure*:

$$\text{Apparent density (SSD), kg/m}^3 = 997.5\ A/(B + A - C) \quad (15)$$

$$\text{Apparent density (SSD), lb/ft}^3 = 62.27\ A/(B + A - C) \quad (16)$$

10.3.3.2 *Volumetric Procedure*:

$$\text{Apparent density (SSD), kg/m}^3, = \frac{997.5\ S_1\ (A/S)}{0.9975\ (R_2 - R_1) - [(S_1/S)(S - A)]} \quad (17)$$

$$\text{Apparent density (SSD), lb/ft}^3, = \frac{62.27\ S_1\ (A/S)}{0.9975\ (R_2 - R_1) - [(S_1/S)(S - A)]} \quad (18)$$

10.4 *Absorption*—Calculate the percentage of absorption as follows:

$$\text{Absorption, \%} = 100\ [(S - A)/A] \quad (19)$$

11. Report

11.1 Report density results to the nearest 10 kg/m^3, or 0.5 lb/ft^3, relative density (specific gravity) results to the nearest 0.01, and indicate the basis for density or relative density (specific gravity), as either oven-dry (OD), saturated-surface-dry (SSD), or apparent.

11.2 Report the absorption result to the nearest 0.1 %.

11.3 If the density and relative density (specific gravity) values were determined without first drying the aggregate, as permitted in 8.2, note that fact in the report.

12. Precision and Bias

12.1 *Precision*—The estimates of precision of this test method (listed in Table 1) are based on results from the AASHTO Materials Reference Laboratory Proficiency Sample Program, with testing conducted by this test method and AASHTO Method T 84. The significant difference between the methods is that Test Method C 128 requires a saturation period of 24 ± 4 h, and AASHTO Test Method T 84 requires a saturation period of 15 to 19 h. This difference has been found to have an insignificant effect on the precision indices. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories. The precision estimates for density were calculated from values determined for relative density (specific gravity), using the density of water at 23 °C for the conversion.

12.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for this test method, no statement on bias is being made.

13. Keywords

13.1 absorption; aggregate; apparent density; apparent relative density; density; fine aggregate; relative density; specific gravity

APPENDIXES

(Nonmandatory Information)

X1. POTENTIAL DIFFERENCES IN BULK RELATIVE DENSITY AND ABSORPTION DUE TO PRESENCE OF MATERIAL FINER THAN 75 µm

X1.1 It has been found that there may be significant differences in bulk relative density and absorption between fine aggregate samples tested with the material finer than 75 µm (No. 200) present and not present in the samples. Samples from which the material finer than 75 µm is not removed usually give a higher absorption and a lower bulk relative density compared with testing the same fine aggregate from which the material finer than 75 µm is removed following the procedures of Test Method C 117. Samples with material finer than 75 µm may build up a coating around the coarser fine aggregate particles during the surface drying process. The resultant relative density and absorption that is subsequently measured is that of the agglomerated and coated particles and not that of the parent material. The difference in absorption and relative density determined between samples from which the material finer than 75 µm have not been removed and samples from which the material finer than 75 µm have been removed depends on both the amount of the material finer than 75 µm present and the nature of the material. When the material finer than 75 µm is less than about 4 % by mass, the difference in relative density between washed and unwashed samples is less than 0.03. When the material finer than 75 µm is greater than about 8 % by mass, the difference in relative density obtained between washed and unwashed samples may be as great as 0.13. It has been found that the relative density determined on fine aggregate from which the material finer than 75 µm has been removed prior to testing more accurately reflects the relative density of the material.

X1.2 The material finer than 75 µm, which is removed, can be assumed to have the same relative density as the fine aggregate. Alternatively, the relative density (specific gravity) of the material finer than 75 µm may be further evaluated using Test Method D 854, however, this test determines the apparent relative density and not the bulk relative density.

X2. INTERRELATIONSHIPS BETWEEN RELATIVE DENSITIES (SPECIFIC GRAVITIES) AND ABSORPTION AS DEFINED IN TEST METHODS C 127 AND C 128

X2.1 This appendix gives mathematical interrelationships among the three types of relative densities (specific gravities) and absorption. These may be useful in checking the consistency of reported data or calculating a value that was not reported by using other reported data.

X2.2 Where:

S_d = relative density (specific gravity) (OD),
S_s = relative density (specific gravity) (SSD),
S_a = apparent relative density (apparent specific gravity), and
A = absorption, in %.

Calculate the values of each as follows:

$$S_s = (1 + A/100)S_d \quad \text{(X2.1)}$$

$$S_s = \frac{1}{\frac{1}{S_d} - \frac{A}{100}} = \frac{S_d}{1 - \frac{AS_d}{100}} \quad \text{(X2.2)}$$

$$\text{or } S_a = \frac{1}{\frac{1 + A/100}{S_s} - \frac{A}{100}} \quad \text{(X2.3)}$$

$$= \frac{S_s}{1 = \frac{A}{100}(S_s - 1)}$$

$$A = \left(\frac{S_s}{S_d} - 1\right) 100 \quad \text{(X2.4)}$$

$$A = \left(\frac{S_a - S_s}{S_a (S_s - 1)}\right) 100 \quad \text{(X2.5)}$$

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 128 – 07, that may impact the use of this test method. (Approved August 1, 2007)

(*1*) Revised 3.1.2.2.

(*2*) Revised 9.2.1.1.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 128 – 04a, that may impact the use of this test method. (Approved February 1, 2007)

(*1*) Revised 9.2.1.1.

(*2*) Added new Appendix X1 and renumbered subsequent sections.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Designation: C 131 – 06

Standard Test Method for Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine[1]

This standard is issued under the fixed designation C 131; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers a procedure for testing sizes of coarse aggregate smaller than 37.5 mm (1½ in.) for resistance to degradation using the Los Angeles testing machine (Note 1).

NOTE 1—A procedure for testing coarse aggregate larger than 19.0 mm (¾ in.) is covered in Test Method C 535.

1.2 The values stated in SI units are to be regarded as the standard. The inch-pound values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

D 75 Practice for Sampling Aggregates

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 *Definitions*—For definitions of terms used in this test method, refer to Terminology C 125.

4. Summary of Test Method

4.1 This test is a measure of degradation of mineral aggregates of standard gradings resulting from a combination of actions including abrasion or attrition, impact, and grinding in a rotating steel drum containing a specified number of steel spheres, the number depending upon the grading of the test sample. As the drum rotates, a shelf plate picks up the sample and the steel spheres, carrying them around until they are dropped to the opposite side of the drum, creating an impact-crushing effect. The contents then roll within the drum with an abrading and grinding action until the shelf plate picks up the sample and the steel spheres, and the cycle is repeated. After the prescribed number of revolutions, the contents are removed from the drum and the aggregate portion is sieved to measure the degradation as percent loss.

5. Significance and Use

5.1 This test has been widely used as an indicator of the relative quality or competence of various sources of aggregate having similar mineral compositions. The results do not automatically permit valid comparisons to be made between sources distinctly different in origin, composition, or structure. Assign specification limits with extreme care in consideration of available aggregate types and their performance history in specific end uses.

6. Apparatus

6.1 *Los Angeles Machine*—A Los Angeles machine, conforming in all essential characteristics to the design shown in Fig. 1, shall be used. The machine shall consist of a hollow steel cylinder, with a wall thickness of not less than 12.4 mm (Note 2) closed at both ends, conforming to the dimensions shown in Fig. 1, having an inside diameter of 711 ± 5 mm (28

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved August 1, 2006. Published August 2006. Originally approved in 1937. Last previous edition approved in 2003 as C 131-03.

Inch Equivalents

mm	6.4	12.7	25.4	89	102	152	190	508	711	1270
in.	¼	½	1	3½	4	6	7½	20	28	50

FIG. 1 Los Angeles Testing Machine

± 0.2 in.), and an inside length of 508 ± 5 mm (20 ± 0.2 in.). The interior surface of the cylinder shall be free from protrusions disrupting the path of the sample and steel spheres except for the shelf described below. The cylinder shall be mounted on stub shafts attached to the ends of the cylinder but not entering it, and shall be mounted in such a manner that it rotates with the axis in a horizontal position within a tolerance in slope of 1 in 100. An opening in the cylinder shall be provided for the introduction of the test sample. A suitable, dust-tight cover shall be provided for the opening with means for bolting the cover in place. The cover shall be so designed as to maintain the cylindrical contour of the interior surface unless the shelf is so located that the charge will not fall on the cover, or come in contact with it during the test. A removable steel shelf extending the full length of the cylinder and projecting inward 89 ± 2 mm (3.5 ± 0.1 in.) shall be mounted on the interior cylindrical surface of the cylinder, in such a way that a plane centered between the large faces coincides with an axial plane. The shelf shall be of such thickness and so mounted, by bolts or other suitable means, as to be firm and rigid. The position of the shelf (Note 3) shall be such that the sample and the steel spheres shall not impact on or near the opening and its cover, and that the distance from the shelf to the opening, measured along the outside circumference of the cylinder in the direction of rotation, shall be not less than 1270 mm (50 in.). Inspect the shelf periodically to determine that it is not bent either lengthwise or from its normal radial position with respect to the cylinder. If either condition is found, repair or replace the shelf before further tests are conducted.

NOTE 2—This is the minimum tolerance permitted on 12.7 mm (½ in.) rolled steel plate as described in Specification A 6/A 6M.

NOTE 3—The use of a shelf of wear-resistant steel, rectangular in cross section and mounted independently of the cover, is preferred. However, a shelf consisting of a section of rolled angle, properly mounted on the inside of the cover plate, may be used provided the direction of rotation is such that the charge will be caught on the outside face of the angle.

6.1.1 The machine shall be so driven and so counterbalanced as to maintain a substantially uniform peripheral speed (Note 4). If an angle is used as the shelf, the direction of rotation shall be such that the charge is caught on the outside surface of the angle.

NOTE 4—Back-lash or slip in the driving mechanism is very likely to furnish test results which are not duplicated by other Los Angeles machines producing constant peripheral speed.

Total		5 000 ± 10	5 000 ± 10	5 000 ± 10	5 000 ± 10

6.2 *Sieves*, conforming to Specification E 11.

6.3 *Balance*—A balance or scale accurate within 0.1 % of test load over the range required for this test.

6.4 *Charge*—The charge shall consist of steel spheres averaging approximately 46.8 mm (1 27/32 in.) in diameter and each having a mass of between 390 and 445 g.

6.4.1 The charge, (Note 5) depending upon the grading of the test sample as described in Section 8, shall be as follows:

Grading	Number of Spheres	Mass of Charge, g
A	12	5000 ± 25
B	11	4584 ± 25
C	8	3330 ± 20
D	6	2500 ± 15

NOTE 5—Steel ball bearings 46.0 mm (1 13/16 in.) and 47.6 mm (1 7/8 in.) in diameter, having a mass of approximately 400 and 440 g each, respectively, are readily available. Steel spheres 46.8 mm (1 27/32 in.) in diameter having a mass of approximately 420 g may also be obtainable. The charge may consist of a mixture of these sizes conforming to the mass tolerances of 6.4 and 6.4.1.

7. Sampling

7.1 Obtain the field sample in accordance with Practice D 75, and reduce the field sample to adequate sample size in accordance with Practice C 702.

8. Test Sample Preparation

8.1 Wash the reduced sample and oven dry at 110 ± 5 °C (230 ± 9 °F) to substantially constant mass (see 9.1.1), separate into individual size fractions, and recombine to the grading of Table 1 most nearly corresponding to the range of sizes in the aggregate as furnished for the work. Record the mass of the sample prior to test to the nearest 1 g.

9. Procedure

9.1 Place the test sample and the charge in the Los Angeles testing machine and rotate the machine at a speed of 30 to 33 r/min for 500 revolutions (Note 6). After the prescribed number of revolutions, discharge the material from the machine and make a preliminary separation of the sample on a sieve coarser than the 1.70-mm (No. 12) sieve. Sieve the finer portion on a 1.70-mm sieve in a manner conforming to Test Method C 136. Wash the material coarser than the 1.70-mm (No. 12) sieve and oven-dry at 110 ± 5 °C (230 ± 9 °F) to substantially constant mass (see 9.1.1), and determine the mass to the nearest 1 g (Note 7).

9.1.1 If the aggregate is essentially free of adherent coatings and dust, the requirement for washing after the test is optional. However, in the case of referee testing, the washing procedure shall be performed.

NOTE 6—Valuable information concerning the uniformity of the sample under test may be obtained by determining the loss after 100 revolutions. The loss should be determined by dry sieving the material on the 1.70-mm sieve without washing. The ratio of the loss after 100 revolutions to the loss after 500 revolutions should not greatly exceed 0.20 for material of uniform hardness. When this determination is made, take care to avoid losing any part of the sample; return the entire sample, including the dust of fracture, to the testing machine for the final 400 revolutions required to complete the test.

NOTE 7—Elimination of washing after test will seldom reduce the measured loss by more than about 0.2 % of the original sample mass.

10. Calculation

10.1 Calculate the loss (difference between the original mass and the final mass of the test sample) as a percentage of the original mass of the test sample. Report this value as the percent loss (Note 8).

NOTE 8—The percent loss determined by this test method has no known consistent relationship to the percent loss for the same material when tested by Test Method C 535.

11. Report

11.1 Report the following information:

11.1.1 Identification of the aggregate as to source, type, and nominal maximum size;

11.1.2 Grading designation from Table 1 used for the test; and

11.1.3 Loss by abrasion and impact of the sample expressed to the nearest 1 % by mass.

12. Precision and Bias

12.1 For nominal 19.0-mm (¾-in.) maximum size coarse aggregate with percent losses in the range of 10 to 45 %, the multilaboratory coefficient of variation has been found to be 4.5 %.[3] Therefore, results of two properly conducted tests from two different laboratories on samples of the same coarse aggregates are not expected to differ from each other by more

[3] These numbers represent, respectively, the (1s%) and (d2s%) limits as described in Practice C 670.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:03:32 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

than 12.7 %[3] (95 % probability) of their average. The single-operator coefficient of variation has been found to be 2.0 %.[3] Therefore, results of two properly conducted tests by the same operator on the same coarse aggregate are not expected to differ from each other by more than 5.7 % (95 % probability) of their average.[3]

12.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for this procedure, no statement on bias is being made.

13. Keywords

13.1 abrasion; aggregate (coarse; small size); degradation; impact; Los Angeles machine

APPENDIX

(Nonmandatory Information)

X1. MAINTENANCE OF SHELF

X1.1 The shelf of the Los Angeles machine is subject to severe surface wear and impact. With use, the working surface of the shelf is peened by the balls and tends to develop a ridge of metal parallel to and about 32 mm (1¼ in.) from the junction of the shelf and the inner surface of the cylinder. If the shelf is made from a section of rolled angle, not only may this ridge develop but the shelf itself may be bent longitudinally or transversely from its proper position.

X1.2 The shelf should be inspected periodically to determine that it is not bent either lengthwise or from its normal radial position with respect to the cylinder. If either condition is found, the shelf should be repaired or replaced before further tests are made. The influence on the test result of the ridge developed by peening of the working face of the shelf is not known. However, for uniform test conditions, it is recommended that the ridge be ground off if its height exceeds 2 mm (0.1 in.).

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 131 – 03, that may impact the use of this test method. (Approved August 1, 2006)

(*1*) Revised 6.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 136 – 06

Standard Test Method for Sieve Analysis of Fine and Coarse Aggregates[1]

This standard is issued under the fixed designation C 136; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the particle size distribution of fine and coarse aggregates by sieving.

1.2 Some specifications for aggregates which reference this test method contain grading requirements including both coarse and fine fractions. Instructions are included for sieve analysis of such aggregates.

1.3 The values stated in SI units are to be regarded as the standard. The values in parentheses are provided for information purposes only. Specification E 11 designates the size of sieve frames with inch units as standard, but in this test method the frame size is designated in SI units exactly equivalent to the inch units.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 702 Practice for Reducing Samples of Aggregate to Testing Size

D 75 Practice for Sampling Aggregates

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

2.2 *AASHTO Standard:*

AASHTO No. T 27 Sieve Analysis of Fine and Coarse Aggregates[3]

3. Terminology

3.1 *Definitions*—For definitions of terms used in this standard, refer to Terminology C 125.

4. Summary of Test Method

4.1 A sample of dry aggregate of known mass is separated through a series of sieves of progressively smaller openings for determination of particle size distribution.

5. Significance and Use

5.1 This test method is used primarily to determine the grading of materials proposed for use as aggregates or being used as aggregates. The results are used to determine compliance of the particle size distribution with applicable specification requirements and to provide necessary data for control of the production of various aggregate products and mixtures containing aggregates. The data may also be useful in developing relationships concerning porosity and packing.

5.2 Accurate determination of material finer than the 75-µm (No. 200) sieve cannot be achieved by use of this test method alone. Test Method C 117 for material finer than 75-µm sieve by washing should be employed.

5.3 Refer to methods of sampling and testing in Specification C 637 for heavyweight aggregates.

6. Apparatus

6.1 *Balances*—Balances or scales used in testing fine and coarse aggregate shall have readability and accuracy as follows:

6.1.1 For fine aggregate, readable to 0.1 g and accurate to 0.1 g or 0.1 % of the test load, whichever is greater, at any point within the range of use.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved Feb. 15, 2006. Published March 2006. Originally approved in 1938. Last previous edition approved in 2005 as C 136 – 05.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.1.2 For coarse aggregate, or mixtures of fine and coarse aggregate, readable and accurate to 0.5 g or 0.1 % of the test load, whichever is greater, at any point within the range of use.

6.2 *Sieves*—The sieve cloth shall be mounted on substantial frames constructed in a manner that will prevent loss of material during sieving. The sieve cloth and standard sieve frames shall conform to the requirements of Specification E 11. Nonstandard sieve frames shall conform to the requirements of Specification E 11 as applicable.

NOTE 1—It is recommended that sieves mounted in frames larger than standard 203.2-mm (8 in.) diameter be used for testing coarse aggregate to reduce the possibility of overloading the sieves. See 8.3.

6.3 *Mechanical Sieve Shaker*—A mechanical sieving device, if used, shall create motion of the sieves to cause the particles to bounce, tumble, or otherwise turn so as to present different orientations to the sieving surface. The sieving action shall be such that the criterion for adequacy of sieving described in 8.4 is met in a reasonable time period.

NOTE 2—Use of a mechanical sieve shaker is recommended when the size of the sample is 20 kg or greater, and may be used for smaller samples, including fine aggregate. Excessive time (more than approximately 10 min) to achieve adequate sieving may result in degradation of the sample. The same mechanical sieve shaker may not be practical for all sizes of samples, since the large sieving area needed for practical sieving of a large nominal size coarse aggregate very likely could result in loss of a portion of the sample if used for a small sample of coarse aggregate or fine aggregate.

6.4 *Oven*—An oven of appropriate size capable of maintaining a uniform temperature of 110 ± 5 °C (230 ± 9 °F).

7. Sampling

7.1 Sample the aggregate in accordance with Practice D 75. The size of the field sample shall be the quantity shown in Practice D 75 or four times the quantity required in 7.4 and 7.5 (except as modified in 7.6), whichever is greater.

7.2 Thoroughly mix the sample and reduce it to an amount suitable for testing using the applicable procedures described in Practice C 702. The sample for test shall be approximately the quantity desired when dry and shall be the end result of the reduction. Reduction to an exact predetermined quantity shall not be permitted.

NOTE 3—Where sieve analysis, including determination of material finer than the 75-µm sieve, is the only testing proposed, the size of the sample may be reduced in the field to avoid shipping excessive quantities of extra material to the laboratory.

7.3 *Fine Aggregate*—The size of the test sample, after drying, shall be 300 g minimum.

7.4 *Coarse Aggregate*—The size of the test sample of coarse aggregate shall conform with the following:

Nominal Maximum Size, Square Openings, mm (in.)	Test Sample Size, min, kg (lb)
9.5 (⅜)	1 (2)
12.5 (½)	2 (4)
19.0 (¾)	5 (11)
25.0 (1)	10 (22)
37.5 (1½)	15 (33)
50 (2)	20 (44)
63 (2½)	35 (77)
75 (3)	60 (130)
90 (3½)	100 (220)
100 (4)	150 (330)
125 (5)	300 (660)

7.5 *Coarse and Fine Aggregate Mixtures*—The size of the test sample of coarse and fine aggregate mixtures shall be the same as for coarse aggregate in 7.4.

7.6 *Samples of Large Size Coarse Aggregate*—The size of sample required for aggregate with 50-mm nominal maximum size or larger is such as to preclude convenient sample reduction and testing as a unit except with large mechanical splitters and sieve shakers. As an option when such equipment is not available, instead of combining and mixing sample increments and then reducing the field sample to testing size, conduct the sieve analysis on a number of approximately equal sample increments such that the total mass tested conforms to the requirement of 7.4.

7.7 In the event that the amount of material finer than the 75-µm (No. 200) sieve is to be determined by Test Method C 117, proceed as follows:

7.7.1 For aggregates with a nominal maximum size of 12.5 mm (1/2 in.) or less, use the same test sample for testing by Test Method C 117 and this test method. First test the sample in accordance with Test Method C 117 through the final drying operation, then dry sieve the sample as stipulated in 8.2-8.7 of this test method.

7.7.2 For aggregates with a nominal maximum size greater than 12.5 mm (½ in.), use a single test sample as described in 7.7.1, or optionally use separate test samples for Test Method C 117 and this test method.

7.7.3 Where the specifications require determination of the total amount of material finer than the 75-µm sieve by washing and dry sieving, use the procedure described in 7.7.1.

8. Procedure

8.1 Dry the sample to constant mass at a temperature of 110 ± 5 °C (230 ± 9 °F).

NOTE 4—For control purposes, particularly where rapid results are desired, it is generally not necessary to dry coarse aggregate for the sieve analysis test. The results are little affected by the moisture content unless: (*1*) the nominal maximum size is smaller than about 12.5 mm (½ in.); (*2*) the coarse aggregate contains appreciable material finer than 4.75 mm (No. 4); or (*3*) the coarse aggregate is highly absorptive (a lightweight aggregate, for example). Also, samples may be dried at the higher temperatures associated with the use of hot plates without affecting results, provided steam escapes without generating pressures sufficient to fracture the particles, and temperatures are not so great as to cause chemical breakdown of the aggregate.

8.2 Select sieves with suitable openings to furnish the information required by the specifications covering the material to be tested. Use additional sieves as desired or necessary to provide other information, such as fineness modulus, or to regulate the amount of material on a sieve. Nest the sieves in order of decreasing size of opening from top to bottom and place the sample on the top sieve. Agitate the sieves by hand or by mechanical apparatus for a sufficient period, established by trial or checked by measurement on the actual test sample, to meet the criterion for adequacy or sieving described in 8.4.

8.3 Limit the quantity of material on a given sieve so that all particles have opportunity to reach sieve openings a number of times during the sieving operation. For sieves with openings

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:03:34 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

smaller than 4.75-mm (No. 4), the quantity retained on any sieve at the completion of the sieving operation shall not exceed 7 kg/m^2 of sieving surface area (Note 5). For sieves with openings 4.75 mm (No. 4) and larger, the quantity retained in kg shall not exceed the product of 2.5 × (sieve opening, mm × (effective sieving area, m^2)). This quantity is shown in Table 1 for five sieve-frame dimensions in common use. In no case shall the quantity retained be so great as to cause permanent deformation of the sieve cloth.

8.3.1 Prevent an overload of material on an individual sieve by one of the following methods:

8.3.1.1 Insert an additional sieve with opening size intermediate between the sieve that may be overloaded and the sieve immediately above that sieve in the original set of sieves.

8.3.1.2 Split the sample into two or more portions, sieving each portion individually. Combine the masses of the several portions retained on a specific sieve before calculating the percentage of the sample on the sieve.

8.3.1.3 Use sieves having a larger frame size and providing greater sieving area.

NOTE 5—The 7 kg/m^2 amounts to 200 g for the usual 203.2-mm (8-in.) diameter sieve (with effective sieving surface diameter of 190.5 mm (7.5 in.)).

8.4 Continue sieving for a sufficient period and in such manner that, after completion, not more than 1 % by mass of the material retained on any individual sieve will pass that sieve during 1 min of continuous hand sieving performed as follows: Hold the individual sieve, provided with a snug-fitting pan and cover, in a slightly inclined position in one hand. Strike the side of the sieve sharply and with an upward motion against the heel of the other hand at the rate of about 150 times per minute, turn the sieve about one sixth of a revolution at intervals of about 25 strokes. In determining sufficiency of sieving for sizes larger than the 4.75-mm (No. 4) sieve, limit the material on the sieve to a single layer of particles. If the size of the mounted testing sieves makes the described sieving motion impractical, use 203-mm (8 in.) diameter sieves to verify the sufficiency of sieving.

TABLE 1 Maximum Allowable Quantity of Material Retained on a Sieve, kg

Sieve Opening Size, mm	Nominal Dimensions of Sieve[A]				
	203.2-mm dia[B]	254-mm dia[B]	304.8-mm dia[B]	350 by 350 mm	372 by 580 mm

12.5	0.89	1.4	2.1	3.8	6.7
9.5	0.67	1.1	1.6	2.9	5.1
4.75	0.33	0.54	0.80	1.5	2.6

[A] Sieve frame dimensions in inch units: 8.0-in. diameter; 10.0-in. diameter, 12.0-in. diameter; 13.8 by 13.8 in. (14 by 14 in. nominal); 14.6 by 22.8 in. (16 by 24 in. nominal).

[B] The sieve area for round sieve frames is based on an effective diameter 12.7 mm (½ in.) less than the nominal frame diameter, because Specification E 11 permits the sealer between the sieve cloth and the frame to extend 6.35 mm (¼ in.) over the sieve cloth. Thus the effective sieving diameter for a 203.2-mm (8.0-in.) diameter sieve frame is 190.5 mm (7.5 in.). Sieves produced by some manufacturers do not infringe on the sieve cloth by the full 6.35 mm (¼ in.).

[C] Sieves indicated have less than five full openings and should not be used for sieve testing except as provided in 8.6.

8.5 In the case of coarse and fine aggregate mixtures, refer to 8.3.1 to prevent overloading of individual sieves.

8.5.1 Optionally, reduce the portion finer than the 4.75-mm (No. 4) sieve using a mechanical splitter according to Practice C 702. If this procedure is followed, compute the mass of each size increment of the original sample as follows:

$$A = \frac{W_1}{W_2} \times B \quad (1)$$

where:

A = mass of size increment on total sample basis,
W_1 = mass of fraction finer than 4.75-mm (No. 4) sieve in total sample,
W_2 = mass of reduced portion of material finer than 4.75-mm (No. 4) sieve actually sieved, and
B = mass of size increment in reduced portion sieved.

8.6 Unless a mechanical sieve shaker is used, hand sieve particles larger than 75 mm (3 in.) by determining the smallest sieve opening through which each particle will pass. Start the test on the smallest sieve to be used. Rotate the particles, if necessary, in order to determine whether they will pass through a particular opening; however, do not force particles to pass through an opening.

8.7 Determine the mass of each size increment on a scale or balance conforming to the requirements specified in 5.1 to the nearest 0.1 % of the total original dry sample mass. The total mass of the material after sieving should check closely with original mass of sample placed on the sieves. If the amounts differ by more than 0.3 %, based on the original dry sample mass, the results should not be used for acceptance purposes.

8.8 If the sample has previously been tested by Test Method C 117, add the mass finer than the 75-µm (No. 200) sieve determined by that test method to the mass passing the 75-µm (No. 200) sieve by dry sieving of the same sample in this test method.

9. Calculation

9.1 Calculate percentages passing, total percentages retained, or percentages in various size fractions to the nearest 0.1 % on the basis of the total mass of the initial dry sample. If the same test sample was first tested by Test Method C 117, include the mass of material finer than the 75-µm (No. 200) size by washing in the sieve analysis calculation; and use the total dry sample mass prior to washing in Test Method C 117 as the basis for calculating all the percentages.

9.1.1 When sample increments are tested as provided in 7.6, total the masses of the portion of the increments retained on each sieve, and use these masses to calculate the percentages as in 9.1.

9.2 Calculate the fineness modulus, when required, by adding the total percentages of material in the sample that is coarser than each of the following sieves (cumulative percentages retained), and dividing the sum by 100: 150-µm (No.

www.technobetar.ir

100), 300-µm (No. 50), 600-µm (No. 30), 1.18-mm (No. 16), 2.36-mm (No. 8), 4.75-mm (No. 4), 9.5-mm (⅜-in.), 19.0-mm (¾-in.), 37.5-mm (1½-in.), and larger, increasing in the ratio of 2 to 1.

10. Report

10.1 Depending upon the form of the specifications for use of the material under test, the report shall include the following:

10.1.1 Total percentage of material passing each sieve, or

10.1.2 Total percentage of material retained on each sieve, or

10.1.3 Percentage of material retained between consecutive sieves.

10.2 Report percentages to the nearest whole number, except if the percentage passing the 75-µm (No. 200) sieve is less than 10 %, it shall be reported to the nearest 0.1 %.

10.3 Report the fineness modulus, when required, to the nearest 0.01.

11. Precision and Bias

11.1 *Precision*—The estimates of precision for this test method are listed in Table 2. The estimates are based on the results from the AASHTO Materials Reference Laboratory Proficiency Sample Program, with testing conducted by Test Method C 136 and AASHTO No. T 27. The data are based on the analyses of the test results from 65 to 233 laboratories that tested 18 pairs of coarse aggregate proficiency test samples and test results from 74 to 222 laboratories that tested 17 pairs of fine aggregate proficiency test samples (Samples No. 21 through 90). The values in the table are given for different ranges of total percentage of aggregate passing a sieve.

11.1.1 The precision values for fine aggregate in Table 2 are based on nominal 500-g test samples. Revision of this test method in 1994 permits the fine aggregate test sample size to be 300 g minimum. Analysis of results of testing of 300-g and 500-g test samples from Aggregate Proficiency Test Samples 99 and 100 (Samples 99 and 100 were essentially identical) produced the precision values in Table 3, which indicate only minor differences due to test sample size.

NOTE 6—The values for fine aggregate in Table 2 will be revised to reflect the 300-g test sample size when a sufficient number of Aggregate Proficiency Tests have been conducted using that sample size to provide reliable data.

TABLE 2 Precision

	Total Percentage of Material Passing		Standard Deviation (1s), %[A]	Acceptable Range of Two Results (d2s), %[A]
Coarse Aggregate:[B]				
Single-operator precision	<100	≥95	0.32	0.9
	<95	≥85	0.81	2.3
	<85	≥80	1.34	3.8
	<80	≥60	2.25	6.4
	<60	≥20	1.32	3.7
	<20	≥15	0.96	2.7
	<15	≥10	1.00	2.8
	<10	≥5	0.75	2.1
	<5	≥2	0.53	1.5
	<2	>0	0.27	0.8
Multilaboratory precision	<100	≥95	0.35	1.0
	<95	≥85	1.37	3.9
	<85	≥80	1.92	5.4
	<80	≥60	2.82	8.0
	<60	≥20	1.97	5.6
	<20	≥15	1.60	4.5
	<15	≥10	1.48	4.2
	<10	≥5	1.22	3.4
	<5	≥2	1.04	3.0
	<2	>0	0.45	1.3
Fine Aggregate:				
Single-operator precision	<100	≥95	0.26	0.7
	<95	≥60	0.55	1.6
	<60	≥20	0.83	2.4
	<20	≥15	0.54	1.5
	<15	≥10	0.36	1.0
	<10	≥2	0.37	1.1
	<2	>0	0.14	0.4
Multilaboratory precision	<100	≥95	0.23	0.6
	<95	≥60	0.77	2.2
	<60	≥20	1.41	4.0
	<20	≥15	1.10	3.1
	<15	≥10	0.73	2.1
	<10	≥2	0.65	1.8
	<2	>0	0.31	0.9

[A] These numbers represent, respectively, the (1s) and (d2s) limits described in Practice C 670.

[B] The precision estimates are based on aggregates with nominal maximum size of 19.0 mm (¾ in.).

11.2 *Bias*—Since there is no accepted reference material suitable for determining the bias in this test method, no statement on bias is made.

12. Keywords

12.1 aggregate; coarse aggregate; fine aggregate; gradation; grading; sieve analysis; size analysis

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 136 – 05, that may impact the use of this test method. (Approved February 15, 2006)

(*1*) Revised 8.5.1.
(*2*) Revised 7.7.2.
(*3*) Revised 8.5.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 136 – 04, that may impact the use of this test method. (Approved February 1, 2005)

(*1*) Added 5.3.
(*2*) Revised 8.5.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 138/C 138M – 09

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T121

Standard Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete[1]

This standard is issued under the fixed designation C 138/C 138M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers determination of the density (see Note 1) of freshly mixed concrete and gives formulas for calculating the yield, cement content, and air content of the concrete. Yield is defined as the volume of concrete produced from a mixture of known quantities of the component materials.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

NOTE 1—Unit weight was the previous terminology used to describe the property determined by this test method, which is mass per unit volume.

1.3 The text of this test method references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this test method.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 29/C 29M Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate
C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field
C 143/C 143M Test Method for Slump of Hydraulic-Cement Concrete
C 150 Specification for Portland Cement
C 172 Practice for Sampling Freshly Mixed Concrete
C 173/C 173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method
C 188 Test Method for Density of Hydraulic Cement
C 231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method

3. Terminology

3.1 *Symbols*:

A = air content (percentage of voids) in the concrete
C = actual cement content, lb/yd^3 or kg/m^3
C_b = mass of cement in the batch, lb or kg
D = density (unit weight) of concrete, lb/ft^3 or kg/m^3
M = total mass of all materials batched, lb or kg (see Note 3)
M_c = mass of the measure filled with concrete, lb or kg
M_m = mass of the measure, lb or kg
R_y = relative yield
T = theoretical density of the concrete computed on an airfree basis, lb/ft^3 or kg/m^3 (see Note 2)
Y = yield, volume of concrete produced per batch, yd^3 or m^3
Y_d = volume of concrete which the batch was designed to produce, yd^3 or m^3
Y_f = volume of concrete produced per batch, ft^3
V = total absolute volume of the component ingredients in the batch, ft^3 or m^3
V_m = volume of the measure, ft^3 or m^3

NOTE 2—The theoretical density is, customarily, a laboratory determination, the value for which is assumed to remain constant for all batches made using identical component ingredients and proportions. It is calculated from the following equation:

$$T = M/V \quad (1)$$

The absolute volume of each ingredient in cubic feet is equal to the quotient of the mass of that ingredient divided by the product of its specific gravity times 62.4. The absolute volume of each ingredient in cubic metres is equal to the mass of the ingredient in kilograms divided by 1000 times its specific gravity. For the aggregate components, the bulk

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.60 on Testing Fresh Concrete.

Current edition approved June 1, 2009. Published July 2009. Originally approved in 1938. Last previous edition approved in 2008 as C 138/C 138M – 08.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

specific gravity and mass should be based on the saturated, surface-dry condition. For cement, the actual specific gravity should be determined by Test Method C 188. A value of 3.15 may be used for cements manufactured to meet the requirements of Specification C 150.

NOTE 3—The total mass of all materials batched is the sum of the masses of the cement, the fine aggregate in the condition used, the coarse aggregate in the condition used, the mixing water added to the batch, and any other solid or liquid materials used.

4. Apparatus

4.1 *Balance*—A balance or scale accurate to 0.1 lb [45 g] or to within 0.3 % of the test load, whichever is greater, at any point within the range of use. The range of use shall be considered to extend from the mass of the measure empty to the mass of the measure plus its contents at 160 lb/ft^3 [2600 kg/m^3].

4.2 *Tamping Rod*—A round, straight steel rod, with a ⅝ in. [16 mm] ± 1/16 in. [2 mm] diameter. The length of the tamping rod shall be at least 4 in. [100 mm] greater than the depth of the measure in which rodding is being performed, but not greater than 24 in. [600 mm] in overall length (See Note 4). The length tolerance for the tamping rod shall be ± ⅛ in. [4 mm]. The rod shall have the tamping end or both ends rounded to a hemispherical tip of the same diameter as the rod.

NOTE 4—A rod length of 16 in. [400 mm] to 24 in. [600 mm] meets the requirements of the following: Practice C 31/C 31M, Test Method C 138/C 138M, Test Method C 143/C 143M, Test Method C 173/C 173M and Test Method C 231.

4.3 *Internal Vibrator*—Internal vibrators may have rigid or flexible shafts, preferably powered by electric motors. The frequency of vibration shall be 7000 vibrations per minute or greater while in use. The outside diameter or the side dimension of the vibrating element shall be at least 0.75 in. [19 mm] and not greater than 1.50 in. [38 mm]. The length of the shaft shall be at least 24 in. [600 mm].

4.4 *Measure*—A cylindrical container made of steel or other suitable metal (see Note 5). The minimum capacity of the measure shall conform to the requirements of Table 1 based on the nominal size of aggregate in the concrete to be tested. All measures, except for measuring bowls of air meters which are also used for Test Method C 138/C 138M tests, shall conform to the requirements of Test Method C 29/C 29M. When measuring bowls of air meters are used, they shall conform to the requirements of Test Method C 231, and shall be calibrated for volume as described in Test Method C 29/C 29M. The top rim of the air meter bowls shall be smooth and plane within 0.01 in. [0.3 mm] (see Note 6).

TABLE 1 Capacity of Measures

Nominal Maximum Size of Coarse Aggregate		Capacity of Measure[A]	
in.	mm	ft^3	L
1	25.0	0.2	6
1½	37.5	0.4	11
2	50	0.5	14
3	75	1.0	28
4½	112	2.5	70
6	150	3.5	100

[A] The indicated size of measure shall be used to test concrete containing aggregates of a nominal maximum size equal to or smaller than that listed. The actual volume of the measure shall be at least 95 % of the nominal volume listed.

NOTE 5—The metal should not be readily subject to attack by cement paste. However, reactive materials such as aluminum alloys may be used in instances where as a consequence of an initial reaction, a surface film is rapidly formed which protects the metal against further corrosion.

NOTE 6—The top rim is satisfactorily plane if a 0.01-in. [0.3-mm] feeler gage cannot be inserted between the rim and a piece of ¼-in. [6-mm] or thicker plate glass laid over the top of the measure.

4.5 *Strike-Off Plate*—A flat rectangular metal plate at least ¼ in. [6 mm] thick or a glass or acrylic plate at least ½ in. [12 mm] thick with a length and width at least 2 in. [50 mm] greater than the diameter of the measure with which it is to be used. The edges of the plate shall be straight and smooth within a tolerance of 1/16 in. [2 mm].

4.6 *Mallet*—A mallet (with a rubber or rawhide head) having a mass of 1.25 ± 0.50 lb [600 ± 200 g] for use with measures of 0.5 ft^3 [14 L] or smaller, and a mallet having a mass of 2.25 ± 0.50 lb [1000 ± 200 g] for use with measures larger than 0.5 ft^3.

4.7 *Scoop*—of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the measure.

5. Sample

5.1 Obtain the sample of freshly mixed concrete in accordance with Practice C 172.

6. Procedure

6.1 Base the selection of the method of consolidation on the slump, unless the method is stated in the specifications under which the work is being performed. The methods of consolidation are rodding and internal vibration. Rod concretes with a slump greater than 3 in. [75 mm]. Rod or vibrate concrete with a slump of 1 to 3 in. [25 to 75 mm]. Consolidate concretes with a slump less than 1 in. by vibration.

NOTE 7—Nonplastic concrete, such as is commonly used in the manufacture of pipe and unit masonry, is not covered by this test method.

6.2 Place the concrete in the measure using the scoop described in 4.7. Move the scoop around the perimeter of the measure opening to ensure an even distribution of the concrete with minimal segregation. Fill the measure in the number of layers required by the consolidation method (6.3 or 6.4).

6.3 *Rodding*—Place the concrete in the measure in three layers of approximately equal volume. Rod each layer with 25 strokes of the tamping rod when nominal 0.5-ft^3 [14-L] or smaller measures are used, 50 strokes when nominal 1-ft^3 [28-L] measures are used, and one stroke per 3 in.^{2} [20 cm^3] of surface for larger measures. Rod each layer uniformly over the cross section with the rounded end of the rod using the required number of strokes. Rod the bottom layer throughout its depth. In rodding this layer, use care not to damage the bottom of the measure. For each upper layer, allow the rod to penetrate through the layer being rodded and into the layer below approximately 1 in. [25 mm]. After each layer is rodded, tap the sides of the measure 10 to 15 times with the appropriate mallet (see 4.6) using such force so as to close any voids left by the tamping rod and to release any large bubbles of air that may have been trapped. Add the final layer so as to avoid overfilling.

www.technobetar.ir

6.4 *Internal Vibration*—Fill and vibrate the measure in two approximately equal layers. Place all of the concrete for each layer in the measure before starting vibration of that layer. Insert the vibrator at three different points for each layer. In compacting the bottom layer, do not allow the vibrator to rest on or touch the bottom or sides of the measure. In compacting the final layer, the vibrator shall penetrate into the underlying layer approximately 1 in. [25 mm]. Take care that the vibrator is withdrawn in such a manner that no air pockets are left in the specimen. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator (see Note 8). Continue vibration only long enough to achieve proper consolidation of the concrete (see Note 9). Observe a constant duration of vibration for the particular kind of concrete, vibrator, and measure involved.

NOTE 8—Usually, sufficient vibration has been applied as soon as the surface of the concrete becomes relatively smooth.

NOTE 9—Overvibration may cause segregation and loss of appreciable quantities of intentionally entrained air.

6.5 On completion of consolidation the measure must not contain a substantial excess or deficiency of concrete. An excess of concrete protruding approximately ⅛ in. [3 mm] above the top of the mold is optimum. A small quantity of concrete may be added to correct a deficiency. If the measure contains a great excess of concrete at completion of consolidation, remove a representative portion of the excess concrete with a trowel or scoop immediately following completion of consolidation and before the measure is struck-off.

6.6 *Strike-Off*—After consolidation, strike-off the top surface of the concrete and finish it smoothly with the flat strike-off plate using great care to leave the measure just level full. The strike-off is best accomplished by pressing the strike-off plate on the top surface of the measure to cover about two thirds of the surface and withdrawing the plate with a sawing motion to finish only the area originally covered. Then place the plate on the top of the measure to cover the original two thirds of the surface and advance it with a vertical pressure and a sawing motion to cover the whole surface of the measure and continue to advance it until it slides completely off the measure. Several final strokes with the inclined edge of the plate will produce a smooth finished surface.

6.7 *Cleaning and Weighing*—After strike-off, clean all excess concrete from the exterior of the measure and determine the mass of the concrete and measure to an accuracy consistent with the requirements of 4.1.

7. Calculation

7.1 *Density (Unit Weight)*—Calculate the net mass of the concrete in pounds or kilograms by subtracting the mass of the measure, M_m, from the mass of the measure filled with concrete, M_c. Calculate the density, D, ft^3 or yd^3,by dividing the net mass of concrete by the volume of the measure, V_m as follows:

$$D = (M_c - M_m)/V_m \quad (2)$$

7.2 *Yield*—Calculate the yield as follows:

$$Y(yd^3) = M/(D \times 27) \quad (3)$$

or

$$Y(m^3) = M/D \quad (4)$$

7.3 *Relative Yield*—Relative yield is the ratio of the actual volume of concrete obtained to the volume as designed for the batch (see Note 10) calculated as follows:

$$R_y = Y/Y_d \quad (5)$$

NOTE 10—A value for R_y greater than 1.00 indicates an excess of concrete being produced whereas a value less than this indicates the batch to be "short" of its designed volume. In practice, a ratio of yield in cubic feet per cubic yard of design concrete mixture is frequently used, for example, 27.3 ft^3/yd^3.

7.4 *Cement Content*—Calculate the actual cement content as follows:

$$C = C_b/Y \quad (6)$$

7.5 *Air Content*—Calculate the air content as follows:

$$A = [(T - D)/T] \times 100 \quad (7)$$

or

$$A = [(Y_f - V)/Y_f] \times 100 \text{ (inch–pound units)} \quad (8)$$

or

$$A = [(Y - V)/Y] \times 100 \text{ (SI units)} \quad (9)$$

8. Report

8.1 Report the following information:

8.1.1 Identification of concrete represented by the sample.

8.1.2 Date of test.

8.1.3 Volume of density measure to the nearest 0.001 ft^3 [0.01 L].

8.1.4 Density (Unit Weight) to the nearest 0.1 lbs/ft^3 [1.0 kg/m^3].

8.1.5 Yield, when requested, to the nearest 0.1 yd^3 [0.1 m^3].

8.1.6 Relative Yield, when requested, to the nearest 0.01.

8.1.7 Cement Content, when requested, to the nearest 1.0 lb [0.5 kg].

8.1.8 Air Content, when requested, to the nearest 0.1 percent.

9. Precision and Bias

9.1 The following estimates of precision for this test method are based on a collection of data from various locations by the National Ready Mixed Concrete Association.[3] The data represent concrete mixtures with slump ranging from 3 to 6 in. [75 to 150 mm] and density ranging from 115 to 155 lb/ft^3 [1842 to 2483 kg/m^3] and included air-entrained and non air-entrained concrete. The study was conducted using 0.25 ft^3 [7-L] and 0.5 ft^3 [14-L] measures.

9.1.1 *Single-Operator Precision*—The single operator standard deviation of density of freshly mixed concrete has been found to be 0.65 lb/ft^3 [10.4 kg/m^3] (1s). Therefore, results of two properly conducted by the same operator on the same sample of concrete should not differ by more than 1.85 lb/ft^3 [29.6 kg/m^3] (d2s).

9.1.2 *Multi-Operator Precision*—The multi-operator standard deviation of density of freshly mixed concrete has been

[3] Mullings, G. M., NRMCA/NAA Joint Research Lab Study "Series D 324 Accuracy of Concrete Density Test," Feb. 17, 2000.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

found to be 0.82 lb/ft^3 [13.1 kg/m^3] (1s). Therefore, results of two properly conducted tests by the two operators on the same sample of concrete should not differ by more than 2.31 lb/ft^3 [37.0 kg/m^3] (d2s).

9.2 *Bias*—This test method has no bias since the density is defined only in terms of this test method.

10. Keywords

10.1 air content; cement content; concrete; relative yield; unit weight; yield

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 138/C 138M – 08, that may impact the use of this test method. (Approved June 1, 2009)

(*1*) Revised 4.2 to alter requirements of tamping rod.
(*2*) Added Note 4 describing acceptable tamping rod length.
(*3*) Revised 6.3 to alter wording of tamping rod use.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 138/C 138M – 07, that may impact the use of this test method. (Approved March 1, 2008)

(*1*) Added new 4.7 to define a scoop.
(*2*) Added new 6.2 to describe how to use a scoop.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C141/C141M – 09

Standard Specification for Hydrated Hydraulic Lime for Structural Purposes[1]

This standard is issued under the fixed designation C141/C141M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers hydrated hydraulic lime for structural purposes.

1.2 Hydrated hydraulic lime may be used in the scratch or brown coat of plaster, stucco, mortar, or in portland-cement concrete either as blend, amendment, or admixture.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 The following precautionary caveat pertains only to the test method portion, Section 11 of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

C50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C51 Terminology Relating to Lime and Limestone (as used by the Industry)

C109/C109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

C187 Test Method for Normal Consistency of Hydraulic Cement

C191 Test Methods for Time of Setting of Hydraulic Cement by Vicat Needle

C230/C230M Specification for Flow Table for Use in Tests of Hydraulic Cement

C270 Specification for Mortar for Unit Masonry

C305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C778 Specification for Standard Sand

3. Terminology

3.1 For definitions of terms related to this specification, see Terminology C51.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *hydrated hydraulic lime*, *n*—the product resulting from the slaking of hydraulic quicklime generally to a powder, without any addition, and with or without grinding. It has the property of setting and hardening under water and by reaction of carbon dioxide from the air. The hydraulic properties of this material comes only from the composition of the raw materials.

3.2.2 *hydraulic quicklime*, *n*—a cementitious product obtained by calcining argillaceous or siliceous limestone, or a mixture of similar composition to form sufficient free lime to permit hydration by slaking.

3.2.3 *reworkability*, *n*—the ability of a material which has setting and hardening properties to be remixed after a given period without significantly compromising the final hardened properties of the material.

3.2.4 *period of reworkability*—the length of time a material can be reworked after initial mixing; it shall be expressed in hours.

NOTE 1—Hydrated hydraulic limes have a long working time lasting up to 24 h. The user should seek advice from the producer as to maximum working time.

4. Chemical Composition

4.1 The hydrated hydraulic lime shall conform to the following requirements as to chemical composition, calculated to the nonvolatile basis:

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines

Current edition approved Oct. 1, 2009. Published November 2009. Originally approved in 1938. Last previous edition approved in 2005 as C141 – 97(2005). DOI: 10.1520/C0141_C0141M-09.

	Min	Max
Calcium and magnesium oxides (CaO and MgO calculated to the nonvolatile basis), %	50	75
Silica (SiO_2 calculated to the nonvolatile basis), %	4	20
Iron and aluminum oxides (Fe_2O_3 and Al_2O_3 caculated to the nonvolatile basis), %	...	7
Carbon dioxide (CO_2 on an as received basis), %	...	16
Available lime (CaO calculated with Test Methods C25 Section 28), %	16	...

5. Fineness

5.1 The sample shall leave a residue of not more than 0.5 % on a 600-µm [No. 30] sieve and not more than 10 % on a 75-µm [No. 200] sieve when tested as described in 11.2.

6. Time of Setting

6.1 The neat lime paste mixed to normal consistency shall not develop an initial set in less than 2 h as determined by the Vicat needle method (see 11.4). Final set shall be attained within 48 h at 100 % RH.

7. Reworkability

7.1 Test for reworkability as described in section 11.7.1. The average compressive strength value of the second set of cubes (set B) shall not be less than 30 % of the first set (set A).

8. Soundness

8.1 The samples when made, stored, and autoclaved as described in 11.5 shall not have an expansion of more than 1.0 %.

9. Compressive Strength

9.1 The average compressive strength of at least three 50-mm [2-in.] cubes, made, stored, and tested in accordance with 11.6, shall be not less than 1.7 N/mm^2 [250 psi] and no more than 10.3 N/mm^2 [1500 psi] at the age of 28 days.

9.2 The producer shall state the compressive strength, when tested in accordance with 11.6, at the age of 28 days.

9.3 The product shall be reworkable at 24 h as tested in accordance with 11.7.

NOTE 2—For quality control convenience, compressive strengths are tested at 28 days. Hydrated hydraulic limes will gain considerably in strength over time (up to 90 % of final strength being realized at 12 months).

10. Sampling

10.1 Each sample selected for purpose of tests shall weigh at least 2.3 kg [5 lb] and shall represent not more than 22 680 kg [50 000 lb]. If only one sample is taken, it shall weigh at least 4.5 kg [10 lb].

10.2 The sample shall be given a preliminary sieving by being passed through a 850-µm [No. 20] sieve in order to thoroughly mix the sample and break up lumps.

10.3 Samples shall be shipped and stored in airtight, moistureproof containers.

10.4 The sampling, inspection, rejection, retesting, packaging, and marking shall be conducted in accordance with Practice C50.

11. Test Methods:

11.1 *Chemical Analysis*:

11.1.1 Analyses for chemical composition shall be carried out in accordance with Test Methods C25.

11.2 *Fineness*:

11.2.1 Wet sieve testing should be determined by Test Methods C110 paragraph 15.4.

11.3 *Normal Consistency*:

11.3.1 Determine normal consistency by the Vicat apparatus in accordance with Test Method C187.

11.4 *Time of Setting*:

11.4.1 Determine time of setting by the Vicat needle method in accordance with Test Method C191. The test will be done on a sample kept at 100 % RH. It will only be removed for measuring.

11.5 *Autoclave Expansion*:

11.5.1 Determine autoclave expansion in accordance with Test Methods C110 paragraph 9.3, with the following modifications:

11.5.1.1 Weigh 25 ± 0.1 g of HHL. Add 3 ± 1 ml of water to the weighed sample and mix by hand until wetted. If the balance allows it, work directly in the specimen mold. If this is not possible, work in an intermediate container and transfer the mixture to the specimen mold in as a complete state as possible. Press to 5.0 ± 1.5 N/mm^2 [725 ± 218 psi] for 10 s and demold specimen and autoclave as described.

11.6 *Compressive Strength*:

11.6.1 *Apparatus*:

11.6.1.1 *Scales and Weights, Sieves, Glass Graduates, Specimen Molds, Tamper, Trowel, and Testing Machine*, in accordance with Test Method C109/C109M.

11.6.1.2 *Flow Table*, conforming to the requirements of Specification C230/C230M.

11.6.1.3 *Mixing Apparatus*, conforming to the requirements of Practice C305.

11.6.2 *Standard Sand*—Use 20–30 sand meeting the requirements of Specification C778.

11.6.3 *Proportions for Standard Mortar*— The mortar shall consist of 1 part of hydrated hydraulic lime to 3 parts of Specification C778 sand, by weight. The quantity of water measured in millilitres shall be such as to produce a flow of 100 to 115 % as determined by the flow table in 11.6.5.

NOTE 3—This proportion is by weight and differs from Specification C270, which is by volume.

11.6.4 *Preparation of Standard Mortar*— Mix the mortar in accordance with Section 7 of Practice C305, using 500 g of hydrated hydraulic lime and 1500 g of Specification C778 sand with the necessary water to give the desired flow.

11.6.5 *Determination of Flow*—Determine the flow in accordance with Section 8.3 of Test Method C109/C109M.

11.6.6 *Molding of Test Specimens*:

11.6.6.1 Prepare molds in accordance with Section 9 of Test Method C109/C109M.

11.6.6.2 The temperature of the air in the vicinity of the mixing slab and of the dry materials, molds, base plates, and mixing bowl, shall be maintained between 20 and 27.5 °C [68 and 81.5 °F]. The temperature of the mixing water, moist closet or moist room, and water in the storage tank shall not vary from 23 °C [73.4 °F] by more than ± 1.7 °C [± 3 °F]. The

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

moist closet or moist room shall be so constructed as to provide storage facilities for test specimens at a relative humidity of not less than 90 %.

11.6.6.3 Mold test specimens in accordance with 10.4 of Test Method C109/C109M.

11.6.7 *Storage of Test Specimens*—Keep all test specimens, immediately after molding, in the molds on plane plates in a damp closet, maintained at a relative humidity of 90 % or more, for from 48 to 52 h in such a manner that the upper surfaces are exposed to the moist air. Then remove the specimens from the molds and maintain them at a relative humidity of not less than 90% until the 28 day tests are performed.

11.6.8 *Testing of Specimens*:

11.6.8.1 Test the specimens for 28-day strengths after removal from storage as described in 11.6.7.

11.6.8.2 The remainder of the testing procedure shall be in accordance with 8.6 and Section 9 of Test Method C109/C109M.

11.6.9 *Faulty Specimens*—Specimens that are manifestly faulty or that give strengths differing by more than 15 % from the average value of all test specimens made from the same sample and tested at the same period, shall not be considered in determining the compressive strength.

11.7 *Reworkability: Testing of Specimen*:

11.7.1 Prepare a mortar mix in accordance with 11.6.4 in sufficient amount to be able to fill two sets of three 2-in. cubes. Cut the mix in half, use first half to prepare a first set of cubes (set A). Store second half in a hermetic container and let rest for 24 (±1) h. Once waiting time is achieved, mix the mortar of the second set to achieve required flow as 11.6.5 and prepare a second set of three cubes (set B). Store all cubes as described in 11.6.7. Measure compressive strength of both sets at 28 days of age starting with first mixing time as per 11.6.

12. Storage

12.1 The hydrated hydraulic lime shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weathertight building that will protect the hydrated hydraulic lime from damage.

13. Inspection

13.1 Every producer shall provide the purchaser with the opportunity to sample and inspect the material either at the place of manufacture or at the destination, as may be specified by the purchaser.

14. Rejection

14.1 *Product*—The hydrated hydraulic lime may be rejected if it fails to meet any of the requirements of this specification. At least 31 days shall be allowed for completion of the 28-day test.

14.2 *Packaging*—Packages varying more than 10 % from the weight marked thereon may be rejected, and if the average weight of packages in any shipment, as shown by weighing 50 packages taken at random, is less than the weight marked thereon, the entire shipment may be rejected.

15. Packaging and Marking

15.1 The hydrated hydraulic lime shall be delivered in suitable containers with the brand and name of the manufacturer and the net weight plainly marked thereon. All packages shall be in good condition at the time of inspection.

16. Keywords

16.1 compressive strength; hydrated hydraulic lime; hydraulic lime; mortar; portland cement concrete; plaster; stucco

SUMMARY OF CHANGES

Committee C07 has identified the location of the selected changes to this specification since the last issue, C141 – 97(2005), that may impact the use of this specification (Approved October 1, 2009)

(*1*) The standard was revised throughout, including changing the title and making the standard a dual units specification.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Designation: C 142 – 97 (Reapproved 2004)

American Association of State
Highway and Transportation Officials Standard
AASHTO No. T112

Standard Test Method for Clay Lumps and Friable Particles in Aggregates[1]

This standard is issued under the fixed designation C 142; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the approximate determination of clay lumps and friable particles in aggregates.

1.2 The values given in SI units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 33 Specification for Concrete Aggregates

C 117 Test Method for Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 1005 Specification for Reference Masses and Devices for Determining Mass for Use in the Physical Testing of Hydraulic Cements

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Significance and Use

3.1 This test method is of primary significance in determining the acceptability of aggregate with respect to the requirements of Specification C 33.

4. Apparatus

4.1 *Balance*—A balance or scale accurate to within 0.1 % of the mass of the test sample at any point within the range of use. Balances shall conform to the accuracy of the applicable sections of Specification C 1005.

4.2 *Containers*—Rust-resistant containers of a size and shape that will permit the spreading of the sample on the bottom in a thin layer.

4.3 *Sieves*—Sieves conforming to Specification E 11.

4.4 *Drying Oven*—An oven providing free circulation of air and capable of maintaining a temperature of 110 ± 5°C (230 ± 9°F).

5. Samples

5.1 Aggregate for this test method shall consist of the material remaining after completion of testing in accordance with Test Method C 117. To provide the quantities designated in 5.3 and 5.4, it may be necessary to combine material from more than one test by Test Method C 117.

5.2 Dry the aggregate to substantially constant mass at a temperature of 110 ± 5°C (230 ± 9°F).

5.3 Test samples of fine aggregate shall consist of the particles coarser than a 1.18-mm (No. 16) sieve and shall have a mass not less than 25 g.

5.4 Separate the test samples of coarse aggregate into different sizes, using the following sieves: 4.75-mm (No. 4), 9.5-mm (⅜-in.), 19.0-mm (¾-in.), and 37.5-mm (1½-in.). The test sample shall have a mass not less than indicated in the following table:

Size of Particles Making Up Test Sample	Mass of Test Sample, min, g
4.75 to 9.5-mm (No. 4 to ⅜-in.)	1000
9.5 to 19.0-mm (⅜ to ¾-in.)	2000
19.0 to 37.5-mm (¾ to 1½-in.)	3000
Over 37.5-mm (1½-in.)	5000

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved Aug. 1, 2004. Published August 2004. Originally approved in 1938. Last previous edition approved in 1997 as C 142 – 97.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

5.5 In the case of mixtures of fine and coarse aggregates, separate the material on the 4.75-mm (No. 4) sieve, and prepare the samples of fine and coarse aggregates in accordance with 5.3 and 5.4.

6. Procedure

6.1 Determine the mass of the test sample to the accuracy specified in 4.1 and spread it in a thin layer on the bottom of the container, cover it with distilled water, and soak it for a period of 24 ± 4 h. Roll and squeeze particles individually between the thumb and forefinger to attempt to break the particle into smaller sizes. Do not use the fingernails to break up particles, or press particles against a hard surface or each other. Classify any particles that can be broken with the fingers into fines removable by wet sieving as clay lumps or friable particles. After all discernible clay lumps and friable particles have been broken, separate the detritus from the remainder of the sample by wet sieving over the sieve prescribed in the following table:

Size of Particles Making Up Sample	Size of Sieve for Removing Residue of Clay Lumps and Friable Particles
Fine aggregate (retained on 1.18-mm (No. 16) sieve)	850-µm (No. 20)
4.75 to 9.5-mm (No. 4 to ⅜-in.)	2.36-mm (No. 8)
9.5 to 19.0-mm (⅜ to ¾-in.)	4.75-mm (No. 4)
19.0 to 37.5-mm (¾ to 1½-in.)	4.75-mm (No. 4)
Over 37.5-mm (1½-in.)	4.75-mm (No. 4)

Perform the wet sieving by passing water over the sample through the sieve while manually agitating the sieve, until all undersize material has been removed.

6.2 Remove the retained particles carefully from the sieve, dry to substantially constant mass at a temperature of 110 ± 5°C (230 ± 9°F), allow to cool, and determine the mass to the nearest 0.1 % of the mass of the test sample as defined in 5.3 or 5.4.

7. Calculation

7.1 Calculate the percent of clay lumps and friable particles in fine aggregate or individual sizes of coarse aggregate as follows:

$$P = [(M - R)/M] \times 100 \quad (1)$$

where:

P = percent of clay lumps and friable particles,
M = mass of test sample (for fine aggregate the mass of the portion coarser than the 1.18-mm (No. 16) sieve as described in 5.3), and
R = mass of particles retained on designated sieve as determined in accordance with 6.2.

7.2 For coarse aggregates, the percent of clay lumps and friable particles shall be an average based on the percent of clay lumps and friable particles in each sieve size fraction weighted in accordance with the grading of the original sample before separation or, preferably, the average grading of the supply represented by the sample. Should the aggregate contain less than 5 % of any of the sizes specified in 6.1, that size shall not be tested but, for the purpose of calculating the weighted average, shall be considered to contain the same percent of clay lumps and friable particles as the next larger or next smaller size, whichever is present.

8. Precision and Bias

8.1 *Precision*[3]—The estimate of the precision of this test method is provisional and is based on samples of one fine aggregate that was tested by ten different operators at nine different laboratories. For that sample, the average "percent of clay lumps and friable particles" in the aggregate was 1.2 %, and the standard deviation was 0.6 %. Based on this standard deviation, the acceptable range of two test results on samples from the same aggregate sent to different laboratories is 1.7 %.

8.2 *Bias*—Since there is no acceptable reference material for determining the bias for the procedure in this test method, no statement is being made.

9. Keywords

9.1 aggregates; clay lumps; friable particles

Designation: C143/C143M – 10

Standard Test Method for Slump of Hydraulic-Cement Concrete[1]

This standard is issued under the fixed designation C143/C143M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers determination of slump of hydraulic-cement concrete, both in the laboratory and in the field.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C31/C31M Practice for Making and Curing Concrete Test Specimens in the Field

C138/C138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

C172 Practice for Sampling Freshly Mixed Concrete

C173/C173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Summary of Test Method

3.1 A sample of freshly mixed concrete is placed and compacted by rodding in a mold shaped as the frustum of a cone. The mold is raised, and the concrete allowed to subside. The vertical distance between the original and displaced position of the center of the top surface of the concrete is measured and reported as the slump of the concrete.

4. Significance and Use

4.1 This test method is intended to provide the user with a procedure to determine slump of plastic hydraulic-cement concretes.

NOTE 1—This test method was originally developed to provide a technique to monitor the consistency of unhardened concrete. Under laboratory conditions, with strict control of all concrete materials, the slump is generally found to increase proportionally with the water content of a given concrete mixture, and thus to be inversely related to concrete strength. Under field conditions, however, such a strength relationship is not clearly and consistently shown. Care should therefore be taken in relating slump results obtained under field conditions to strength.

4.2 This test method is considered applicable to plastic concrete having coarse aggregate up to 1½ in. [37.5 mm] in size. If the coarse aggregate is larger than 1½ in. [37.5 mm] in size, the test method is applicable when it is performed on the fraction of concrete passing a 1½-in. [37.5-mm] sieve, with the larger aggregate being removed in accordance with the section titled "Additional Procedure for Large Maximum Size Aggregate Concrete" in Practice C172.

4.3 This test method is not considered applicable to non-plastic and non-cohesive concrete.

NOTE 2—Concretes having slumps less than ½ in. [15 mm] may not be adequately plastic and concretes having slumps greater than about 9 in.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.60 on Testing Fresh Concrete.

Current edition approved Feb. 1, 2010. Published March 2010. Originally approved in 1922. Last previous edition approved in 2009 as C143/C143M–09. DOI: 10.1520/C0143_C0143M-10.

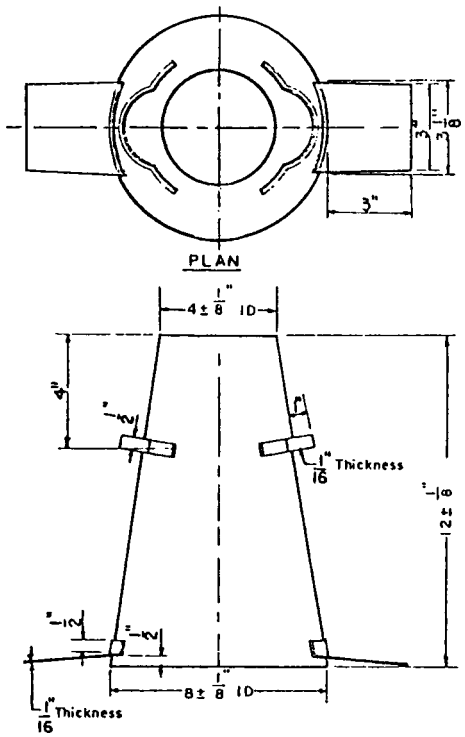
[230 mm] may not be adequately cohesive for this test to have significance. Caution should be exercised in interpreting such results.

5. Apparatus

5.1 *Mold*—The test specimen shall be formed in a mold made of metal not readily attacked by the cement paste. The metal shall not be thinner than 0.060 in. [1.5 mm] and if formed by the spinning process, there shall be no point on the mold at which the thickness is less than 0.045 in. [1.15 mm]. The mold shall be in the form of the lateral surface of the frustum of a cone with the base 8 in. [200 mm] in diameter, the top 4 in. [100 mm] in diameter, and the height 12 in. [300 mm]. Individual diameters and heights shall be within ±⅛ in. [3 mm] of the prescribed dimensions. The base and the top shall be open and parallel to each other and at right angles to the axis of the cone. The mold shall be provided with foot pieces and handles similar to those shown in Fig. 1. The mold shall be constructed without a seam. The interior of the mold shall be relatively smooth and free from projections. The mold shall be free from dents, deformation, or adhered mortar. A mold which clamps to a nonabsorbent base plate is acceptable instead of the one illustrated, provided the clamping arrangement is such that it can be fully released without movement of the mold and the base is large enough to contain all of the slumped concrete in an acceptable test.

5.1.1 Check and record conformance to the mold's specified dimensions when it is purchased or first placed in service and at least annually thereafter.

5.1.2 Mold with alternative materials.



Dimensional Units									
in.	1/16	1/8	1/2	1	3	3 1/8	4	8	12
mm	[2]	[3]	[15]	[25]	[75]	[80]	[100]	[200]	[300]

FIG. 1 Mold for Slump Test

5.1.2.1 Molds other than metal are allowed if the following requirements are met: The mold shall meet the shape, height, and internal dimensional requirements of 5.1. The mold shall be sufficiently rigid to maintain the specified dimensions and tolerances during use, resistant to impact forces, and shall be nonabsorbent. The mold shall be demonstrated to provide test results comparable to those obtained when using a metal mold meeting the requirements of 5.1. Comparability shall be demonstrated on behalf of the manufacturer by an independent testing laboratory. Test for comparability shall consist of not less than 10 consecutive pairs of comparisons performed at each of 3 different slumps ranging from 2 to 8 in. [50 to 200 mm] (Note 3). No individual test results shall vary by more than 0.50 in. [15 mm] from that obtained using the metal mold. The average test results of each slump range obtained using the mold constructed of alternative material shall not vary by more than 0.25 in. [6 mm] from the average of test results obtained using the metal mold. Manufacturer comparability test data shall be available to users and laboratory inspection authorities (Note 4). If any changes in material or method of manufacture are made, tests for comparability shall be repeated.

NOTE 3—The phrase "consecutive pairs of comparisons" does not mean without interruption or all in one day. At a schedule selected by the testing entity, the pairs of tests leading to 10 consecutive pairs may be accomplished in small groups. The word "consecutive" prevents ignoring pairs of tests which may not meet the criteria.

NOTE 4—Because the slump of concrete decreases with time and higher temperatures, it will be advantageous for the comparability tests to be performed by alternating the use of metal cones and alternative material cones, to utilize several technicians, and to minimize the time between test procedures.

5.1.2.2 If the condition of any individual mold is suspected of being out of tolerance from the as manufactured condition, a single comparative test shall be performed. If the test results differ by more than 0.50 in. [15 mm] from that obtained using the metal mold, the mold shall be removed from service.

5.2 *Tamping Rod*—A round, straight steel rod, with a ⅝ in. [16 mm] ± 1/16 in. [2 mm] diameter. The length of the tamping rod shall be at least 4 in. [100 mm] greater than the depth of the mold in which rodding is being performed, but not greater than 24 in. [600 mm] in overall length (Note 5). The length tolerance for the tamping rod shall be ± ⅛ in. [4 mm]. The rod shall have the tamping end or both ends rounded to a hemispherical tip of the same diameter as the rod.

NOTE 5—A rod length of 16 in. [400 mm] to 24 in. [600 mm] meets the requirements of the following: Practice C31/C31M, Test Method C138/C138M, Test Method C143/C143M, Test Method C173/C173M, and Test Method C231.

5.3 *Measuring Device*—A ruler, metal roll-up measuring tape, or similar rigid or semi-rigid length measuring instrument marked in increments of ¼ in. [5 mm] or smaller. The instruement length shall be at least 12 in. [300 mm].

5.4 *Scoop*—of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the mold.

6. Sample

6.1 The sample of concrete from which test specimens are made shall be representative of the entire batch. It shall be obtained in accordance with Practice C172.

7. Procedure

7.1 Dampen the mold and place it on a rigid, flat, level, moist, nonabsorbent surface, free of vibration, and that is large enough to contain all of the slumped concrete. It shall be held firmly in place during filling and perimeter cleaning by the operator standing on the two foot pieces or by a clamping arrangement to a base plate as described in 5.1. From the sample of concrete obtained in accordance with Section 6, immediately fill the mold in three layers, each approximately one third the volume of the mold (See Note 6). Place the concrete in the mold using the scoop described in 5.4. Move the scoop around the perimeter of the mold opening to ensure an even distribution of the concrete with minimal segregation.

NOTE 6—One third of the volume of the slump mold fills it to a depth of 2⅝ in. [70 mm]; two thirds of the volume fills it to a depth of 6⅛ in. [160 mm].

7.2 Rod each layer 25 times uniformly over the cross section with the rounded end of the rod. For the bottom layer, this will necessitate inclining the rod slightly and making approximately half of the strokes near the perimeter, and then progressing with vertical strokes spirally toward the center. Rod the bottom layer throughout its depth. For each upper layer, allow the rod to penetrate through the layer being rodded and into the layer below approximately 1 in. [25 mm].

7.3 In filling and rodding the top layer, heap the concrete above the mold before rodding is started. If the rodding operation results in subsidence of the concrete below the top edge of the mold, add additional concrete to keep an excess of concrete above the top of the mold at all times. After the top layer has been rodded, strike off the surface of the concrete by means of a screeding and rolling motion of the tamping rod. Continue to hold the mold down firmly and remove concrete from the area surrounding the base of the mold to preclude interference with the movement of slumping concrete. Remove the mold immediately from the concrete by raising it carefully in a vertical direction. Raise the mold a distance of 12 in. [300 mm] in 5 ± 2 s by a steady upward lift with no lateral or torsional motion. Complete the entire test from the start of the filling through removal of the mold without interruption and complete it within an elapsed time of 2½ min.

7.4 Immediately measure the slump by determining the vertical difference between the top of the mold and the displaced original center of the top surface of the specimen. If a decided falling away or shearing off of concrete from one side or portion of the mass occurs (Note 7), disregard the test and make a new test on another portion of the sample.

NOTE 7—If two consecutive tests on a sample of concrete show a falling away or shearing off of a portion of the concrete from the mass of the specimen, the concrete probably lacks necessary plasticity and cohesiveness for the slump test to be applicable.

8. Report

8.1 Report the slump in terms of inches [millimetres] to the nearest ¼ in. [5 mm] of subsidence of the specimen during the test.

9. Precision and Bias [4]

9.1 *Precision*—The estimates of precision for this test method are based upon results from tests conducted in Fayetteville, Arkansas by 15 technicians from 14 laboratories representing 3 states. All tests at 3 different slump ranges, from 1.0 in. [25 mm] to 6.5 in. [160 mm], were performed using one load of truck-mixed concrete. The concrete was delivered and tested at a low slump, with water then being added and mixed into the remaining concrete to independently produce moderate and finally high-slump concrete. The concrete mixture that used a No. 67 crushed limestone aggregate and a washed river sand, contained 500 lb of cementitious materials per cubic yard [297 kg of cementitious material per cubic metre]. The 500 lb [227 kg] were equally divided between a C150, Type I/II cement and a Class C fly ash. A double dosage of a chemical retarder was used in an attempt to minimize slump losses and maintain workability of the concrete. Concrete temperatures ranged from 86 to 93 °F [30 to 34 °C]. Slump losses averaged 0.68 in. [17 mm] during the 20 min required to perform a series of 6 tests at 1 slump range. Testing was performed alternately using metal and plastic molds, which were determined to produce comparable results. Precision data thus applies to both metal and plastic molds. A total of 270 slump tests were performed.

9.1.1 *Inch-Pound [SI]*—The data used to develop the precision statement were obtained using metric units (millimetres). The precision values shown in inch-pound units are conversions from the millimetre measurements, which were recorded to the nearest 1 mm.

9.1.2 *Measure of Variability*—The standard deviation was determined to be the most consistent measure of variability and was found to vary with the slump value.

9.1.3 *Single-Operator Precision*—The single-operator standard deviation represented by (1s) is shown in Table 1 by average slump values. The reported results for the replicate

[4] The test data used to develop this precision statement were based on tests performed in September 1997. Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR:C09-1022.

TABLE 1 Precision

Slump and Type Index	Standard Deviation (1s)[A]		Acceptable Range of Two Results (d2s)[A]	
Single-Operator Precision:	in.	[mm]	in.	[mm]
Slump 1.2 in. [30 mm]	0.23	[6]	0.65	[17]
Slump 3.4 in. [85 mm]	0.38	[9]	1.07	[25]
Slump 6.5 in. [160 mm]	0.40	[10]	1.13	[28]
Multilaboratory Precision:				
Slump 1.2 in. [30 mm]	0.29	[7]	0.82	[20]
Slump 3.4 in. [85 mm]	0.39	[10]	1.10	[28]
Slump 6.5 in. [160 mm]	0.53	[13]	1.50	[37]

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C670.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

readings apply to tests conducted by the same operator performing successive tests, one immediately following the other. Acceptable results of two properly conducted tests by the same operator on the same material (Note 8) will not differ from each other by more than the (d2s) value of the last column of Table 1 for the appropriate slump value and single-operator precision.

9.1.4 *Multilaboratory Precision*—The multilaboratory standard deviation represented by (1s) is shown in Table 1 by average slump values. The reported results for the replicate readings apply to tests conducted by different operators from different laboratories performing tests less than 4 min apart. Therefore, acceptable results of two properly conducted slump tests on the same material (Note 8) by two different laboratories will not differ from each other by more than the (d2s) value of the last column of Table 1 for the appropriate slump value and multilaboratory precision.

NOTE 8—"Same materials," is used to mean freshly mixed concrete from one batch.

9.2 *Bias*—This test method has no bias since slump is defined only in terms of this test method.

10. Keywords

10.1 concrete; cone; consistency; plasticity; slump; workability

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C143/C143M – 09, that may impact the use of this test method. (Approved February 1, 2010)

(*1*) Revised the first sentence of 7.1.

Committee C09 has identified the location of selected changes to this test method since the last issue, C143/C143M – 08, that may impact the use of this test method. (Approved August 1, 2009)

(*1*) Revised 5.2 to alter tamping rod requirements.
(*2*) Added Note 5 describing acceptable tamping rod length.
(*3*) Revised 7.2 to alter wording of tamping rod use.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 150/C 150M – 09

Standard Specification for Portland Cement[1]

This standard is issued under the fixed designation C 150/C 150M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers ten types of portland cement, as follows (see Note 2):

1.1.1 *Type I*—For use when the special properties specified for any other type are not required.

1.1.2 *Type IA*—Air-entraining cement for the same uses as Type I, where air-entrainment is desired.

1.1.3 *Type II*—For general use, more especially when moderate sulfate resistance is desired.

1.1.4 *Type IIA*—Air-entraining cement for the same uses as Type II, where air-entrainment is desired.

1.1.5 *Type II(MH)*—For general use, more especially when moderate heat of hydration and moderate sulfate resistance are desired.

1.1.6 *Type II(MH)A*—Air-entraining cement for the same uses as Type II(MH), where air-entrainment is desired.

1.1.7 *Type III*—For use when high early strength is desired.

1.1.8 *Type IIIA*—Air-entraining cement for the same use as Type III, where air-entrainment is desired.

1.1.9 *Type IV*—For use when a low heat of hydration is desired.

1.1.10 *Type V*—For use when high sulfate resistance is desired.

NOTE 1—Some cements are designated with a combined type classification, such as Type I/II, indicating that the cement meets the requirements of the indicated types and is being offered as suitable for use when either type is desired.

NOTE 2—Cement conforming to the requirements for all types are not carried in stock in some areas. In advance of specifying the use of cement other than Type I, determine whether the proposed type of cement is, or can be made, available.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. Values in SI units [or inch-pound units] shall be obtained by measurement in SI units [or inch-pound units] or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units [or SI units]. Values are stated in only SI units when inch-pound units are not used in practice.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

3. Terminology

3.1 *Definitions*—See Terminology C 219.

4. Ordering Information

4.1 Orders for material under this specification shall include the following:

4.1.1 This specification number and date,

4.1.2 Type or types allowable. If no type is specified, Type I shall be supplied,

4.1.3 Any optional chemical requirements from Table 2, if desired, and

4.1.4 Any optional physical requirements from Table 4, if desired.

5. Ingredients

5.1 The cement covered by this specification shall contain no ingredients except as follows:

5.1.1 Portland cement clinker.

5.1.2 Water or calcium sulfate, or both. The amounts shall be such that the limits shown in Table 1 for sulfur trioxide and loss-on-ignition are not exceeded.

5.1.3 Limestone. The amount shall not be more than 5.0 % by mass such that the chemical and physical requirements of this standard are met (See Note 3). The limestone, defined in Terminology C 51, shall be naturally occurring and consist of at least 70 % by mass of one or more of the mineral forms of calcium carbonate.

NOTE 3—The standard permits up to 5 % by mass of the final cement product to be naturally occurring, finely ground limestone, but does not require that limestone be added to the cement. Cement without ground limestone can be specified in the contract or order.

5.1.4 Inorganic processing additions. The amount shall be not more than 5.0 % by mass of cement. Not more than one inorganic processing addition shall be used at a time. For amounts greater than 1.0 %, they shall have been shown to meet the requirements of Specification C 465 for the inorganic processing addition in the amount used or greater. If an inorganic processing addition is used, the manufacturer shall report the amount (or range) used, expressed as a percentage of cement mass, along with the oxide composition of the processing addition.

5.1.5 Organic Processing additions. They shall have been shown to meet the requirements of Specification C 465 in the amounts used or greater and the total amount of organic processing additions used shall not exceed 1.0 % by mass of cement.

5.1.6 Air-entraining addition (for air-entraining portland cement only). The interground addition shall conform to the requirements of Specification C 226.

TABLE 1 Standard Composition Requirements

Cement Type[A]	Applicable Test Method	I and IA	II and IIA	II(MH) and II(MH)A	III and IIIA	IV	V
Aluminum oxide (Al_2O_3), max, %	C 114	...	6.0	6.0	...	...	...
Ferric oxide (Fe_2O_3), max, %	C 114	...	6.0[B]	6.0[B,C]	...	6.5	...
Magnesium oxide (MgO), max, %	C 114	6.0	6.0	6.0	6.0	6.0	6.0
Sulfur trioxide (SO_3),[D] max, %	C 114						
When $(C_3A)^E$ is 8 % or less		3.0	3.0	3.0	3.5	2.3	2.3
When $(C_3A)^E$ is more than 8 %		3.5	[F]	[F]	4.5	[F]	[F]
Loss on ignition, max, %	C 114	3.0	3.0	3.0	3.0	2.5	3.0
Insoluble residue, max, %	C 114	0.75	0.75	0.75	0.75	0.75	0.75
Tricalcium silicate $(C_3S)^E$, max, %	See Annex A1	...	...	...	...	35[C]	...

Tricalcium aluminate $(C_3A)^E$, max, %	See Annex A1	...	8	8	15	7[C]	5[B]
Sum of $C_3S + 4.75C_3A^G$, max, %	See Annex A1	...	...	100[H]	...	...	...
Tetracalcium aluminoferrite plus twice the tricalcium aluminate $(C_4AF + 2(C_3A))$, or solid solution $(C_4AF + C_2F)$, as applicable, max, %	See Annex A1	...	...	...	...	...	25[B]

[A] See Note 2.
[B] Does not apply when the sulfate resistance limit in Table 4 is specified.
[C] Does not apply when the heat of hydration limit in Table 4 is specified.
[D] It is permissible to exceed the values in the table for SO_3 content, provided it has been demonstrated by Test Method C 1038 that the cement with the increased SO_3 will not develop expansion exceeding 0.020 % at 14 days. When the manufacturer supplies cement under this provision, supporting data shall be supplied to the purchaser. See Note 5.
[E] See Annex A1 for calculation.
[F] Not applicable.
[G] See Note 4.
[H] In addition, 7-day heat of hydration testing by Test Method C 186 shall be conducted at least once every six months. Such testing shall not be used for acceptance or rejection of the cement, but results shall be reported for informational purposes.

TABLE 2 Optional Composition Requirements[A]

Cement Type	Applicable Test Method	I and IA	II and IIA	II(MH) and II(MH)A	III and IIIA	IV	V	Remarks
Tricalcium aluminate (C_3A)[B], max, %	See Annex A1	...	...	...	8	...	...	for moderate sulfate resistance
Tricalcium aluminate (C_3A)[B], max, %	See Annex A1	...	...	...	5	...	...	for high sulfate resistance
Equivalent alkalies ($Na_2O + 0.658K_2O$), max, %	C 114	0.60[C]	0.60[C]	0.60[C]	0.60[C]	0.60[C]	0.60[C]	low-alkali cement

[A] These optional requirements apply only when specifically requested. Verify availability before ordering. See Note 2.
[B] See Annex A1 for calculation.
[C] Specify this limit when the cement is to be used in concrete with aggregates that are potentially reactive and no other provisions have been made to protect the concrete from deleteriously reactive aggregates. Refer to Specification C 33 for information on potential reactivity of aggregates.

6. Chemical Composition

6.1 Portland cement of each of the ten types shown in Section 1 shall conform to the respective standard chemical requirements prescribed in Table 1. In addition, optional chemical requirements are shown in Table 2.

NOTE 4—The limit on the sum, $C_3S + 4.75C_3A$, in Table 1 provides control on the heat of hydration of the cement and is consistent with a Test Method C 186 7-day heat of hydration limit of 335 kJ/kg [80 cal/g].

NOTE 5—There are cases where performance of a cement is improved with SO_3 in excess of the Table 1 limits in this specification. Test Method C 563 is one of several methods a manufacturer can use to evaluate the effect of sulfate content on cement characteristics. Whenever SO_3 content of a cement exceeds Table 1 limits, Test Method C 1038 results provide evidence that excessive expansion does not occur at this higher sulfate content.

7. Physical Properties

7.1 Portland cement of each of the ten types shown in Section 1 shall conform to the respective standard physical requirements prescribed in Table 3. In addition, optional physical requirements are shown in Table 4.

8. Sampling

8.1 When the purchaser desires that the cement be sampled and tested to verify compliance with this specification, perform sampling and testing in accordance with Practice C 183.

8.2 Practice C 183 is not designed for manufacturing quality control and is not required for manufacturer's certification.

9. Test Methods

9.1 Determine the applicable properties enumerated in this specification in accordance with the following test methods:

9.1.1 *Air Content of Mortar*—Test Method C 185.

9.1.2 *Chemical Analysis*—Test Methods C 114.

9.1.3 *Strength*—Test Method C 109/C 109M.

9.1.4 *False Set*—Test Method C 451.

9.1.5 *Fineness by Air Permeability*—Test Method C 204.

9.1.6 *Fineness by Turbidimeter*—Test Method C 115.

9.1.7 *Heat of Hydration*—Test Method C 186.

9.1.8 *Autoclave Expansion*—Test Method C 151.

9.1.9 *Time of Setting by Gillmore Needles*—Test Method C 266.

9.1.10 *Time of Setting by Vicat Needles*—Test Method C 191.

9.1.11 *Sulfate Resistance*—Test Method C 452 (sulfate expansion).

9.1.12 *Calcium Sulfate (expansion of) Mortar*—Test Method C 1038.

10. Inspection

10.1 Inspection of the material shall be made as agreed upon between the purchaser and the seller as part of the purchase contract.

11. Rejection

11.1 The cement shall be rejected if it fails to meet any of the requirements of this specification.

11.2 At the option of the purchaser, retest, before using, cement remaining in bulk storage for more than 6 months or cement in bags in local storage in the custody of a vendor for more than 3 months after completion of tests and reject the cement if it fails to conform to any of the requirements of this specification. Cement so rejected shall be the responsibility of the owner of record at the time of resampling for retest.

11.3 Packages shall identify the mass contained as net weight. At the option of the purchaser, packages more than 2 % below the mass marked thereon shall be rejected and if the average mass of packages in any shipment, as shown by determining the mass of 50 packages selected at random, is less than that marked on the packages, the entire shipment shall be rejected.

12. Manufacturer's Statement

12.1 At the request of the purchaser, the manufacturer shall state in writing the nature, amount, and identity of any air-entraining addition and of any processing addition used, and also, if requested, shall supply test data showing compliance of such air-entraining addition with Specification C 226 and of such processing addition with Specification C 465.

12.2 When limestone is used, the manufacturer shall state in writing the amount thereof and, if requested by the purchaser, shall supply comparative test data on chemical and physical properties of the cement with and without the limestone (See Note 6). The comparative tests do not supersede the normal

TABLE 3 Standard Physical Requirements

Cement Type[A]	Applicable Test Method	I	IA	II	IIA	II(MH)	II(MH)A	III	IIIA	IV	V
Air content of mortar,[B] volume %:	C 185										
max		12	22	12	22	12	22	12	22	12	12
min		...	16	...	16	...	16	...	16	...	...
Fineness,[C] specific surface, m^2/kg (alternative methods):											
Turbidimeter test	C 115										
min		150	150	150	150	150	150	...	...	150	150
max		...	...	...	...	245[D]	245[D]	...	...	245	...
Air permeability test	C 204										
min		260	260	260	260	260	260	...	...	260	260
max		...	...	...	...	430[D]	430[D]	...	...	430	...
Autoclave expansion, max, %	C 151	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80
Strength, not less than the values shown for the ages indicated as follows:[E]											
Compressive strength, MPa [psi]:	C 109/ C 109M										
1 day		...	...	...	...	...	...	12.0 [1740]	10.0 [1450]	...	...
3 days		12.0 [1740]	10.0 [1450]	10.0 [1450]	8.0 [1160]	10.0 [1450] 7.0[F] [1020][F]	8.0 [1160] 6.0[F] [870][F]	24.0 [3480]	19.0 [2760]	...	8.0 [1160]
7 days		19.0 [2760]	16.0 [2320]	17.0 [2470]	14.0 [2030]	17.0 [2470] 12.0[F] [1740][F]	14.0 [2030] 9.0[F] [1310][F]	...	...	7.0 [1020]	15.0 [2180]
28 days		...	...	...	...	...	...	...	...	17.0 [2470]	21.0 [3050]
Time of setting; Vicat test:[G]	C 191										
Time of setting, min, not less than		45	45	45	45	45	45	45	45	45	45
Time of setting, min, not more than		375	375	375	375	375	375	375	375	375	375

[A] See Note 2.
[B] Compliance with the requirements of this specification does not necessarily ensure that the desired air content will be obtained in concrete.
[C] The testing laboratory shall select the fineness method to be used. However, when the sample fails to meet the requirements of the air-permeability test, the turbidimeter test shall be used, and the requirements in this table for the turbidimetric method shall govern.
[D] Maximum fineness limits do not apply if the sum of $C_3S + 4.75C_3A$ is less than or equal to 90.
[E] The strength at any specified test age shall be not less than that attained at any previous specified test age.
[F] When the optional heat of hydration in Table 4 is specified.
[G] The time of setting is that described as initial setting time in Test Method C 191.

TABLE 4 Optional Physical Requirements[A]

Cement Type	Applicable Test Method	I and II	IA and IIA	II(MH)	II(MH)A	III	IIIA	IV	V
False set, final penetration, min, %	C 451	50	50	50	50	50	50	50	50
Heat of hydration:	C 186								
7 days, max, kJ/kg [cal/g]		...	...	290 [70][B]	290 [70][B]	...	...	250 [60][C]	...
28 days, max, kJ/kg [cal/g]		...	...	...	...	...	...	290 [70][C]	...
Strength, not less than the values shown:									
Compressive strength, MPa [psi]	C 109/ C 109M								
28 days		28.0 [4060]	22.0 [3190]	28.0 [4060] 22.0[B] [3190][B]	22.0 [3190] 18.0[B] [2610][B]	...	...	...	...
Sulfate resistance,[D] 14 days, max, % expansion	C 452	...[E]	...[E]	...[E]	...[E]	...	...	...	0.040
Gillmore test:	C 266								
Initial set, min, not less than		60	60	60	60	60	60	60	60
Final set, min, not more than		600	600	600	600	600	600	600	600

[A] These optional requirements apply only when specifically requested. Verify availability before ordering. See Note 2.
[B] The limit for the sum of $C_3S + 4.75C_3A$ in Table 1 shall not apply when this optional limit is requested. These strength requirements apply when the optional heat of hydration requirement is requested.
[C] When the heat of hydration limit is specified, it shall be instead of the limits of C_3S, C_2S, C_3A, and Fe_2O_3 listed in Table 1.
[D] When the sulfate resistance is specified, it shall be instead of the limits of C_3A, $C_4AF + 2\ C_3A$, and Fe_2O_3 listed in Table 1.
[E] Cement meeting the high sulfate resistance limit for Type V is deemed to meet the moderate sulfate resistance requirement of Type II and Type II(MH).

testing to confirm that the cement meets chemical and physical requirements of this standard. The amount of limestone in cement shall be determined in accordance with Annex A2.

NOTE 6—Comparative test data may be from qualification tests performed by the manufacturer during formulation of the cement with limestone.

13. Packaging and Package Marking

13.1 When the cement is delivered in packages, the words "Portland Cement," the type of cement, the name and brand of the manufacturer, and the mass of the cement contained therein shall be plainly marked on each package. When the cement is an air-entraining type, the words "air-entraining" shall be plainly marked on each package. Similar information shall be provided in the shipping documents accompanying the shipment of packaged or bulk cement. All packages shall be in good condition at the time of inspection.

NOTE 7—With the change to SI units, it is desirable to establish a standard SI package for portland cements. To that end 42 kg [92.6 lb] provides a convenient, even-numbered mass reasonably similar to the traditional 94-lb [42.6-kg] package.

14. Storage

14.1 The cement shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weather-tight building that will protect the cement from dampness and minimize warehouse set.

15. Manufacturer's Certification

15.1 Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at the time of shipment stating the results of tests made on samples of the material taken during production or transfer and certifying that the cement conforms to applicable requirements of this specification.

NOTE 8—Guidance on preparing the manufacturer's report is provided in Appendix X1.

16. Keywords

16.1 hydraulic cement; portland cement; specification

ANNEXES

(Mandatory Information)

A1. CALCULATION OF POTENTIAL CEMENT PHASE COMPOSITION

A1.1 All values calculated as described in this annex shall be rounded according to Practice E 29. When evaluating conformance to a specification, round values to the same number of places as the corresponding table entry before making comparisons. The expressing of chemical limitations by means of calculated assumed phases does not necessarily mean that the oxides are actually or entirely present as such phases.

A1.2 When expressing phases, $C = CaO$, $S = SiO_2$, $A = Al_2O_3$, $F = Fe_2O_3$. For example, $C_3A = 3CaO{\cdot}Al_2O_3$. Titanium dioxide and phosphorus pentoxide (TiO_2 and P_2O_5) shall not be included with the Al_2O_3 content. See Note A1.1.

NOTE A1.1—When comparing oxide analyses and calculated phases from different sources or from different historic times, be aware that they may not have been reported on exactly the same basis. Chemical data obtained by Reference and Alternate Test Methods of Test Methods C 114

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:05:24 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

(wet chemistry) may include titania and phosphorus as alumina unless proper correction has been made (see Test Methods C 114), while data obtained by rapid instrumental methods usually do not. This can result in small differences in the calculated phases. Such differences are usually within the precision of the analytical methods, even when the methods are properly qualified under the requirements of Test Methods C 114.

A1.3 When the ratio of percentages of aluminum oxide to ferric oxide is 0.64 or more, the percentages of tricalcium silicate, dicalcium silicate, tricalcium aluminate, and tetracalcium aluminoferrite shall be calculated from the chemical analysis as follows:

$$\text{Tricalcium silicate } (C_3S) = (4.071 \times \%\ CaO) - (7.600 \times \%\ SiO_2) - (6.718 \times \%\ Al_2O_3) - (1.430 \times \%\ Fe_2O_3) - (2.852 \times \%\ SO_3) \quad \text{(A1.1)}$$

$$\text{Dicalcium silicate } (C_2S) = (2.867 \times \%\ SiO_2) - (0.7544 \times \%\ C_3S) \quad \text{(A1.2)}$$

$$\text{Tricalcium aluminate } (C_3A) = (2.650 \times \%\ Al_2O_3) - (1.692 \times \%\ Fe_2O_3) \quad \text{(A1.3)}$$

$$\text{Tetracalcium aluminoferrite } (C_4AF) = 3.043 \times \%\ Fe_2O_3 \quad \text{(A1.4)}$$

A1.3.1 When the alumina-ferric oxide ratio is less than 0.64, a calcium aluminoferrite solid solution (expressed as $ss(C_4AF + C_2F)$) is formed. No tricalcium aluminate will be present in cements of this composition. Dicalcium silicate shall be calculated as in Eq A1.2. Contents of this solid solution and of tricalcium silicate shall be calculated by the following formulas:

$$ss\ (C_4AF + C_2F) = (2.100 \times \%\ Al_2O_3) + (1.702 \times \%\ Fe_2O_3) \quad \text{(A1.5)}$$

$$\text{Tricalcium silicate } (C_3S) = (4.071 \times \%\ CaO) - (7.600 \times \%\ SiO_2) - (4.479 \times \%\ Al_2O_3) - (2.859 \times \%\ Fe_2O_3) - (2.852 \times \%\ SO_3) \quad \text{(A1.6)}$$

A1.4 If no limestone or inorganic processing additions are used in the cement, or in the absence of information on limestone or inorganic processing additions use in the cement, phases shall be calculated using procedures in Eq A1.1-A1.6 without adjustment.

A1.5 In absence of information on limestone or inorganic processing additions content, results shall note that no adjustment has been made for possible use of limestone or inorganic processing additions.

A1.6 When inorganic processing additions or limestone or both are used with the base cement (portland cement clinker and any added calcium sulfate), the contents of C_3S, C_2S, C_3A, and C_4AF, shall be adjusted as follows:

A1.6.1 The percentage of C_3S, C_2S, C_3A, and C_4AF in the base cement shall be determined based on chemical analyses using methods in Test Methods C 114 and using Eq A1.1-A1.6 as appropriate. The contents of each of these phases shall be adjusted to account for the use of limestone or inorganic processing additions as follows:

$$X_f = X_b \times \frac{(100 - L - P)}{100}$$

where:

X_b = the percentage by mass of C_3S, C_2S, C_3A, or C_4AF in the base cement (portland cement clinker and any calcium sulfate),
L = the percentage by mass of limestone,
P = the percentage by mass of inorganic processing addition, and
X_f = the percentage by mass of C_3S, C_2S, C_3A, or C_4AF in the finished cement.

The adjusted values for the finished cement shall be reported on the manufacturer's report.

NOTE A1.2—For example:

Where the cement includes 3.5 % limestone and 3.0 % of an inorganic processing addition and the base cement has 60 % C_3S, 15 % C_2S, 7 % C_3A, and 10 % C_4AF, the adjusted phase composition is:

$$C_3S_f = \frac{60 \times (100 - 3.5 - 3.0)}{100} = 56\ \%$$

$$C_2S_f = \frac{15 \times (100 - 3.5 - 3.0)}{100} = 14\ \%$$

$$C_3A_f = \frac{7 \times (100 - 3.5 - 3.0)}{100} = 7\ \%$$

$$C_4AF_f = \frac{10 \times (100 - 3.5 - 3.0)}{100} = 9\ \%$$

A2. LIMESTONE CONTENT OF PORTLAND CEMENT

A2.1 When limestone is used, the limestone content in portland cement shall be derived from the determination of CO_2 in the finished cement. Analysis of CO_2 shall be based on methods described in Test Methods C 114. The percent limestone in the cement is calculated from the CO_2 analysis based on the CO_2 content of the limestone used.

The manufacturer shall include the CO_2 content and calculated limestone content of the cement on the Mill Test Report.

The limestone content of the cement is calculated as follows:

$$\frac{\%\ CO_2 \text{ in the cement}}{\%\ CO_2 \text{ in the limestone}} \times 100 = \%\ \text{limestone in cement}$$

NOTE A2.1—*For example*:

Where the determined CO_2 content in the finished cement = 1.5 % and the CO_2 content of the limestone = 43 % ($CaCO_3$ in limestone = 98 %)

Then:

$$\frac{1.5}{43} \times 100 = 3.5\ \%\ \text{limestone content in cement}$$

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:05:24 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

A2.2 This specification requires that the limestone to be used must contain a minimum of 70 % $CaCO_3$. The manufacturer shall include the $CaCO_3$ content of the limestone on the manufacturer's report. Calculate the $CaCO_3$ content of the limestone as follows: % $CaCO_3 = 2.274 \times$ % CO_2.

NOTE A2.2—For verification of limestone content of cement, the purchaser must analyze for CO_2 content and make a correction for the content of $CaCO_3$ in the limestone in order for the data to be comparable to the manufacturer's report.

A2.3 Portland cements that do not contain limestone can contain baseline levels of CO_2 inherent in manufacture, for example, due to carbonation. This baseline CO_2 content is included as part of any calculated limestone content.

APPENDIX

(Nonmandatory Information)

X1. MANUFACTURER'S CERTIFICATION (MILL TEST REPORT)

X1.1 To provide uniformity for reporting the results of tests performed on cements under this specification, as required by Section 15 of Specification C 150 entitled "Manufacturer's Certification," an example Mill Test Report is shown in Fig. X1.1.

X1.2 The identity information given should unambiguously identify the cement production represented by the Mill Test Report and may vary depending upon the manufacturer's designation and purchaser's requirements.

X1.3 The Manufacturer's Certification statement may vary depending upon the manufacturer's procurement order, or legal requirements, but should certify that the cement shipped is represented by the certificate and that the cement conforms to applicable requirements of the specification at the time it was tested (or retested) or shipped.

X1.4 The sample Mill Test Report has been developed to reflect the chemical and physical requirements of this specification and recommends reporting all analyses and tests normally performed on cements meeting Specification C 150. Purchaser reporting requirements should govern if different from normal reporting by the manufacturer or from those recommended here.

X1.5 Cements may be shipped prior to later-age test data being available. In such cases, the test value may be left blank. Alternatively, the manufacturer can generally provide estimates based on historical production data. The report should indicate if such estimates are provided.

X1.6 In reporting limits from the tables in Specification C 150 on the Mill Test Report, only those limits specifically applicable should be listed. In some cases, Specification C 150 table limits are superceded by other provisions.

X1.7 When limestone or inorganic processing additions or both are used in the cement, additional data are reported by the manufacturer. An example additional data report is shown in Fig. X1.2.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C 150 – 07, that may impact the use of this specification. (Approved June 15, 2009)

(*1*) Revised the standard as a dual units specification, including revision to the units statement in 1.2.
(*2*) Revised the desciption of Type II in 1.1.3.
(*3*) Included new designations for Type II(MH) and Type II(MH)A as new paragraphs 1.1.5 and 1.1.6.
(*4*) Added IEEE/ASTM SI 10 to 1.2 and Referenced Documents.
(*5*) Revised Table 1 to remove heat index requirement from Type II and include new columns for Type II(MH) and Type II(MH)A with those requirements.
(*6*) Revised Footnote D in Table 1.
(*7*) Revised Table 2 to include Type II(MH) and Type II(MH)A.
(*8*) Removed limits in Table 3 for average fineness.
(*9*) Revised Table 3 to remove maximum fineness and alternate 3- and 7-day strength requirements from Type II and include new columns for Type II(MH) and Type II(MH)A with those requirements.
(*10*) Deleted Footnotes D and E in Table 3 and renumbered subsequent footnotes.
(*11*) Revised Table 4 to include appropriate optional 28-day strength criteria for Type II, Type IIA, Type II(MH), and Type II(MH)A.
(*12*) Added new 5.1.4 on "inorganic processing additions" and renumbered subsequent paragraphs.
(*13*) Revised 5.1.5 as paragraph on "organic processing additions."
(*14*) Added new Note 5 and renumbered subsequent notes.
(*15*) Deleted 9.1.13.
(*16*) Revised Annex A1 calculation to drop CO_2 term and associated text.
(*17*) Added new A1.4-A1.6 with guidance on and adjustments to Bogue calculations.
(*18*) Added new X1.7 with information on additional reporting requirements noted in 5.1.4.
(*19*) Revised Fig. X1.1.
(*20*) Added new Fig. X1.2.

Designation: C 151/C 151M – 09

Standard Test Method for Autoclave Expansion of Hydraulic Cement[1]

This standard is issued under the fixed designation C 151/C 151M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers determination of the autoclave expansion of hydraulic cement by means of a test on a neat cement specimen.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*For specific precaution statements, see the section on Safety Precautions.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 187 Test Method for Normal Consistency of Hydraulic Cement

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 856 Practice for Petrographic Examination of Hardened Concrete

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

C 1157 Performance Specification for Hydraulic Cement

3. Significance and Use

3.1 The autoclave expansion test provides an index of potential delayed expansion caused by the hydration of CaO, or MgO, or both, when present in hydraulic cement.[3]

4. Interferences

4.1 Pozzolans containing fine-grained quartz have been reported to cause excessive expansion under autoclave test conditions due to alkali-silica reaction that will not occur under normal service conditions.[4] When excessive expansion of paste containing pozzolans occurs, it is recommended that the specimens be examined (See Practice C 856) for evidence of alkali-silica reaction (Note 1).

NOTE 1—If the excessive expansion has resulted from alkali-silica reaction under autoclave conditions, the pozzolan can be evaluated for alkali reactivity using the procedure described in Performance Specification C 1157.

5. Apparatus

5.1 *Weighing Devices and Weights*, for determining the mass of materials conforming to the requirements of Specification C 1005.

5.2 *Glass Graduates*, 200 or 250-mL capacity, and conforming to the requirements of Practice C 490.

5.3 *Molds*, conforming to the requirements of Practice C 490 for test specimens used in the determination of length change of cement paste.

5.4 *Flat Trowel*, conforming to the requirements of Test Method C 187.

5.5 *Autoclave*, consisting of a high-pressure steam vessel provided with a thermometer well. The autoclave shall be equipped with automatic controls and a rupture disk with a bursting pressure of 2.4 MPa [350 psi] ± 5 %. In locations where the use of a rupture disk is not permitted, the autoclave shall be equipped with a safety valve. In addition, the autoclave shall be equipped with a vent valve to allow the escape of air during the early part of the heating period and to release any

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.31 on Volume Change.

Current edition approved Jan. 1, 2009. Published January 2009. Originally approved in 1940. Last previous edition approved in 2005 as C 151 – 05.

www.technobetar.ir

steam pressure remaining at the end of the cooling period. The pressure gage shall have a nominal capacity of 4.0 MPa [600 psi], a dial with a nominal diameter of 115 mm [4½ in.] and shall be graduated from 0 to 4.0 MPa [0 to 600 psi] with scale divisions not exceeding 0.03 MPa [5 psi]. The error in the gage shall not exceed ± 0.02 MPa [± 3 psi] at the operating pressure of 2 MPa [295 psi]. The capacity of the heating unit shall be such that with maximum load (water plus specimens) the pressure of the saturated steam in the autoclave may be raised to a gage pressure of 2 MPa [295 psi] in 45 to 75 min from the time the heat is turned on. The automatic control shall be capable of maintaining the gage pressure at 2 ± 0.07 MPa [295 ± 10 psi] for at least 3 h. A gage pressure of 2 ± 0.07 MPa [295 ± 10 psi] corresponds to a temperature of 216 ± 2 °C [420 ± 3 °F]. The autoclave shall be designed to permit the gage pressure to drop from 2 MPa to less than 0.07 MPa [295 psi to less than 10 psi] in 1½ h after the heat supply has been shut off.

5.5.1 *Rupture Disk*—The rupture disk shall be made of a material having a tensile strength that is relatively insensitive to temperature in the range 20 to 216 °C [68 to 420 °F] and that is electrochemically compatible with the pipe leading to it and to its holder.[5]

5.6 *Length Comparator*—The comparator used for measuring length change of specimens shall conform to the requirements of Practice C 490.

6. Temperature and Humidity

6.1 *Molding Room*—Maintain the temperature of the molding room, dry materials and mixing water, and the relative humidity of the molding room within the limits of Practice C 490.

6.2 *Moist Storage Facilities*—Maintain the temperature and humidity of the moist storage facilities to the requirements of Specification C 511.

7. Safety Precautions

7.1 The pressure gage shall have a capacity of 4.0 MPa [600 psi]. A gage with too small or too large a capacity may be a hazard, since for pressure above the specified maximum working pressure, with a smaller capacity gage, the pressure may be off scale, and with a larger capacity gage, the arc of movement may be too small to invite attention. The operator shall be sure the gage hand has not passed the maximum graduation on the scale.

7.2 Test the pressure gage for proper operation. Always use a thermometer together with the pressure gage, so as to provide a means of detecting any failure of the pressure gage to operate properly, and to indicate any unusual condition.

7.3 Maintain the automatic control in proper working order at all times.

7.4 Set the safety valve to relieve the pressure at about 6 to 10 % above the maximum of 2.1 MPa [305 psi] specified in this test method, that is, at about 2.3 MPa [330 psi]. Unless the manufacturer has given specific instructions as to maintenance of the safety valve, test the valve twice each year.[6] Test with a gage testing device, or by adjusting the automatic controls to allow the autoclave to reach a pressure of about 2.3 MPa [330 psi], at which pressure the safety valve will either open or be adjusted to open. Direct the safety valve discharge away from the operator.

NOTE 2—Unexpected combinations of conditions may occur. For example, in one case the automatic control had failed, the safety valve had become stuck, and the gage hand, which at first glance appeared to be at about zero, had passed the maximum graduation and had come to stop on the wrong side of the pin. This condition of the gage was finally detected and the pressure, then of an unknown magnitude, was released before failure could occur in the apparatus.

7.5 Wear heavy leather work gloves to prevent burning of the hands when removing the top of the autoclave at the end of the test. Direct the vent valve away from the operator. When removing the autoclave lid, tilt it so that any steam escaping from beneath the lid will be discharged away from the operator. Care shall be taken to avoid scalding by any liquid that may have been used in the autoclave well.

7.6 The operator shall be made aware that for many autoclave pressure gages the return of the gage hand to the initial rest or starting point does not necessarily indicate zero pressure within the autoclave; there may then still remain an appreciable dangerous pressure.

8. Number of Test Specimens

8.1 Make at least one test specimen.

9. Preparation of Specimen Molds

9.1 Prepare the specimen molds in accordance with the requirements of Practice C 490 except that molds need not be sealed.

10. Preparation of Test Specimens

10.1 *Mixing Cement Paste*—Prepare the standard batch consisting of 650 g of cement and sufficient water to give a paste of normal consistency in accordance with the procedure described in Test Method C 187. Mix this batch in accordance with the procedure described in Practice C 305. Both a time of setting specimen and an autoclave bar may be made from the same batch. If the paste to be used for time of setting is the paste sample already used to determine normal consistency, then the autoclave bar may be prepared immediately from the remainder of the batch.

10.2 *Molding Specimens*—Immediately following preparation of the time of setting specimen or completion of mixing, mold the test specimen in two approximately equal layers, each layer being compacted with the thumbs or forefingers by pressing the paste into the corners, around the gage studs, and along the surface of the mold until a homogeneous specimen is obtained. Compact the top layer, cut off the paste flush with the top of the mold with a thin-edged trowel, and smooth the surface with a few strokes of the flat trowel. During the operations of mixing and molding, protect the hands with rubber gloves.

[5] A list of suppliers of autoclave rupture disks and gaskets is maintained at ASTM Headquarters.

[6] A list of facilities for testing autoclave safety valves is maintained at ASTM Headquarters.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.3 *Storage of Test Specimens*—After filling the mold, place it in the moist closet or moist room. Store the specimens in the molds in the moist enclosure for at least 20 h; if removed from the molds before 24 h, they shall be kept in the moist closet or moist room until time of test.

11. Procedure

11.1 At 24 h ± 30 min after molding, remove the specimens from the moist atmosphere, immediately obtain a length comparator reading for each specimen, and place in the autoclave at room temperature in a rack so that all sides of the specimen will be exposed to saturated steam. The autoclave shall contain enough water, at an initial temperature of 20 to 28 °C [68 to 82 °F], to maintain an atmosphere of saturated steam vapor during the entire test. Ordinarily 7 to 10 % of the volume of the autoclave should be occupied by the water.

11.2 To permit air to escape from the autoclave during the early portion of the heating period, leave the vent valve open until steam begins to escape. (**Warning**—See the section on Safety Precautions). Close the valve and raise the temperature of the autoclave at a rate that will bring the gage pressure of the steam to 2 MPa [295 psi] in 45 to 75 min from the time the heat is turned on. Maintain the 2 ± 0.07 MPa [295 ± 10 psi] pressure for 3 h. At the end of the 3-h period, shut off the heat supply and cool the autoclave at such a rate that the pressure will be less than 0.07 MPa [10 psi] at the end of 1½ h. At the end of the 1½-h period, slowly release any remaining pressure by partially opening the vent valve until atmospheric pressure is attained. Then open the autoclave and place the test specimen in water at a temperature above 90 °C [194 °F]. Cool the water surrounding the bars at a uniform rate by adding cold water so that the temperature of the water will be lowered to 23 °C [74 °F] in 15 min. Maintain the water surrounding the specimens at 23 °C [74 °F] for an additional 15 min; then, remove one specimen at a time from the water, blot the pins, but not the specimen, and obtain a length comparator reading.

12. Calculation

12.1 Calculate the change in length of the test specimen by subtracting the length comparator reading before autoclaving from that after autoclaving, and report as percent of effective gage length to the nearest 0.01 %. Report the percentage of increase in length as the autoclave expansion. Indicate a decrease in length by a minus sign prefixed to the percent value.

13. Precision and Bias

13.1 *Precision*—The single-operator (within-laboratory) standard deviation has been found to be 0.024 % throughout the range of 0.11 % to 0.94 % expansions. Therefore, results of two properly conducted tests by the same operator for expansions of similar batches should not differ from each other by more than 0.07 % expansion. The multi-laboratory (between laboratory) standard deviation has been found to be 0.030 % throughout the range of 0.11 % to 0.94 % expansions. Therefore, results of two properly conducted tests from two different laboratories for expansions of similar batches should not differ from each other by more than 0.09 % expansion.

13.2 *Bias*—Since there is no accepted reference material suitable for determining bias, bias has not been determined.

14. Keywords

14.1 autoclave; autoclave expansion; expansion; hydraulic cement; soundness

For additional useful information on details of cement test methods, reference may be made to the "Manual of Cement Testing," which appears in the *Annual Book of ASTM Standards,* **Vol 04.01.**

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 151 – 05, that may impact the use of this test method. (Approved January 1, 2009)

(*1*) Revised the standard as a combined units standard.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C156 – 09a

Standard Test Method for Water Loss [from a Mortar Specimen] Through Liquid Membrane-Forming Curing Compounds for Concrete[1]

This standard is issued under the fixed designation C156; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers laboratory determination of the efficiency of liquid membrane-forming compounds for curing concrete, as measured by their ability to reduce moisture loss during the early hardening period.

1.2 The values stated in SI units are to be regarded as standard. The values given in parentheses are mathematical conversions to inch-pound units that are provided for information only and are not considered standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*(**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

2. Referenced Documents

2.1 *ASTM Standards:*[3]

D1653 Test Methods for Water Vapor Transmission of Organic Coating Films

D2369 Test Method for Volatile Content of Coatings

E178 Practice for Dealing With Outlying Observations

3. Significance and Use

3.1 The moisture retaining ability of a product as determined by this test method is used to assess the suitability of materials for contributing to an appropriate curing environment for concrete. The laboratory test method is used both in formulating and in specifying or qualifying curing products. This test method gives the user a measure of the ability of tested curing materials to impede the escape of moisture from a hydraulic cement mortar. Since it is desirable to retain moisture in fresh concrete to promote the hydration process, failure of the product to minimize the escape of moisture may lead to loss of strength, cracking, shrinkage, or low abrasion resistance of the hardened concrete, or a combination thereof.

3.2 Many factors affect the laboratory test results. Test results obtained may be highly variable as indicated by the precision statement. Critical factors include the precision of the control of the temperature, humidity and air circulation in the curing cabinet, preparation and sealing of the mortar specimens, the age and surface condition of the mortar specimen when the curing product is applied, and the uniformity and quantity of application of the curing membrane.

4. Apparatus

4.1 *Mechanical Mortar Mixer*, as described in Practice C305, or a larger size mixture operating on the same principle.

4.2 *Flow Table*, as described in Specification C230/C230M.

4.3 *Molds* shall be made of metal, glass, hard rubber, or plastic, and shall be watertight and rigidly constructed to prevent distortion during molding of the specimens or handling of the mold containing fresh mortar. They shall have a minimum surface area of 12000 mm^2 (18.6 $in.^2$), and a minimum depth of 19 mm (¾ in.). The top surface shall be

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.22 on Materials Applied to New Concrete Surfaces.

Current edition approved Dec. 15, 2009. Published January 2010. Originally approved in 1940. Last previous edition approved in 2009 as C156 – 09. DOI: 10.1520/C0156-09a.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

round, square, or rectangular with length not more than twice the width. The top of the mold shall have a rim to provide a firm level surface to support the wood float and to facilitate the grooving and sealing steps of the procedure. The rim shall be parallel with the bottom surface of the mold.

NOTE 1—Take care to avoid use of an excessive amount of oil, grease, or mold release compound on molds, particularly along the top rim where sealing compound will be applied. Use of masking tape on the top rim during application of release compound to prevent contamination has been found expedient.

4.4 *Spoon*—A stainless steel serving spoon having a bowl 75 to 100 mm (3 to 4 in.) long and 50 to 75 mm (2 to 3 in.) wide for transferring the mortar from the mixing bowl to the mold.

4.5 *Gloves*, of rubber or plastic, to be worn while molding the specimens.

4.6 *Tamper*, of a nonabsorptive, nonabrasive material such as medium-hard rubber or seasoned oak rendered nonabsorptive by immersion for 15 min in paraffin at approximately 200 °C. The tamper shall be rectangular with a 25 by 50-mm (1 by 2-in.) cross section and it shall be a convenient length (150 to 300 mm (6 to 12 in.)).

4.7 *Wood Float*, approximately 75 by 280 by 20 mm thick (3 by 11 by ¾ in.).

NOTE 2—A commercial wood float equipped with a substantial handle can be readily reduced to these dimensions. The float shall be resurfaced or replaced when there is noticeable wear to the floating surface.

4.8 *Brush*, medium-soft bristle 50-mm (2-in.) paint brush to brush the surface of the specimens prior to sealing.

4.9 *Curing Cabinet*, maintained at a temperature of 37.8 ± 1.1°C (100± 2 °F) and a relative humidity of 32 ± 2 %. The curing cabinet shall be of a design that allows movement of conditioned air such that the solvent from the curing compound will be readily evaporated and eliminated from the system. Air flow over the specimens shall be adjusted to provide an evaporation rate of 2.0 to 3.4 g/h as measured by the procedure of Annex A1. The evaporation rate shall initially be measured for each position in the cabinet in which a specimen will be placed, and shall be verified annually and whenever any changes are made to the cabinet. The range of evaporation rates for all specimen positions in the test cabinet shall be reported.

4.10 *Balance*, having the capacity to determine the mass of a filled specimen mold to the nearest 0.1 g or less.

4.11 *Applicator*—For spray application, any apparatus that can be used to apply the curing compound uniformly and with minimum overspray is acceptable. For brush or roller application, use the equipment recommended by the curing compound manufacturer.

5. Materials

5.1 *Portland Cement*, conforming to the requirements for Type I of Specification C150.

5.2 *Graded Standard Sand*, conforming to the requirements of Specification C778.

5.3 *Sealing Compound*, that will not be affected by the curing material and which effectively seals against moisture loss between the boundary of the specimen and the edge of the mold.

NOTE 3—Tissue embedding wax, readily available from scientific supply houses, is a convenient and reliable sealant.

6. Conditioning

6.1 The temperature of the room and of all materials when used in this test shall be 23 ± 2 °C (73 ± 4 °F) unless otherwise specified, and the room humidity shall be 50 ± 10 %.

7. Number of Specimens

7.1 A set of three or more test specimens shall be made in order to constitute a test of a given curing material.

NOTE 4—When more than one set of specimens is to be prepared, each set should be handled as a group throughout the preparation to make the elapsed time between molding and application of the curing product as uniform as possible. This may require mixing the mortar for each set separately.

7.2 For determining the quantity of curing compound to be applied (MA) calculate the total top surface area of the specimen, including the seal and the rim of the mold in square millimetres using appropriate geometric formulae.

NOTE 5—The area (A) used in calculating the mass loss per unit area (L) is calculated in 14.2 from the surface dimensions measured inside the seal of the specimen.

8. Proportioning and Mixing Mortar

8.1 *Proportioning*—Determine the sand content of the mortar by adding dry sand to a cement paste having a water-cement ratio of 0.40 by weight, to produce a flow of 35 ± 5 in 10 drops of the flow table, following the procedure described in Test Method C87. Discard the mix used to determine the proportion of sand to cement.

NOTE 6—The sand:cement ratio required varies with the source of the cement. A ratio of 2.5:1 is suggested as a starting point. Flow may be determined on a 3 to 4 kg batch of mortar which is conveniently mixed in the mixer described in Practice C305. The mixture used to establish the sand:cement ratio is discarded because it is thought that the age and mixing history of the mortar affect the final moisture loss results and must be controlled.

8.2 *Mixing*—Combine the components of the mortar in a mortar-mixing machine to produce a homogeneous mortar not more than 6 min from the time the water and the cement are combined.

NOTE 7—A generally effective sequence is to add the cement to all of the water in the mixing bowl and allow it to stand for 30 s. Then, mix at low speed for 30 s and, without stopping the mixer, add the sand within 30 s and continue mixing for 1 min. Stop the mixer for 1 min. During the first 15 s, scrape down the sides of the bowl. Finish by mixing for an additional 1 min, and promptly begin molding the specimens.

9. Preparing Specimens

9.1 Thoroughly clean the molds before each use. Use of a mold release is acceptable provided that care is taken to avoid its application to the top rim of the mold to prevent interference with sealing of the edge.

9.2 Half fill the mold and spread the mortar with the back of the spoon to create a layer of approximately uniform thickness. Tamp over the entire surface with one stroke of the 25 by 50 mm (1 by 2 in.) face of the tamper per 1000 mm^2 of surface

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:05:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

area rounded to the nearest integer. Place a second layer of mortar, sufficient in amount to slightly overfill the mold and tamp in a similar manner. Using the 25-mm (1-in.) wide by 150 to 300-mm (6 to 12-in.) long edge of the tamper, fill the indentations made by the tamping and level the surface by pressing down firmly with a series of contacts across the entire surface. Strike off the specimen level with the top of the mold using a wood float with one pass only, in the direction of the long axis of the specimen for rectangular molds, using a sawing motion of the float. Keep the 75-mm (3-in.) face of the float firmly in contact with the mortar and edges of the mold so that the float creates a uniformly dense surface free of voids and cracks.

9.3 Immediately after molding, wipe the outside surfaces of the molds clean, and place the specimens in the curing cabinet maintained at the conditions specified in 4.9. The specimens shall be level and not subject to vibration. The spacing between the individual specimens and between the specimens and the side walls of the cabinet shall be between 50 and 175 mm (2 to 7 in.). Within these limits the spacing shall be the same for all specimens. Use dummy specimens to fill any empty spaces in the cabinet.

10. Surface Preparation and Edge Sealing

10.1 Remove the specimens from the cabinet immediately upon disappearance of the surface water and lightly brush the surface using just sufficient force to remove the laitance and glaze without scarifying the mortar surface. If surface water appears after brushing, return the specimen to the cabinet but immediately remove the specimen upon the disappearance of the surface water brought to the surface by the brushing operation, and brush again. The mortar shall be free of surface water but shall not be dry below the surface. The proper surface condition will be attained when brushing does not bring free water to the surface, or produce smearing, and can be determined by gently rubbing an area with the finger tip.

NOTE 8—The exposure time in the cabinet and the initial moisture loss that will result in the proper surface condition is characteristic of the curing cabinet used and other testing conditions related to the laboratory performing the test. Uniformity of test surface conditions may be maintained by setting an expected exposure time or initial moisture loss. When any test condition is changed (sand, cement, and so forth), a new exposure time or initial moisture loss, or both, shall be determined.

10.2 Form a V-shaped groove approximately 3 mm (⅛ in.) deep and not more than 3 mm (⅛ in.) wide between the edge of the mortar specimen and the mold. Fill the groove with the sealing compound. The sealing compound shall not extend more than 6 mm (¼ in.) from the edge of the mold onto the surface of the specimen.

NOTE 9—To cut out the groove for sealing, the tip of a pointed trowel, a pointed spatula, a pointed triangular can opener, or a "hawksbill point" ground on the end of a spatula or knife blade have all been reported to be effective.

11. Application of Curing Materials

11.1 Calculate the mass of the curing compound to be applied, *MA*, to the nearest 0.1 g based on the specified application rate, the total surface area calculated per 7.2, and the density of the curing compound determined in accordance with Test Method D1475. If no rate is specified, apply the curing compound at the rate of 5.0 m^2/L (200 ft^2/gal). The method of application shall be in accordance with the manufacturer's recommendations.

11.2 Immediately after sealing, weigh the specimen to the nearest 0.1 g (M_1); then uniformly apply the curing compound at the specified rate of application. Application shall be made expeditiously to only one specimen at a time.

NOTE 10—It is desirable to use a spray booth or a laboratory hood to control overspray and solvent fumes especially for curing compounds that are sprayed. However, the velocity of air movement in the vicinity of the specimen must be kept at a minimum so as to prevent, as much as possible, significant loss of volatiles during spraying and before the final weighing. Spraying shall be accomplished with the minimum pressure and flow rate of air with which an acceptable spray pattern can be attained.

11.3 Determine the proper coverage by comparing the initial mass of the specimen (M_1), before applying the curing compound, to the mass after coating. The final mass shall equal the initial mass of the specimen plus the predetermined mass of the curing compound to be applied. This will necessitate frequent weighing of the specimen during application as full coverage is approached. In the case of brush application, proper coverage may be determined by weighing the container, brush, and curing compound before and after application of the compound to the specimen. Total time for application shall not exceed 2 min. Weigh to the nearest 0.1 g (M_2). If the final amount of curing compound applied differs from the calculated amount for the specified coverage by more than 10 %, the specimen shall be discarded.

NOTE 11—In previous versions of this test method, coverage was determined by weighing the application equipment and the curing compound before and after application to the specimen. Which method is more precise has not been established.

11.4 Return the specimens to the cabinet without delay.

NOTE 12—Unusual loss caused by a leaking mold or a faulty seal may be detected by weighing the specimens 3 to 4 h after application of the curing material. If one specimen has lost considerably more than the others, this specimen is probably faulty. If only three specimens are being tested, consider the test invalid (see 14.4).

12. Determination of Non-Volatile Content of Curing Compounds

12.1 Determine the proportion of non-volatile matter in the curing compound (*NV*) in accordance with Test Method D2369.

13. Duration of Test

13.1 Specimens shall be stored in the test cabinet for 72 h, then removed, and immediately weighed (M_3). Other test times may be specified by the purchaser.

14. Calculation

14.1 *Loss of Mass*:

14.1.1 Calculate the loss of mass from each specimen in grams as follows:

$$ML = M_1 + (NV \times MA) - M_3 \quad (1)$$

where:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:05:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

ML = mass loss of the specimen, g,
M_1 = mass of the sealed specimen, g,
NV = proportion of non-volatile matter in the curing compound, g,
MA = mass of the curing compound applied, g, = $M_2 - M_1$,
M_2 = mass of the specimen immediately after applying curing compound, g, and
M_3 = mass of specimen at the conclusion of the test, g.

14.2 *Specimen Area*:

14.2.1 Calculate the area of the specimen (A) in square millimetres by measuring the dimensions of the surface from the inner edges of the seal to the nearest millimetre and applying the appropriate geometric formula.

14.3 For each specimen, calculate the mass loss per unit area (L) in kg/m^2 as:

$$L = 1000 \times ML/A \quad (2)$$

14.4 *Rejection of Results*:

14.4.1 In a set of three or more specimens, if the difference in moisture loss between the specimen having the greatest loss and that with the least loss exceeds 0.15 kg/m^2, the test shall be repeated and the average taken as that of all specimens in the original and repeat tests. If, after the repeat test, it is determined that the result on a single specimen, whether from the original or repeat test, meets the criteria for rejection as an outlier as given in Practice E178, such value shall be disregarded and a new average calculated that does not include such outlying value.

15. Report

15.1 Report the following information for the materials tested:

15.1.1 Manufacturer's name, address, and brand designation,

15.1.2 Type of curing material,

15.1.3 Manufacturer's batch number,

15.1.4 Quantity of material represented by the sample,

15.1.5 Date sampled, and

15.1.6 Source of the sample.

15.2 Report the following information regarding the test:

15.2.1 Laboratory sample identification,

15.2.2 Surface area inside the seal and depth of mortar specimens,

15.2.3 Brand of cement used,

15.2.4 Proportions of mortar by weight,

15.2.5 Method of application,

15.2.6 Duration of the test,

15.2.7 Range of evaporation rates of test cabinet,

15.2.8 Rate of application, and

15.2.9 Average loss of water per unit area.

16. Precision and Bias

16.1 *Precision*—Efforts to establish a more meaningful measure of the precision of this test method continue. The previous version of this test method, containing some differences in testing technique, contained a precision statement. The single-operator standard deviation was reported as 0.13 kg/m^2 and the multilaboratory standard deviation as 0.30 kg/m^2.[4]

16.2 *Bias*—Since there is no accepted reference material suitable for determining the bias of this test method, no statement on bias is being made.

17. Keywords

17.1 concrete curing materials; liquid membrane-forming curing compounds; moisture retention by concrete curing materials

[4] See Test Method C156 – 80a, *1987 Annual Book of ASTM Standards*, Vol 04.02.

ANNEX

(Mandatory Information)

A1. STANDARDIZATION OF EVAPORATION RATE IN TEST CABINETS

A1.1 This procedure provides a means for measuring the rate of evaporation of water from a standard surface in order to characterize a controlled set of environmental conditions (temperature, humidity, air circulation) by providing a system which will lose water at a nearly constant rate for a period of time long enough to establish a characteristic rate. Comparison of results from different positions in the same cabinet can establish whether or not conditions are uniform throughout the cabinet. Comparisons between labs may help to rationalize differing results.

A1.2 *Apparatus:*

A1.2.1 *Cup*—A permeability cup, conforming to the specifications of Test Method D1653.

A1.2.2 *Filter Paper*—7 cm disks.

A1.2.3 *Absorbent Filler*—Absorbent cotton balls.

A1.2.4 *Mold Cover*—Stiff cardboard or sheet metal plate having the same dimensions as the top of the specimen mold, and having a 63 mm (2½ in.) diameter hole in its center.

A1.2.5 *Balance*—Any balance having a capacity of 200 g or more and a sensitivity and accuracy of 0.01 g or less.

A1.3 *Procedure:*

A1.3.1 Fill the permeability cup with the absorbent filler using three cotton balls pulled together to make a uniform sponge. Fill the cup with distilled water, lay a disk of filter paper over the cup, and complete assembly of the cup. Place the mold cover on top of an empty specimen mold and fasten it in place with masking tape. Put the cup in the hole in the center of the mold. Place the mold and cup in the test cabinet in the position to be tested and allow 1 h for it to reach temperature equilibrium. Determine the mass of the cup to the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:05:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

nearest 0.01 g and immediately return it to the cabinet. Reweigh at approximately 1 h intervals for 5 to 7 h. Record the mass and the total elapsed time to the nearest 2 min for each interval.

A1.4 *Calculation:*

A1.4.1 Calculate the total mass loss at each time interval as follows:

$$L = m_i - m_t \quad \text{(A1.1)}$$

where:
L = cumulative mass loss,
m_i = initial mass, and
m_t = mass at time, t.

A1.4.2 Plot the cumulative mass loss (L) versus elapsed time (t) and determine the slope for the test period. Report as loss rate in grams per hour. Alternatively, the slope may be calculated by a "least squares" method. (The rate of loss should be nearly constant throughout the test period.)

A1.5 : *Precision and Bias:*

A1.5.1 *Precision*—Data for a precision statement is being collected.

A1.5.2 *Bias*—This test method has no bias because the evaporation rate is defined only in terms of this test method.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C156 – 09, that may impact the use of this test method. (Approved December 15, 2009)

(*1*) Revised the title of the standard.

Committee C09 has identified the location of selected changes to this test method since the last issue, C156 – 05, that may impact the use of this test method. (Approved November 1, 2009)

(*1*) Replaced the word "sample" with the word "specimen" in 4.9, 11.3, and Eq 1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 157/C 157M – 08

Standard Test Method for Length Change of Hardened Hydraulic-Cement Mortar and Concrete[1]

This standard is issued under the fixed designation C 157/C 157M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the length changes that are produced by causes other than externally applied forces and temperature changes in hardened hydraulic-cement mortar and concrete specimens made in the laboratory and exposed to controlled conditions of temperature and moisture.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. An exception is with regard to sieve sizes and nominal size of aggregate, in which the SI values are the standard as stated in Specification E 11. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 143/C 143M Test Method for Slump of Hydraulic-Cement Concrete

C 172 Practice for Sampling Freshly Mixed Concrete

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 596 Test Method for Drying Shrinkage of Mortar Containing Hydraulic Cement

C 1347 Practice for Preparation and Dissolution of Uranium Materials for Analysis

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

E 337 Test Method for Measuring Humidity with a Psychrometer (the Measurement of Wet- and Dry-Bulb Temperatures)

3. Terminology

3.1 *Definitions*—The terms used in this test method are defined in Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *length change*, *n*—an increase or decrease in the length of a test specimen that has been caused to change by any factor other than externally applied forces and temperature changes.

4. Significance and Use

4.1 Measurement of length change permits assessment of the potential for volumetric expansion or contraction of mortar or concrete due to various causes other than applied force or temperature change. This test method is particularly useful for comparative evaluation of this potential in different hydraulic-cement mortar or concrete mixtures.

4.2 This test method provides useful information for experimental purposes or for products that require testing under nonstandard mixing, placing, handling, or curing conditions, such as high product workability or different demolding times. Standard conditions are described in 5.4.1.

4.3 If conditions for mixing, curing, sampling, and storage other than specified in this test method are required, they shall be reported but are not to be considered as standard conditions

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.68 on Volume Change.

Current edition approved Oct. 1, 2008. Published November 2008. Originally approved in 1940. Last previous edition approved in 2006 as C 157/C 157M – 06.

of this test method. Nonstandard conditions and the reasons for departure from standard conditions shall be reported clearly and prominently with comparator values.

5. Apparatus

5.1 *Molds and Length Comparator*—The molds for casting test specimens and the length comparator for measuring length change shall conform to the requirements of Practice C 490.

5.2 *Tamper*—The tamper shall be made of a nonabsorptive, nonabrasive material such as medium-hard rubber or seasoned oak wood rendered nonabsorptive by immersion for 15 min in paraffin at approximately 392 °F [200 °C], and shall have a cross section of ½ by 1.0 in. [13 by 25 mm] and a convenient length of about 6 in. [150 mm]. The tamping face of the tamper shall be flat and at right angles to the length of the tamper.

5.3 *Tamping Rod*—The tamping rod shall be a straight steel rod ⅜ in. [10 mm] in diameter and not less than 10 in. [250 mm] in length, having at least the tamping end rounded to a hemispherical tip of the same diameter.

5.4 *Drying Room and Controls*—A drying room with suitable racks shall be provided when storing specimens in air. The racks shall be designed for free circulation of air around specimens, except for necessary supports, and shall be so situated with respect to the nearest wall or other obstruction that air circulation is not restricted in the intervening space. The supports shall be horizontal and shall consist of two nonabsorptive members not deeper than 1 in. [25 mm] and having a bearing area of not more than ¼ in. [6 mm] in width. Conditioned air shall be circulated into and out of the room in a uniform manner so that the specified rate of evaporation is attained adjacent to all specimens.

5.4.1 The air in the room shall be maintained at a temperature of 73 ± 3 °F [23 ± 2 °C] and a relative humidity of 50 ± 4 %. The air movement past all specimens shall be such that the rate of evaporation is 77 ± 30-mL/24 h from an atmometer or 13 ± 5-mL/24 h from a 400-mL Griffin low-form beaker filled to ¾ in. [20 mm] from the top. The temperature and relative humidity of the air in the room shall be measured with either a sling or Assmann psychrometer at least twice each working day. The psychrometer shall comply with Test Method E 337, except that thermometers having an overall length of 10 in. [250 mm] and marked in subdivisions of 0.5 °F [0.25 °C] are permitted. The room shall be equipped with a means of measuring and recording wet- and dry-bulb temperatures continuously. Correction factors as indicated by the sling or Assmann psychrometer shall be applied to the recorded data. The rate of evaporation within the room shall be determined daily by the use of the atmometer or by the loss of mass of water from a 400-mL Griffin low-form beaker filled initially to ¾ in. [20 mm] from the top.

5.5 *Atmometer*—The atmometer shall be constructed as shown in Fig. 1.

5.5.1 *Mounting*—Fig. 2 shows a suggested arrangement for operating the atmometer. Punch a central hole ½ in. [13 mm] in diameter in a filter paper, place it on the atmometer, and secure it in place while dry, by turning the torque handle only, until it just starts to slip. Mount the atmometer on a stand with the filter paper in a horizontal position. Mount a 100-mL glass graduate so that the 100-mL mark is from 1 to 3 in. [25 to 75 mm] below the level of the filter paper. Stopper the graduate so that entrance is provided for two short glass tubes not extending to the water level and one long tube extending to the bottom of the graduate. Connect the glass tubing leading from the bottom of the graduate to the inlet of the atmometer by means of clear plastic tubing.

5.5.2 *Operation*—Use clear plastic tubing to connect a squeeze bottle containing distilled or deionized water to one of the short glass tubes into the graduate. Force water into the graduate until it is about half full and then close the remaining glass tube into the graduate. Continue to force water through the graduate into the atmometer until the filter paper is saturated and there are no air bubbles in the system. Open the glass tube into the graduate and release pressure on the squeeze bottle gradually to avoid trapping air in the tube leading to the atmometer. Adjust the level of water in the graduate to approximately the 100-mL mark. If the atmometer is to be used under variable temperature conditions, disconnect the squeeze bottle after filling the graduate to avoid the possibility of additional water being forced into the graduate. Permit evaporation of water from the filter paper for 1 h before recording the time and initial reading of the graduate. It is not permitted to omit the waiting period during subsequent use of the atmometer provided the filter paper does not become dry. Change the filter paper whenever it shows signs of contamination but not less frequently than once every two weeks.

5.6 *Filter Paper*—The filter paper to be used with the atmometer shall be white with a smooth surface texture. It shall be 6 in. [152 mm] in diameter and 0.050 ± 0.003 in. [1.27 ± 0.08 mm] thick and shall have a cotton fiber content of not less than 75 weight %. The density shall be between 0.400 and 0.425 g/cm^3. The Mullen bursting strength shall not be less than 50 psi [345 kPa].

NOTE 1—E and D filter paper No. 625[3] has been found suitable.

5.7 *Apparatus for Demolding Specimens*—It is useful to construct an apparatus for demolding specimens molded in double molds as detailed in Fig. 3 or to a different design that serves the same purpose. When this device is to be used, the center side plate of the double mold must be appropriately drilled and tapped to receive the 8-32 by ⅝ in. [4.5-0.74 IMC by 16 mm] machine screw of the demolding thumbscrew. Fig. 4 shows the details of a suitable apparatus for demolding specimens molded in single molds.

[3] The sole source of supply of the apparatus known to the committee at this time is Ahlstrom Filtration Co., Mt. Holly Springs, PA 17065. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

6. Sampling

6.1 Take samples according to the applicable provisions of Practice C 192/C 192M from batches of hydraulic-cement mortar or concrete made in the laboratory (Note 2).

NOTE 2—When collecting samples in nonstandard conditions, such as field concrete, it is suggested that Practice C 172 be followed. Field cast specimens can show up to twice as much drying shrinkage as laboratory cast specimens from the same materials and proportions.

7. Test Specimens

7.1 *Mortar*—The test specimen for mortar shall be a prism of 1-in. [25-mm] square cross-section and approximately 11¼ in. [285 mm] in length. Three specimens shall be prepared for each test condition.

7.2 *Concrete*—The test specimen for concrete, in which all of the aggregate passes a 2-in. [50-mm] sieve, shall be a prism of 4-in. [100-mm] square cross-section and approximately 11¼ in. [285 mm] long. However, a prism of 3-in. [75-mm] square cross-section shall be used if all of the aggregate passes a 1-in. sieve [25.0-mm]. Three specimens shall be prepared for each test condition. Since length change is capable of being influenced by the size of the specimen, specimens to be compared shall have the same dimensions, and any specification limit based upon this method shall be applied to a specified size of specimen.

8. Procedure for Mixing Mortars and Concrete

8.1 If the mortar or concrete to be tested is made in accordance with requirements other than those given in one of the following paragraphs, samples shall be taken and specimens molded as described in the sections on sampling and on molding specimens.

8.2 Bring all materials to a temperature between 65 and 75 °F [18 and 24 °C] before using to make mortar or concrete. Proportion solid materials by mass (that is, not by volume). It is permissible to batch water and liquid admixtures either by mass or by volume. For calculation of batch quantities, assume aggregates to be saturated and surface-dry; if they are not in this condition at the time of use, apply appropriate corrections, as necessary, to batch quantities to compensate for absorption or free moisture.

8.3 *Mortar*—Mix mortar in a mechanical mixer as described in Practice C 305. The clearances between paddle and bowl specified in Practice C 305 are suitable only for mortars made with fine aggregates that are finer than the 2.36 mm (No. 8) sieve. Mortars made with aggregates containing particles coarser than this sieve require special clearances or a different type of paddle to permit the mixer to operate freely and to avoid damage to the paddle and bowl. The sequence of mixing shall be in accordance with the applicable provisions of Practice C 305. Determine the flow of the mortar in accordance with the applicable provisions of Test Method C 1437, and use sufficient mixing water to produce a flow of 110 ± 5 %.

8.4 *Concrete*—Mix concrete in a suitable laboratory mixer in accordance with the applicable provisions of Practice C 192/C 192M. Determine the slump of the concrete using Test Method C 143/C 143M, and use sufficient mixing water to produce a slump of 3.5 ± ½ in. [90 ± 15 mm].

9. Procedure for Molding Specimens

9.1 *Mortar Specimens*—Place the mortar in the mold in two approximately equal layers. Compact each layer with the tamper. Work the mortar into the corners, around the gage studs, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, strike off the mortar flush with the top of the mold, and smooth the surface with a few strokes of a trowel. Immediately after completion of molding, loosen the device by holding the gage studs in position at each end of the mold in order to prevent any restraint of the gage studs during initial shrinkage of the specimen.

9.2 *Concrete Specimens*—Place the concrete in the mold in two approximately equal layers in accordance with the general instructions for placing concrete in specimens given in Practice C 192/C 192M. Consolidate each layer by rodding, except use external vibration if the slump is less than 3 in. [75 mm] in accordance with the instructions for consolidation of flexure test specimens given in Practice C 192/C 192M. The same method of consolidation is to be used for all specimens to be compared. In addition, as the top layer is being placed, work the concrete thoroughly around each gage stud with the fingers. The top layer shall slightly overfill the mold. After consolidation is complete, strike off the excess material with a straightedge. Immediately after completion of molding, loosen the device by holding the gage studs in position at each end of the mold in order to prevent any restraint of the gage studs before the test specimens are demolded.

10. Procedure for Curing of Specimens

10.1 Cure the test specimens in the molds in a moist cabinet or room in accordance with Specification C 511. Protect specimens from dripping water.

10.2 Remove specimens from the molds at an age of 23½ ± ½ h after the addition of water to the cement during the mixing operation. In order to avoid damage during removal from the molds, it is not permitted, especially in the case of certain slow-hardening cements, to allow specimens to remain in the molds for more than 24 h. When this is found necessary the moist curing schedule shall be extended, but all specimens that are to be directly compared with each other shall be subjected to the same conditions of moist-curing and shall have their initial comparator reading made within ±½ h of the same age. It is permitted to use the demolding device to remove specimens without striking or jarring and with particular care not to exert pressure directly against the gage studs. The gage stud holder shall remain attached to the stud during this operation. Marks placed on the specimens for identification or positioning are only to be made by graphite applied either by a soft pencil or as a liquid that deposits essentially graphite without binder or made with waterproof indelible ink. Upon removal of the specimens from the molds, place them in lime-saturated water maintained at 73 ± 1 °F [23 ± 0.5 °C] for a minimum of 15 min in the case of 1-in. [25-mm] square cross-section specimens, and for a minimum of 30 min in the case of 3-in. [75-mm] or 4-in. [100-mm] square cross section specimens before being measured for length. This is to minimize variation in length due to variation in temperature. At an age of 24 ± ½ h after the addition of water to the cement during the mixing operation, remove the specimens from water storage one at a time, wipe with a damp cloth, and immediately take the initial comparator reading.

10.3 After the initial comparator reading, store the specimens in lime-saturated water at 73 ± 3 °F [23 ± 2 °C] until they have reached an age of 28 days, including the period in the molds. At the end of the curing period, take a second comparator reading after the specimens have been brought to a

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

more closely controlled temperature as was done prior to the earlier reading and in the manner described above.

NOTE 3—To determine the drying shrinkage of concrete subjected to elevated temperature curing in the laboratory, a modification of the previous method is necessary. Where concrete is cured with elevated (non-autoclave) temperatures, the curing cycle for this test method shall be that to be used for the project structural members. The elevated temperature curing cycle consists of pre-steam, steam cure, and post-steam periods. To avoid measuring thermal volume change, after the molds are stripped, cool drying-shrinkage specimens at laboratory temperature until they reach equilibrium (approximately 6 h for 4 by 4 by 11-in. [100 by 100 by 280-mm] bars). Then place them in lime-saturated water prior to the initial reading (see 10.2).

11. Procedure for Storage of Specimens

11.1 After measurement at the end of the curing period, store the specimens as described in either of the following:

11.1.1 *Water Storage*—Immerse the specimens in lime-saturated water storage in accordance with Specification C 511. Take comparator readings of each specimen when it has reached an age, including the curing period of 8, 16, 32, and 64 weeks. Make these readings immediately after the specimens have been subjected to storage in water at 73 ± 1 °F [23 ± 0.5 °C] for at least 15 min in the case of 1-in. [25-mm] specimens or 30 min in the case of 3-in. [75-mm] or 4-in. [100-mm] specimens.

11.1.2 *Air Storage*—Store the specimens in the drying room, so that the specimens have a clearance of at least 1 in. or 25 mm on all sides. Take comparator readings of each specimen after periods of air storage after curing of 4, 7, 14, and 28 days, and after 8, 16, 32, and 64 weeks. Preferably, take these readings in a room maintained at a relative humidity of 50 ± 4 % while the specimens are at a temperature of 73 ± 3 °F [23 ± 2 °C].

12. Procedure for Calculating Length Change

12.1 *Comparator Reading*—Read the comparator dial with the test specimen in the comparator; then read the comparator dial with the reference bar in the comparator. Calculate the difference between the two readings as described in Practice C 490.

12.2 *Length Change*—Calculate the length change of any specimen at any age after the initial comparator reading as follows:

$$\Delta L_x = \frac{CRD - \text{initial } CRD}{G} \times 100 \quad (1)$$

where:

ΔL_x = length change of specimen at any age, %,
CRD = difference between the comparator reading of the specimen and the reference bar at any age, and
G = the gage length (10 in. [250 mm]) (see Note 4).

NOTE 4—In Practice C 490, the comparator dial gage specified for use with 10-in. gage length specimens shall be graduated in fractions of an inch; the comparator dial gage specified for use with 250-mm gage length specimens shall be graduated in fractions of a millimetre.

13. Report

13.1 Report the following information:

13.1.1 Identification as mortar or concrete specimens, number of specimens for each condition, and date molded,

13.1.2 Source and identification of each material employed,

13.1.3 Type, maximum size, moisture condition, and grading of the aggregate,

13.1.4 Size of specimens,

13.1.5 Mortar or concrete mixture data at time of mixing, including flow or slump and temperature of mixture,

13.1.6 Description of consolidation of concrete, specifying whether rodding or external vibration was used,

13.1.7 Conditions and periods of moist curing prior and subsequent to removal of molds, if different from those specified,

13.1.8 Description of storage condition, including temperature and humidity, either by indicating whether the water or air storage was followed or by giving the details of any procedure not conforming to either of these conditions,

13.1.9 Total elapsed time of storage and total age of specimen, or total elapsed time of curing and storage if the same condition was used for both,

13.1.10 Length change data, reported as percent increase or decrease in linear dimension to the nearest 0.001 % of the gage length based on the initial measurement made at the time of removal from the molds, and

13.1.11 Any other pertinent information.

14. Precision and Bias

14.1 *Precision*:

14.1.1 When this test method was used for the purpose of determining drying shrinkage of mortar as affected by the choice of portland cement used in making it, the precision was found to be as reported in Test Method C 596.

14.1.1.1 The following single-laboratory, multiple-operator precision applies to concrete specimens measured at 180 days.

14.1.1.2 For specimens stored in water, the standard deviation (1s) among specimens is 0.0045 %. When three replicate specimens are tested, the maximum range among them is not expected to exceed 0.0266 % in 95 % of the sets tested. When a test result represents the mean of three specimens, the 1s is 0.0026 %. The difference between two such means is not expected to exceed 0.0074 % in 95 % of such duplicate tests performed.

14.1.1.3 For specimens stored in air, the standard deviation (1s) among specimens is 0.0084 %. When three replicate specimens are tested, the maximum range among them is not expected to exceed 0.0496 % in 95 % of the sets tested. When a test result represents the mean of 3 specimens, the 1s is 0.0048 %. The difference between two such means is not expected to exceed 0.0137 % in 95 % of such duplicate tests performed.

NOTE 5—These precision values were calculated from data taken on specimens described on p. 47 of STP 205,[4] representing 193 concrete mixtures; two specimens made from each of three batches made on separate days, one of each two specimens stored in water, the other stored at nominal 50 % relative humidity.

Designation: C 171 – 07

Standard Specification for Sheet Materials for Curing Concrete[1]

This standard is issued under the fixed designation C 171; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers materials in sheet form used for covering the surfaces of hydraulic cement concrete to inhibit moisture loss during the curing period and, in the case of the white reflective type materials, to also reduce temperature rise in concrete exposed to radiation from the sun. The following types are included:

1.1.1 *Curing Paper*:

1.1.1.1 Regular.

1.1.1.2 White.

1.1.2 *Polyethylene Film*:

1.1.2.1 Clear.

1.1.2.2 White Opaque.

1.1.3 *White-Burlap-Polyethylene Sheet*.

1.2 The values stated in SI units are to be regarded as the standard. Inch-pound units are provided in parentheses for information only.

NOTE 1—This specification does not cover materials such as burlap, cotton mats, or rugs used with additional applications of water to maintain a water-saturated environment on such surfaces. Procedures employing these materials are discussed in ACI 308R. Sheet materials having additional characteristics such as insulating properties and the ability to carry additional water to the curing region are commercially available but are not currently addressed in this specification.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 156 Test Method for Water Retention by Liquid Membrane-Forming Curing Compounds for Concrete

D 829 Test Methods for Wet Tensile Breaking Strength of Paper and Paper Products

D 4397 Specification for Polyethylene Sheeting for Construction, Industrial, and Agricultural Applications

E 96/E 96M Test Methods for Water Vapor Transmission of Materials

E 1347 Test Method for Color and Color-Difference Measurement by Tristimulus Colorimetry

2.2 *ACI Standard:*

ACI 308R Standard Practice for Curing Concrete[3]

3. Terminology

3.1 *Definitions:*

3.1.1 *curing paper*, *n*—a composite consisting of two layers of kraft paper bonded together with a bituminous material and reinforced with fiber, used for covering the surface of fresh concrete to inhibit moisture loss during the curing period.

4. Ordering Information

4.1 The purchaser shall specify the type of curing material to be furnished under this specification.

4.2 Lengths and widths of the rolls or mats of the sheet materials furnished shall be as agreed upon between the purchaser and seller.

5. Performance Requirements

5.1 The sheet materials furnished under this specification shall be tough, strong, resilient, and capable of withstanding normal job use without puncturing or tearing.

5.2 The sheet material shall exhibit a water vapor transmission rate (WVTR) of no more than 10 g/m^2 in 24 h when tested according to Test Methods E 96/E 96M using the Water Method in the environment (test cabinet) specified in Test Method C 156.

5.3 The daylight reflectance of the white side of white curing paper shall be at least 50 % when measured by Test Method E 1347. The daylight reflectance of white polyethylene film and the polyethylene side of white burlap-polyethylene sheet shall be at least 70 % when measured according to Test Method E 1347.

NOTE 2—Daylight reflectance is total luminous reflectance factor, CIE

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.22 on Materials Applied to New Concrete Surfaces.

Current edition approved Nov. 1, 2007. Published December 2007. Originally approved in 1942. Last previous edition approved in 2003 as C 171–03.

tristimulus value Y for the CIE 1931 (2°) standard observer and CIE standard illuminant C or D65.

6. Physical Requirements

6.1 *Curing Paper* shall consist of two sheets of kraft paper cemented together with a bituminous material in which are embedded cords or strands of fiber running in both directions and not more than 32 mm (1¼ in.) apart. The paper shall be light in color, shall be free of visible defects, and shall have a uniform appearance. White paper shall have a white surface on at least one side.

6.1.1 The tensile strength of curing paper shall be no less than 5.25 kN/m of width (30 lbf/in. of width) in the machine direction and 2.62 kN/m of width (15 lbf/in. of width) in the cross direction when measured according to Test Methods D 829.

6.2 *Polyethylene Film* shall consist of a single sheet manufactured from polyethylene resins. It shall be free of visible defects and shall have a uniform appearance. The clear type shall be essentially transparent. The opaque film shall contain white pigment.

6.2.1 The nominal thickness of polyethylene film shall be no less than 0.10 mm (4 mil) as determined according to Specification D 4397 . Thickness at any point shall be no less than 0.075 mm (0.0030 in.).

6.2.2 The impact resistance and mechanical properties shall be as required in Specification D 4397.

6.3 *White Burlap-Polyethylene Sheeting* shall consist of burlap weighing not less than 305 g/m^2(9 oz./yd^2) extrusion coated on one side with white opaque polyethylene at least 0.10 mm (0.004 in.) thick and meeting the other requirements of 6.2. The polyethylene material shall be securely bonded to the burlap so that there will be no separation of the materials during handling and curing of the concrete.

7. Sampling

7.1 Samples of film or sheeting sufficient to determine conformance with this specification shall be taken at random.

8. Keywords

8.1 concrete curing materials; polyethylene film; sheet material for curing concrete; curing paper; white burlap-polyethylene sheet

SUMMARY OF CHANGES

Designation: C 172 – 08

Standard Practice for Sampling Freshly Mixed Concrete[1]

This standard is issued under the fixed designation C 172; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This practice covers procedures for obtaining representative samples of fresh concrete as delivered to the project site on which tests are to be performed to determine compliance with quality requirements of the specifications under which the concrete is furnished (Note 1). The practice includes sampling from stationary, paving and truck mixers, and from agitating and nonagitating equipment used to transport central-mixed concrete.

1.2 The values stated in SI units are to be regarded as standard. The values given in parentheses are mathematical conversions to inch-pound units that are provided for information only and are not considered standard.

NOTE 1—Composite samples are required by this practice, unless specifically excepted by procedures governing the tests to be performed such as tests to determine uniformity of consistency and mixer efficiency. Procedures used to select the specific test batches are not described in this practice, but it is recommended that random sampling be used to determine overall specification compliance.

1.3 This practice also covers the procedures to be used for preparing a sample of concrete for further testing where it is desirable or necessary to remove the aggregate larger than a designated size. This removal of larger aggregate particles is preferably accomplished by wet-sieving.

1.4 The text of this standard references notes and footnotes which provide explanatory material and shall not be considered as requirements of the practice.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:* [3]

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Significance and Use

3.1 This practice is intended to provide standard requirements and procedures for sampling freshly mixed concrete from different containers used in the production or transportation of concrete. The detailed requirements as to materials, mixtures, air content, temperature, number of specimens, slump, interpretation of results, and precision and bias are in specific test methods.

4. Sampling

4.1 The elapsed time shall not exceed 15 min. between obtaining the first and final portions of the composite sample.

4.1.1 Transport the individual samples to the place where fresh concrete tests are to be performed or where test specimens are to be molded. They shall be combined and remixed with a shovel the minimum amount necessary to ensure uniformity and compliance with the maximum time limits specified in 4.1.2.

4.1.2 Start tests for slump, temperature, and air content within 5 min after obtaining the final portion of the composite sample. Complete these tests expeditiously. Start molding specimens for strength tests within 15 min after fabricating the composite sample. Expeditiously obtain and use the sample and protect the sample from the sun, wind, and other sources of rapid evaporation, and from contamination.

5. Procedure

5.1 *Size of Sample*—Make the samples to be used for strength tests a minimum of 28 L (1 ft^3). Smaller samples are not prohibited for routine air content, temperature, and slump tests. The size of the samples shall be dictated by the maximum aggregate size.

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.60 on Testing Fresh Concrete.

Current edition approved June 1, 2008. Published July 2008. Originally approved in 1942. Last previous edition approved in 2007 as C 172 – 07a.

www.technobetar.ir

5.2 The procedures used in sampling shall include the use of every precaution that will assist in obtaining samples that are truly representative of the nature and condition of concrete sampled as follows:

NOTE 2—Sampling should normally be performed as the concrete is delivered from the mixer to the conveying vehicle used to transport the concrete to the forms; however, specifications may require other points of sampling, such as the discharge of a concrete pump.

5.2.1 *Sampling from Stationary Mixers, Except Paving Mixers*—Sample the concrete by collecting two or more portions taken at regularly spaced intervals during discharge of the middle portion of the batch. Obtain these portions within the time limit specified in Section 4. Combine into one composite sample for testing purposes. Do not obtain portions of the composite sample from the very first or last part of the batch discharge (Note 3). Perform sampling by passing a receptacle completely through the discharge stream, or by completely diverting the discharge into a sample container. If discharge of the concrete is too rapid to divert the complete discharge stream, discharge the concrete into a container or transportation unit sufficiently large to accommodate the entire batch and then accomplish the sampling in the same manner as given above. Take care not to restrict the flow of concrete from the mixer, container, or transportation unit so as to cause segregation. These requirements apply to both tilting and nontilting mixers.

NOTE 3—No samples should be taken before 10 % or after 90 % of the batch has been discharged. Due to the difficulty of determining the actual quantity of concrete discharged, the intent is to provide samples that are representative of widely separated portions, but not the beginning and the end of the load.

5.2.2 *Sampling from Paving Mixers*—Sample the concrete after the contents of the paving mixer have been discharged. Obtain samples from at least five different portions of the pile and then composite into one sample for test purposes. Avoid contamination with subgrade material or prolonged contact with and absorptive subgrade. To preclude contamination or absorption by the subgrade, sample the concrete by placing three shallow containers on the subgrade and discharging the concrete across the container. Combine the samples so obtained into one composite sample for test purposes. The containers shall be of a size sufficient to provide a composite sample size that is in agreement with the maximum aggregate size.

NOTE 4—In some instances, the containers may have to be supported above the subgrade to prevent displacement during discharge.

5.2.3 *Sampling from Revolving Drum Truck Mixers or Agitators*—Sample the concrete by collecting two or more portions taken at regularly spaced intervals during discharge of the middle portion of the batch. Take the samples so obtained within the time limit specified in Section 4 and combine them into one composite sample for test purposes. In any case do not obtain samples until after all of the water and any admixtures have been added to the mixer; also do not obtain samples from the very first or last portions of the batch discharge (Note 3). Sample by repeatedly passing a receptacle through the entire discharge stream or by completely diverting the discharge into a sample container. Regulate the rate of discharge of the batch by the rate of revolution of the drum and not by the size of the gate opening.

5.2.4 *Sampling from Open-Top Truck Mixers, Agitators, Nonagitating Equipment, or Other Types of Open-Top Containers*—Take samples by whichever of the procedures described in 5.2.1, 5.2.2, or 5.2.3 is most applicable under the given conditions.

6. Additional Procedure for Large Maximum Size Aggregate Concrete

6.1 When the concrete contains aggregate larger than that appropriate for the size of the molds or equipment to be used, wet-sieve the sample as described below except perform density (unit weight) tests for use in yield computations on the full mix.

NOTE 5—The effect of wet-sieving on the test results should be considered. For example, wet-sieving concrete causes the loss of a small amount of air due to additional handling. The air content of the wet-sieved fraction of concrete is greater than that of the total concrete because the larger size aggregate which is removed does not contain air. The apparent strength of wet-sieved concrete in smaller specimens is usually greater than that of the total concrete in larger appropriate size specimens. The effect of these differences may need to be considered or determined by supplementary testing for quality control or test result evaluation purposes.

6.2 *Definition*:

6.2.1 *wet-sieving concrete*—the process of removing aggregate larger than a designated size from the fresh concrete by sieving it on a sieve of the designated size.

6.3 *Apparatus*:

6.3.1 *Sieves*, as designated, conforming to Specification E 11.

6.3.2 *Receptacle*—A container of suitable size having a nonabsorbent surface.

6.3.3 *Wet-Sieving Equipment*—Equipment for wet-sieving concrete shall be a sieve as noted in 6.3.1 of suitable size and conveniently arranged and supported so that one can shake it rapidly by either hand or mechanical means. Generally, a horizontal back and forth motion is preferred. The equipment shall be capable of rapidly and effectively removing the designated size of aggregate.

6.3.4 *Hand Tools*—Shovels, hand scoops, plastering trowels, and rubber gloves as required.

6.4 *Procedure*:

6.4.1 *Wet-Sieving*—After sampling the concrete, pass the concrete over the designated sieve and remove and discard the aggregate retained. This shall be done before remixing. Shake or vibrate the sieve by hand or mechanical means until no undersize material remains on the sieve. Mortar adhering to the aggregate retained on the sieve shall not be wiped from it before it is discarded. Place only enough concrete on the sieve at any one time so that after sieving, the thickness of the layer of retained aggregate is not more than one particle thick. The concrete which passes the sieve shall fall into a batch pan of suitable size which has been dampened before use or onto a clean, moist, nonabsorbent surface. Scrape any mortar adhering to the sides of the wet-sieving equipment into the batch. After removing the larger aggregate particles by wet-sieving

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 172 – 07a, that may impact the use of this practice. (Approved June 1, 2008)

(*1*) Added wording to 5.2.3 to make it clear that sampling should not be done until all admixtures have been added to the mixer.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 172 – 07, that may impact the use of this practice. (Approved December 15, 2007)

(*1*) Changed "composite" to "combine" in 5.2.1, 5.2.2, and 5.2.3.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 172 – 04, that may impact the use of this practice. (Approved July 15, 2007)

(*1*) Added a definition for receptacle as new 6.3.2 and renumbered subsequent paragraphs.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C173/C173M – 10

Standard Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method[1]

This standard is issued under the fixed designation C173/C173M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers determination of the air content of freshly mixed concrete containing any type of aggregate, whether it be dense, cellular, or lightweight.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*(**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C29/C29M Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate

C31/C31M Practice for Making and Curing Concrete Test Specimens in the Field

C138/C138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

C143/C143M Test Method for Slump of Hydraulic-Cement Concrete

C172 Practice for Sampling Freshly Mixed Concrete

C173/C173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Significance and Use

3.1 This test method covers the determination of the air content of freshly mixed concrete. It measures the air contained in the mortar fraction of the concrete, but is not affected by air that may be present inside porous aggregate particles.

3.1.1 Therefore, this is the appropriate test to determine the air content of concretes containing lightweight aggregates, air-cooled slag, and highly porous or vesicular natural aggregates.

3.2 This test method requires the addition of sufficient isopropyl alcohol, when the meter is initially being filled with water, so that after the first or subsequent rollings little or no foam collects in the neck of the top section of the meter. If more foam is present than that equivalent to 2 % air above the water level, the test is declared invalid and must be repeated using a larger quantity of alcohol. Addition of alcohol to dispel foam any time after the initial filling of the meter to the zero mark is not permitted.

3.3 The air content of hardened concrete may be either higher or lower than that determined by this test method. This depends upon the methods and amounts of consolidation effort applied to the concrete from which the hardened concrete specimen is taken; uniformity and stability of the air bubbles in the fresh and hardened concrete; accuracy of the microscopic examination, if used; time of comparison; environmental exposure; stage in the delivery, placement and consolidation processes at which the air content of the unhardened concrete is determined, that is, before or after the concrete goes through a pump; and other factors.

4. Apparatus

4.1 *Air Meter*—An air meter consisting of a bowl and a top section (Fig. 1) conforming to the following requirements:

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.60 on Testing Fresh Concrete.

Current edition approved Feb. 1, 2010. Published March 2010. Originally approved in 1942. Last previous edition approved in 2009 as C173/C173M–09 DOI: 10.1520/C0173_C0173M-10

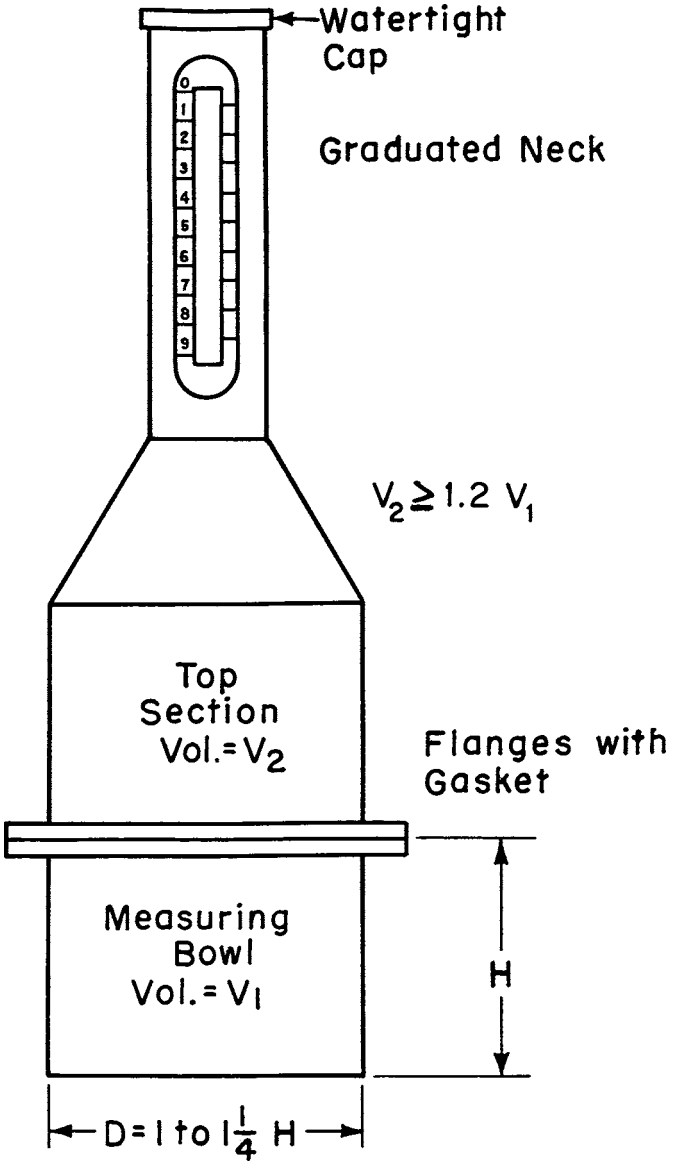

FIG. 1 Apparatus for Measuring Air Content of Fresh Concrete by Volumetric Method

4.1.1 The bowl and top sections shall be of sufficient thickness and rigidity to withstand rough field use. The material shall not be attacked by high pH cement paste, deform when stored at high temperatures in closed spaces, or become brittle or crack at low temperatures. A watertight seal must be obtained when the top section is attached to the bowl.

4.1.2 *Bowl*—The bowl shall have a diameter equal to 1 to 1.25 times the height and be constructed with a flange at or near the top surface. Bowls shall not have a capacity of less than 0.075 ft^3 [2.0 L].

4.1.3 *Top Section*—The top section shall have a capacity at least 20 % larger than the bowl and shall be equipped with a flexible gasket and a device to attach the top section to the bowl. The top section shall be equipped with a transparent scale, graduated in increments not greater than 0.5 % from 0 at the top to 9 %, or more, of the volume of the bowl. Graduations shall be accurate to ±0.1 % by volume of the bowl. The upper end of the neck shall have a watertight cap that will maintain a watertight seal when the meter is inverted and rolled.

4.2 *Funnel*—A funnel with a spout of a size permitting it to be inserted through the neck of the top section and long enough to extend to a point just above the bottom of the top section. The discharge end of the spout shall be so constructed that when water is added to the container there will be a minimum disturbance of the concrete.

4.3 *Tamping Rod*—A round, straight steel, high-density polyethylene, or other plastic rod of equal or greater abrasion resistance with a ⅝ in. [16 m] ± 1⁄16 in. [2 mm] diameter. The length of the tamping rod shall be at least 4 in. [100 mm] greater than the depth of the bowl in which rodding is being performed, but not greater than 24 in. [600 mm] in overall length (Note 1). The length tolerance for the tamping rod shall be ± ⅛ in. [4 mm]. The rod shall have the tamping end or both ends rounded to a hemispherical tip of the same diameter as the rod.

NOTE 1—A rod length of 16 in. [400 mm] to 24 in. [600 mm] meets the requirements of the following: Practice C31/C31M, Test Method C138/C138M, Test Method C143/C143M, Test Method C173/C173M, and Test Method C231.

4.4 *Strike-off Bar*—A flat, straight steel bar at least ⅛ by ¾ by 12 in. [3 by 20 by 300 mm] or a flat, straight high-density polyethylene bar, or other plastic of equal or greater abrasion resistance, at least ¼ by ¾ by 12 in. [6 by 20 by 300 mm].

4.5 *Calibrated Cup*—A metal or plastic cup either having a capacity of or being graduated in increments equal to 1.00 ± 0.04 % of the volume of the bowl of the air meter. The calibrated cup is only to be used to add water when the concrete air content exceeds 9 % or the calibrated range of the meter.

4.6 *Measuring Vessel for Isopropyl Alcohol*—A vessel with a minimum capacity of at least 1 pt [500 mL] with graduations not larger than 4 oz [100 mL] for measuring a quantity of isopropyl alcohol.

4.7 *Syringe*—A rubber syringe having a capacity of at least 2 oz [50 mL].

4.8 *Pouring Vessel for Water*—A container of approximately 1 qt [1 L] capacity.

4.9 *Scoop*—of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the bowl.

4.10 *Isopropyl Alcohol*—Use 70 % by volume isopropyl alcohol (approximately 65 % by weight) (Note 2). Other foam-dispersing agents are permitted if tests demonstrate that the use of the agent does not change the indicated air content, in the amounts being used, by more than 0.1 % or if correction factors are developed similar to those in Table 1. When other dispersing agents are used, a copy of the records documenting the testing or calculations shall be available in the laboratory.

NOTE 2—Seventy percent isopropyl alcohol is commonly available as rubbing alcohol. More concentrated grades can be diluted with water to the required concentration.

4.11 *Mallet*—A mallet (with a rubber or rawhide head) with a mass of approximately 1.25 ± 0.5 lb [600 ± 200 g].

TABLE 1 Correction for the Effect of Isopropyl Alcohol on C173/C173M Air Meter Reading

70 % Isopropyl Alcohol Used			
Pints	Fluid Ounces	Litres	Correction, %[A]
≤ 2.0	≤ 32	≤ 1.0	0.0[B]
3.0	48	1.5	0.25
4.0	64	2.0	0.50
5.0	80	2.5	0.75

[A] Subtract from final meter reading.

[B] Corrections are applied only when 2.5 pt [1.25 L] or more of isopropyl alcohol is used. The values given are for air meters that have a bowl volume of 0.075 ft^3 [2.1 L] and a top section that is 1.2 times the volume of the bowl.

5. Calibration

5.1 Calibrate the meter and calibrated cup initially and annually or whenever there is reason to suspect damage or deformation of the meter or calibrated cup.

5.2 Determine the volume of the bowl with an accuracy of at least 0.1 % by determining the mass of water required to fill it at room temperature and dividing it by the density of the water at the same temperature. Follow the calibration procedure outlined in Test Method C29/C29M.

5.3 Determine the accuracy of the graduations on the neck of the top section of the air meter by filling the assembled measuring bowl and top section with water to the level of the mark for highest air content graduation.

5.3.1 Add water in increments of 1.0 % of the volume of the bowl to check accuracy throughout the graduated range of air content. The error at any point throughout the graduated range shall not exceed 0.1 % of air.

5.4 Determine the volume of the calibrated cup using water at 70 °F [21.1 °C] by the method outlined in 5.2. A quick check can be made by adding one or more calibrated cups of water to the assembled apparatus and observing the increase in the height of the water column after filling to a given level.

6. Sampling

6.1 Obtain the sample of freshly mixed concrete in accordance with Practice C172. If the concrete contains coarse aggregate particles that would be retained on a 1½-in. [37.5-mm] sieve, wet sieve a representative sample over a 1-in. [25-mm] sieve to yield somewhat more than enough material to fill the measuring bowl. The wet sieving procedure is described in Practice C172. Carry out the wet sieving operation with the minimum practicable disturbance of the mortar. Make no attempt to wipe adhering mortar from coarse aggregate particles retained on the sieve.

7. Procedure

7.1 *Rodding and Tapping*—Wet the inside of the bowl and dry it to a damp but not shiny appearance. Using the scoop described in 4.9, fill the bowl with freshly mixed concrete in two layers of equal depth. While placing the concrete in the bowl, move the scoop around the perimeter of the bowl opening to ensure an even distribution of the concrete with minimal segregation. Rod each layer 25 times uniformly over the cross section with the rounded end of the rod. Rod the bottom layer throughout its depth. In rodding this layer, use care not to damage the bottom of the bowl. For the upper layer, allow the rod to penetrate through the layer being rodded and into the layer below approximately 1 in. [25 mm]. After each layer is rodded, tap the sides of the bowl 10 to 15 times with the mallet to close any voids left by the tamping rod and to release any large bubbles of air that may have been trapped. After tapping the final layer, a slight excess of concrete, ⅛ in. [3 mm] or less, above the rim is acceptable. Add or remove a representative sample of concrete if necessary to obtain the required amount of concrete.

7.2 *Striking Off*—After rodding and tapping of the second layer, strike off the excess concrete with the strike-off bar until the surface is flush with the top of the bowl. Wipe the flange of the bowl clean.

7.3 *Adding Water and Alcohol*—Wet the inside of the top section of the meter, including the gasket. Attach the top section to the bowl and insert the funnel. Add at least 1 pt [0.5 L] of water followed by the selected amount (Note 3) of isopropyl alcohol. Record the amount of isopropyl alcohol added. Continue adding water until it appears in the graduated neck of the top section (Note 4). Remove the funnel. Adjust the liquid level until the bottom of the meniscus is level with the zero mark. A rubber syringe is useful for this purpose. Attach and tighten the watertight cap.

NOTE 3—The amount of isopropyl alcohol necessary to obtain a stable reading and a minimum of foam at the top of the water column will depend upon a number of factors. Many concretes made with less than 500 lb/yd^3 [300 kg/m^3] of cement and air contents less than 4 % may require less than 0.5 pt [200 mL] of alcohol. Some high-cement mixes made with silica fume that have air contents of 6 % or more may require more than 3 pt [1400 mL] of alcohol. The amount required will vary with the concrete air content, the amount and type of air-entraining admixture, the cement content and cement alkali content, and perhaps other factors. Generally, the amount of alcohol necessary can be established for given mixture proportions and should not change greatly during the course of a job.

NOTE 4—When, if ever, it is necessary to use more than 4 or 4.5 pt [2.0 L] of isopropyl alcohol, it may be necessary to restrict the amount of water added initially to avoid overfilling the meter. However, it is desirable to add at least some water initially to aid in mixing the alcohol and limit the contact of the concentrated alcohol with the top surface of the concrete.

7.4 *Displacing the Volume of Air in the Concrete Specimen Using These Procedures*:

7.4.1 *Free the Concrete from the Base*— Quickly invert the meter, shake the base horizontally, and return the meter to the upright position. To prevent the aggregate from lodging in the neck of the unit, do not keep it inverted for more than 5 s at a time. Repeat the inversion and shaking process for a minimum of 45 s and until the concrete has broken free and the aggregate can be heard moving in the meter as it is inverted.

7.4.2 *Rolling*—Place one hand on the neck of the meter and the other on the flange. Using the hand on the neck, tilt the top of the meter approximately 45° from the vertical position with the bottom edge of the base of the meter resting on the floor or on the work surface. Maintain this position through the procedures described in this section. Using the hand on the flange to rotate the meter, vigorously roll the meter ¼ to ½ turn forward and back several times, quickly starting and stopping the roll. Turn the base of the meter about ⅓ turn and repeat the rolling procedure as stated previously. Continue the turning

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:05:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

and rolling procedures for approximately 1 min. The aggregate must be heard sliding in the meter during this process.

7.4.2.1 If, at any time, during the inversion and rolling procedures liquid is found to be leaking from the meter, the test is invalid and a new test shall be started as in 6.1.

7.4.2.2 Set the unit upright and loosen the top to allow any pressure to stabilize. Allow the meter to stand while the air rises to the top and until the liquid level stabilizes. The liquid level is considered stable when it does not change more than 0.25 % air within a 2-min period.

7.4.2.3 If it takes more than 6 min for the liquid level to stabilize or if there is more foam than that equivalent to 2 full percent air content divisions on the meter scale over the liquid level, discard the trial and start a new test as in 6.1. Use a larger addition of alcohol than was used in the initial trial.

7.4.2.4 If the level is stable without excessive foam, read the bottom of the meniscus to the nearest 0.25 % and record the *initial meter reading*.

7.4.2.5 If the air content is greater than the 9 % range of the meter, add a sufficient number of calibrated cups of water to bring the liquid level within the graduate range. Read the bottom of the meniscus to the nearest 0.25 %. Record the number of calibrated cups of water to be added to the final meter reading in 8.2.

7.5 *Confirmation of the Initial Meter Reading*:

7.5.1 When an initial meter reading is obtained as in 7.4.2.4, retighten the top and repeat the 1-min rolling as in 7.4.2, 7.4.2.2, and 7.4.2.3.

7.5.2 When the liquid level is stable as in 7.4.2.2 and the requirements of 7.4.2.3 are met, make a direct reading to the bottom of the meniscus and estimate to 0.25 % air. If this reading has not changed more than 0.25 % from the initial meter reading in 7.4.2.4, record it as the *final meter reading* of the sample tested.

7.5.2.1 If the reading has changed from the *initial meter reading* by more than 0.25 % air, record this reading as a new "*initial reading*" and repeat the 1-min rolling as in 7.4.2. Read the indicated air content. If this reading has not changed by more than 0.25 % air from the "*newest initial reading*" record it as the *final meter reading*.

7.5.2.2 If the reading has changed by more than 0.25 %, discard the test and start a new test on a new sample of concrete as in 6.1 using more alcohol.

7.6 Disassemble the apparatus. Dump the base and examine the contents to be sure that there are no portions of undisturbed, tightly packed concrete in the base. If portions of undisturbed concrete are found, the test is invalid.

8. Calculation

8.1 If more than 2.5 pt [1.25 L] of alcohol is used in 7.3, a correction to the final meter reading is required. Round the volume of alcohol used to the nearest pint [0.5 L] and select the correction factor from Table 1.

NOTE 5—When the top section is initially filled to the zero mark with water and isopropyl alcohol that mixture has a defined volume; however, when that solution is further mixed with the water present in the concrete, the concentration of alcohol changes and the new solution occupies a volume slightly smaller than it did when the meter was initially filled to the zero mark. For this reason, the meter tends to indicate a higher than actual air content when more than about 2.5 pt [1.2 L] of alcohol is used. Therefore, when large amounts of alcohol are used, the correction factors in Table 1 reduce the air content indicated by the meter.

8.2 *Air Content*—Calculate the air content of the concrete in the measuring bowl as follows:

$$A = A_R - C + W \quad (1)$$

where:

A = air content, %,
A_R = final meter reading, %,
C = correction factor from Table 1, %, and
W = number of calibrated cups of water added to the meter (See 7.4.2.5)

8.2.1 Report the air content to the nearest 0.25 %.

8.3 When the sample tested represents that portion of the mixture obtained by wet sieving over a 1-in. (25-mm) sieve, calculate the air content of the mortar or of the full mixture using the formulas given in Test Method C231. Use appropriate quantities coarser or finer than the 1-in. sieve instead of the 1½-in. (37.5-mm) sieve specified in Test Method C231.

9. Precision and Bias

9.1 The standard deviation is essentially proportional to the average for different levels of air content. The following precision statement is based on 979 tests made in 6 field experiments by the West Virginia D.O.T. The multi-operator coefficient of variation has been found to be 11 % of the measured air content. Therefore, results of tests by two different operators on specimens taken from a single concrete sample should not differ from each other by more than 32 % of their average air content (Note 6).

NOTE 6—These numbers represent, respectively, the 1s % and d2s % limits described in Practice C670. The data collected for the precision statement was obtained using procedures standard prior to the use of large amounts of isopropyl alcohol in Test Method C173/C173M-01.

9.2 This test method provides volumetric procedures for determining the air content of freshly mixed concrete. When conducted properly, this test method has no bias because the value of the air content can only be defined in terms of this test method.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C173/C173M–09 that may impact the use of this test method. (Approved February 1, 2010)

(*1*) Revised 4.3 to alter requirements of tamping rod.

(*2*) Added new Note 1 describing acceptable tamping rod length and renumbered subsequent notes.

(*3*) Revised 7.1 to alter wording of tamping rod use.

Committee C09 has identified the location of selected changes to this test method since the last issue, C173/C173M–08a, that may impact the use of this test method. (Approved June 1, 2009)

(*1*) Revised Table 1, including Footnote B.

(*2*) Revised Section 8. Much of the text in Section 8 was removed and replaced by Eq 1 to clarify the calculation of air content.

Committee C09 has identified the location of selected changes to this test method since the last issue, C173/C173M–08, that may impact the use of this test method. (Approved December 15, 2008)

(*1*) Revised Table 1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 174/C 174M – 06

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T 148

Standard Test Method for Measuring Thickness of Concrete Elements Using Drilled Concrete Cores[1]

This standard is issued under the fixed designation C 174/C 174M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the thickness of a concrete pavement, slab, or structural element by measuring the length of a core drilled from a concrete structure.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Significance and Use

2.1 This test method is used to determine the compliance of concrete construction with design specifications. It is especially important in determining the thickness of pavements and other slab construction.

3. Apparatus

3.1 The apparatus shall consist of a 3-point calipering device that will measure the length of axial elements of the core. While the details of the mechanical design are not prescribed, the apparatus shall conform to the requirements of 3.2 to 3.6.[2] An example of the apparatus is illustrated in Fig. 1.[3]

FIG. 1 Core Measuring Apparatus

3.2 The apparatus shall be so designed that the specimen will be held with its axis in a vertical position by three symmetrically placed supports bearing against the lower end. These supports shall be short posts or studs of hardened steel, and the ends that bear against the surface of the specimen shall be rounded to a radius of not less than 6 mm [¼ in.] and not more than 13 mm [½ in.].

3.3 The apparatus shall provide for the accommodation of specimens of different nominal lengths over a range of at least 100 to 250 mm [4 to 10 in.].

3.4 The calipering device shall be so designed that it will be possible to make a length measurement at the center of the upper end of the specimen, and at eight additional points spaced at equal intervals along the circumference of a circle

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.69 on Miscellaneous Tests.

Current edition approved Feb. 1, 2006. Published February 2006. Originally approved in 1942. Last previous edition approved in 1997 as C 174/C 174M – 97.

[2] For further information relating to the development of this test method and apparatus, reference should be made to the "Project Report on a Study of Methods of Measurement of the Length of Cores Drilled from Concrete Structures," prepared by L. W. Teller for Subcommittee VII on Methods and Apparatus for Testing Concrete, of Committee C09, see *Proceedings*, Am. Soc. Testing Mats., ASTM, Vol 42, 1942.

[3] The sole source of supply of the apparatus known to the committee at this time is Humboldt Mfg. Co., 7300 West Agatite, Norridge, IL 80656-4704, Catalog No. H-2939. If you are aware of alternative suppliers, please provide this information to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend.

www.technobetar.ir

whose center point coincides with that of the end area of the specimen and whose radius is not less than one half nor more than three fourths of the radius of the specimen.

3.5 The measuring rod or other device that makes contact with the end surface of the specimen for measurement shall be rounded to a radius of 3 mm [⅛ in.]. The scale on which the length readings are made shall be marked with clear, definite, accurately spaced graduations. The spacing of the graduations shall be 1.0 mm [0.10 in.] or a decimal part thereof.

3.6 The apparatus shall be stable and sufficiently rigid to maintain its shape and alignment without a distortion or deflection of more than 0.25 mm [0.01 in.] during all normal measuring operations.

4. Test Specimens

4.1 Cores used as specimens for length measurement shall be in every way representative of the concrete in the structure from which they are removed. The specimen shall be drilled with the axis normal to the surface of the structure, and the ends shall be free from all conditions not typical of the surfaces of the structure. Cores that show abnormal defects or that have been damaged appreciably in the drilling operation shall not be used. If a core drilled from a pavement or structure placed on dense-graded aggregate base course includes particles of the aggregate bonded to the bottom surface of the concrete, the bonded particles shall be removed by wedging or by chisel and hammer applied so as to expose the lower surface of the concrete. If the concrete is placed on an open-graded aggregate base course, the mortar in the concrete may penetrate into the base and surround some particles. Use sufficient force with a wedge or chisel and hammer to remove bonded particles but not such force as to fracture particles substantially surrounded by mortar. If during the removal of bonded aggregate the concrete is broken so that the instructions of 5.4 cannot be followed, the core shall not be used for length measurement.

5. Procedure

5.1 Before any measurements of the core length are made, calibrate the apparatus with suitable gages so that errors caused by mechanical imperfections in the apparatus are known. When these errors exceed 0.25 mm [0.01 in.], apply suitable corrections to the core length measurements.

5.2 Place the specimen in the measuring apparatus with the smooth end of the core, that is, the end that represents the upper surface of a pavement slab or a formed surface in the case of other structures, placed down so as to bear against the three hardened-steel supports. So place the specimen on the supports that the central measuring position of the measuring apparatus is directly over the midpoint of the upper end of the specimen.

5.3 Make nine measurements of the length on each specimen, one at the central position and one each at eight additional positions spaced at equal intervals along the circumference of the circle of measurement. Read each of these nine measurements to the nearest 1.0 mm [0.05 in.].

5.4 If, in the course of the measuring operation, it is discovered that at one or more of the measuring points the surface of the specimen is not representative of the general plane of the core end because of a small projection or depression, the specimen shall be rotated slightly about its axis and a complete set of nine measurements made with the specimen in the new position. With cores from pavements placed over open-graded aggregate bases the foregoing provisions frequently cannot be met because of the great number of projections or voids on the bottom surface.

6. Report

6.1 The individual observations shall be recorded to the nearest 1.0 mm [0.05 in.], and the average of the nine measurements expressed to the nearest 1.0 mm [0.1 in.] shall be reported as the length of the concrete core.

7. Precision and Bias

7.1 *Precision*:

7.1.1 *3-Point Caliper*—No statement is made about the precision of this test procedure. An interlaboratory test program for the determination of core length by this procedure is being studied by Subcommittee C09.69 and will be included in a later revision of this test method.

7.2 *Bias*—Since there are not acceptable reference cores suitable for determining the bias of these procedures, no statement on bias is being made.

8. Keywords

8.1 3-point caliper; concrete; cores; length measurement; thickness measurement

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 174/C 174M – 97, that may impact the use of this test method. (Approved February 1, 2006)

(*1*) Added Keywords.

Designation: C 183 – 08

Standard Practice for Sampling and the Amount of Testing of Hydraulic Cement[1]

This standard is issued under the fixed designation C 183; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This practice covers procedures for sampling and for the amount of testing of hydraulic cement after it has been manufactured and is ready to be offered for sale.

1.2 The values stated in SI units are to be regarded as the standard. The inch-pound units in parentheses are for information purposes only.

1.2.1 A ton as used in this practice is 907 kg (2000 lb).

1.2.2 Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in Standard IEEE/ASTM SI 10, of measurement made in other units.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

www.technobetar.ir

storage bins filled consecutively. A lot may also be the contents of one or more transport units representing cement drawn from the same storage bin.

3.1.2 *reduced testing rate*—test program that provides for the testing of only two samples from any given lot of samples obtained and prepared for testing at the normal rate as described herein. The program utilizes probability factors and is so designed that when results from the two samples fulfill the requirements of the program it may be said with 95 % confidence that less than 5 % of the samples would be outside the specification limits.

4. Significance and Use

4.1 The sampling procedures described are intended for use in the procurement of samples of hydraulic cement after it has been manufactured and is ready to be offered for sale. They are not intended as sampling procedures for quality control purposes during manufacturing. The testing procedures outlined cover the amount of testing to be done and provide guidance for reporting on conformance or non-conformance of cements with requirements of purchase specifications.

4.2 This practice is referenced as the procedure for sampling masonry cement (Specification C 91), portland cement (Specification C 150), blended hydraulic cement (Specification C 595), expansive hydraulic cement (Specification C 845), plastic stucco cement (Specification C 1328), mortar cement (Specification C 1329), and hydraulic cement based on a performance specification (Specification C 1157).

4.3 Most building codes and construction specifications require that hydraulic cement to be used in the work meet the applicable requirements of the relevant purchase specifications, such as Specifications C 91, C 150, C 595, C 1157, C 1328, C 1329, or C 845. If the code or specification requires sampling of the manufactured cement, the provisions given in 4.4 are applicable. Not much cement is sold on the basis of such sampling and testing. A useful discussion of sampling and testing cement is contained in ACI 225.1R.

4.4 The procedures covered in this practice should be done by or for purchasers of hydraulic cement who are using a code or specification that requires sampling and testing to determine if the samples conform to the relevant acceptance specifications. The testing is done using specified methods to determine whether the samples yield test results that conform to the specification, and the tests serve as a basis for acceptance or rejection of the lot of material sampled.

4.5 It is neither intended nor required that all cements be tested using all the test methods referenced in Section 2.

5. Kinds and Size of Samples and by Whom Taken

5.1 A cement sample secured from a conveyor, from bulk storage, or from a bulk shipment in one operation, shall be termed a "grab sample." A sample obtained during a 10-min interval using an automatic sampling device that continuously samples a cement stream may also be termed a grab sample. Grab samples taken at prescribed intervals over a period of time may be combined to form a "composite sample'' representative of the cement produced during that period of time.

5.2 All samples, whether grab or composite, shall have a mass of at least 5 kg (10 lb).

5.3 The purchaser may designate a representative to supervise the sampling, packing, and shipping of samples when it is so specified in the purchase contract.

5.4 Package the samples in moisture-proof, airtight containers numbered consecutively in the order in which the samples are taken. The purchase contract shall state who will pay for the costs of sampling, packaging, shipping and testing the samples.

NOTE 1—Polyvinyl chloride sample containers, upon occasion, have been found to affect the air-entraining potential of a cement sample. The same problem might be experienced with containers made from other plastics.

6. Testing-Time Requirements for the Completion of Tests

6.1 When tests of hydraulic cement are made at a laboratory other than that of the cement manufacturer, the cement sampling schedule, sample transportation time, and sample testing schedule must be coordinated among the purchaser, the manufacturer, and the testing laboratory so that the tests results will be available when required.

6.2 The manufacturer of the cement shall make the cement available to be sampled for testing early enough before the time the test results are needed so that at least the applicable time intervals listed in 6.3 exist.

6.3 When this has been done, the testing laboratory shall provide test results not later than the indicated number of days after sampling:

Test Methods	Time Interval, days
C 109/C 109M (1-day results), C 114, C 115, C 151, C 185, C 191, C 204, C 451, C 265, C 266, C 563	8
C 109/C 109M (3-day results)	10
C 109/C 109M and C 186 (7-day results)	14
C 227, C 452, and C 1012 (14-day results)	21
C 109/C 109M and C 186 (28-day results)	35
C 157/C 157M (34-day results)	41
C 227 (56-day results)	63
C 227 (91-day results)	98

7. Sampling

7.1 The cement may be sampled by any of the applicable methods described in this section.

7.1.1 *From the Conveyor Delivering to Bulk Storage*—Take one grab sample, having a mass of at least 5 kg (10 lb), at approximately 6-h intervals.

7.1.2 *Transfer Sampling*—Sample cement in storage while the cement is being transferred from one bin to another. Take one grab sample from the transfer stream for each 360 Mg (400 tons) of cement, or fraction thereof, but take no less than two grab samples and combine them to produce a composite sample.

7.1.3 *Other Sampling Methods*—When neither of the above sampling methods is applicable, samples may, when authorized by the purchaser, be taken by one of the following methods:

7.1.3.1 *From Bulk Storage at Points of Discharge*—Withdraw cement from the discharge openings in a steady stream until sampling is completed. Estimate the quantity of cement in Mg to be withdrawn from one discharge opening as $0.055\ d^3 \times 0.2$, where d is the depth in metres of cement above the discharge opening. If a high circular silo is being sampled, take all samples from one opening. If the quantity of the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:05:43 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

cement in the bin exceeds 1100 Mg (1200 tons) when low rectangular bins are being sampled, discharge openings employed in the sampling shall be such that for no opening shall the number of samples represent more than one half the contents of the bin or more than 1800 Mg (2000 tons). In sampling bulk storage at points of discharge, while the cement is flowing through the openings, take samples at such intervals so that at least two grab samples shall be secured for each 360 Mg (400 tons) in the bin or silo.

7.1.3.2 *From Bulk Storage and Bulk Shipment by Means of a Slotted Tube Sampler*—When the depth of the cement to be sampled does not exceed 2.1 m (7 ft), obtain samples using a slotted tube sampler similar to that shown in Fig. 1. It shall be between 1.5 and 1.8 m (5 and 6 ft) long and approximately 35 mm (1⅜ in.) in outside diameter and consist of two polished brass telescopic tubes with registering slots that are opened or closed by rotation of the inner tube, the outer tube being provided with a sharp point to facilitate penetration. Take samples from well-distributed points and various depths of the cement so that the samples taken will represent the cement involved.

7.1.3.3 *From Packaged Cement by Means of Tube Sampler*—Insert the sampler, shown in Fig. 2, diagonally into the valve of the bag and place the thumb over the air hole. Then withdraw the sampler. Take one sample from a bag in each 4.5 Mg (5 tons) or fraction thereof.

7.1.3.4 *From Bulk Shipment of Car or Truck*:

(a) (a) Single Shipment—If only one car or truck is being loaded and the loading is continuous and all from the same source, take a 5-kg (10-lb) sample. If not continuous or unknown, combine five or more portions from different points in the load to form the test sample.

(b) (b) Multiple Shipments—When the shipment consists of several cars or trucks loaded from the same source and on the same day, sample the shipment at the rate of one sample for each 90 Mg (100 tons) of cement or fraction thereof, but take not less than two samples. Consider cement represented by such samples as a lot, and test the samples in accordance with the procedure outlined in the section on Amount of Testing.

7.2 *Protection of Samples*—As samples are taken, place them directly in moisture-proof airtight containers to avoid moisture absorption and aeration of the sample. If the samples are placed in cans, fill the can completely and immediately seal. Use moisture-proof multiple-wall paper bags or plastic bags if they are strong enough to avoid breakage, and if they can be sealed immediately after filling in such a manner as to eliminate excess air in the sample and avoid moisture absorption and aeration of the sample. Samples shall be treated as described in the section on Preparation of Sample.

8. Preparation of Sample

8.1 Before testing, pass each sample through an 850-µm (No. 20) sieve,[6] or any other sieve having approximately the same size openings, in order to mix the sample, break up lumps, and remove foreign material. Discard the foreign materials and hardened lumps that do not break up on sieving or brushing. Store the cement in airtight moisture-proof containers to prevent aeration or absorption of moisture prior to test.

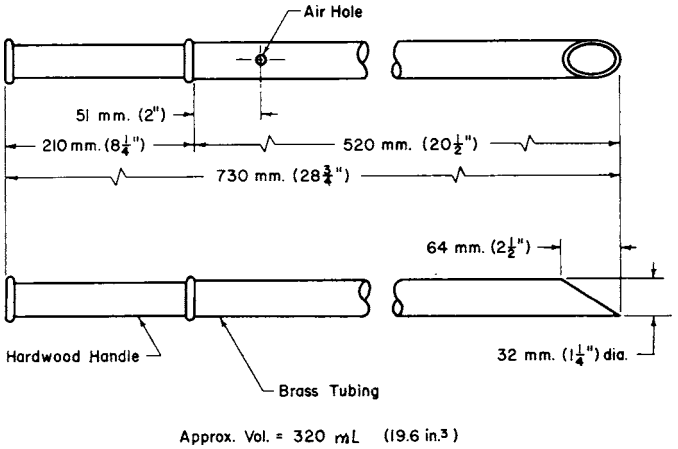

FIG. 2 Tube Sampler for Packaged Cement

9. Amount of Testing

9.1 *General*—When required, the purchaser shall specify the amount of testing for heat of hydration (Test Method C 186), alkali reactivity (Test Method C 227), and sulfate resistance (Test Method C 1012). Make all other tests on individual grab or composite samples chosen as specified herein under Selection of Samples for Testing. Do only those tests required by the applicable specification.

9.2 *Normal Testing*—Determine the number of samples to be tested in accordance with Table 1. The normal testing rate shall be used under the following conditions:

9.2.1 Before the quality history has been established,

9.2.2 When no samples from a particular mill have been tested within a year,

9.2.3 When the quality history is based entirely on data more than two years old, and

9.2.4 When it is deemed necessary to recalculate the critical limit because of indicated lack of control as shown by the control chart of the range.

NOTE 2—Random grab samples taken at inappropriate times, such as immediately following the repair or adjustment of manufacturing equipment, or from inappropriate places, such as from the top surface of the material in a car, will not suitably reflect the properties of a cement, and therefore should not be used as the basis for acceptance or rejection of a lot of cement.

9.3 *Reduced Testing*—After the quality history has been established, test at the reduced testing rate. If the results of these tests are within the critical range, make additional tests (total equal to the number of tests at the normal rate as shown in Table 1).

FIG. 1 Slotted Tube Sampler for Bulk Cement

www.technobetar.ir

TABLE 1 Number of Samples for Test

Lot Size—Number of Samples	Number of Tests	
	Normal Rate	Reduced Rate
2	2	2
3	3	2
4 to 10	4	2
11 to 20	6	2
Over 20	8	2

NOTE 3—When the quality history indicates that the results for a given requirement will probably be within the critical range, and substantial delay in completion of the tests would result from making additional tests (for example, compressive strength), it may be desirable to make the tests at the normal rate, rather than the reduced testing rate.

9.4 *Selection of Samples for Testing*— Take samples to be tested from each lot by some random method. The following method is suggested: Place a group of consecutively numbered markers equal to the number of samples in a container and mix, then draw one marker at a time from the container until the number drawn is equal to the number of samples to be tested at the normal rate. If the testing is to be done at the reduced rate, mix the drawn markers and draw two to select the numbers of the samples to be tested.

9.5 *Establishing a Quality History and Control Charts*:

9.5.1 *Quality History*—The quality history shall represent cement from the same source as the cement to be tested, and shall be based on data not more than 2 years old. There shall be available test results for not less than 40 test samples representing not less than 7 lots of cement. The test samples shall conform to the applicable provisions of this practice. A pair shall be two test samples from the same lot, in numerical sequence. Several pairs from the same lot may be used where available. The number of paired samples representing a large lot may be reduced as follows: From the consecutively numbered group of tested samples representing the entire lot, select a subgroup by some random method. List the numbers identifying the subgroup in numerical sequence, and pair in the order of listing. Compute the range (difference between the test results of a pair) for each pair of test results. Total the ranges and divide their sum by the total number of ranges used to obtain the average range, $\bar{r}$. Compute the average range, $\bar{r}$, for each included physical and chemical property limited by specification requirements.

9.5.2 *Critical Limit*—Calculate the critical limit, *C*, for each included physical and chemical property limited by a specification requirement. First, multiply the average range, $\bar{r}$, by the probability factor, 2.49, this will yield a number that for convenience is called *d*. If the requirement has a maximum specification limit, obtain *C* by subtracting *d* from the specification limit and, if a minimum, add *d* to the specification limit. Maintain quality history charts.

NOTE 4—Improved estimates of the range $\bar{r}$, and consequently of *C*, will result if the test results are not rounded. For example, the test result of 21.78 % for SiO_2 is preferred to the rounded value of 21.8 %. For the fineness, the calculated value of 3243 is preferred to the rounded value of 3240.

9.5.3 *Control Chart of the Range*—Maintain a control chart of the range to indicate when the critical limit needs to be recomputed. Multiply the average range. $\bar{r}$, as obtained in 9.5.2, by the probability factor 3.267 to obtain the upper control limit for the range between each consecutive pair of test results. The horizontal scale of the chart will be successive groups of two, and the vertical scale will be the range. Where the range chart indicates lack of control (points beyond the upper control limit), the critical limit, *C*, may need to be recalculated. Consider the occurrence of two consecutive points beyond the upper control limit for the range, or the occurrence of three points beyond the upper control limit in any series of five consecutive points cause to recalculate the critical limit. Where it becomes necessary to recalculate the critical limit, discontinue reduced testing until a new quality history has been established.

NOTE 5—Examples of the calculation of $\bar{r}$, *d*, and quality history and control charts are shown in Table 2 and Fig. 3 and Fig. 4. The specification limits used in these examples are hypothetical.

9.5.4 When the hydraulic cement sampled is to conform to Specification C 150, and the manufacturer has chosen the optimized cement SO_3 option as described in Specification C 150 Table 1 footnote D, the critical limit described in paragraph 9.5.2 using the specification limit for SO_3 is not applicable. Paragraphs 9.5.2 and 9.5.3 dealing with the calculation of critical limit are not required for SO_3 in this case.

9.5.5 When the hydraulic cement sampled is to conform to Specification C 595, and the manufacturer has chosen the optimized cement SO_3 content option as described in Specification C 595 Table 1 footnote A, the critical limit described in paragraph 9.5.2 using the specification limit for SO_3 is not applicable. Paragraphs 9.5.2 and 9.5.3 dealing with the calculation of critical limit are not required for SO_3 in this case.

9.6 *Reporting for Normal Testing*—When the testing is done at the normal testing rate, report the cement as complying with the specification if it meets the specification requirements, and report it as failing to meet the specification requirements if it does not meet each of the requirements as specified.

9.7 *Reporting for Reduced Testing*— When the testing is done at the reduced testing rate, report the cement as complying with the specification if the average of the test results is further from the specified limit than the critical limit. If the average of the results for one or more requirements are between the critical limit and the specification limit, test additional samples (total equal to the number of tests at the normal rate) for that requirement, and if on completion of the additional tests, all of the results meet the specified requirements report the cement as complying with the specification. Report the cement as failing to meet the specification requirements if any test result does not conform to the respective requirements.

9.8 When a cement is reported as failing to meet the specification requirements, state in the report which requirement the cement failed and the applicable limit.

10. Noncompliance and Retest

10.1 If any test result fails to meet the specification requirement, the lot of cement shall not be reported as not complying with the specification unless noncompliance is confirmed by retest as described in 10.2.

10.2 A retest is considered to be an additional test of a certain property that is made when the initial test of that property produces a result not complying with the specification requirements. A retest may consist of either a single determination or a set of replicate determinations.

10.3 Retests shall be conducted in accordance with the provisions, if given, of the applicable specification. If no provisions are given, the following procedure shall be used:

10.3.1 Make the retest on a portion of the same sample as was used for the initial test. Use referee methods whenever they are provided for determination of the property requiring retest and in such case use only the results obtained by referee methods. The retest shall consist of the same number of determinations required for the initial test, or, if a within-laboratory precision statement is given which is based on a specified number of replicates (that is, duplicate or triplicate determinations), the number of replicates used as the basis of such precision statement. If two or more determinations are required, the value reported shall be the average of all results that are within the limits of precision of the method at the 95 % confidence level, as stated in the applicable specification or as generally recognized.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this practice since the last issue, C 183 – 02, that may impact the use of this practice. (Approved December 15, 2008)

(*1*) Added new 9.5.4 and 9.5.5.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 185 – 08

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T137

Standard Test Method for Air Content of Hydraulic Cement Mortar[1]

This standard is issued under the fixed designation C 185; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the air content of hydraulic cement mortar under the conditions hereinafter specified.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 Values in SI shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding in IEEE/ASTM SI 10, of measurements made in other units.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.5 **Warning—** Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2]

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Summary of Test Method

3.1 Prepare a mortar with standard sand and the cement to be tested, using a water content sufficient to give a required flow. Compact the mortar into a measure of known volume and determine mass. Calculate the air content from the measured density of the mortar, the known densities of the constituents, and the mixture proportions.

4. Significance and Use

4.1 The purpose of this test method is to determine whether or not the hydraulic cement under test meets the air-entraining or non-air-entraining requirements of the applicable hydraulic cement specification for which the test is being made. The air content of concrete is influenced by many factors other than the potential of the cement for air entrainment.

5. Apparatus

5.1 *Flow Table, Flow Mold, and Caliper*, shall conform to Specification C 230/C 230M.

5.2 *Measure*—A cylindrical measure having an inside diameter of 76 ± 2 mm and a depth (approximately 88 mm) adjusted by standardization with water to contain 400 ± 1 mL

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.21 on Air Entrainment.

Current edition approved July 1, 2008. Published August 2008. Originally approved in 1944. Last previous edition approved in 2002 as C 185 – 02.

www.technobetar.ir

at 23.0 ± 2.0 °C (Note 1). For the purposes of this test, the capacity of the measure in millilitres is the mass of the water content of the measure, in grams, divided by 0.9976, no correction in mass being made for the buoyant effect of air. The measure shall have a uniform wall thickness. The thickness of the wall and bottom shall not be less than 2.9 mm. The total mass of the empty measure shall not be more than 900 g. The measure shall be made of a metal not attacked by the cement mortar.

NOTE 1—Calibrate the 400-mL measure by filling with distilled water at 23.0± 2.0 °C to a point where the meniscus extends appreciably above the top of the measure, placing a clean piece of plate glass on the top of the measure, and allowing the excess water to be squeezed out. The absence of air bubbles as seen through the glass ensures that the measure is completely full. Care shall be taken that the excess water is wiped from the sides of the container before weighing.

5.3 *Mixer, Bowl, and Paddle*, shall conform to the apparatus section of Practice C 305.

5.4 *Straightedge*—A steel straightedge not less than 200 mm long and not less than 1.5 mm nor more than 3.5 mm in thickness.

5.5 *Weights and Weighing Devices*, shall conform to Specification C 1005. Evaluate the weighing device for precision and accuracy at a total load of 2 kg.

5.6 *Glass Graduates*—Glass graduates of 250-mL capacity, conforming to the requirements of Specifications E 438 and E 694.

5.7 *Tamper*, conforming to the requirements of Test Method C 109/C 109M. The tamping face of the tamper shall be flat and at right angles to the length of the tamper.

5.8 *Tapping Stick*, a piece of hard wood having a diameter of approximately 16 mm and a length of approximately 152 mm.

5.9 *Spoon*—A metal restaurant-type serving spoon not less than 230 mm in length and with a bowl approximately 100 mm in length.

6. Temperature and Humidity

6.1 Maintain the temperature of the room and dry materials at 23.0 ± 4.0 °C.

6.2 Condition the mixing water and the measure, if it is being calibrated at 23 ± 2 °C.

6.3 Maintain the relative humidity of the laboratory at not less than 50 %.

7. Standard Sand

7.1 Use sand conforming to the requirements of Specification C 778 for 20–30 sand.

8. Sampling

8.1 Sample the cement in accordance with Practice C 183.

NOTE 2—Polyvinyl chloride (PVC) sample containers, upon occasion, have been found to affect the air-entraining potential of a cement sample. The same problem might be experienced with containers made from other plastics.

9. Procedure

9.1 *Batch*—Proportion the standard mortar using 350 g cement to 1400 g 20–30 standard sand and sufficient water to give a flow of 87½ ± 7½ % when determined in accordance with 9.3.

NOTE 3—Test Method C 185 refers to hydraulic cements that comply under Specification C 150, Specification C 595, and Performance Specification C 1157. Masonry cements (see Specification C 91), mortar cements (see Specification C 1329), and plastic cements (see Specification C 1328) require different sand, mass, and flow. Refer to the applicable specification.

9.2 *Mixing of Mortar*—Mix the mortar in accordance with Practice C 305.

9.3 *Flow Determination*—Carefully wipe dry the flow-table top and place the flow mold at the center of it. Using the spoon, place a layer of mortar about 25 mm in thickness in the mold and tamp 20 times with the tamper. The tamping pressure shall be just sufficient to ensure uniform filling of the mold. Overfill the top of the mold approximately 20 mm with mortar and tamp as specified for the first layer. Then cut off the mortar to a plane surface, flush with the top of the mold, by drawing the straightedge with a sawing motion across the top of the mold. Wipe the flow table top clean and dry, being especially careful to remove any water from around the edge of the mold. Lift the mold away from the mortar 1 min after completing the mixing operation. Immediately drop the table 10 times in accordance with Specification C 230/C 230M. The flow is the resulting increase in average diameter of the mortar mass, as determined with the calipers, measured on at least four diameters at approximately equispaced intervals, expressed as a percentage of the original diameter. Make trial mortars with varying percentages of water until the specified flow is obtained. Make each trial with fresh mortar.

9.4 *Mass per 400 mL of Mortar*—When the quantity of mixing water has been found that produces a flow of 87½ ± 7½ %, immediately determine the mass per 400 mL of mortar, using the mortar remaining in the mixing bowl after the flow has been determined. In the determination of the mass per 400 mL, do not use the portion of the mortar used in the flow determination. Using the spoon, place the mortar gently into the 400–ml measure in three equal layers. Tamp each layer 20 times around the inner surface of the measure. For the final layer of mortar, overfill the 400–ml measure approximately 20 mm. The position of the tamper shall be that: the broad side of the tamper is parallel to the radius and is perpendicular to the inner surface of the measure. Each layer is tamped in one complete revolution (rotation) with only sufficient pressure to adequately fill the measure and eliminate voids within the mortar. After the measure has been filled and tamped in the above prescribed manner, tap the sides of the measure lightly with the side of the tapping stick, one each at five different points at approximately equal spacing around the outside of the measure, in order to preclude entrapment of extraneous air (Note 4). No obvious space shall be left between the mortar and the inner surface of the measure as a result of the tamping operation. Then cut the mortar off to a plane surface, flush with the top of the measure, by drawing the straightedge with a sawing motion across the top of the measure, making two

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

passes over the entire surface, the second pass being made at right angles to the first. If, in the striking-off operation, loose sand grains cause the straightedge to ride above the top surface of the measure, these grains shall be removed, and the operation repeated. Complete the entire operation of filling and striking off the measure within 1½ min. Wipe off all mortar and water adhering to the outside of the measure. Determine the mass of the measure and its contents. Subtract the mass of the container, and record the mass of the mortar in grams.

NOTE 4—This operation may be facilitated by placing the measure on a steady flat-surfaced support of lesser diameter than the measure while filling and wiping.

10. Calculation

10.1 Calculate the air content of the mortar from the following formula which is based on the batch proportions given in 9.1, taking the specific gravity of portland cement as 3.15 and of 20–30 standard sand as 2.65. When the hydraulic cement is other than portland, the appropriate value for its specific gravity shall be substituted for the value of 3.15 and the formula rederived accordingly:

$$\text{Air content, volume \%} = 100 - W[(182.7 + P)/(2000 + 4P)] \quad (1)$$

where:

W = mass of 400 mL of mortar, g, and

P = percentage of mixing water, based on mass of cement used.

NOTE 5—This formula is derived as follows:

$$\text{Air content, volume \%} = 100[1 - (W_a/W_c)] \quad (2)$$

where:

W_a = actual mass per unit of volume as determined by this test method.

= W/400 g/mL, where W is the mass in grams of the specified 400 mL of mortar (9.4),

W_c = theoretical mass per unit of volume, calculated on an air-free basis as follows and using the values for quantities of materials and specific gravities as given in 9.1 and 10.1,

$$= \frac{350 + 1400 + 350 \times P \times 0.01}{\frac{350}{3.15} + \frac{1400}{2.65} + \frac{350 \times P \times 0.01}{1}}$$

$$= \frac{(5 + 0.01P)}{(1.827 + 0.01P)}, \text{ and}$$

P = percentage of mixing water, based on mass of cement.

Substituting for W_a and W_c we have:

$$\text{Air content, volume \%} = 100\left(1 - \frac{W}{400} \times \frac{1.827 + 0.01P}{5 + 0.01P}\right)$$

$$\text{Air content, volume \%} = 100 - \frac{W}{4} \times \frac{(1.827 + 0.01P)}{(5 + 0.01P)}$$

$$\text{Air content, volume \%} = 100 - 2.5W\frac{(182.7 + P)}{(5000 + 10P)}$$

$$\text{Air content, volume \%} = 100 - W\frac{(182.7 + P)}{(2000 + 4P)}$$

10.2 Make only one determination of air content on a batch.

NOTE 6—Difficulty has occasionally been experienced with this test method by some persons. These difficulties usually have taken the form of values for air content that are abnormally high and that may be greater than the specified maxima in specifications for hydraulic cement. The air-entraining potential of the sand may be reduced by washing in the laboratory with potable water by decantation until a clear, colorless supernatant liquid is obtained. In case of dispute, such freshly washed sand shall be used.

11. Report

11.1 When this test method is used for specific action in compliance testing, report the value for the air content to the nearest 1 %.

12. Precision and Bias

12.1 The single-operator, within-laboratory, standard deviation has been found to be 0.56 % air content throughout the range of 8 to 19 % air. Therefore, results of two properly conducted tests by the same operator on similar batches should not differ by more than 1.6 % air.

12.2 The multilaboratory standard deviation has been found to be 1.0 % air content throughout the range from 8 to 19 % air. Therefore, results of two different laboratories on similar batches should not differ from each other by more than 2.8 % air.

13. Keywords

Designation: C 186 – 05

Standard Test Method for Heat of Hydration of Hydraulic Cement[1]

This standard is issued under the fixed designation C 186; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the heat of hydration of a hydraulic cement by measuring the heat of solution of the dry cement and the heat of solution of a separate portion of the cement that has been partially hydrated for 7 and for 28 days, the difference between these values being the heat of hydration for the respective hydrating period.

1.2 The results of this test method may be inaccurate if some of the components of the hydraulic cement are insoluble in the nitric acid/hydrofluoric acid solution.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in Standard IEEE/ASTM SI 10, or measurements made in other units.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability or regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

E 11 Specification for Wire-Cloth Sieves for Testing Purposes

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Significance and Use

3.1 The purpose of this test is to determine if the hydraulic cement under test meets the heat of hydration requirement of the applicable hydraulic cement specification.

3.2 This test may also be used for research purposes when it is desired to determine the heat of hydration of hydraulic cement at any age.

NOTE 1—When tests are performed for research purposes, useful additional information can be obtained by determining fineness, chemical and compound compositions.

3.3 Determination of the heat of hydration of hydraulic cements provides information that is helpful for calculating temperature rise in mass concrete.

4. Apparatus

4.1 *Calorimetric Apparatus*:

4.1.1 *Calorimeter*—The calorimeter, such as that illustrated in Fig. 1 shall consist of a 0.5-L (1-pt), wide-mouth vacuum jar, with cork stopper, or other suitable non-reactive stopper held in a suitably insulated container (See 4.1.2) to keep the vacuum jar in position and to protect the jar from undue temperature fluctuations. The vacuum jar shall be coated on the interior with a material resistant to hydrofluoric acid, such as a baked phenolic resin, a baked vinyl chloride acetate resin, or beeswax. The acid-resistant coating shall be intact and free of cracks at all times; it shall be examined frequently and renewed whenever necessary. As another means of protecting the vacuum jar, a plastic liner of suitable size may be used instead of coating the interior of the jar. The contents of the vacuum jar shall not change more than 0.001 °C/min per degree difference from room temperature when filled with 425 g of the acid specified in 6.2, stoppered, and allowed to stand unstirred for 30 min. The temperature for this check shall approximate the starting temperatures to be used in making the determination.

4.1.2 *Insulated Container*—The container shall have an insulating layer of a material such as non-reactive foam, cotton,

Metric Units	Inch-Pound Equivalents	Metric Units	Inch-Pound Equivalents
250 mm	10 in.	6 mm	1/4 in.
12 mm	1/2 in.	3 mm	1/8 in.
37 W	1/20 hp	0.47 litre	1 pt

FIG. 1 Calorimeter

or fiber-glass, which shall be at least 25 mm (1 in.) in thickness and shall encase the sides and bottom of the vacuum jar, but shall be so arranged as to permit easy removal of the jar.

4.1.3 *Thermometers*—Two thermometers are required. One is a high precision thermometer required to determine temperature rise associated with dissolution of cement during determinations. For purposes of this test method, this thermometer is called the *solution thermometer*. The other thermometer is used for measuring sample temperature before introduction into the calorimeter and air temperature during the determination. For purposes of this test method, it is called the *reference thermometer*.

4.1.3.1 *Solution thermometer*—The solution thermometer shall be readable to 0.001 °C. The solution thermometer may be either a Beckman type (See Note 2), which is a mercury-in-glass type that only outputs temperature differentials, or a digital type that gives actual temperature outputs. If a Beckman type is used, it shall be graduated to at least 0.01 °C, with readings to 0.001 °C that can be estimated by interpolation between these graduations. It shall also have a temperature range of at least 6 °C.

NOTE 2— If the part of the thermometer that will be in contact with the test solution is sensitive to the nitric and hydrofluoric acids in the test solution, then it is recommended that this part of the thermometer be coated with a resistant material to prolong the service life of the thermometer.

4.1.3.2 *Reference thermometer*—The reference thermometer shall be any type that reads to a precision of at least 0.1 °C.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:06:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

4.1.4 *Funnel*—The funnel through which the sample is introduced into the calorimeter shall be glass or plastic and shall have a stem inside diameter of at least 6 mm (See Note 3).

NOTE 3—The minimum diameter is to prevent clogging of the powdered cement sample. The length of the stem will need to be adjusted so that the sample is delivered without the tip becoming wet from the acid solution, which will cause the funnel to become clogged and necessitate aborting the determination. The angle of the stem will need to be adjusted so that sample is not delivered onto the rotating stirrer, which will cause sample to cake at the liquid line.

4.1.5 *Stirring Assembly*—The stirrer shall be a three-bladed polyethylene propeller having the dimensions shown in Fig. 2, and shall extend as closely as possible to the bottom of the calorimeter. The motor shall be of the constant-speed type, at least 37 W (1/20 hp), and shall be equipped with a geared speed reducer so that one speed, in the range of 350 to 700 r/min, can be maintained constant.

NOTE 4—The stirrer shown in Fig. 2 may be readily made from a commercially available three-bladed polyethylene propeller having a propeller diameter of 34 mm (1⅜ in.), shaft diameter of 6 mm (¼ in.), and a shaft length of approximately 455 mm (18 in.). The function of the stirrer is two-fold: to maintain uniform temperature throughout the liquid and to supply sufficient agitation to keep the solid in suspension in the acid mixture. Since a stirrer capable of keeping the solid in suspension generates considerable heat in the calorimeter, it is important that the stirrer speed, and hence the rate of heat generation, be maintained constant. Because such constancy is difficult to achieve with other types of motors, a synchronous motor with a geared speed reducer is recommended.

4.2 *Mixer*—A moderate-speed mechanical mixer, such as a milk-shake type stirrer, capable of intimately mixing the cement and water to a uniform paste.

4.3 *Storage*—Storage space with temperature controlled at 23.0 ± 2.0 °C (73.5 ± 3.5 °F).

4.4 *Mortar*, approximately 200 mm (8 in.) in diameter, and pestle for grinding the partially hydrated samples.

4.5 *Drying Oven*, maintained at 100 to 110 °C.

4.6 *Sieves*, 150-µm (No. 100) and 850-µm (No. 20), conforming to Specification E 11.

4.7 *Crucibles*, platinum, 30-mL capacity, with covers, for loss on ignition determination.

4.8 *Muffle Furnace*, or suitable burners capable of maintaining a temperature of 900 to 950 °C.

4.9 *Analytical Balance and Analytical Weights*, conforming to the requirements prescribed in Test Methods C 114 for weighing out calorimetric samples and for loss on ignition weighings.

4.10 *Weights and Weighing Devices*, conforming to the requirements of Specification C 1005. The weighing device shall be evaluated at a total load of 1000 g.

5. Reagents and Materials

5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society,

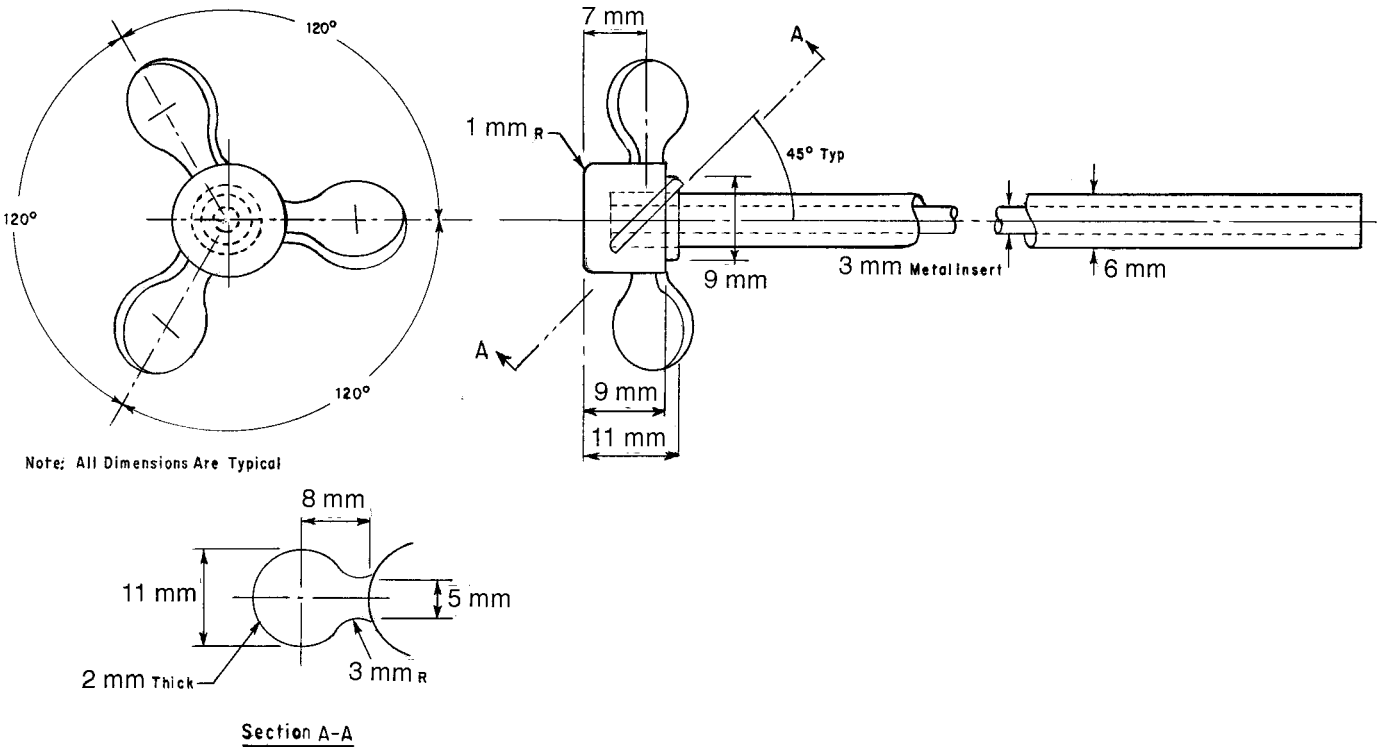

FIG. 2 Stirrer

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:06:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

where such specifications are available.[3] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 *Hydrofluoric Acid (sp gr 1.15)*—Concentrated hydrofluoric acid (HF).

5.3 *Nitric Acid (2.00 N)*—The 2.00 *N* HNO_3, for use in the calorimeter, shall be prepared and standardized in large quantities. Optionally, the dilute HNO_3 may be made up with 127 mL of concentrated HNO_3(sp gr 1.42) per litre of solution, provided that heat capacity determinations are made with each batch of diluted HNO_3 so prepared.

5.4 *Wax*—Paraffin wax, or other suitable wax, for sealing vials.

5.5 *Zinc Oxide (ZnO)*—The ZnO shall be heated at 900 to 950 °C for 1 h, then cooled in a desiccator, ground to pass a 150-µm (No. 100) sieve, and stored. Immediately prior to a heat capacity determination, 7 g of the ZnO so prepared shall be heated for not more than 5 min at 900 to 950 °C, cooled to room temperature in a desiccator, and weighed accurately for introduction into the calorimeter.

NOTE 5—The rate of solution of the ZnO varies with the preliminary treatment. The procedure described results in a product which dissolves at about the same rate as the dry cement.

6. Determination of Heat Capacity of Apparatus

6.1 To determine the heat capacity of the system (that is, the number of joules or calories required to raise the temperature of the calorimeter and contents 1 °C), measure the corrected temperature rise obtained by dissolving 7 g of ignited ZnO in the specified acid mixture (See 6.2-6.7).

6.2 Transfer approximately 400 g of the 2.00 *N* HNO_3, which has been cooled to the temperature indicated by the lower range of the Beckmann thermometer (ordinarily about 4 to 5 °C below room temperature), into the vacuum jar, add 8.0 mL of HF (sp gr 1.15), weigh, and add sufficient additional 2.00 *N* HNO_3 to bring the total weight of the solution to 425.0 g. Then, assemble the calorimeter and start the stirring motor. Take care that the stirrer blades or shaft do not touch the thermometer, the sides or bottom of the jar, or the cork stopper. The lower end of the funnel stem shall extend approximately 6 mm (¼ in.) below the lower surface of the stopper and at least 12 mm (½ in.) above the level of the liquid. The upper end of the bulb of the Beckmann thermometer shall be at least 38 mm (1½ in.) below the surface of the liquid. Place it at the same depth in all determinations. After an initial stirring period of at least 20 min to allow the temperature of the system to become uniform, record the temperature of the room to the nearest 0.1 °C, the temperature of the acid to the nearest 0.001 °C, record the time, and then immediately introduce the prepared ZnO through the funnel at a uniform rate (See Note 6). Complete the introduction of the ZnO in not less than 1 or more than 2 min. Brush any ZnO clinging to the funnel stem into the acid mixture by means of a small "camel's-hair" brush.

NOTE 6—The temperature of the sample shall be identical with that of the room when the sample is introduced into the calorimeter.

6.3 Read the temperature, to the nearest 0.001 °C, at 20 min and again at 40 min after beginning the introduction of the sample. The temperature rise in the first 20 min includes temperature rise due to the heat of solution of the sample and any heat gain or heat loss to the environment. This is called the solution period. The temperature change during the second 20-min period is due to heat loss or gain to or from the environment. It is used to correct the temperature rise in the solution period to give the actual heat of solution of the sample. The second 20-min period is called the correction period.

6.4 Calculate the corrected temperature rise as follows:

$$R_o = \theta_{20} - \theta_0 \tag{1}$$

$$R = R_o - (\theta_{40} - \theta_{20})$$

where:

R_o = observed temperature rise, °C,
θ_{20} = calorimeter temperature at the end of the solution period,
θ_0 = calorimeter temperature when sample was introduced,
R = corrected temperature rise, °C, and
θ_{40} = calorimeter temperature at the end of the correction period.

6.5 Calculate the heat capacity of the calorimeter and contents as follows (See Note 7):

$$C = \frac{W[1072 + 0.4(30 - t) + 0.5(T - t)]}{R} \tag{2}$$

where:

C = heat capacity, kJ/°C,
W = mass of ZnO, g,
t = final temperature of the calorimeter, °C (θ_{20} plus temperature, °C, at which the Beckmann thermometer reading is zero),
T = temperature of the ZnO (room temperature), °C, when introduced into the calorimeter, and
R = corrected temperature rise, °C.

NOTE 7—The heat of solution of ZnO is 1072 kJ/kg (256.1 cal/g) at 30 °C. This value increases 0.4 kJ/kg (0.1 cal/g) for each degree decrease in temperature below 30 °C. The heat capacity of ZnO is 0.5 kJ/kg·K (0.12 cal/g·°C). The heat required to bring the ZnO to the final temperature of the calorimeter must be included in the effective heat of solution.

6.6 If more than a trace of ZnO is found adhering to the tip of the funnel or to the stopper when the calorimeter is opened, reject the test.

6.7 Redetermine the heat capacity at the following times:

6.7.1 When the Beckmann thermometer (if used) is reset,

6.7.2 When a new coating is applied to the solution thermometer, stirrer, or flask,

6.7.3 When a new solution thermometer, stirrer, or flask is put in service,

6.7.4 When a new batch of acid is used, and

[3] *Reagent Chemicals, American Chemical Society Specifications*, American Chemical Society, Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see *Analar Standards for Laboratory Chemicals*, BDH Ltd., Poole, Dorset, U.K., and the *United States Pharmacopeia and National Formulary*, U.S. Pharmacopeial Convention, Inc. (USPC), Rockville, MD.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.7.5 At other times when, according to the judgment of the operator, the need is indicated.

7. Sampling and Test Specimens

7.1 *Preparation of Cement Paste*—Store the cement and the mixing water in a constant-temperature room at 23.0 ± 2.0 °C (73.5 ± 3.5 °F) until the materials are at ambient temperature before preparation of the paste. Mix 150 g of cement and 60 mL of distilled water by means of a spatula, and then vigorously stir the mixture with a mechanical stirrer for 5 min. Place approximately equal representative portions of the paste in four or more plastic vials, filling the vials to within about 13 mm (½ in.) of the top. Immediately after filling the vials, close them with tight-fitting stoppers or caps. (If there is any doubt regarding the tightness of the seal, the sealed ends of the vials should be dipped in molten paraffin wax.) Store the vials in an upright position in a water bath at 23 ± 2.0 °C until the time of test.

7.2 *Preparation of Partially Hydrated Sample for Heat of Solution Test*—At the specified age of test or age of interest, remove a vial of the partially hydrated sample from storage within the test time tolerances of Test Method C 109/C 109M, and, during a 20-min initial stirring period of the calorimeter, break the plastic away from the sample and rapidly crush the entire sample with a mortar and pestle so that all the material will pass through a 850-μm (No. 20) sieve; then quickly place the sample in a well-stoppered weighing bottle. Take care, particularly with the 7-day partially hydrated sample, to expose the sample to the air as little as possible, and thus minimize the action of CO_2 or the loss of moisture from the sample.

8. Procedure

8.1 *Calorimetric Procedure, Dry Cement*—Determine the heat of solution of the dry cement sample according to the procedure described for the heat capacity determination (See Section 6), but use a 3-g sample (weighed to the nearest 0.001 g) of the dry cement instead of the prepared ZnO (See Note 6). (Exercise care in securing a uniform and representative sample.) Calculate and report the results on the ignited mass basis (See 8.3).

8.2 *Calorimetric Procedure, Partially Hydrated Sample*—For the heat of solution of the partially hydrated sample follow the same procedure as for the dry cement described in 8.1, but use a 4.18 ± 0.05-g calorimetric sample of the partially hydrated cement, weighed to the nearest 0.001 g (See Note 6). Calculate the results on the ignited basis.

8.3 *Loss on Ignition*:

8.3.1 *Portland Cement*—Immediately before and after the calorimetric sample is being weighed out, weigh a sample of similar amount into a platinum crucible for determination of loss on ignition, the value to be used being the average of the two determinations. Ignite the dry cement at 950 ± 50 °C for at least 1½ h or to constant mass. Immediately place the crucible containing the sample in a desiccator and allow to cool to room temperature; then quickly weigh the crucible. When determining the loss on ignition of the hydrated cement, first dry the weighed sample in an oven at 100 to 110 °C for 1 h; then place the sample in a muffle furnace at 950 ± 50 °C overnight, or bring to constant mass. Reduce the mass of the cement sample that was introduced into the calorimeter to the ignited mass basis for use in the final calculations as follows:

$$W_i = (A/B)W \tag{3}$$

where:

W_i = mass of calorimetric sample, on ignited basis, g,
A = mass of ignited sample, g,
B = mass of sample before ignition, g, and
W = mass of calorimetric sample, g.

8.3.2 *Blended Hydraulic Cements*—In addition to the procedures described in 8.3.1, determine the loss on ignition by the reference method given in Test Methods C 114 for portland blast-furnace slag cement and slag cement.

8.3.2.1 Determine the SO_3 content by the reference method given in Test Methods C 114 (See Note 8). Also determine the SO_3 content of a portion of the same cement that has not been ignited, using the same procedure.

8.3.2.2 Calculate the percentage of mass gain from sulfide sulfur as follows:

$$G = 0.8\,(S_1 - S_2) \tag{4}$$

where:

G = percent mass gain in ignited sample,
S_1 = SO_3 determined on ignited sample, and
S_2 = SO_3 determined on unignited sample.
0.8 = molecular weight ratio of 4(0)/SO_3

NOTE 8—Some of the acid used for dissolving the sample may first be warmed in the platinum crucible to dissolve any adhering material.

8.3.2.3 Calculate the mass of the dry calorimetric sample on the ignited basis as follows:

$$W_i = \frac{\left(A - \frac{BG}{100}\right) W}{B} \tag{5}$$

where:

W_i = mass of dry calorimetric sample, on ignited basis, g,
A = mass of ignited dry sample, g,
B = mass of dry sample before ignition, g,
G = percentage mass gain from sulfide sulfur, and
W = mass of dry calorimetric sample, g.

Calculate the mass of the partially hydrated calorimetric sample on the ignited basis as follows: (See Note 9)

$$W_i = \frac{A\,W\left(1 - \frac{G}{100}\right)}{B} \tag{6}$$

where:

W_i = mass of calorimetric sample, on ignited basis, g,
A = mass of partially hydrated sample after ignition, g,
B = mass of partially hydrated sample before ignition, g,
G = percentage mass gain from sulfide sulfur, and
W = mass of partially hydrated calorimetric sample, g.

NOTE 9—An assumption is made in the calculation that the same percentage of sulfide sulfur is present prior to ignition in the partially hydrated sample as was determined in the cement. Tests have confirmed

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:06:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

that the assumption is reasonably correct and will not alter the precision of the test method.

9. Calculation

9.1 *Heat of Solution of Dry Cement*—Calculate the corrected temperature rise as described in 6.3 and 6.4. Also, correct the heat of solution value if the final calorimeter temperature of the heat of solution test is different from the temperature of the calorimetric sample when introduced. Thus, for the dry cement, which has a specific heat of approximately 0.8 kJ/kg·K (0.2 cal/g·°C), if the final calorimeter temperature exceeds the temperature of the cement sample at the time it was introduced, add a correction of 0.8 kJ/kg·K (0.2 cal/g·°C) difference in those temperatures when calculating the heat of solution. Calculate the heat of solution of the dry cement as follows:

$$H_1 = (RC/W_i) - 0.8(T - t_d) \quad (7)$$

where:

H_1 = heat of solution of dry cement, kJ/kg,
R = corrected temperature rise, °C,
C = heat capacity, kJ/°C,
W_i = mass of sample on ignited basis, g,
T = room temperature, when sample is introduced, °C, and
t_d = final calorimeter temperature at end of determination on dry cement, °C.

9.2 *Heat of Solution of Partially Hydrated Sample*—Calculate the heat of solution of the partially hydrated sample in the same way as for the dry cement (See 9.1), except make additional corrections, as follows:

9.2.1 Since an increase of 1 °C in the temperature at which the heat of solution test occurs causes a decrease of approximately 1.3 kJ/kg (0.3 cal/g) in the heat of solution, if the temperature of the heat of solution test of the partially hydrated sample exceeds the temperature of the dry cement determination, a correction of 1.3 kJ/kg·K (°C) difference in temperature shall be added to the heat of solution value obtained for the partially hydrated sample (See Eq 8).

9.2.2 Also, correct the heat of solution value if the final calorimeter temperature of the solution test is different from the temperature of the calorimetric sample when introduced. Thus, for the partially hydrated sample, which has a specific heat of approximately 1.7 kJ/kg (0.4 cal/g) of ignited cement, if the final calorimeter temperature exceeds the temperature of the sample at the time it was introduced, add a correction of 1.7 kJ/kg·K (°C) difference in those temperatures when calculating the heat of solution (See Eq 8).

9.2.3 Calculate the heat of solution of the partially hydrated sample as follows:

$$H_2 = (RC/W_i) - 1.7(T - t_h) - 1.3(t_d - t_h) \quad (8)$$

where:

H_2 = heat of solution of partially hydrated sample, kJ/kg,
R, C, W_i, and T = the same definition as in 9.1 except that they relate to the partially hydrated sample,
t_d = the same numerical value as in 9.1, and
t_h = final calorimeter temperature at end of determination on partially hydrated sample, °C.

9.3 *Heat of Hydration*—A final calorimeter temperature of 25 °C shall be considered as the basis to which the heat of hydration shall be referred, and the effects of variation in that temperature should be kept in mind when considering test results. An increase in the final temperature raises the heat of hydration approximately 0.4 kJ/kg·K (0.1 cal/g·°C) of ignited cement. For example, if the final temperature is 27 °C, 0.8 kJ/kg (0.2 cal/g) should be subtracted from the observed heat of hydration in order to refer the results to 25 °C. In borderline cases, proper correction should be made for the effects of final calorimeter temperature. Calculate the heat of hydration of the cement to the nearest kilojoule, as follows:

$$H = H_1 - H_2 - 0.4(t_h - 25.0) \quad (9)$$

where:

H = heat of hydration of ignited cement, kJ/kg,
H_1 = heat of solution of dry cement (See 9.1),
H_2 = heat of solution of partially hydrated sample (See 9.2), and
t_h = the same numerical value as in 9.2.3

NOTE 10—To convert cal/g to kJ/kg multiply by 4.184 in accordance with Standard IEEE/ASTM SI 10.

10. Retests

10.1 In case of failure to meet the 28-day requirement for heat of hydration, a reserve sample of paste may be tested at a later age and a correction of 2.1 kJ/kg (0.5 cal/g) per day of excess age added to bring the retested heat of solution to a 28-day basis. The period over which this correction may be made shall be limited to 4 days. In case of failure to meet the 7-day requirement, a complete retest including mixing of the paste should be made.

11. Report

11.1 Report the following information:

11.1.1 Sample identification, which may include the source and type of hydraulic cement and sampling date, and

11.1.2 The heat of hydration results at each of the test ages required by the applicable specification.

12. Precision and Bias

12.1 *Precision*:

12.1.1 *Single-Operator Precision*—The single-operator standard deviations have been found to be 12.2 kJ/kg(1s) (2.91 cal/g)(1s) and 14.8 kJ/kg(1s) (3.54 cal/g)(1s) for the determinations of heat of solution and heat of hydration, respectively. Therefore, results of two properly conducted tests by the same operator on samples of the same cement should not differ from each other by more than 34 kJ/kg (8 cal/g) in the determination of heat of solution or 42 kJ/kg (10 cal/g) in the determination of heat of hydration.[4]

[4] These numbers represent, respectively the (1s) and (d2s) limits as described in Practice C 670.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:06:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

12.1.2 *Multilaboratory Precision*—The multilaboratory standard deviations have been found to be 18.5 kJ/kg(1s) (4.42 cal/g)(1s) and 16.9 kJ/kg(1s) (4.03 cal/g)(1s) for the determinations of heat of solution and heat of hydration respectively. Therefore, results of two properly conducted tests from two different laboratories on samples of the same cement should not differ from each other by more than 52 kJ/kg (13 cal/g) in the determination of heat of solution or 48 kJ/kg (11 cal/g) in the determination of heat of hydration.[4]

12.2 *Bias*—Since there is no accepted reference material, no statement on bias is being made.

13. Keywords

13.1 blended cement; heat of hydration; heat of solution; hydraulic cements; portland cement

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 187 – 04

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T 129

Standard Test Method for Normal Consistency of Hydraulic Cement[1]

This standard is issued under the fixed designation C 187; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the normal consistency of hydraulic cement.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* See 1.4 for a specific warning statement.

1.4 **Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 min. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.[2]

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

D 1193 Specification for Reagent Water

E 177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods

3. Significance and Use

3.1 This test method is intended to be used to determine the amount of water required to prepare hydraulic cement pastes for testing.

4. Apparatus

4.1 *Reference Masses and Devices for Determining Mass*, conforming to the requirements of Specification C 1005. The devices for determining mass shall be evaluated for precision and bias at a total load of 1000 g.

4.2 *Glass Graduates*, 200 or 250-mL capacity, and conforming to the requirements of Practice C 490.

4.3 *Vicat Apparatus*—The Vicat apparatus shall consist of a frame *A* (Fig. 1) bearing a movable rod *B,* weighing 300 g, one end *C,* the plunger end, being 10 mm in diameter for a distance of at least 50 mm, and the other end having a removable needle *D,* 1 mm in diameter and 50 mm in length. The rod *B* is reversible, and can be held in any desired position by a set screw *E,* and has an adjustable indicator *F,* which moves over a scale (graduated in millimetres) attached to the frame *A*. The paste is held in a rigid conical ring *G,* resting on a plane nonabsorptive square base plate *H,* about 100 mm on each side. The rod *B* shall be made of stainless steel having a hardness of not less than 35 HRC (See Note 1), and shall be straight with the plunger end which is perpendicular to the rod axis. The ring shall be made of a noncorroding, nonabsorbent material, and shall have an inside diameter of 70 mm at the base and 60 mm at the top, and a height of 40 mm. In addition to the above, the Vicat apparatus shall conform to the following requirements:

Weight of movable rod	300 ± 0.5 g (0.661 lb ± 8 grains) in
Diameter of plunger end of rod	10 ± 0.05 mm (0.394 ± 0.002 in.)
Diameter of needle	1 ± 0.05 mm (0.039 ± 0.002 in.)
Inside diameter of ring at bottom	70 ± 3 mm (2.75 ± 0.12 in.)
Inside diameter of ring at top	60 ± 3 mm (2.36 ± 0.12 in.)
Height of ring	40 ± 1 mm (1.57 ± 0.04 in.)
Graduated scale	The graduated scale, when compared with a standard scale accurate to within 0.1 mm at all points, shall not show a deviation at any point greater than 0.25 mm.

NOTE 1—The requirement that the rod be made of stainless steel shall apply only to new Vicat apparatus or replacement rods and not to equipment in use which meets the other requirements of this test method.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.22 on Workability.

Current edition approved Dec. 1, 2004. Published December 2004. Originally approved in 1944. Last previous edition approved in 1998 as C 187 – 98.

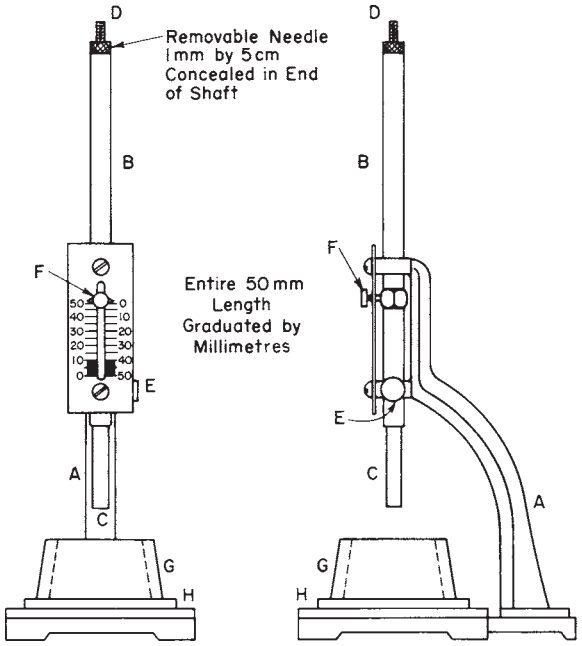

FIG. 1 Vicat Apparatus

4.4 *Flat Trowel*, having a sharpened straight-edged steel blade 100 to 150 mm in length.

5. Temperature and Humidity

5.1 The temperature of the air in the vicinity of the mixing slab, the dry cement, molds, and base plates shall be maintained between 20 and 27.5 °C (68 and 81.5 °F). The temperature of the mixing water shall not vary from 23.0 °C (73.5 °F) by more than ±2.0 °C (3.5 °F).

5.2 The relative humidity of the laboratory shall be not less than 50 %.

6. Procedure

6.1 *Preparation of Cement Paste*—Mix 650 g of cement with a measured quantity of water following the procedure prescribed in the Procedure for Mixing Pastes of Practice C 305. The water shall conform to the numerical limits of Specification D 1193 for Type III or Type IV grade of reagent water.

6.2 *Molding Test Specimen*—Quickly form the cement paste, prepared as described in 6.1, into the approximate shape of a ball with gloved hands. Then toss six times through a free path of about 150 mm (6 in.) from one hand to another so as to produce a nearly spherical mass that may be easily inserted into the Vicat ring with a minimum amount of additional manipulation. Press the ball, resting in the palm of one hand, into the larger end of the conical ring *G,* Fig. 1, held in the other hand, completely filling the ring with paste. Remove the excess at the larger end by a single movement of the palm of the hand. Place the ring on its larger end on the base plate *H,* and slice off the excess paste at the smaller end at the top of the ring by a single oblique stroke of a sharp-edged trowel held at a slight angle with the top of the ring, and smooth the top, if necessary, with a few light touches of the pointed end of the trowel. During these operations of cutting and smoothing, take care not to compress the paste.

6.3 *Consistency Determination*—Center the paste confined in the ring, resting on the plate, under the rod *B,* Fig. 1, the plunger end *C* of which shall be brought in contact with the surface of the paste, and tighten the set-screw *E.* Then set the movable indicator *F* to the upper zero mark of the scale, or take an initial reading, and release the rod immediately. This must not exceed 30 s after completion of mixing. The apparatus shall be free of all vibrations during the test. The paste shall be of normal consistency when the rod settles to a point 10 ± 1 mm below the original surface in 30 s after being released. Make trial pastes with varying percentages of water until the normal consistency is obtained. Make each trial with fresh cement.

7. Calculation

7.1 Calculate the amount of water required for normal consistency to the nearest 0.1 % and report it to the nearest 0.5 % of the weight of the dry cement.

8. Precision and Bias

8.1 The single operator-instrument precision has been found to be 0.25 (1S), and the multilaboratory precision has been found to be 0.35 (1S) as defined in Practice E 177; therefore, the results of two properly conducted tests by the same operator in a laboratory should agree within 0.7 percentage point, and test results between two laboratories should agree with 1.0 percentage point 95 % of the time.

9. Keywords

9.1 consistency; normal consistency; Vicat needles

Designation: C188 – 09

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T133

Standard Test Method for Density of Hydraulic Cement[1]

This standard is issued under the fixed designation C188; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the density of hydraulic cement. Its particular usefulness is in connection with the design and control of concrete mixtures.

1.2 The density of hydraulic cement is defined as the mass of a unit volume of the solids.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

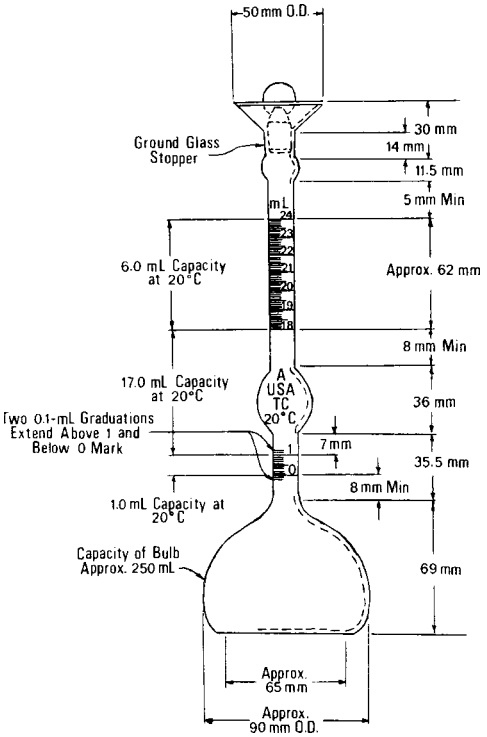
C114 Test Methods for Chemical Analysis of Hydraulic Cement

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Apparatus

3.1 *Le Chatelier flask*—The standard flask, which is circular in cross section, with shape and dimensions conforming essentially to Fig. 1 (Note 1). The requirements in regard to tolerance, inscription and length, spacing, and uniformity of graduation will be rigidly observed. There shall be a space of at least 10 mm between the highest graduation mark and the lowest point of grinding for the glass stopper.

3.1.1 The material of construction shall be excellent quality glass, transparent and free of striae. The glass shall be chemically resistant and shall have small thermal hysteresis. The flasks shall be thoroughly annealed before being graduated. They shall be of sufficient thickness to ensure reasonable resistance to breakage.



NOTE—Variations of a few millimetres in such dimensions as total height of flask, diameter of base, and so forth, are to be expected and will not be considered sufficient cause for rejection. The dimensions of the flask shown in Fig. 1 apply only to new flasks and not to flasks in use which meet the other requirements of this test method.

FIG. 1 Le Chatelier Flask for Density Test

3.1.2 The neck shall be graduated from 0 to 1 mL and from 18 to 24 mL in 0.1-mL graduations. The error of any indicated capacity shall not be greater than 0.05 mL.

3.1.3 Each flask shall bear a permanent identification number and the stopper, if not interchangeably ground, shall bear the same number. Interchangeable ground-glass parts shall be marked on both members with the standard-taper symbol, followed by the size designation. The standard temperature shall be indicated, and the unit of capacity shall be shown by the letters "mL" placed above the highest graduation mark.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.25 on Fineness.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 1944. Last previous edition approved in 2003 as C188 – 95(2003). DOI: 10.1520/C0188-09.

www.technobetar.ir

3.2 Kerosine, free of water, or naphtha, having a density greater than 0.73 g/mL at 23 ± 2° C shall be used in the density determination.

3.3 The use of alternative equipment or methods for determining density is permitted provided that a single operator can obtain results within ± 0.03 Mg/m^3 of the results obtained using the flask method.

NOTE 1—The design is intended to ensure complete drainage of the flask when emptied, and stability of standing on a level surface, as well as accuracy and precision of reading.

4. Procedure

4.1 Determine the density of cement on the material as received, unless otherwise specified. If the density determination on a loss-free sample is required, first ignite the sample as described in the test for loss on ignition in section 16.1 on Portland Cement of Test Methods C114.

4.2 Fill the flask (Note 2) with either of the liquids specified in 3.2 to a point on the stem between the 0 and the 1-mL mark. Dry the inside of the flask above the level of the liquid, if necessary, after pouring. Record the first reading after the flask has been immersed in the water bath (Note 3) in accordance with 4.4.

NOTE 2—It is advisable to use a rubber pad on the table top when filling or rolling the flask.

NOTE 3—Before the cement has been added to the flask, a loose-fitting, lead-ring weight around the stem of the flask will be helpful in holding the flask in an upright position in the water bath, or the flask may be held in the water bath by a buret clamp.

4.3 Introduce a quantity of cement, weighed to the nearest 0.05 g, (about 64 g for portland cement) in small increments at the same temperature as the liquid (Note 2). Take care to avoid splashing and see that the cement does not adhere to the inside of the flask above the liquid. A vibrating apparatus may be used to accelerate the introduction of the cement into the flask and to prevent the cement from sticking to the neck. After all the cement has been introduced, place the stopper in the flask and roll the flask in an inclined position (Note 2), or gently whirl it in a horizontal circle, so as to free entrapped air from the cement until no further air bubbles rise to the surface of the liquid. If a proper amount of cement has been added, the level of the liquid will be in its final position at some point of the upper series of graduations. Take the final reading after the flask has been immersed in the water bath in accordance with 4.4.

4.4 Immerse the flask in a constant-temperature water bath for sufficient periods of time in order to avoid flask temperature variations greater than 0.2°C between the initial and the final readings.

5. Calculation

5.1 The difference between the first and the final readings represents the volume of liquid displaced by the mass of cement used in the test.

5.2 Calculate the cement density, ρ, as follows:

$$\rho(Mg/m^3) = \rho(g/cm^3) = \text{mass of cement, g/displaced volume, } cm^3$$

NOTE 4—The displaced volume in millilitres is numerically equal to the displaced volume in cubic centimetres.

NOTE 5—Density in megagrams per cubic metre (Mg/m^3) is numerically equal to grams per cubic centimetre (g/cm^3). Calculate the cement density, ρ, to three decimal places and round to the nearest 0.01 Mg/m^3.

NOTE 6—In connection with proportioning and control of concrete mixtures, density may be more usefully expressed as specific gravity, the latter being a dimensionless number. Calculate the specific gravity as follows: Sp gr = cement density/water density at 4°C (at 4°C the density of water is 1 Mg/m^3($1 g/cm^3$)).

6. Precision and Bias

6.1 The single-operator standard deviation for portland cements has been found to be 0.012.[3] Therefore, the results of two properly conducted tests by the same operator on the same material should not differ by more than 0.03.

6.2 The multilaboratory standard deviation for portland cements has been found to be 0.037.[3] Therefore, the results of two properly conducted tests from two different laboratories on samples of the same cement should not differ by more than 0.10.[3]

6.3 Since there is no accepted reference material suitable for determining any bias that might be associated with this test method, no statement on bias is being made.

7. Keywords

7.1 density; hydraulic cement; specific gravity

[3] These numbers represent the 1s and d2s limits described in Practice C670.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C188 – 95(2003), that may impact the use of this test method. (Approved December 1, 2009)

Designation: C 191 – 08

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T131

Standard Test Methods for Time of Setting of Hydraulic Cement by Vicat Needle[1]

This standard is issued under the fixed designation C 191; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 These test methods determine the time of setting of hydraulic cement by means of the Vicat needle. Two test methods are given; Method A is the Reference Test Method using the manually operated standard Vicat apparatus, while Method B permits the use of an automatic Vicat machine that has, in accordance with the qualification requirements of this method, demonstrated acceptable performance.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* See 1.4 for a specific warning statement.

1.4 **Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 min. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.[2]

1.5 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

NOTE 1—For the method for determining the time of setting by Gillmore needles, see Test Method C 266.

C 1157 Performance Specification for Hydraulic Cement

D 1193 Specification for Reagent Water

3. Terminology

3.1 *Definitions*—The terms used in this test method are defined in accordance with Terminology C 219.

4. Summary of Test Method

4.1 A paste that is proportioned and mixed to normal consistency, as described in the Test Method C 187, is molded and placed in a moist cabinet and allowed to start setting. Periodic penetration tests are performed on this paste by allowing a 1-mm Vicat needle to settle into this paste. The Vicat initial time of setting is the time elapsed between the initial contact of cement and water and the time when the penetration is measured or calculated to be 25 mm. The Vicat final time of setting is the time elapsed between initial contact of cement and water and the time when the needle does not leave a complete circular impression in the paste surface.

5. Significance and Use

5.1 This test method provides a means of determining compliance with a specification limit for Vicat time of setting. Refer to the appropriate specification for the cement to determine if this test method is used for specification compliance.

[1] These test methods are under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.30 on Time of Set.

Current edition approved June 1, 2008. Published July 2008. Originally approved in 1944. Last previous edition approved in 2007 as C 191 – 07.

5.2 Time of setting measured by this method will not necessarily provide the same results as the time of setting of hydraulic cement paste measured by other methods, or the time of setting of mortar or concrete.

6. Apparatus

6.1 *Vicat Apparatus*—See Annex A1.1 and Fig. A1.1. The Vicat apparatus for this test method shall have a movable rod, B, of mass 300 ± 0.5g.

6.1.1 The end of the rod used for measuring penetration shall have a straight steel removable needle with a diameter of 1.00 ± 0.05 mm and length no less than 50 mm.

6.1.2 The needle end that contacts the specimen shall be flat, plane, and at right angles to the axis of the rod.

6.2 *Reference Masses and Devices for Determining Mass*, conforming to the requirements of Specification C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

6.3 *Glass Graduates*, 200 or 250-mL capacity, and conforming to the requirements of Specification C 1005.

6.4 *Plane non-adsorptive plate*, 100 ± 5 mm square of similar planeness, corrosivity, and absorptivity to that of glass (see Annex A1.1, Fig. A1.1, H).

6.5 *Flat trowel*, having a sharpened straight-edged steel blade 100 to 150 mm in length. The edges when placed on a plane surface shall not depart from straightness by more than 1 mm.

6.6 *Conical ring*, made of a rigid, non-corroding, non-absorbent material and having a height of 40 ± 1 mm, an inside diameter at the bottom of 70 ± 3 mm, and an inside diameter at the top of 60 ± 3 mm (see Annex A1.1, Fig. A1.1, G).

6.7 *Mixer, bowl, and paddle*, conforming to Practice C 305.

6.8 *Automatic Vicat Needle Apparatus for Method B*—The apparatus shall be equipped with a Vicat needle as described in 6.1.1 and 6.1.2. The total mass supported by the needle tip at the time of measurement shall be 300 ± 0.5 g. The instrument shall be capable of automatically completing and recording penetration measurements of a test specimen at predetermined time intervals not exceeding 10 min and make each penetration test at least 5 mm away from any previous penetration and at least 10 mm away from the inner side of the mold.

6.9 *Specimen Mold for Method B*—The cement paste is held in a conical ring with the height of 40 ± 1 mm and a removable base plate. The test surface shall have a minimum diameter of 60 ± 3 mm.

6.10 Inspect and document Section 6 apparatus for conformance to the requirements of this test method at least every 2 ½ years.

7. Reagents and Materials

7.1 *Mixing Water*—Potable water is satisfactory for routine tests. Use water conforming to the requirements of Specification D 1193 for Type III or Type IV grade reagent water for all referee and cooperative tests.

8. Sampling

8.1 When the test is required for acceptance testing, sample cement in accordance with Practice C 183.

9. Conditioning

9.1 Maintain the temperature of the air in the vicinity of the mixing slab, the dry cement, molds, and base plates at 23.0 ± 3.0 °C.

9.2 Maintain the temperature of the mixing water at 23.0 ± 2.0 °C.

9.3 The relative humidity of the mixing room shall be not less than 50 %.

9.4 The moist cabinet or moist room shall be in accordance with Specification C 511.

10. Preparation of Cement Paste[4]

10.1 The cement paste used for the determination of the time of setting is obtained from one of the following methods:

10.1.1 Prepare a new batch of paste by mixing 650 g of cement with the percentage of mixing water required for normal consistency (Test Method C 187), following the procedure described in Practice C 305.

10.1.2 For method A, at the option of the tester, use the test specimen used for determining normal consistency (see Note 2).

10.1.3 At the option of the tester, use the paste remaining from the batch used for the autoclave specimen (Test Method C 151) or from the normal consistency determination (Test Method C 187).

NOTE 2—The specimen used for the determination of the normal consistency will have an irregular surface, making it unsuitable for method B.

11. Calculation

11.1 Calculate the Vicat time of setting to the nearest 1 min as follows:

$$\left(\left(\frac{(H-E)}{(C-D)}\right)\times(C-25)\right)+E \qquad (1)$$

where:

E = time in minutes of last penetration greater than 25 mm,
H = time in minutes of first penetration less than 25 mm,
C = penetration reading at time E, and
D = penetration reading at time H.

11.2 Calculate the Vicat final time of setting by determining the elapsed time between the time of the initial contact between cement and water and the time when the needle does not sink visibly into the paste, rounded to the nearest 5 min.

12. Report

12.1 Report the time of setting and the method used as follows:

Vicat time of setting (*A* or *B*) _____ min
Vicat final time of setting (*A* or *B*) _____ min

Method A—Manual Vicat Needle Apparatus

13. Manual Vicat Apparatus

13.1 Refer to the Apparatus section, paragraphs 6.1, 6.4, and 6.6, and Annex A1 for a description of the Vicat apparatus.

[4] See Test Method C 187.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

14. Procedure A

14.1 *Molding Test Specimen*—Quickly form the cement paste, prepared as described in the section on preparation of cement paste, into a ball with gloved hands and toss six times from one hand to the other, maintaining the hands about 150 mm (6 in.) apart. Press the ball, resting in the palm of the hand, into the larger end of the conical ring, *G*, Fig. A1.1, held in the other hand, completely filling the ring with paste. Remove the excess at the larger end by a single movement of the palm of the hand. Place the ring on its larger end onto the non-absorptive plate, *H*, and slice off the excess paste at the smaller end at the top of the ring by a single oblique stroke of the trowel held at a slight angle with the top of the ring. Smooth the top of the specimen, if necessary, with one or two light touches of the pointed end of the trowel. During the operation of cutting and smoothing, take care not to compress the paste. Immediately after molding, place the test specimen in the moist cabinet or moist room and allow it to remain there except when penetration measurements are being made. The specimen shall remain in the conical mold, supported by the non-absorptive plate throughout the test period.

14.2 *Time of Setting Determination*—Allow the time of setting specimen to remain in the moist cabinet or moist room for 30 min after molding without being disturbed. Determine the penetration of the 1-mm needle at this time and every 15 min thereafter (every 10 min for Type III cements) until a penetration of 25 mm or less is obtained. Perform the penetration test by lowering the needle *D* of the rod *B* until it rests on the surface of the cement paste. Tighten the setscrew, *E*, and set the indicator, *F*, at the upper end of the scale, or take an initial reading. Release the rod quickly by releasing the set screw, *E*, and allow the needle to settle for 30 s; then take the reading to determine the penetration. At the option of the tester, if the paste is obviously quite soft on the early readings, retard the fall of the rod to avoid bending the 1-mm needle, but when actual penetration measurements to determine the time of setting are made, release the rod only by the setscrew. Make each penetration test at least 5 mm away from any previous penetration and at least 10 mm away from the inner side of the mold. Record the results of all penetration tests and, by interpolation, determine the time when a penetration of 25 mm is obtained. The elapsed time between the initial contact of cement and water and the penetration of 25 mm is the Vicat time of setting or Vicat initial time of setting.

14.3 Determine the Vicat final time of setting end point to be the first penetration measurement that does not mark the specimen surface with a complete circular impression. Verify final set by performing two additional penetration measurements on different areas of the specimen surface. Obtain verification measurements within 90 s of the first "final set" measurement. The elapsed time between the initial contact of cement and water and the end point determination above is the Vicat final time of setting.

14.4 *Precautions*—Keep all the apparatus free from vibration during the penetration test. Keep the 1-mm needle straight and clean. The needle must be kept clean to prevent cement from adhering to the sides of the needle and decreasing penetration, and to prevent cement from adhering to the point and increasing penetration.

15. Precision and Bias

15.1 *Precision*:

15.1.1 The single-operator (within-laboratory) standard deviation has been found to be 12 min for the initial time of setting, throughout the range of 49 to 202 min, and 20 min for the final time of settings throughout the range of 185 to 312 min. Therefore, results of two properly conducted tests by the same operator on Vicat initial time of setting of similar paste should not differ from each other by more than 34 min and on Vicat final time of setting of similar pastes should not differ from each other by more than 56 min.

15.1.2 The multilaboratory (between-laboratory) standard deviation has been found to be 16 min for the initial time of setting throughout the range of 49 to 207 min, and 43 min for the final time of setting throughout the range of 185 to 312 min. Therefore, results of two properly conducted tests from two different laboratories on Vicat initial time of setting of similar pastes should not differ from each other by more than 45 min, and on Vicat final time of setting of similar pastes should not differ from each other by more than 122 min.

15.2 *Bias*—Since there are no accepted reference materials suitable for determining the bias for the procedure in this test method, no statement on bias is presented.

Method B—Automatic Vicat

16. Automatic Vicat Apparatus

16.1 *Automatic Vicat Needle Apparatus*—Refer to the Apparatus section, paragraphs 6.8 and 6.9, for a description of the Automatic Vicat needle apparatus.

17. Procedure

17.1 *Molding the Specimen*—Quickly form the cement paste, prepared as described in the section on preparation of cement paste, into a ball with gloved hands and toss six times from one hand to the other, maintaining the hands about 150 mm apart. Press the ball, resting in the palm of the hand, into the larger end of the conical ring, held in the other hand, completely filling the ring with paste. Remove the excess at the larger end by a single movement of the palm of the hand. Place the ring on its larger end on the base plate. Use a trowel to remove the excess paste at the top of the mold. Holding the trowel at about a 30° incline with the leading edge raised and starting near the center of the mold, level the paste by drawing the trowel across the top of the mold using a sawing motion; repeat the procedure for the other half of the surface. Then smooth the surface level to the top of the mold making steady and complete strokes across the entire surface with the trailing edge of the trowel. Repeat the cutting and smoothing steps but at 90° from the previous cut. Repeat the steps as required to produce a surface level with the top of the mold. Usually the paste is level within two cycles, but occasionally three will be required. Avoid excessive strokes and compaction. Since the automatic Vicat device references to the top edge of the mold, it is imperative that the top surface of the paste be uniform and level with the top of the mold.

www.technobetar.ir

17.2 *Time of Setting Determinations*—Follow the manufacturer's instructions and complete the required instrument calibration and zero procedures. Set the instrument to measure no less frequently than every 10 min (see Note 3). Position the molded specimen in the automatic Vicat apparatus and initiate the measurements (see Note 4).

NOTE 3—Automatic devices are usually capable of measurement more frequently than once every 10 min and more frequent measurement minimizes interpolation.

NOTE 4—The initial time of setting according to Method A is determined as the elapsed time required to achieve a penetration of 25 mm and the final time of setting as the total time elapsed until the needle does not leave a complete circular impression in the paste surface. The end points established by a qualified automatic Vicat test method may deviate significantly from end points specified in Method A, and require standardization to correct bias.

17.3 Determine the range of applicability of the method from the range of the average time of setting of the cements used for qualification and standardization, and limit that range to 30 min greater than the maximum, and 30 min less than the minimum.

17.4 *Performance Requirement (Qualification) for Automatic Vicat Instrument*:

17.4.1 When time of setting results from the automatic Vicat apparatus are to be used for acceptance or rejection of cement, the method used shall comply with the qualification requirements covered in Annex A2.

18. Performance Requirement (Qualification) for Automatic Vicat Instrument

18.1 *Scope*—When time of setting results from the automatic Vicat apparatus are to be used for acceptance or rejection of cement, the method used shall comply with the qualification requirements of this section. A method is considered to consist of the specific instrument and the molding procedure meeting the requirements of this standard, and used in a consistent manner by a given laboratory.

18.2 *Hydraulic Cement Samples Required*—Select three cements that comply with requirements of Specifications C 150, C 595, or C 1157, and that when tested in accordance with Method A, shall include the following:

18.2.1 One cement that has an initial time of setting of less than 110 min,

18.2.2 One cement with an initial time of setting of greater than 150 min,

18.2.3 One cement with a final time of setting of less than 180 min, and

18.2.4 One cement with a final time of setting of greater than 210 min (see Note 5).

NOTE 5—Laboratories are advised to reserve sufficient cement for future qualification and standardization.

18.3 *Tests*—Using the method to be qualified and including the standardization formula described in the section on standardization, make single determinations of the times of initial and final setting on each of the three cements. On the same day, conduct companion time of setting determinations according to Method A. Make single determinations of the normal consistency on each cement, and use that amount of water for all replicate batches. Complete three rounds of tests on different days, repeating all the steps of the methods. Conduct the qualification tests on specimens prepared separately from the standardization testing.

18.4 *Calculations*—Calculate the three–round averages for initial and final time of setting for each cement and method. A method complies with the initial time of setting qualification requirements if the difference between the initial time of setting average values for Method A and the corresponding average values of Method B is not greater than 25 min for any sample, and the range for any three replicate tests by Method B does not exceed 30 min. Likewise, a method complies with the final time of setting qualification requirements if the difference between the final time of setting average values for Method A and corresponding average values for Method B is not greater than 45 min for any sample, and the range for any three replicate tests by Method B does not exceed 30 min. Example qualification data are given in Appendix X1.

18.5 *Standardization*—When standardization is required in order to achieve agreement between Method A and Method B, it can be applied to either the initial time of setting, final time of setting, or both. A standardization formula shall be based on a comparison of test results obtained using Method A and the chosen method using the automatic instrument (Method B). Results of tests from at least five different hydraulic cements shall be required for standardization. The cements shall have a minimum range of 60 min initial time of setting, and a minimum range of 90 min final time of setting when tested in accordance with Method A. If desired, the three cements used for instrument qualification may be used, but make new determinations. Use the same method as used for instrument qualification, including all the same steps. Valid standardization formulas shall be mathematically derived and applied to all samples (see Note 6).

NOTE 6—Generally, the automatic instruments are computer operated and easily adapted to standardization calculations.

19. Requalification of a Method

19.1 Requalify the method at least once per year and when any of the following conditions occur:

19.1.1 The instrument has been significantly modified.

19.1.2 The instrument has been substantially repaired.

19.1.3 Substantial evidence indicates that the method is not providing data meeting the performance requirements.

19.1.4 The average of a Cement and Concrete Reference Laboratory (CCRL) sample differs from the value obtained by the method by more than 45 min for either the initial or final time of setting.

20. Precision and Bias

20.1 *Precision*—Since Method B represents procedures specific to a laboratory that have been qualified in comparison to Method A, no statement on precision is being made.

20.2 *Bias*—Since there are no accepted reference materials suitable for determining the bias for the procedure in this test method, no statement on bias is presented.

ANNEXES

(Mandatory Information)

A1. VICAT APPARATUS

A1.1 The Vicat apparatus shall consist of a frame, A, Fig. A1.1, bearing a movable rod, B, with a mass as specified by the method referencing this apparatus, one end, C, the plunger end, with a diameter as specified by the method referencing this apparatus, and the other end having a mass or a removable steel needle, D, as specified by the method referencing this apparatus. The rod, B, is reversible, and can be held in any desired position by a setscrew, E, and has an adjustable indicator, F, which moves over a scale graduated in millimetres and attached to the frame, A. The gradations on the graduated scale, when compared to a scale accurate to within 0.1 mm at all points, shall not show a variance from the reference scale greater than 0.25 mm.

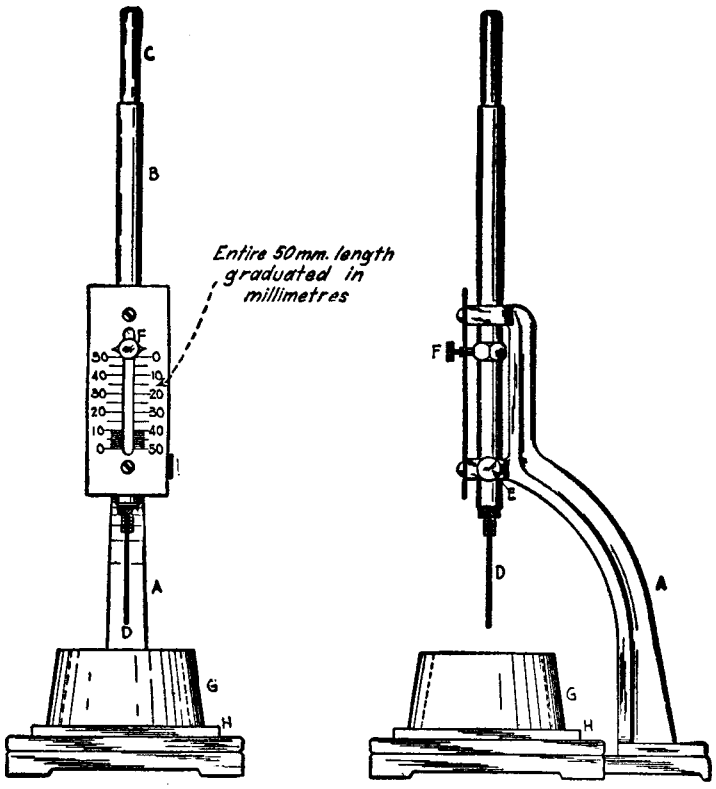

FIG. A1.1 Vicat Apparatus

A2. PERFORMANCE REQUIREMENT (QUALIFICATION) FOR AUTOMATIC VICAT INSTRUMENT

A2.1 When time of setting results from the automatic Vicat apparatus are to be used for acceptance or rejection of cement, the method used shall comply with the qualification requirements covered in this section. A method is considered to consist of the specific instrument and the molding procedure meeting the requirements of this test method, and used in a consistent manner by a given laboratory.

A2.2 *Hydraulic Cement Samples Required*—Select three cements that comply with requirements of Specifications C 150, C 595, or C 1157, and that when tested in accordance with Method A, shall include the following:

A2.2.1 One cement that has an initial time of setting of less than 110 min,

A2.2.2 One cement with an initial time of setting of greater than 150 min,

A2.2.3 One cement with a final time of setting of less than 180 min, and

A2.2.4 One cement with a final time of setting of greater than 210 min (see Note A2.1).

NOTE A2.1—Laboratories are advised to reserve sufficient cement for future qualification and standardization.

A2.3 *Tests*—Using the method to be qualified and including the standardization formula described in the section on standardization, make single determinations of the times of initial and final setting on each of the three cements. On the same day, conduct companion time of setting determinations according to Method A. Make single determinations of the normal consistency on each cement, and use that amount of water for all replicate batches. Complete three rounds of tests on different days, repeating all the steps of the methods. Conduct the qualification tests on specimens prepared separately from the standardization testing.

A2.4 *Calculations*—Calculate the three-round averages for initial and final time of setting for each cement and method. A method complies with the initial time of setting qualification requirements if the difference between the initial time of setting average values for Method A and the corresponding average values of Method B is not greater than 25 min for any sample, and the range for any three replicate tests by Method B does not exceed 30 min. Likewise, a method complies with the final time of setting qualification requirements if the difference between the final time of setting average values for Method A and corresponding average values for Method B is not greater than 45 min for any sample, and the range for any three replicate tests by Method B does not exceed 30 min. Example qualification data are given in Appendix X1.

A2.5 *Standardization*—When standardization is required in order to achieve agreement between Method A and Method B, it can be applied to either the initial time of setting, final time of setting, or both. A standardization formula shall be based on a comparison of test results obtained using Method A and the chosen method using the automatic instrument (Method B). Results of tests from at least five different hydraulic cements shall be required for standardization. The cements shall have a minimum range of 60 min initial time of setting, and a minimum range of 90 min final time of setting when tested in accordance with Method A. If desired, the three cements used for instrument qualification may be used, but make new determinations. Use the same method as used for instrument qualification, including all the same steps. Valid standardization formulas shall be mathematically derived and applied to all samples (see Note A2.2).

NOTE A2.2—Generally, the automatic instruments are computer operated and easily adapted to standardization calculations.

A3. REQUALIFICATION OF A METHOD

A3.1 Requalify the method at least once per year and when any of the following conditions occur:

A3.2 The instrument has been significantly modified.

A3.3 The instrument has been substantially repaired.

A3.4 Substantial evidence indicates that the method is not providing data meeting the performance requirements.

A3.5 The average of a Cement and Concrete Reference Laboratory (CCRL) sample differs from the value obtained by the method by more than 45 min for either the initial or final time of setting.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to these test methods since the last issue, C 191 – 07, that may impact the use of these test methods. (Approved June 1, 2008)

(*1*) Revised 6.2 and 6.5.

Committee C01 has identified the location of selected changes to these test methods since the last issue, C 191 – 04b, that may impact the use of these test methods. (Approved July 15, 2007)

(*1*) Added new 6.10.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 192/C 192M – 07

Standard Practice for Making and Curing Concrete Test Specimens in the Laboratory[1]

This standard is issued under the fixed designation C 192/C 192M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This practice covers procedures for making and curing test specimens of concrete in the laboratory under accurate control of materials and test conditions using concrete that can be consolidated by rodding or vibration as described herein.

1.2 The values stated in either inch-pound units or SI units shall be regarded separately as standard. The SI units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of each other. Combining values from the two systems may result in nonconformance.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to exposed skin and tissue upon prolonged exposure.[2])

3. Significance and Use

3.1 This practice provides standardized requirements for preparation of materials, mixing concrete, and making and curing concrete test specimens under laboratory conditions.

3.2 If specimen preparation is controlled as stipulated herein, the specimens may be used to develop information for the following purposes:

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved Aug. 1, 2007. Published September 2007. Originally approved in 1944. Last previous edition approved in 2006 as C 192/C 192M – 06.

[2] See section on Safety Precautions, *Manual of Aggregate and Concrete Testing*, *Annual Book of ASTM Standards*, Vol. 04.02.

[3] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

3.2.1 Mixture proportioning for project concrete,
3.2.2 Evaluation of different mixtures and materials,
3.2.3 Correlation with nondestructive tests, and
3.2.4 Providing specimens for research purposes.

NOTE 1—The concrete test results for concrete specimens made and cured using this practice are widely used. They may be the basis for acceptance testing for project concrete, research evaluations, and other studies. Careful and knowledgeable handling of materials, mixing concrete, molding test specimens, and curing test specimens is necessary. Many laboratories performing this important work are independently inspected or accredited. Practice C 1077 identifies and defines duties, responsibilities, including minimum responsibilities of the laboratory personnel and minimum technical requirements for laboratory equipment used. Many laboratories ensure qualified technicians by participating in national certification programs such as the American Concrete Institute Laboratory Technician Program or an equivalent program.

4. Apparatus

4.1 *Molds, General*—Molds for specimens or fastenings thereto in contact with the concrete shall be made of steel, cast iron, or other nonabsorbent material, nonreactive with concrete containing portland or other hydraulic cements. Molds shall conform to the dimensions and tolerances specified in the method for which the specimens are required. Molds shall hold their dimensions and shape under all conditions of use. Watertightness of molds during use shall be judged by their ability to hold water poured into them. Test procedures for watertightness are given in the section on Test Methods for Elongation, Absorption, and Watertightness of Specification C 470/C 470M. A suitable sealant, such as heavy grease, modeling clay, or microcrystalline wax, shall be used where necessary to prevent leakage through the joints. Positive means shall be provided to hold base plates firmly to the molds. Reusable molds shall be lightly coated with mineral oil or a suitable nonreactive release material before use.

4.2 *Cylinder Molds:*

4.2.1 *Molds for Casting Specimens Vertically* shall conform to the requirements of 4.1 and Specification C 470/C 470M.

4.2.2 *Horizontal Molds for Creep Test Cylinders* shall conform to the requirements of 4.1 and to the requirements for symmetry and dimensional tolerance in the section on General Requirements except for verticality requirements of Specification C 470/C 470M. The use of horizontal molds is intended only for creep specimens that contain axially embedded strain gages. Molds for creep cylinders to be filled while supported in a horizontal position shall have a filling slot parallel to the axis of the mold which extends the full length to receive the concrete. The width of the slot shall be one half the diameter of the specimen. If necessary the edges of the slot shall be reinforced to maintain dimensional stability. Unless specimens are to be capped or ground to produce plane ends, the molds shall be provided with two machined metal end plates at least 1 in. [25 mm] thick and the working surfaces shall comply with the requirements for planeness and surface roughness given in the section on Capping Plates of Practice C 617. Provision shall be made for fixing both end plates firmly to the mold. The inside surface of each end plate shall be provided with at least three lugs or studs approximately 1 in. [25 mm] long, firmly fastened to the plate for embedment in the concrete. One base plate shall be drilled from the inside at an angle to permit the lead wire from the strain gage to exit the specimen through the edge of the plate. Provision shall be made for accurately positioning the strain gage. All necessary holes shall be as small as possible to minimize disturbance to subsequent strain measurements and shall be sealed to prevent leakage.

4.3 *Beam and Prism Molds* shall be rectangular in shape (unless otherwise specified) and of the dimensions required to produce the desired specimen size. The inside surfaces of the molds shall be smooth and free from indentations. The sides, bottom, and ends shall be at right angles to each other and shall be straight and true and free of warpage. Maximum variation from the nominal cross section shall not exceed ⅛ in. [3 mm] for molds with depth or breadth of 6 in. [150 mm] or more, or 1⁄16 in. [2 mm] for molds of smaller depth or breadth. Except for flexure specimens, molds shall not vary from the nominal length by more than 1⁄16 in. [2 mm]. Flexure molds shall not be shorter than 1⁄16 in. [2 mm] of the required length, but may exceed it by more than that amount.

4.4 *Tamping Rods*—Two sizes are specified in ASTM methods. Each shall be a round, straight steel rod with at least the tamping end rounded to a hemispherical tip of the same diameter as the rod. Both ends may be rounded, if preferred.

4.4.1 *Larger Rod*, ⅝ in. [16 mm] in diameter and approximately 24 in. [600 mm] long.

4.4.2 *Smaller Rod*, ⅜ in. [10 mm] in diameter and approximately 12 in. [300 mm] long.

4.5 *Mallets*—A mallet with a rubber or rawhide head weighing 1.25 ± 0.50 lb [0.6 ± 0.20 kg] shall be used.

4.6 *Vibrators*:

4.6.1 *Internal Vibrators*—The vibrator frequency shall be at least 7000 vibrations per minute [115 Hz] while the vibrator is operating in the concrete. The diameter of a round vibrator shall be no more than one fourth the diameter of the cylinder mold or one fourth the width of the beam or prism mold. Other shaped vibrators shall have a perimeter equivalent to the circumference of an appropriate round vibrator. The combined length of the vibrator shaft and vibrating element shall exceed the depth of the section being vibrated by at least 3 in. [75 mm].

NOTE 2—For information on size and frequency of various vibrators and method to periodically check vibrator frequency, see ACI 309.

4.6.2 *External Vibrators*—The two types of external vibrators permitted are either table or plank. The external vibrator frequency shall be 3600 vibrations per minute [60 Hz] or higher.

4.6.3 Provisions shall be made for clamping the mold securely to the apparatus for both types of vibrators.

NOTE 3—Vibratory impulses are frequently imparted to a table or plank vibrator through electromagnetic means, or by use of an eccentric weight on the shaft of an electric motor or on a separate shaft driven by a motor.

4.7 *Small Tools*—Tools and items such as shovels, pails, trowels, wood float, blunted trowels, straightedge, feeler gage, scoops, rulers, rubber gloves, and metal mixing bowls shall be provided.

4.8 *Slump Apparatus*—The apparatus for measurement of slump shall conform to the requirements of Test Method C 143/C 143M.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:06:57 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

4.9 *Sampling and Mixing Pan*—The pan shall be flat-bottom and of heavy-gage metal, watertight, of convenient depth, and of sufficient capacity to allow easy mixing by shovel or trowel of the entire batch; or, if mixing is by machine, to receive the entire batch on discharge of the mixer and allow remixing in the pan by trowel or shovel.

4.10 *Wet-Sieving Equipment*—If wet-sieving is required, the equipment shall conform to the requirements of Practice C 172.

4.11 *Air Content Apparatus*—The apparatus for measuring air content shall conform to the requirements of either Test Methods C 231 or C 173.

4.12 *Scales*—Scales for determining the mass of batches of materials and concrete shall be accurate within 0.3 % of the test load at any point within the range of use.

NOTE 4—In general the mass of small quantities should not be determined on large capacity scales. In many applications the smallest mass determined on a scale should be greater than about 10 % of the maximum capacity of the scale; however, this will vary with the performance characteristics of the scale and the required accuracy of the determination. Acceptable scales used for determining the mass for concrete materials preferably should determine mass accurately to about 0.1 % of total capacity and the foregoing precaution is applicable. However, certain analytical and precision balances are exceptions to this rule and should weigh accurately to 0.001 %. Particular care must be exercised in measuring small quantities of material by determining the difference between two much larger masses.

4.13 *Temperature Measuring Device*—The temperature measuring device shall conform to the requirements of Test Method C 1064.

4.14 *Concrete Mixer*—A power-driven concrete mixer shall be a revolving drum, tilting mixer, or suitable revolving pan or revolving-paddle mixer capable of thoroughly mixing batches of the prescribed sizes at the required slump.

NOTE 5—A pan mixer is usually more suitable for mixing concrete with less than 1-in. [25 mm] slump than a revolving drum mixer. The rate of rotation, degree of tilt, and rated capacity of tilting mixers are not always suitable for laboratory mixed concrete. It may be found desirable to reduce the rate of rotation, decrease the angle of tilt from the horizontal, and use the mixer at somewhat less than the manufacturer's rated capacity.

5. Specimens

5.1 *Cylindrical Specimens*—Cylinder dimensions shall be as stipulated in the specification, test method or practice for the laboratory studies being performed and shall meet the requirements of 5.4. If dimensions are not stipulated in a specification, test method, or practice, the specimen selected shall have a length that is twice the diameter and meet the requirements of 5.4.

NOTE 6—The same cylinder size should be used for the reference (control) concrete mixture and test concrete mixtures when conducting comparative studies such as those required in Specification C 494/C 494M. For mixture proportioning of project concrete, it is preferable for the cylinder size in the laboratory to be the same as that specified for acceptance testing.

NOTE 7—When molds in SI units are required and not available, equivalent inch-pound unit size mold should be permitted.

5.1.1 Cylindrical specimens for tests other than creep shall be molded and allowed to harden with the axis of the cylinder vertical.

5.1.2 Cylindrical creep specimens may be cast with the cylindrical axis either vertical or horizontal and allowed to harden in the position in which cast.

5.2 *Prismatic Specimens*—Beams for flexural strength, prisms for freezing and thawing, bond, length change, volume change, etc., shall be formed with their long axes horizontal, unless otherwise required by the method of test in question, and shall conform in dimension to the requirements of the specific test method.

5.3 *Other Specimens*—Other shapes and sizes of specimens for particular tests may be molded as desired following the general procedures set forth in this practice.

5.4 *Specimen Size versus Aggregate Size*—The diameter of a cylindrical specimen or minimum cross-sectional dimension of a rectangular section shall be at least three times the nominal maximum size of the coarse aggregate in the concrete as defined in Terminology C 125. When the nominal maximum size of the coarse aggregate exceeds 2 in. [50 mm], the sample shall be treated by wet sieving through a 2-in. [50-mm] sieve as described in Practice C 172, unless otherwise stipulated.

5.5 *Number of Specimens*—The number of specimens and the number of test batches are dependent on established practice and the nature of the test program. Guidance is usually given in the test method or specification for which the specimens are made. Usually three or more specimens are molded for each test age and test condition unless otherwise specified (Note 8). Specimens involving a given variable should be made from three separate batches mixed on different days. An equal number of specimens for each variable should be made on any given day. When it is impossible to make at least one specimen for each variable on a given day, the mixing of the entire series of specimens should be completed in as few days as possible, and one of the mixtures should be repeated each day as a standard of comparison.

NOTE 8—Test ages often used are 7 and 28 days for compressive strength tests, or 14 and 28 days for flexural strength tests. Specimens containing Type III cement are often tested at 1, 3, 7, and 28 days. For later test ages, 3 months, 6 months, and 1 year are often used for both compressive and flexural strength tests. Other test ages may be required for other types of specimens.

6. Preparation of Materials

6.1 *Temperature*—Before mixing the concrete, bring the concrete materials to room temperature in the range from 68 to 86 °F [20 to 30 °C], except when the temperature of the concrete is stipulated. When a concrete temperature is stipulated, the method proposed to obtain the concrete temperature needs approval of the stipulator.

6.2 *Cement*—Store the cement in a dry place, in moisture-proof containers, preferably made of metal. The cement shall be thoroughly mixed to provide a uniform supply throughout the tests. It shall be passed through a 850-μm [No. 20] or finer sieve to remove all lumps, remixed on a plastic sheet, and returned to sample containers.

6.3 *Aggregates*—In order to preclude segregation of a coarse aggregate, separate into individual size fractions and for each batch recombine in the proper proportions to produce the desired grading.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 9—Only rarely is a coarse aggregate batched as a single size fraction. The number of size fractions will generally be between 2 and 5 for aggregate smaller than 2½ in. [60 mm]. When a size fraction to be batched is present in amounts in excess of 10 %, the ratio of the opening of the larger to the smaller sieve should not exceed 2.0. More closely sized groups are sometimes advisable.

6.3.1 Unless fine aggregate is separated into individual size fractions, maintain it in a damp condition or restore to a damp condition until use, to prevent segregation, unless material uniformly graded is subdivided into batch size lots using a sample splitter with proper size openings. If unusual gradings are being studied, the fine aggregate may need to be dried and separated into individual sizes. In this instance, if the total quantity of fine aggregate required is larger than can be efficiently blended in a single unit, then the individual size fractions should be determined in a mass required for each individual batch. When the total quantity of fine aggregate needed for the complete investigation is such that it can be thoroughly mixed, blended, and maintained in a damp condition, then it should be handled in that manner. Determine the specific gravity and absorption of aggregates in accordance with either Test Methods C 127 or C 128.

6.3.2 Before incorporating in concrete, prepare the aggregate to ensure a definite and uniform condition of moisture. Determine the weight of aggregate to be used in the batch by one of the following procedures:

6.3.2.1 Determine the mass of low-absorption aggregates (absorption less than 1.0 %) in the room-dry condition with allowance made for the amount of water that will be absorbed from the unset concrete (Note 10). This procedure is particularly useful for coarse aggregate which must be batched as individual sizes; because of the danger of segregation it can be used for fine aggregate only when the fine aggregate is separated into individual size fractions.

NOTE 10—When using aggregates with low absorption in room-dry condition the amount of water that will be absorbed by the aggregates before the concrete sets may be assumed to be 80 % of the difference between the 24-h absorption of the aggregates determined by Test Methods C 127 or C 128, and the amount of water in the pores of the aggregates in their room-dry state, as determined by Test Method C 566.

6.3.2.2 Individual size fractions of aggregate may be weighed separately, recombined into a tared container in the amounts required for the batch, and immersed in water for 24 h prior to use. After immersion the excess water is decanted and the combined weight of aggregate and mixing water determined. Allowance shall be made for the amount of water absorbed by the aggregate. The moisture content of the aggregates may be determined in accordance with Test Methods C 70 and C 566.

6.3.2.3 The aggregate may be brought to and maintained in a saturated condition, with surface moisture contained in sufficiently small amounts to preclude loss by draining, at least 24 h prior to use. When this method is used, the moisture content of the aggregate must be determined to permit calculation of proper quantities of the damp aggregate. The quantity of surface moisture present must be counted as a part of the required amount of mixing water. Surface moisture in fine aggregate may be determined in accordance with Test Methods C 70 and C 566, making due allowance for the amount of water absorbed. The method outlined here (moisture content slightly exceeding absorption) is particularly useful for fine aggregate. It is used less frequently for coarse aggregate because of the difficulty of accurately determining the moisture content, but if used, each size fraction must be handled separately to ensure that the proper grading is obtained.

6.3.2.4 Aggregates, fine or coarse, may be brought to and maintained in a saturated surface-dry condition until batched for use. This method is used primarily to prepare material for batches not exceeding ¼ ft^3 [0.007 m^3] in volume. Care must be taken to prevent drying during weighing and use.

6.4 *Lightweight Aggregates*—The procedures for specific gravity, absorption, and preparation of aggregates mentioned in this practice pertain to materials with normal absorption values. Lightweight aggregates, air-cooled slag, and certain highly porous or vesicular natural aggregate may be so absorptive as to be difficult to treat as described. The moisture content of lightweight aggregate at the time of mixing may have important effects on properties of freshly mixed and hardened concretes such as slump loss, compressive strength, and resistance to freezing and thawing.

6.5 *Admixtures*—Powdered admixtures that are entirely or largely insoluble, that do not contain hygroscopic salts and are to be added in small quantities, should be mixed with a portion of the cement before introduction into the batch in the mixer so as to ensure thorough distribution throughout the concrete. Essentially insoluble materials which are used in amounts exceeding 10 % by mass of cement, such as pozzolans, should be handled and added to the batch in the same manner as cement. Powdered admixtures which are largely insoluble but contain hygroscopic salts may cause balling of cement and should be mixed with the sand. Water-soluble and liquid admixtures should be added to the mixer in solution in the mixing water. The quantity of such solution used shall be included in the calculation of the water content of the concrete. Admixtures, incompatible in concentrated form, such as solutions of calcium chloride and certain air-entraining and set-retarding admixtures, should not be intermixed prior to their addition to concrete. The time, sequence, and method of adding some admixtures to a batch of concrete can have important effects on concrete properties such as time of set and air content. The method selected must remain unchanged from batch to batch.

NOTE 11—The mixing apparatus and accessories shall be thoroughly cleaned to ensure that chemical additions or admixtures used in dissimilar batches of concrete do not affect subsequent batches.

7. Procedure

7.1 *Mixing Concrete:*

7.1.1 *General*—Mix concrete in a suitable mixer or by hand in batches of such size as to leave about 10 % excess after molding the test specimens. Hand-mixing procedures are not applicable to air-entrained concrete or concrete with no measurable slump. Hand mixing should be limited to batches of ¼ ft^3 [0.007 m^3] volume or less. Mixing procedures are given in 7.1.2 and 7.1.3. However, other procedures may be used when it is desired to simulate special conditions or practices, or when the procedures specified are impracticable. A machine-mixing

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:06:57 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

procedure suitable for drum-type mixers is described. It is important not to vary the mixing sequence and procedure from batch to batch unless the effect of such variation is under study.

7.1.2 *Machine Mixing*—Prior to starting rotation of the mixer add the coarse aggregate, some of the mixing water, and the solution of admixture, when required, in accordance with 6.5. When feasible, disperse the admixture in the mixing water before addition. Start the mixer, then add the fine aggregate, cement, and water with the mixer running. If it is impractical for a particular mixer or for a particular test to add the fine aggregate, cement, and water while the mixer is running, these components may be added to the stopped mixer after permitting it to turn a few revolutions following charging with coarse aggregate and some of the water (Note 12). Mix the concrete, after all ingredients are in the mixer, for 3 min followed by a 3-min rest, followed by a 2-min final mixing. Cover the open end or top of the mixer to prevent evaporation during the rest period. Take precautions to compensate for mortar retained by the mixer so that the discharged batch, as used, will be correctly proportioned (Note 13). To eliminate segregation, deposit machine-mixed concrete in the clean, damp mixing pan and remix by shovel or trowel until it appears to be uniform.

NOTE 12—An experienced operator may add water incrementally during mixing to adjust to the desired slump.

NOTE 13—It is difficult to recover all of the mortar from mixers. To compensate for this difficulty one of the following procedures may be used to ensure the correct final proportions in the batch:

(1) "*Buttering*" *the Mixer*—Just prior to mixing the test batch, the mixer is "buttered" by mixing a batch proportioned to simulate closely the test batch. The mortar adhering to the mixer after discharging is intended to compensate for loss of mortar from the test batch.

(2) "*Over-Mortaring*" *the Mix*—The test mix is proportioned by the use of an excess mortar, the amount established in advance, to compensate for that which, on the average, adheres to the mixer. In this case the mixer is cleaned before mixing the test batch.

7.1.3 *Hand Mixing*—Mix the batch in a watertight, clean (Note 11), damp, metal pan or bowl, with a bricklayer's blunted trowel, using the following procedure when aggregates have been prepared in accordance with 6.3.2.1, 6.3.2.3, and 6.3.2.4.

7.1.3.1 Mix the cement, powdered insoluble admixture, if used, and fine aggregate without addition of water until they are thoroughly blended.

7.1.3.2 Add the coarse aggregate and mix the entire batch without addition of water until the coarse aggregate is uniformly distributed throughout the batch.

7.1.3.3 Add water, and the admixture solution if used, and mix the mass until the concrete is homogeneous in appearance and has the desired consistency. If prolonged mixing is necessary because of the addition of water in increments while adjusting the consistency, discard the batch and make a new batch in which the mixing is not interrupted to make trial consistency tests.

7.1.4 *Mixed Concrete*—Select the portions of the batch of mixed concrete to be used in tests for molding specimens so as to be representative of the actual proportions and condition of the concrete. When the concrete is not being remixed or sampled cover it to prevent evaporation.

7.2 *Slump, Air Content, Yield, and Temperature:*

7.2.1 *Slump*—Measure the slump of each batch of concrete immediately after mixing in accordance with Test Method C 143/C 143M.

NOTE 14—The slump test is unsuitable for concrete so dry that it slumps less than ¼ in. [6 mm]. No-slump concrete may be tested by one of several means described in ACI 211.3.

7.2.2 *Air Content*—Determine the air content, when required, in accordance with either Test Methods C 173 or C 231. Test Method C 231 should not be used with concretes made with lightweight aggregates, air-cooled blast-furnace slag, or aggregates of high porosity. Discard the concrete used for the determination of air content.

7.2.3 *Yield*—Determine the yield of each batch of concrete, if required, in accordance with Test Method C 138. Concrete used for slump and yield tests may be returned to the mixing pan and remixed into the batch.

7.2.4 *Temperature*—Determine the temperature of each batch of concrete in accordance with Test Method C 1064.

7.3 *Making Specimens:*

7.3.1 *Place of Molding*—Mold specimens as near as practicable to the place where they are to be stored during the first 24 h. If it is not practicable to mold the specimens where they will be stored, move them to the place of storage immediately after being struck off. Place molds on a rigid surface free from vibration and other disturbances. Avoid jarring, striking, tilting, or scarring of the surface of the specimens when moving the specimens to the storage place.

7.3.2 *Placing*—Place the concrete in the molds using a scoop, blunted trowel, or shovel. Select each scoopful, trowelful, or shovelful of concrete from the mixing pan to ensure that it is representative of the batch. It may be necessary to remix the concrete in the mixing pan with a shovel or trowel to prevent segregation during the molding of specimens. Move the scoop or trowel around the top edge of the mold as the concrete is discharged in order to ensure a symmetrical distribution of the concrete and to minimize segregation of coarse aggregate within the mold. Further distribute the concrete by use of a tamping rod prior to the start of consolidation. In placing the final layer the operator shall attempt to add an amount of concrete that will exactly fill the mold after compaction. Do not add nonrepresentative samples of concrete to an underfilled mold.

7.3.2.1 *Number of Layers*—Make specimens in layers as indicated in Table 1.

7.4 *Consolidation:*

7.4.1 *Methods of Consolidation*—Preparation of satisfactory specimens requires different methods of consolidation. The methods of consolidation are rodding, and internal or external vibration. Base the selection of the method on the slump, unless the method is stated in the specifications under which the work is being performed. Rod or vibrate concrete with slump greater than or equal to 1 in. [25 mm]. Vibrate concrete with slump less than 1 in. (Note 15). Do not use internal vibration for cylinders with a diameter less than 4 in. [100 mm], and for beams or prisms with breath or depth less than 4 in.

NOTE 15—Concrete of such low water content that it cannot be properly consolidated by the methods described herein is not covered by

TABLE 1 Number of Layers Required for Specimens

Specimen Type and Size	Mode of Consolidation	Numbers of Layers of Approximate Equal Depth
Cylinders: Diameter, in. [mm]		
3 or 4 [75 to 100]	rodding	2
6 [150]	rodding	3
9 [225]	rodding	4
up to 9 [225]	vibration	2
Prisms and horizontal creep Cylinders: Depth, in. [mm]		
up to 8 [200]	rodding	2
over 8 [200]	rodding	3 or more
up to 8 [200]	vibration	1
over 8 [200]	vibration	2 or more

this practice. Provisions for specimens and methods of testing will be found in the standards concerned. There are concretes that can be consolidated by external vibration, but additional forces on the surface are required to embed the coarse aggregate thoroughly and consolidate the mixture. For such mixtures the following procedures may be followed: using external vibration fill 6 by 12-in. [150 by 300-mm] cylinder molds in 3 in. [75 mm] lifts using a 10-lb [4.5-kg] cylindrical surcharge, or 3 by 6-in. [75 by 150-mm] cylinder molds in 2 in. [50 mm] lifts using a 2.5-lb [1-kg] cylindrical surcharge. The surcharge should have a diameter ¼ in. [6 mm] less than the inside of the mold. Simultaneously each lift should be compacted by external vibration with the surcharge on the top surface of the concrete, until the mortar begins to ooze around the bottom of the surcharge.

7.4.2 *Rodding*—Place the concrete in the mold, in the required number of layers of approximately equal volume. Rod each layer with the rounded end of the rod using the number of strokes and size of rod specified in Table 2. Rod the bottom layer throughout its depth. Distribute the strokes uniformly over the cross section of the mold and for each upper layer allow the rod to penetrate through the layer being rodded and into the layer below about 1 in. [25 mm]. After each layer is rodded, tap the outsides of the mold lightly 10 to 15 times with the mallet to close any holes left by rodding and to release any large air bubbles that may have been trapped. Use an open hand to tap light-gage single-use molds which are susceptible to damage if tapped with a mallet. After tapping, spade the concrete along the sides and ends of beam and prism molds with a trowel or other suitable tool.

7.4.3 *Vibration*—Maintain a uniform duration of vibration for the particular kind of concrete, vibrator, and specimen mold involved. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator. Usually sufficient vibration has been applied as soon as the surface of the concrete becomes relatively smooth and large air bubbles cease to break through the top surface. Continue vibration only long enough to achieve proper consolidation of the concrete (see Note 16). Overvibration may cause segregation. Fill the molds and vibrate in the required number of approximately equal layers (Table 2). Place all the concrete for each layer in the mold before starting vibration of that layer. When placing the final layer, avoid overfilling by more than ¼ in. [6 mm]. When the finish is applied after vibration, add only enough concrete with a trowel to overfill the mold about ⅛ in. [3 mm], work it into the surface and then strike it off.

NOTE 16—Generally, no more than 5 s of vibration should be required for each insertion to adequately consolidate the concrete with a slump greater than 3 in. [75 mm]. Longer times may be required for lower slump concrete, but the vibration time should rarely have to exceed 10 s per insertion.

7.4.3.1 *Internal Vibration*—In compacting the specimen insert the vibrator slowly and do not allow the vibrator to rest on or touch the bottom or sides of the mold or strike embedded items such as strain meters. Slowly withdraw the vibrator so that no large air pockets are left in the specimen.

7.4.3.2 *Cylinders*—The number of insertions of the vibrator is given in Table 3. When more than one insertion per layer is required, distribute the insertions uniformly within each layer. Allow the vibrator to penetrate into the layer below about 1 in. [25 mm]. After each layer is vibrated, tap the outside of the mold at least 10 times with the mallet to close the holes that remain and to release entrapped air voids. Use an open hand to tap cardboard or single-use metal molds that are susceptible to damage if tapped with a mallet.

7.4.3.3 *Beams, Prisms, and Horizontal Creep Cylinders*—Insert the vibrator at intervals not exceeding 6 in. [150 mm] along the center line of the long dimension of the specimen, or along both sides but not in contact with the strain gage in the case of creep cylinders. For specimens wider than 6 in. [150 mm], use alternating insertions along two lines. Allow the shaft of the vibrator to penetrate into the bottom layer about 1 in. [25 mm]. After each layer is vibrated, tap the outsides of the mold

TABLE 2 Diameter of Rod and Number of Roddings to be Used in Molding Test Specimens

Cylinders		
Diameter of Cylinder, in. [mm]	Diameter of Rod in. [mm]	Number of Strokes/Layer
3 [75] to < 6 [150]	⅜ [10]	25
6 [150]	⅝ [16]	25
8 [200]	⅝ [16]	50
10 [250]	⅝ [16]	75
Beams and Prisms		
Top Surface Area of Specimen, in.^{2}[cm^2]	Diameter of Rod in. (mm)	Number of Roddings/Layer
25 [160] or less	⅜ [10]	25
26 to 49 [165 to 310]	⅜ [10]	one for each 1 in.^{2}[7 cm^2] of surface
50 [320] or more	⅝ [16]	one for each 2 in.^{2}[14 cm^2] of surface
Horizontal Creep Cylinders		
Diameter of Cylinder in. [mm]	Diameter of Rod in. [mm]	Number of Roddings/Layer
6 [150]	⅝ [16]	50 total, 25 along both sides of axis

TABLE 3 Number of Vibrator Insertions per Layer

Specimen Type and Size	Number of Insertions per Layer
Cylinder: Diameter, in. [mm]	
4 in. [200 mm]	1
6 in. [150 mm]	2
9 in. [225 mm]	4

sharply at least 10 times with the mallet to close holes left by vibrating and to release entrapped air voids.

7.4.4 *External Vibration*—When external vibration is used, take care to ensure that the mold is rigidly attached to or securely held against the vibrating element or vibrating surface (Note 15).

7.5 *Finishing*—After consolidation by any of the methods, strike off the surface of the concrete and float or trowel it in accordance with the method concerned. If no finish is specified, finish the surface with a wood or magnesium float. Perform all finishing with the minimum manipulation necessary to produce a flat even surface that is level with the rim or edge of the mold and which has no depressions or projections larger than ⅛ in. [3 mm].

7.5.1 *Cylinders*—After consolidation finish the top surfaces by striking them off with the tamping rod where the consistency of the concrete permits, or with a wood float or trowel. If desired, cap the top surface of freshly made cylinders with a thin layer of stiff portland cement paste which is permitted to harden and cure with the specimen. See the section on Capping Materials of Practice C 617.

7.5.2 *Horizontally Cast Creep Cylinders*—After consolidation strike off the specimen with a trowel or float, then trowel the minimum amount required to form the concrete in the opening concentrically with the rest of the specimen. Use a screed curved to the radius of the specimen to more precisely shape and finish the concrete in the opening.

8. Curing

8.1 *Initial Curing*—To prevent evaporation of water from unhardened concrete, cover the specimens immediately after finishing, preferably with a nonabsorptive, nonreactive plate or a sheet of tough, durable impervious plastic. Specimens shall be stored immediately after finishing until the removal of the molds to prevent loss of moisture from the specimens. Select an appropriate procedure or combination of procedures that will prevent moisture loss and is nonabsorptive and nonreactive with the concrete. When wet burlap is used for covering, the burlap must not be in contact with the fresh concrete surface and care must be exercised to keep the burlap wet until the specimens are removed from the molds. Placing a sheet of plastic over the burlap will facilitate keeping it wet. To prevent damage to specimens, protect the outside of cardboard molds from contact with wet burlap or other sources of water until the molds are removed. Record the maximum and minimum ambient temperatures during the initial curing.

8.2 *Removal from Molds*—Remove the specimens from the molds 24 ± 8 h after casting. For concrete with prolonged setting time, molds shall not be removed until 20 ± 4 h after final set. If needed, determine the setting times in accordance with Test Method C 403/C 403M.

8.3 *Curing Environment*—Unless otherwise specified all specimens shall be moist cured at 73.5 ± 3.5 °F [23.0 ± 2.0 °C] from the time of molding until the moment of test (Note 17). Storage during the first 48 h of curing shall be in a vibration-free environment. As applied to the treatment of demolded specimens, moist curing means that the test specimens shall have free water maintained on the entire surface area at all times. This condition is met by using water storage tanks or a moist room in accordance with the requirements of Specification C 511. Cure structural lightweight concrete cylinders in accordance with Specification C 330.

NOTE 17—The temperature within damp sand and under wet burlap or similar materials will always be lower than the temperature in the surrounding atmosphere if evaporation takes place.

8.4 *Flexural Strength Test Specimens*—Cure the flexural strength test specimens in accordance with 8.1 and 8.2 except that while in storage for a minimum period of 20 h immediately prior to testing they shall be immersed in water saturated with calcium hydroxide at 73 ± 3 °F [23 ± 2 °C]. At the end of the curing period, between the time the specimen is removed from curing until testing is completed, drying of the surfaces shall be prevented.

NOTE 18—Relatively small amounts of drying of the surface of flexural strength specimens will induce tensile stresses in the extreme fibers that will markedly reduce the indicated flexural strength.

9. Precision and Bias

9.1 Data to establish precision statements for various testing required by this standard were obtained in the Concrete Proficiency Sample Program of the Cement and Concrete Reference Laboratory.

9.2 The single-operator standard deviations for slump, unit weight, air content, and 7-day compressive strength of trial batches have been found to be 0.7 in., 0.9 lb/ft^3, 0.3 %, and 203 psi, respectively; therefore the results of properly conducted tests on two trial batches made in the same laboratory should not differ by more than 2.0 in., 2.5 lb/ft^3, 0.8 %, and 574 psi, respectively. This precision statement is considered applicable to laboratory trial batches proportioned to contain prescribed quantities of materials and to have a constant water-cement ratio. The values should be used with caution for air-entrained concrete, concrete with slump less than 2 in. [50 mm] or over 6 in. [150 mm], or concrete made with other than normal weight aggregate or aggregate larger than 1 in. [25 mm] nominal maximum size.

9.3 The multilaboratory standard deviations for slump, unit weight, air content, and 7-day compressive strength of trial batches have been found to be 1.0 in., 1.4 lb/ft^3 0.4 %, and 347 psi, respectively; therefore, the results of properly conducted tests on single trial batches made in two different laboratories should not differ by more than 2.8 in., 4.0 lb/ft^3, 1.1 %, and 981 psi, respectively. This precision statement is considered applicable to laboratory trial batches proportioned to contain prescribed quantities of materials and to have a prescribed water-cement ratio. The values should be used with caution for air-entrained concrete, concrete with slump less than 2 in. [50 mm] or over 6 in. [150 mm], or concrete made with other than

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

normal weight aggregate or aggregate larger than 1 in. [25 mm] nominal maximum size.

9.4 *Bias*—The procedures for the test methods in 9.3 have no bias because the values obtained from each of those test methods are defined only in terms of the test method.

Designation: C 204 – 07

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T 153

Standard Test Methods for Fineness of Hydraulic Cement by Air-Permeability Apparatus[1]

This standard is issued under the fixed designation C 204; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers determination of the fineness of hydraulic cement, using the Blaine air-permeability apparatus, in terms of the specific surface expressed as total surface area in square centimetres per gram, or square metres per kilogram, of cement. Two test methods are given: Test Method A is the Reference Test Method using the manually operated standard Blaine apparatus, while Test Method B permits the use of automated apparatus that has in accordance with the qualification requirements of this test method demonstrated acceptable performance. Although the test method may be, and has been, used for the determination of the measures of fineness of various other materials, it should be understood that, in general, relative rather than absolute fineness values are obtained.

1.1.1 This test method is known to work well for portland cements. However, the user should exercise judgement in determining its suitability with regard to fineness measurements of cements with densities, or porosities that differ from those assigned to Standard Reference Material No. 114.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

TEST METHOD A: REFERENCE METHOD

3. Apparatus

3.1 *Nature of Apparatus*—The Blaine air-permeability apparatus consists essentially of a means of drawing a definite quantity of air through a prepared bed of cement of definite porosity. The number and size of the pores in a prepared bed of definite porosity is a function of the size of the particles and determines the rate of airflow through the bed. The apparatus, illustrated in Fig. 1, shall consist specifically of the parts described in 3.2-3.8.

3.2 *Permeability Cell*—The permeability cell shall consist of a rigid cylinder 12.70 ± 0.10 mm in inside diameter, constructed of austenitic stainless steel. The interior of the cell shall have a finish of 0.81 µm (32 µin.). The top of the cell shall be at right angles to the principal axis of the cell. The lower portion of the cell must be able to form an airtight fit with the upper end of the manometer, so that there is no air leakage between the contacting surfaces. A ledge ½ to 1 mm in width shall be an integral part of the cell or be firmly fixed in the cell 55 ± 10 mm from the top of the cell for support of the perforated metal disk. The top of the permeability cell shall be fitted with a protruding collar to facilitate the removal of the cell from the manometer.

NOTE 1—Specification A 582/A 582M Type 303 stainless steel (UNS designation S30300) has been found to be suitable for the construction of the permeability cell and the plunger.

3.3 *Disk*—The disk shall be constructed of noncorroding metal and shall be 0.9 ± 0.1 mm in thickness, perforated with 30 to 40 holes 1 mm in diameter equally distributed over its area. The disk shall fit the inside of the cell snugly. The center

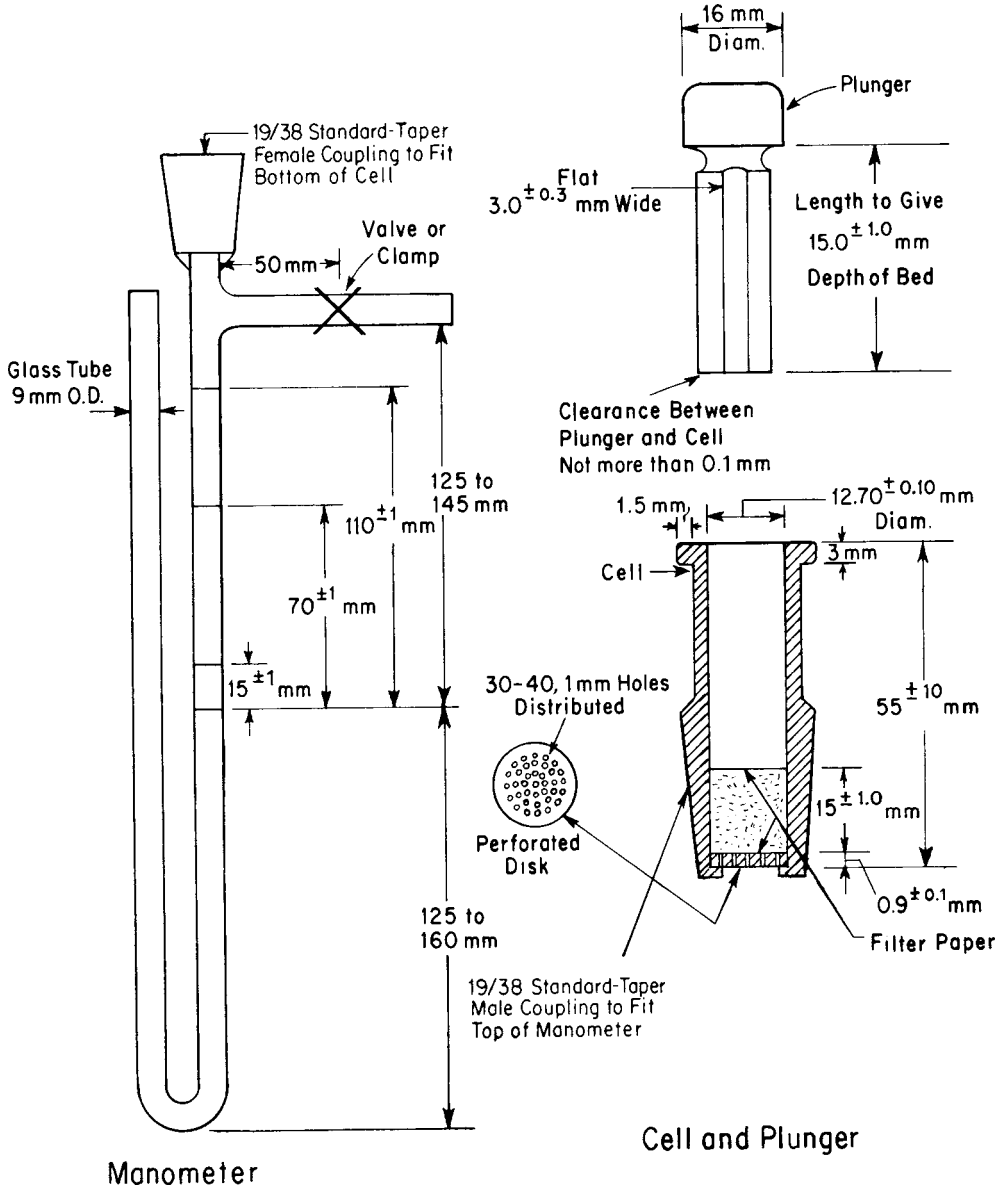

FIG. 1 Blaine Air-Permeability Apparatus

portion of one side of the disk shall be marked or inscribed in a legible manner so as to permit the operator always to place that side downwards when inserting it into the cell. The marking or inscription shall not extend into any of the holes, nor touch their peripheries, nor extend into that area of the disk that rests on the cell ledge.

3.4 *Plunger*—The plunger shall be constructed of austenitic stainless steel and shall fit into the cell with a clearance of not more than 0.1 mm. The bottom of the plunger shall sharply meet the lateral surfaces and shall be at right angles to the principal axis. An air vent shall be provided by means of a flat 3.0 ± 0.3 mm wide on one side of the plunger. The top of the plunger shall be provided with a collar such that when the plunger is placed in the cell and the collar brought in contact with the top of the cell, the distance between the bottom of the plunger and the top of the perforated disk shall be 15 ± 1 mm.

3.5 *Filter Paper*—The filter paper shall be medium retentive, corresponding to Type 1, Grade B, in accordance with Specification E 832. The filter paper disks shall be circular, with smooth edges, and shall have the same diameter (Note 2) as the inside of the cell.

NOTE 2—Filter paper disks that are too small may leave part of the sample adhering to the inner wall of the cell above the top disk. When too large in diameter, the disks have a tendency to buckle and cause erratic results.

3.6 *Manometer*—The U-tube manometer shall be constructed according to the design indicated in Fig. 1, using nominal 9-mm outside diameter, standard-wall, glass tubing. The top of one arm of the manometer shall form an airtight connection with the permeability cell. The manometer arm connected to the permeability cell shall have a midpoint line etched around the tube at 125 to 145 mm below the top side outlet and also others at distances of 15 ± 1 mm, 70 ± 1 mm, and 110 ± 1 mm above that line. A side outlet shall be provided at 250 to 305 mm above the bottom of the manometer for use

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

in the evacuation of the manometer arm connected to the permeability cell. A positive airtight valve or clamp shall be provided on the side outlet not more than 50 mm from the manometer arm. The manometer shall be mounted firmly and in such a manner that the arms are vertical.

3.7 *Manometer Liquid*—The manometer shall be filled to the midpoint line with a nonvolatile, nonhygroscopic liquid of low viscosity and density, such as dibutyl phthalate (dibutyl 1,2-benzene-dicarboxylate) or a light grade of mineral oil. The fluid shall be free of debris.

3.8 *Timer*—The timer shall have a positive starting and stopping mechanism and shall be capable of being read to the nearest 0.5 s or less. The timer shall be accurate to 0.5 s or less for time intervals up to 60 s, and to 1 % or less for time intervals of 60 to 300 s.

4. Calibration of Apparatus

4.1 *Sample*—The calibration of the air permeability apparatus shall be made using the current lot of NIST Standard Reference Material No. 114. The sample shall be at room temperature when tested.

4.2 *Bulk Volume of Compacted Bed of Powder*—Determine the bulk volume of the compacted bed of powder by the mercury displacement method as follows:

4.2.1 Place two filter paper disks in the permeability cell, pressing down the edges, using a rod having a diameter slightly smaller than that of the cell, until the filter disks are flat on the perforated metal disk; then fill the cell with mercury, ACS reagent grade or better, removing any air bubbles adhering to the wall of the cell. Use tongs when handling the cell. If the cell is made of material that will amalgamate with mercury, the interior of the cell shall be protected by a very thin film of oil just prior to adding the mercury. Level the mercury with the top of the cell by lightly pressing a small glass plate against the mercury surface until the glass is flush to the surface of the mercury and rim of the cell, being sure that no bubble or void exists between the mercury surface and the glass plate. Remove the mercury from the cell and measure and record the mass of the mercury. Remove one of the filter disks from the cell. Using a trial quantity of 2.80 g of cement (Note 3) compress the cement (Note 4) in accordance with 4.5 with one filter disk above and one below the sample. Into the unfilled space at the top of the cell, add mercury, remove entrapped air, and level off the top as before. Remove the mercury from the cell and measure and record the mass of the mercury.

4.2.2 Calculate the bulk volume occupied by the cement to the nearest 0.005 cm^3 as follows:

$$V = (W_A - W_B)/D \quad (1)$$

where:

V = bulk volume of cement, cm^3,
W_A = grams of mercury required to fill the cell, no cement being in the cell,
W_B = grams of mercury required to fill the portion of the cell not occupied by the prepared bed of cement in the cell, and
D = density of mercury at the temperature of test, Mg/m^3 (see Table 1).

4.2.3 Make at least two determinations of bulk volume of cement, using separate compactions for each determination. The bulk volume value used for subsequent calculations shall be the average of two values agreeing within ± 0.005 cm^3. Note the temperature in the vicinity of the cell and record at the beginning and end of the determination.

NOTE 3—It is not necessary to use the standard sample for the bulk volume determination.

NOTE 4—The prepared bed of cement shall be firm. If too loose or if the cement cannot be compressed to the desired volume, adjust the trial quantity of cement used.

4.3 *Preparation of Sample*—Enclose the contents of a vial of the standard cement sample in a jar, approximately 120 cm^3 (4 oz), and shake vigorously for 2 min to fluff the cement and break up lumps or agglomerates. Allow the jar to stand unopened for a further 2 min, then remove the lid and stir gently to distribute throughout the sample the fine fraction that has settled on the surface after fluffing.

4.4 *Mass of Sample*—The mass of the standard sample used for the calibration test shall be that required to produce a bed of cement having a porosity of 0.500 ± 0.005, and shall be calculated as follows:

$$W = \rho V(1 - \epsilon) \quad (2)$$

where:

W = grams of sample required,
ρ = density of test sample (for portland cement a value of 3.15 Mg/m^3 or 3.15 g/cm^3 shall be used),
V = bulk volume of bed of cement, cm^3, as determined in accordance with 4.2, and
ϵ = desired porosity of bed of cement (0.500 ± 0.005) (Note 5).

NOTE 5—The porosity is the ratio of volume of voids in a bed of cement to the total or bulk volume of the bed, V.

4.5 *Preparation of Bed of Cement*—Seat the perforated disk on the ledge in the permeability cell, inscribed or marked face down. Place a filter paper disk on the metal disk and press the edges down with a rod having a diameter slightly smaller than that of the cell. Measure the mass to the nearest 0.001 g the quantity of cement determined in accordance with 4.4 and place in the cell. Tap the side of the cell lightly in order to level the bed of cement. Place a filter paper disk on top of the cement and compress the cement with the plunger until the plunger collar is in contact with the top of the cell. Slowly withdraw the

TABLE 1 Density of Mercury, Viscosity of Air (η), and $\sqrt{\eta}$ at Given Temperatures

Room Temperature, °C	Density of Mercury, Mg/m^3	Viscosity of Air, η μPa·s	$\sqrt{\eta}$

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

plunger a short distance, rotate about 90°, repress, and then slowly withdraw. Use of fresh paper filter disks is required for each determination.

4.6 *Permeability Test*:

4.6.1 Attach the permeability cell to the manometer tube, making certain that an airtight connection is obtained (Note 6) and taking care not to jar or disturb the prepared bed of cement.

4.6.2 Slowly evacuate the air in the one arm of the manometer U-tube until the liquid reaches the top mark, and then close the valve tightly. Start the timer when the bottom of the meniscus of the manometer liquid reaches the second (next to the top) mark and stop when the bottom of the meniscus of liquid reaches the third (next to the bottom) mark. Note the time interval measured and record in seconds. Note the temperature of test and record in degrees Celsius.

4.6.3 In the calibration of the instrument, make at least three determinations of the time of flow on each of three separately prepared beds of the standard sample (Note 7). The calibration shall be made by the same operator who makes the fineness determination.

NOTE 6—A little stopcock grease should be applied to the standard taper connection. The efficiency of the connection can be determined by attaching the cell to the manometer, stoppering it, partially evacuating the one arm of the manometer, then closing the valve. Any continuous drop in pressure indicates a leak in the system.

NOTE 7—The sample may be refluffed and reused for preparation of the test bed, provided that it is kept dry and all tests are made within 4 h of the opening of the sample.

4.7 *Recalibration*—The apparatus shall be recalibrated (Note 8):

4.7.1 At periodic intervals, the duration of which shall not exceed 2½ years, to correct for possible wear on the plunger or permeability cell, or upon receipt of evidence that the test is not providing data in accordance with the precision and bias statement in Section 8.

4.7.2 If any loss in the manometer fluid occurs, recalibrate starting with 4.5, or

4.7.3 If a change is made in the type or quality of the filter paper used for the tests.

NOTE 8—It is suggested that a secondary sample be prepared and used as a fineness standard for the check determinations of the instrument between regular calibrations with the standard cement sample.

5. Procedure

5.1 *Temperature of Cement*—The cement sample shall be at room temperature when tested.

5.2 *Size of Test Sample*—The weight of sample used for the test shall be the same as that used in the calibration test on the standard sample, with these exceptions: When determining the fineness of Type III or other types of fine-ground portland cement whose bulk for this mass is so great that ordinary thumb pressure will not cause the plunger collar to contact the top of the cell, the weight of the sample shall be that required to produce a test bed having a porosity of 0.530 ± 0.005. When determining the fineness of materials other than portland cement, or if for a portland cement sample one of the required porosities cannot be attained, the mass of the sample shall be adjusted so that a firm, hard bed is produced by the compacting process. In no case, however, shall more than thumb pressure be used to secure the proper bed, nor shall such thumb pressure be used that the plunger "rebounds" from the cell top when pressure is removed.

5.3 *Preparation of Bed of Cement*—Prepare the test bed of cement in accordance with the method described in 4.5.

5.4 *Permeability Tests*—Make the permeability tests in accordance with the method described in 4.6, except that only one time-of-flow determination need be made on each bed.

6. Calculation

6.1 Calculate the specific surface values in accordance with the following equations:

$$S = \frac{S_s\sqrt{T}}{\sqrt{T_s}} \tag{3}$$

$$S = \frac{S_s\sqrt{\eta_s}\sqrt{T}}{\sqrt{T_s}\sqrt{\eta}} \tag{4}$$

$$S = \frac{S_s(b-\epsilon_s)\sqrt{\epsilon^3}\sqrt{T}}{\sqrt{\epsilon_s^3}\sqrt{T_s}(b-\epsilon)} \tag{5}$$

$$S = \frac{S_s(b-\epsilon_s)\sqrt{\epsilon^3}\sqrt{\eta}\sqrt{T}}{\sqrt{\epsilon_s^3}\sqrt{T_s}\sqrt{\eta}(b-\epsilon)} \tag{6}$$

$$S = \frac{S_s\rho_s(b_s-\epsilon_s)\sqrt{\epsilon^3}\sqrt{T}}{\rho(b-\epsilon)\sqrt{\epsilon_s^3}\sqrt{T_s}} \tag{7}$$

$$S = \frac{S_s\rho_s(b_s-\epsilon_s)\sqrt{\eta_s}\sqrt{\epsilon^3}\sqrt{T}}{\rho(b-\epsilon)\sqrt{\epsilon_s^3}\sqrt{T_s}\sqrt{\eta}} \tag{8}$$

where:

S = specific surface of the test sample, m^2/kg,
S_s = specific surface of the standard sample used in calibration of the apparatus, m^2/kg (Note 9),
T = measured time interval, s, of manometer drop for test sample (Note 10),
T_s = measured time interval, s, of manometer drop for standard sample used in calibration of the apparatus (Note 10),
η = viscosity of air, micro pascal seconds (μPa·s), at the temperature of test of the test sample (Note 10),
η_s = viscosity of air, micro pascal seconds (μPa·s), at the temperature of test of the standard sample used in calibration of the apparatus (Note 10),
ϵ = porosity of prepared bed of test sample (Note 10),
$\epsilon\epsilon_s$ = porosity of prepared bed of standard sample used in calibration of apparatus (Note 10),
ρ = density of test sample (for portland cement a value of 3.15 Mg/m^3 or 3.15 g/cm^3 shall be used),
ρ_s = density of standard sample used in calibration of apparatus (assumed to be 3.15 Mg/m^3 or 3.15 g/cm^3),
b = a constant specifically appropriate for the test sample (for hydraulic cement a value of 0.9 shall be used), and
b_s = 0.9, the appropriate constant for the standard sample.

NOTE 9—Upon purchase of SRM 114 series samples, a certificate comes with them that indicates the proper specific surface value.

NOTE 10—Values for $\sqrt{\eta}$, $\sqrt{\epsilon 3}$, and $\sqrt{T}$ may be taken from Tables 1-3, respectively.

0.533	0.389
0.534	0.390
0.535	0.391

6.1.1 Eq 3 and 4 shall be used in calculations of fineness of portland cements compacted to the same porosity as the standard fineness sample. Eq 3 is used if the temperature of test of the test sample is within ± 3 °C of the temperature of calibration test, and Eq 4 is used if the temperature of test of the test sample is outside of this range.

6.1.2 Eq 5 and 6 shall be used in calculation of fineness of portland cements compacted to some porosity other than that of the standard fineness sample used in the calibration test. Eq 5 is used if the temperature of test of the test sample is within ± 3 °C of the temperature of calibration test of the standard fineness sample, and Eq 6 is used if the temperature of test of the test sample is outside of this range.

6.1.3 Eq 7 and 8 shall be used in calculation of fineness of materials other than portland cement. Eq 7 shall be used when the temperature of test of the test sample is within ± 3 °C of the temperature of calibration test, and Eq 8 is used if the temperature of test of the test sample is outside of this range.

6.1.4 It is recommended that values of b be determined on no less than three samples of the material in question. Test each sample at a minimum of four different porosities over a porosity range of at least 0.06. Correlation coefficients should exceed 0.9970 for the correlation of $\sqrt{\epsilon^3 T}$ versus ϵ on each sample tested (see Appendix X1).

6.2 To calculate the specific surface values in square metres per kilogram, multiply the surface area in cm^2/g by the factor of 0.1.

6.3 Round values in cm^2/g to the nearest 10 units (in m^2/kg to the nearest unit). Example: 3447 cm^2/g is rounded to 3450 cm^2/g or 345 m^2/kg.

7. Report

7.1 For portland cements and portland cement-based materials, report results on a single determination on a single bed.

7.2 For very high fineness materials with long time intervals, report the average fineness value of two permeability tests, provided that the two agree within 2 % of each other. If they do not agree, discard the values and repeat the test (Note 11) until two values so agreeing are obtained.

NOTE 11—Lack of agreement indicates a need for checks of procedure and apparatus. See also the "Manual of Cement Testing."

8. Precision and Bias

8.1 *Single-Operator Precision*—The single-operator coefficient of variation for portland cements has been found to be 1.2 % (Note 12). Therefore, results of two properly conducted tests, by the same operator, on the same sample, should not differ by more than 3.4 % (Note 12) of their average.

8.2 *Multilaboratory Precision*—The multilaboratory coefficient of variation for portland cements has been found to be 2.1 % (Note 12). Therefore, results of two different laboratories on identical samples of a material should not differ from each other by more than 6.0 % (Note 12) of their average.

NOTE 12—These numbers represent, respectively, the 1s % and d2s % limits as described in Practice C 670.

8.3 Since there is no accepted reference material suitable for determining any bias that may be associated with Test Method C 204, no statement is being made.

TEST METHOD B: AUTOMATED APPARATUS

9. Apparatus

9.1 The automated test method shall employ apparatus designed either on the principles of the Blaine air-permeability method (See Note 13) or apparatus based on the air-permeability principles of the Lea and Nurse method (See Note 14).

NOTE 13—Automated apparatus is generally equipped with a microprocessor capable of operating the measuring devices, calculating and displaying the test results. Commercially available units may have significantly different dimensions for manometer and cement bed than those specified by standard methods.

NOTE 14—The Lea and Nurse constant flow rate air permeability method is described in BS 4359: 1971.

10. Calibration of Apparatus

10.1 Follow the manufacturer's directions for calibrating the apparatus (See Note 15). If the apparatus is equipped with more than one cell, each cell will require a separate calibration. The manufacturer's procedure shall detail the method for bed preparation and the steps required to initiate the automated measurement. It is essential that the procedure be followed precisely and consistently for all tests.

NOTE 15—The manufacturer of the apparatus will generally provide standard samples that can be used for calibration.

11. Procedure

11.1 *Temperature of Cement*—The cement sample shall be at room temperature when tested.

11.2 *Size of the Test Sample*—The mass of the sample used for the test shall be the same as used in the calibration test unless cements of different density or porosity are to be tested and then follow the manufacturer's guidelines for adjusting mass.

11.3 *Permeability Tests*—Make permeability tests using the same procedure used for the calibration tests. Only one determination need be made for each bed preparation.

12. Performance Requirement (Qualification) for the Automated Apparatus

12.1 *Scope*—When the specific surface values determined by an automated apparatus are to be used for acceptance or rejection of cement, the method used shall comply with the qualification requirements of this section. A method is considered to consist of the specific instrument and testing procedure

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:06:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

meeting the requirements of this standard and used in a consistent manner by a given laboratory.

12.2 *Samples*—Select two cement samples that have surface area and density that bracket the desired test range. The range of the surface area shall not exceed 2000 cm^2/g (200 m^2/kg) and shall have densities that differ no more than 0.06 g/cm^3 (60 Mg/m^3).

12.3 *Tests*—Make triplicate determinations on each cement sample following Test Method A (Reference Method). On the same day, complete a second round of triplicate tests using the method to be qualified (Test Method B) and including the standardization formula described in this section. Prepare a new cell bed and repeat all the steps of the test procedures for each determination. Report values to the nearest 10 cm^2/g (1 m^2/kg).

12.4 *Calculations*—Calculate the range and the mean of the three replicate tests for each method and each cement. A method complies with the qualification requirements if the absolute difference between the average value of Test Method A and the corresponding average value for Test Method B (each with three replicates) is not greater than 2.7 % of the Test Method A average (See Note 16) and the range for any three replicate tests does not exceed 4.0 % of the average (See Note 17). The method is qualified only if both cement samples shall meet the above requirements. Example qualification data are given in Appendix X2.

NOTE 16—This value represents the least-significant-difference (lsd) for 95 % confidence as applied to the coefficient of variation of 1.2 % (Single-Operator-Precision) for Test Method A, given in section 8.1. The equation is:

$$1sd\ (95\ \%) = t_{0.05,\,df}[(2CV^2/n)]^{\frac{1}{2}} \qquad (9)$$

where:

df	=	4, degree of freedom, two from each of the two sets of results
n	=	3, the number of replicates
CV	=	1.2 %, the Single-Operator-Precision, and
$t_{0.05,\,4}$	=	2.776, Students-t statistic for a 5 % probability with a df = 4.

NOTE 17— This value represents the d2s % calculation for 3 replicates in accordance with Table 1 of Practice C 670 and applied to the coefficient of variation of 1.2 % (Single-Operator-Precision) for Test Method A, given in section 8.1.

12.5 *Standardization*:

12.5.1 When standardization is required in order to achieve agreement between Test Method A and Test Method B, standardize the apparatus as follows:

12.5.1.1 Prepare a separate standardization for each type of cement to be tested, using reference samples of density within 0.06 g/cm^3(60 Mg/m^3) of the cement to be tested, and packed to the same bed porosity.

12.5.1.2 For each standardization, obtain five reference samples with a minimum air permeability fineness range of 800 cm^2/g (80 m^2/kg) and a minimum difference between samples of 50 cm^2/g (5 m^2/kg). If cements samples used for qualification are used, make new determinations. Use the same method as used for the instrument qualification and follow all the steps. Valid standardization formulas shall be mathematically derived and applied to all samples.

13. Requalification of a Method

13.1 Requalify the method at least once per year and when any of the following conditions occur:

13.1.1 The instrument has been significantly modified.

13.1.2 The instrument has been substantially repaired.

13.1.3 Substantial evidence indicates that the method is not providing data meeting the performance requirements.

13.1.4 The average of a Cement and Concrete Reference Laboratory (CCRL) proficiency test sample differs from the value obtained by the method by more than 6 %.

14. Precision and Bias

14.1 *Precision*—No precision data are available at this time. Based on qualification requirements, the precision of the method should not be greater than that of Test Method A

14.2 *Bias*—Since there are no acceptable reference materials suitable for determining any bias that may be associated with Test Methods C 204, no statement on bias is presented.

15. Keywords

15.1 air-permeability; apparatus; fineness

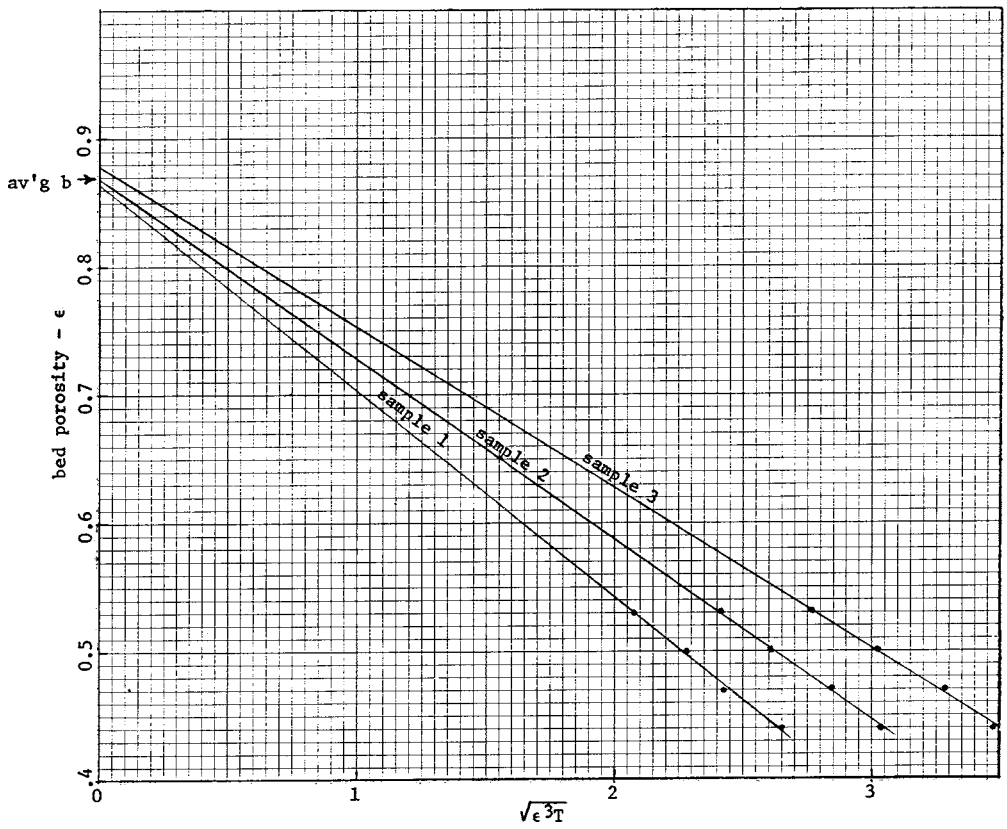
APPENDIXES

(Nonmandatory Information)

X1. ILLUSTRATIVE METHOD FOR THE DETERMINATION OF THE VALUE FOR THE CONSTANT *b*



Material: Silica flour
ρ = density of test sample = 2.65 Mg/m^3
V = bulk volume of sample bed = 1.887 cm^3
ϵ = desired porosity of test
W = grams of sample required = $\rho V(1 - \epsilon)$
T = measured test time interval, seconds

Computed values of b by linear regression:
Sample 1 b = 0.863 (correlation coefficient = 0.9980)
Sample 2 b = 0.869 (correlation coefficient = 0.9993)
Sample 3 b = 0.879 (correlation coefficient = 0.9973)
Average b = 0.870

ϵ	W	T	$\sqrt{\epsilon^3 T}$
		Sample 1	
0.530	2.350	29.0	2.078
0.500	2.500	42.0	2.291
0.470	2.650	57.5	2.443
0.440	2.800	82.5	2.651
		Sample 2	
0.530	2.350	39.0	2.410
0.500	2.500	55.5	2.634
0.470	2.650	79.0	2.864

Designation: C 206 – 03

Standard Specification for Finishing Hydrated Lime[1]

This standard is issued under the fixed designation C 206; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers two types of finishing hydrated lime that are suitable for use in the scratch, brown, and finish coats of plaster, for stucco, for mortar, and as an addition to portland-cement concrete. The two types of lime sold under this specification shall be designated as follows:

1.1.1 *Type N*—Normal hydrated lime for finishing purposes, and

1.1.2 *Type S*—Special hydrated lime for finishing purposes.

NOTE 1—Type N, normal finishing hydrated lime, is differentiated from Type S, special finishing hydrated lime, in that no limitation on the amount of unhydrated oxides is specified for Type N hydrate, and the plasticity requirement for Type N hydrate shall be determined after soaking for 16 to 24 h.

NOTE 2—For lime putty, refer to Specification C 1489.

2. Referenced Documents

2.1 *ASTM Standards:*

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime[2]

C 50 Methods of Sampling, Inspection, Packing, and Marking of Lime and Limestone Products[2]

C 51 Terminology Relating to Lime and Limestone (As Used by the Industry)[2]

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone[2]

C 842 Specification for Application of Interior Gypsum Plaster[2]

C 1489 Specification of Lime Putty for Structural Purposes[2]

3. Terminology

3.1 *Definitions*—For definitions of terms relating to hydrated lime, refer to Terminology C 51.

4. Chemical Composition

4.1 Hydrated lime for finishing purposes shall conform to the following requirements as to chemical composition:

	Type N	Type S
Calcium and magnesium oxides (nonvolatile basis), min, %	95	95
Carbon dioxide (as-received basis), max, %		
If sample is taken at the place of manufacture	5	5
If sample is taken at any other place	7	7
Unhydrated oxides (as-received basis), max, %	...	8

5. Residue

5.1 The percentage residue of finishing hydrated lime shall conform to the following requirements:

Residue retained on No. 30 (600-μm) sieve, max, %	0.5
Residue retained on No. 200 (75-μm) sieve, max, %	15

6. Popping and Pitting

6.1 Finishing hydrated lime shall show no pops or pits when tested in accordance with the method prescribed in 10.1.2.

7. Plasticity

7.1 The putty made from Type N, normal finishing hydrated lime, shall have a plasticity figure of not less than 200 when soaked for a period of not less than 16 h nor more than 24 h.

7.2 The putty made from Type S, special finishing hydrated lime, shall have a plasticity figure of not less than 200 when tested commencing within 30 min after mixing with water.

8. Application of Interior Gypsum Plaster

8.1 For recommended application procedures refer to Specification C 842.

9. Sampling, Inspection, etc.

9.1 The sampling, inspection, rejection, retesting, packing, and marking shall be conducted in accordance with Methods C 50.

10. Test Methods

10.1 The properties enumerated in this specification shall be determined in accordance with the following methods:

10.1.1 *Chemical Analysis*—Test Methods C 25.

10.1.2 *Physical Tests*—Test Methods C 110.

11. Package Marking

11.1 Type N hydrated lime, in bags, conforming to this specification, shall be soaked for a minimum of 16 h prior to use.

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Structural Lime.

Current edition approved May 10, 2003. Published July 2003. Originally approved in 1946. Replaces C 6 – 49 (1974). Last previous edition approved in 1997 as C 206 – 84 (1997).

Designation: C 207 – 06

Standard Specification for Hydrated Lime for Masonry Purposes[1]

This standard is issued under the fixed designation C 207; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers four types of hydrated lime. Types N and S are suitable for use in mortar, in scratch and brown coats of cement plaster, for stucco, and for addition to portland-cement concrete. Types NA and SA are air-entrained hydrated limes that are suitable for use in any of the above uses where the inherent properties of lime and air-entrainment are desired. The four types of lime sold under this specification shall be designated as follows:

1.1.1 *Type N*—Normal hydrated lime for masonry purposes.

1.1.2 *Type S*—Special hydrated lime for masonry purposes.

1.1.3 *Type NA*—Normal air-entraining hydrated lime for masonry purposes.

1.1.4 *Type SA*—Special air-entraining hydrated lime for masonry purposes.

NOTE 1—Type S, special hydrated lime, and Type SA, special air-entraining hydrated lime, are differentiated from Type N, normal hydrated lime, and Type NA, normal air-entraining hydrated lime, principally by their ability to develop high, early plasticity and higher water retentivity, and by a limitation on their unhydrated oxide content.

NOTE 2—For normal (Type N) and special (Type S) finishing hydrated lime, refer to Specification C 206.

NOTE 3—Some building codes prohibit the use of air-entraining materials in mortar, because of the accompanying reduction in bond and compressive strength. Where increased freeze-thaw resistance is important, air-entraining may be beneficial. Air-entraining lime should not be used as a finishing lime.

NOTE 4—For lime putty, refer to Specification C 1489.

1.2 This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

C 206 Specification for Finishing Hydrated Lime

C 226 Specification for Air-Entraining Additions for Use in the Manufacture of Air-Entraining Hydraulic Cement

C 778 Specification for Sand

C 1489 Specification for Lime Putty for Structural Purposes

3. Terminology

3.1 *Definitions:*

3.1.1 *standard mortar*, *n*—a mortar containing only hydrated lime and sand meeting the requirements of Specification C 778. The mortar proportions are one part hydrated lime to three parts of sand by volume as indicated in Table 4 of Test Methods C 110.

4. Additions

4.1 Types NA and SA hydrated lime covered by this specification shall contain additives for the purpose of entraining air, and such additives shall conform to the requirements of Specification C 226.

5. Manufacturer's Statement

5.1 At the request of the purchaser, the manufacturer shall state in writing the nature, amount, and identity of the air-entraining agent used and of any processing addition that may have been used, and also, if requested, shall supply test data showing compliance of such air-entraining addition with the provisions of Specification C 226.

---

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Structural Lime.

Current edition approved Jan. 1, 2006. Published January 2006. Originally approved in 1946. Last previous edition approved in 2005 as C 207 – 05.

6. Chemical Composition

6.1 Hydrated lime for masonry purposes shall conform to the following requirements as to chemical composition:

	Hydrate Types:			
	N	NA	S	SA
Calcium and magnesium oxides (nonvolatile basis), min, %	95	95	95	95
Carbon dioxide (as-received basis), max, %:				
If sample is taken at place of manufacture	5	5	5	5
If sample is taken at any other place	7	7	7	7
Unhydrated oxides (as-received basis), max, %	···	···	8	8

7. Residue, Popping, and Pitting

7.1 The four types of hydrated lime for masonry purposes shall conform to one of the following requirements:

7.1.1 The residue retained on a No. 30 (600-µm) sieve shall not be more than 0.5 %, or

7.1.2 If the residue retained on a No. 30 (600-µm) sieve is over 0.5 %, the lime shall show no pops or pits when tested in accordance with the method prescribed in 12.1.2.

8. Plasticity

8.1 The putty made from Type S, special hydrate, or Type SA, special air-entraining hydrate, shall have a plasticity figure of not less than 200 Elmey units when tested within 30 min after mixing with water using Test Methods C 110.

9. Water Retention

9.1 Hydrated lime mortar made with Type N (normal hydrated lime) or Type NA (normal air-entraining hydrated lime), after suction for 60 s, shall have a water retention value of not less than 75 % when tested in a standard mortar made from the dry hydrate or from putty made from the hydrate which has been soaked for a period of 16 to 24 h.

9.2 Hydrated lime mortar made with Type S (special hydrated lime) or Type SA (special air-entraining hydrated lime), tested in accordance with Section 10 of Test Methods C 110, shall have a water retention value of not less than 85 % when tested in a standard mortar made from the dry hydrate using Test Methods C 110.

10. Air-Entrainment

10.1 The hydrated lime covered by Types N or S in this specification shall contain no additives for the purpose of entraining air. The air content of a standard mortar made with Types N or S shall not exceed 7 % as determined in accordance with the requirements of Section 13 of Test Methods C 110. The air content of standard mortar made with Types NA or SA shall have a minimum of 7 % and a maximum of 12 % when tested in accordance with the requirements of Section 13 of Test Methods C 110.

11. Sampling and Inspection

11.1 The sampling, inspection, rejection, retesting, packaging, and marking shall be conducted in accordance with Practice C 50.

12. Test Methods

12.1 Determine the properties enumerated in this specification in accordance with the following methods:

12.1.1 *Chemical Analysis*— Test Methods C 25.

12.1.2 *Physical Tests*—Test Methods C 110.

13. Special Package Marking

13.1 When Types NA or SA air-entraining hydrated lime are delivered in packages, the name and brand of the manufacturer, the type under this specification, and the words "AIR-ENTRAINING" shall be plainly indicated thereon or in case of bulk shipments, so indicated on shipping notices.

14. Keywords

14.1 hydrated lime; masonry; mortar; plasticity; popping and pitting; residue; stucco; Type N; Type NA; Type S; Type SA; unhydrated oxides; water retention; air entraining

Designation: C 215 – 08

Standard Test Method for Fundamental Transverse, Longitudinal, and Torsional Resonant Frequencies of Concrete Specimens[1]

This standard is issued under the fixed designation C 215; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers measurement of the fundamental transverse, longitudinal, and torsional resonant frequencies of concrete prisms and cylinders for the purpose of calculating dynamic Young's modulus of elasticity, the dynamic modulus of rigidity (sometimes designated as "the modulus of elasticity in shear"), and dynamic Poisson's ratio.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

E 1316 Terminology for Nondestructive Examinations

3. Terminology

3.1 *Definitions*—Refer to Terminology C 125 and the section related to ultrasonic examination in Terminology E 1316 for definitions of terms used in this test method.

4. Summary of Test Method

4.1 The fundamental resonant frequencies are determined using one of two alternative procedures: (*1*) the forced resonance method or (*2*) the impact resonance method. Regardless of which testing procedure is selected, the same procedure is to be used for all specimens of an associated series.

4.2 In the forced resonance method, a supported specimen is forced to vibrate by an electro-mechanical driving unit. The specimen response is monitored by a lightweight pickup unit on the specimen. The driving frequency is varied until the measured specimen response reaches a maximum amplitude. The value of the frequency causing maximum response is the resonant frequency of the specimen. The fundamental frequencies for the three different modes of vibration are obtained by proper location of the driver and the pickup unit.

4.3 In the impact resonance method, a supported specimen is struck with a small impactor and the specimen response is measured by a lightweight accelerometer on the specimen. The output of the accelerometer is recorded. The fundamental frequency of vibration is determined by using digital signal processing methods or counting zero crossings in the recorded waveform. The fundamental frequencies for the three different modes of vibration are obtained by proper location of the impact point and the accelerometer.

5. Significance and Use

5.1 This test method is intended primarily for detecting significant changes in the dynamic modulus of elasticity of laboratory or field test specimens that are undergoing exposure

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.64 on Nondestructive and In-Place Testing.

Current edition approved Oct. 1, 2008. Published November 2008. Originally approved in 1947. Last previous edition approved in 2002 as C 215 – 02.

www.technobetar.ir

to weathering or other types of potentially deteriorating influences. The test method may also be used to monitor the development of dynamic elastic modulus with increasing maturity of test specimens.

5.2 The value of the dynamic modulus of elasticity obtained by this test method will, in general, be greater than the static modulus of elasticity obtained by using Test Method C 469. The difference depends, in part, on the strength level of the concrete.

5.3 The conditions of manufacture, the moisture content, and other characteristics of the test specimens (see section on Test Specimens) materially influence the results obtained.

5.4 Different computed values for the dynamic modulus of elasticity may result from widely different resonant frequencies of specimens of different sizes and shapes of the same concrete. Therefore, it is not advisable to compare results from specimens of different sizes or shapes.

6. Apparatus

6.1 *Forced Resonance Apparatus (Fig. 1)*:

6.1.1 *Driving Circuit*—The driving circuit shall consist of a variable frequency audio oscillator, an amplifier, and a driving unit. The oscillator shall be calibrated to read within ±2 % of the true frequency over the range of use (about 100 to 10 000 Hz). The combined oscillator and amplifier shall be capable of delivering sufficient power output to induce vibrations in the test specimen at frequencies other than the fundamental and shall be provided with a means for controlling the output. The driving unit for creating the vibration in the specimen shall be capable of handling the full power output of the oscillator and amplifier. The driving unit is used in contact with the test specimen or separated from the specimen by an air gap. When the test specimen is contact-driven, the vibrating parts of the driving unit shall be small in mass compared with that of the specimen. The oscillator and amplifier shall be capable of producing a voltage that does not vary more than ±20 % over the frequency range and, in combination with the driving unit, shall be free from spurious resonances that will be indicated in the output.

NOTE 1—It is recommended that the calibration of the variable frequency audio oscillator be checked periodically against signals transmitted by the National Institute of Standards and Technology radio station WWV, or against suitable electronic equipment such as a frequency counter, the calibration of which has been previously checked and found to be adequate.

6.1.2 *Pickup Circuit*—The pickup circuit shall consist of a pickup unit, an amplifier, and an indicator. The pickup unit shall generate a voltage proportional to the displacement, velocity, or acceleration of the test specimen, and the vibrating parts shall be small in mass compared with the mass of the test specimen. The pickup unit shall be free from spurious resonances in the normal operating range. Either a piezoelectric or magnetic pickup unit meeting these requirements is acceptable. The amplifier shall have a controllable output of sufficient magnitude to actuate the indicator. The indicator shall consist of a voltmeter, milliammeter, or a real-time graphic display such as an oscilloscope or a data acquisition system with monitor (see Note 2).

NOTE 2—For routine testing of specimens whose fundamental frequency may be anticipated within reasonable limits, a meter-type indicator is satisfactory and may be more convenient to use than an oscilloscope or computer monitor. It is, however, strongly recommended that whenever feasible a graphic display be provided for supplementary use or to replace the meter-type indicator. The use of a graphic display as an indicator may be necessary when specimens are to be tested for which the fundamental frequency range is unpredictable. The graphic display is valuable also for checking the equipment for drift and for use in the event that it should be desired to use the equipment for certain other purposes than those specifically contemplated by this test method.

6.1.3 *Specimen Support*—The support shall permit the specimen to vibrate freely (Note 3). The location of the nodal points for the different modes of vibration are described in Notes 4, 5, and 6. The support system shall be dimensioned so that its resonant frequency falls outside the range of use (from 100 to 10 000 Hz).

NOTE 3—This may be accomplished by placing the specimen on soft rubber supports located near the nodal points or on a thick pad of sponge rubber.

6.2 *Impact Resonance Apparatus (Fig. 2)*:

6.2.1 *Impactor*—The impactor shall be made of metal or rigid plastic and shall produce an impact duration that is sufficiently short to excite the highest resonant frequency to be measured. The manufacturer shall indicate the maximum resonant frequency that can be excited when the impactor strikes a concrete specimen with surfaces formed by a metal or plastic mold.

NOTE 4—A 19 mm diameter solid steel ball mounted on a thin rod to produce a hammer is capable of exciting resonant frequencies up to about 10 kHz when impacting a smooth concrete surface. A 110 g steel ball peen hammer may act similarly. Larger steel balls will reduce the maximum

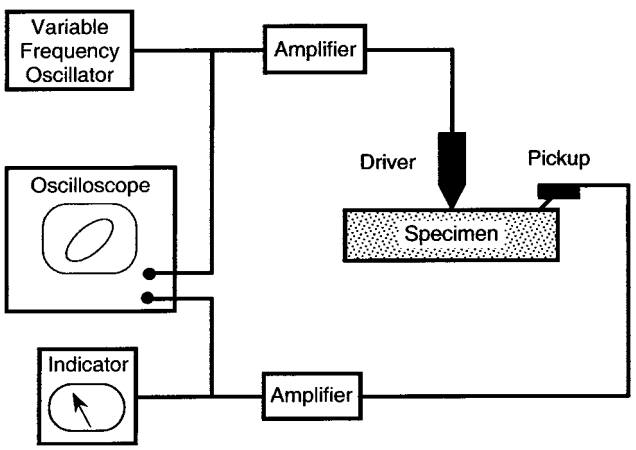

FIG. 1 Schematic of Apparatus for Forced Resonance Test

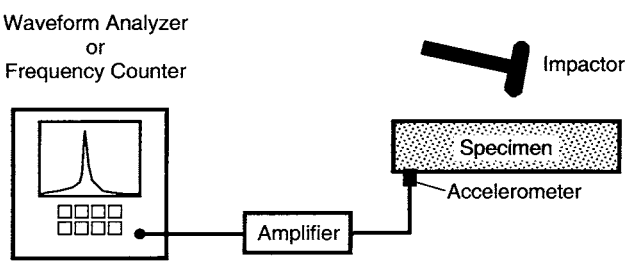

FIG. 2 Schematic of Apparatus for Impact Resonance Test

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

resonant frequencies that can be excited.

6.2.2 *Sensor*—The sensor shall be a piezoelectric accelerometer with a mass less than 30 g and having an operating frequency range from 100 to 10 000 Hz. The resonant frequency of the accelerometer shall be at least two times the maximum operating frequency.

6.2.3 *Frequency Analyzer*—Determine the frequency of the specimen vibration by using either a digital waveform analyzer or a frequency counter to analyze the signal measured by the sensor. The waveform analyzer shall have a sampling rate of at least 20 kHz and shall record at least 1024 points of the waveform. The frequency counter shall have an accuracy of ±1 % over the range of use.

6.2.4 *Specimen Support*—Support shall be provided as specified in 6.1.3 for the forced resonance method.

7. Test Specimens

7.1 *Preparation*—Make the cylindrical or prismatic test specimens in accordance with Practice C 192/C 192M, Practice C 31/C 31M, Test Method C 42/C 42M, or other specified procedures.

7.2 *Measurement of Mass and Dimensions*—Determine the mass and average length of the specimens within ±0.5 %. Determine the average cross-sectional dimensions within ±1 %.

7.3 *Limitations on Dimensional Ratio*—Specimens having either small or large ratios of length to maximum transverse direction are frequently difficult to excite in the fundamental mode of vibration. Best results are obtained when this ratio is between 3 and 5. For application of the formulas in this test method, the ratio must be at least 2.

8. Determination of Resonant Frequencies—Forced Resonance Method

8.1 *Transverse Frequency*:

8.1.1 Support the specimen so that it is able to vibrate freely in the transverse mode (Note 5). Position the specimen and driver so that the driving force is perpendicular to the surface of the specimen. Locate the driving unit at the approximate middle of the specimen. Place the pickup unit on the specimen so that the direction of pickup sensitivity coincides with the vibration direction, that is, the transverse direction (see Fig. 3a). Position the pickup near one end of the specimen. It is permissible to position the driver on the vertical face so that the specimen vibrates perpendicular to the direction shown in Fig. 3a.

8.1.2 Force the test specimen to vibrate at varying frequencies. At the same time, observe the indication of the amplified output of the pickup. Record the fundamental transverse frequency of the specimen, which is the frequency at which the indicator shows the maximum reading and observation of nodal points indicates fundamental transverse vibration (Note 5). Adjust the amplifiers in the driving and pickup circuits to

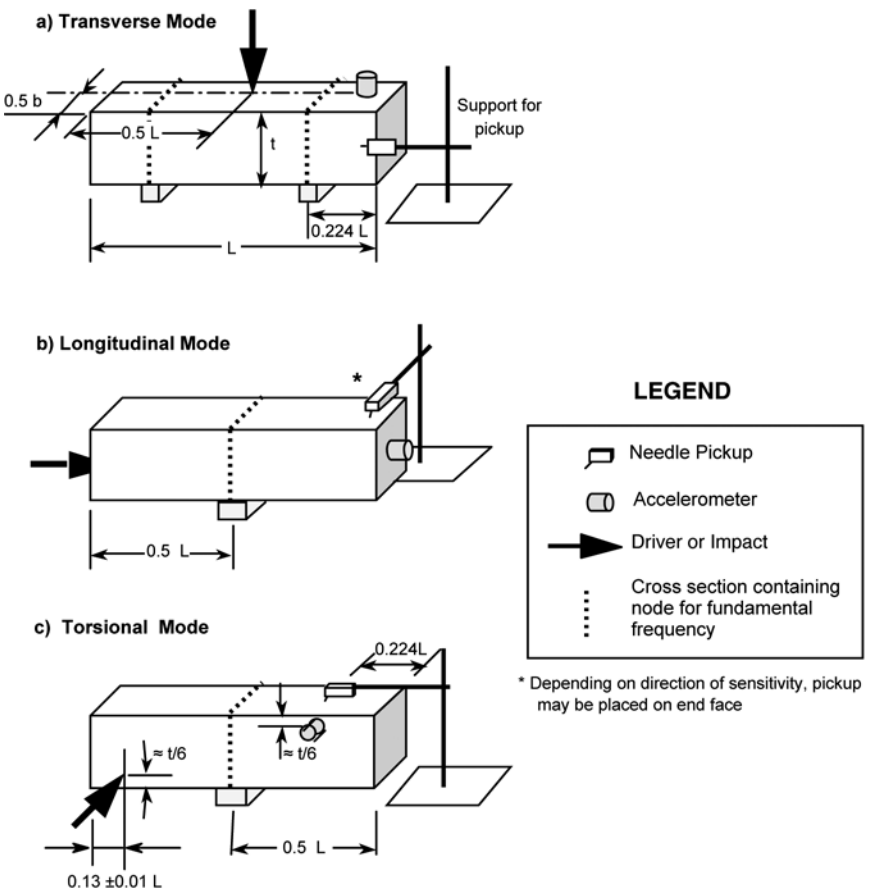

FIG. 3 Locations of Driver (or Impact) and Needle Pickup (or Accelerometer)

www.technobetar.ir

provide a satisfactory indication. To avoid distortion, maintain the driving force as low as is feasible for good response at resonance.

NOTE 5—For fundamental transverse vibration, the nodal points are located 0.224 of the length of the specimen from each end (approximately the quarter points). Vibrations are a maximum at the ends, approximately three fifths of the maximum at the center, and zero at the nodal points; therefore, movement of the pickup along the length of the specimen will inform the operator whether the vibrations observed in the indicator are from the specimen vibrating in its fundamental transverse mode. An oscilloscope may also be used to determine whether the specimen is vibrating in its fundamental transverse mode. The driver signal is connected to the horizontal sweep and the pickup signal is connected to the vertical sweep of the oscilloscope. When the pickup is located at the end of the specimen, which is vibrating in its fundamental transverse mode, the oscilloscope will display an inclined elliptical pattern. When the pickup is placed at a node, the oscilloscope displays a horizontal line. When the pickup is placed at the center of the specimen, the display will be an elliptical pattern but inclined in the opposite direction to when the pickup was placed at the end of the specimen. The oscilloscope can also be used to verify that the driving frequency is the fundamental resonant frequency. Resonance can occur when the driving frequency is a fraction of the fundamental frequency. In this case, however, the oscilloscope pattern will not be an ellipse.

8.2 *Longitudinal Frequency*:

8.2.1 Support the specimen so that it is able to vibrate freely in the longitudinal mode (Note 6). Position the specimen and driver so that the driving force is perpendicular to and approximately at the center of one end surface of the specimen. Place the pickup unit on the specimen so that the direction of pickup sensitivity coincides with the vibration direction, that is, the longitudinal axis of the specimen (see Fig. 3b).

8.2.2 Force the test specimen to vibrate at varying frequencies. At the same time, observe the indication of the amplified output of the pickup. Record the fundamental longitudinal frequency of the specimen, which is the frequency at which the indicator shows the maximum reading and observation of the nodal point indicates fundamental longitudinal vibration (Note 6).

NOTE 6—For the fundamental longitudinal mode, there is one node at the center of length of the specimen. Vibrations are a maximum at the ends.

8.3 *Torsional Frequency*:

8.3.1 Support the specimen so that it is able to vibrate freely in the torsional mode (Note 7). Position the specimen and driver so that the driving force is perpendicular to the surface of the specimen. For prismatic specimens, locate the driving unit near the upper or lower edge of the specimen at a distance from the end that is 0.13 ± 0.01 of the length of the specimen and approximately ⅙ of the depth of the specimen from the edge (see Fig. 3c). For cylindrical specimens, locate the driving unit above or below the mid-line of the cylinder. Place the pickup unit on the surface of the specimen at a position on the opposite end that coincides with the node point for fundamental transverse vibration (see Fig. 3a). Position the pickup so that the direction of pickup sensitivity coincides with the vibration direction, that is, perpendicular to the longitudinal axis of the specimen.

8.3.2 Force the test specimen to vibrate at varying frequencies. At the same time, observe the indication of the amplified output of the pickup. Record the fundamental torsional frequency of the specimen, which is the frequency at which the indicator shows the maximum reading and observation of the nodal point indicates fundamental torsional vibration (Note 7).

NOTE 7—For the fundamental torsional mode, there is one node at the center of the specimen. Vibrations are maximum at the ends. Locating the driving unit and pickup as shown in Fig. 3c minimizes interferences from transverse vibrations that can occur simultaneously with torsional vibration.

9. Determination of Resonant Frequencies—Impact Resonance Method

9.1 *Transverse Frequency*:

9.1.1 Support the specimen so that it is able to vibrate freely in the transverse mode (Note 5). Attach the accelerometer near the end of the specimen as shown in Fig. 3a.

NOTE 8—The accelerometer may be attached to the specimen using soft wax or other suitable materials, such as glue or grease. If the specimen is wet, an air jet may be used to surface dry the region where the accelerometer is to be attached. Alternatively, the accelerometer may be held in position with a rubber band, but a coupling material should still be used to ensure good contact with the specimen.

9.1.2 Prepare the waveform analyzer or frequency counter for recording data. Set the digital waveform analyzer to a sampling rate of 20 kHz (Note 9) and a record length of 1024 points. Use the accelerometer signal to trigger data acquisition. Using the impactor, strike the specimen perpendicular to the surface and at the approximate middle of the specimen.

NOTE 9—The sampling frequency must be at least twice the resonant frequency of the specimen. A sampling frequency of 20 kHz is applicable to specimens with a resonant frequency less than 10 kHz, which is typical of the usual laboratory specimens. When higher resonant frequencies are involved, increase the sampling frequency accordingly.

9.1.3 Record the resonant frequency indicated by the waveform analyzer (Note 10) or frequency counter. Repeat the test two more times, and record the average transverse resonant frequency. If a frequency measurement deviates from the average value by more than 10 %, disregard that measurement and repeat the test. When using a frequency counter based on zero crossings, delay the start of recording until approximately the first 10 cycles of transverse vibration have occurred (Note 11).

NOTE 10—When using a waveform analyzer, the resonant frequency is the frequency with the highest peak in the amplitude spectrum or the power spectrum obtained from the fast Fourier transform of the recorded accelerometer signal. The fundamental resonant frequency can be verified by impacting the specimen at one of the nodal points. The amplitude spectrum should show a small or no peak at the value of the fundamental frequency.

NOTE 11—Care should be exercised when using a test instrument based on the zero-crossing method to evaluate the resonant frequency of a specimen that is undergoing degradation, such as by cycles of freezing and thawing. As the specimen degrades, the damping value increases and the amplitude of vibration after impact decays more rapidly compared with an undamaged specimen. For accurate determination of frequency, the duration of the sampling time must be compatible with the decay time of the specimen. In addition, a lower number of cycles of delay prior to starting the sampling record may be acceptable.

9.2 *Longitudinal Frequency*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:07:05 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.2.1 Support the specimen so that it is able to vibrate freely in the longitudinal mode (Note 6). Attach the accelerometer (Note 8) at the approximate center of one end surface of the specimen as shown in Fig. 3b.

9.2.2 Prepare the waveform analyzer or frequency counter for recording data. Set the digital waveform analyzer to a sampling rate of 20 kHz (Note 10) and a record length of 1024 points. Use the accelerometer signal to trigger data acquisition. Using the impactor, strike the specimen perpendicular to and at the approximate center of the end surface without the accelerometer.

9.2.3 Record the resonant frequency indicated by the waveform analyzer (Note 10) or frequency counter. Repeat the test two more times, and record the average longitudinal resonant frequency. If a frequency measurement deviates from the average value by more than 10 %, disregard that measurement and repeat the test. When using a frequency counter based on zero crossings, delay the start of recording until approximately the first 30 cycles of longitudinal vibration have occurred, and ensure a perpendicular impact with the surface (Note 11).

9.3 *Torsional Frequency*:

9.3.1 Support the specimen so that it is able to vibrate freely in the torsional mode (Note 7). For a prismatic specimen, attach the accelerometer near an edge of the specimen at a cross section that contains a node point for fundamental transverse vibration as shown in Fig. 3c. For a cylindrical specimen, mount the accelerometer so that its direction of sensitivity is tangential to a circular cross section that contains a node point for fundamental transverse vibration.

NOTE 12—One approach is to attach the accelerometer to a tab glued to the cylinder as shown in Fig. 4.

9.3.2 Prepare the waveform analyzer or frequency counter for recording data. Set the digital waveform analyzer to a sampling rate of 20 kHz (Note 10) and a record length of 1024 points. Use the accelerometer signal to trigger data acquisition. For prismatic specimens, strike the specimen with the impactor at a point near the upper or lower edge of the specimen at a distance from the end that is 0.13 ± 0.01 of the length of the specimen and approximately 1⁄6 of the depth of the specimen from the edge (see Fig. 3c). For cylindrical specimens, strike the specimen tangentially to the surface at a similar distance from the end as shown in Fig. 4.

9.3.3 Record the resonant frequency indicated by the waveform analyzer (Note 10) or frequency counter. Repeat the test two more times, and record the average torsional resonant frequency. If a frequency measurement deviates from the average value by more than 10 %, disregard that measurement and repeat the test. When using a frequency counter based on zero crossings, delay the start of recording until approximately the first 10 cycles of torsional vibration have occurred (Note 11).

10. Calculation

10.1 Calculate dynamic Young's modulus of elasticity, E, in pascals from the fundamental transverse frequency, mass, and dimensions of the test specimen as follows:

$$\text{Dynamic } E = CMn^2 \quad (1)$$

where:

M = mass of specimen, kg,
n = fundamental transverse frequency, Hz,
C = $1.6067\ (L^3T/d^4)$, m^{-1} for a cylinder, or
= $0.9464\ (L^3T/bt^3)$, m^{-1} for a prism,
L = length of specimen, m,
d = diameter of cylinder, m,
t, b = dimensions of cross section of prism, m, t being in the direction in which it is driven, and
T = correction factor that depends on the ratio of the radius of gyration, K (the radius of gyration for a cylinder is $d/4$ and for a prism is $t/3.464$), to the length of the specimen, L, and on Poisson's ratio. Table 1 gives values of T for various values of K/L and Poisson's ratio.

10.2 Calculate dynamic Young's modulus of elasticity, E, in pascals from the fundamental longitudinal frequency, mass, and dimensions of the test specimen as follows:

TABLE 1 Values of Correction Factor, *T*

K/L	Value of T^A			
	μ = 0.17	μ = 0.20	μ = 0.23	μ = 0.26
0.00	1.00	1.00	1.00	1.00
0.01	1.01	1.01	1.01	1.01
0.02	1.03	1.03	1.03	1.03
0.03	1.07	1.07	1.07	1.07
0.04	1.13	1.13	1.13	1.14
0.05	1.20	1.20	1.21	1.21
0.06	1.28	1.28	1.29	1.29
0.07	1.38	1.38	1.39	1.39
0.08	1.48	1.49	1.49	1.50
0.09	1.60	1.61	1.61	1.62
0.10	1.73	1.74	1.75	1.76
0.12	2.03	2.04	2.05	2.07
0.14	2.36	2.38	2.39	2.41
0.16	2.73	2.75	2.77	2.80
0.18	3.14	3.17	3.19	3.22
0.20	3.58	3.61	3.65	3.69
0.25	4.78	4.84	4.89	4.96
0.30	6.07	6.15	6.24	6.34

[A]Values of *T* for Poisson's ratio of 0.17 are derived from Fig. 1 of the paper by Gerald Pickett, "Equations for Computing Elastic Constants from Flexural and Torsional Resonant Frequencies of Vibration of Prisms and Cylinders," *Proceedings*, ASTEA, Am. Soc. Testing Mats., Vol 45, 1945, pp. 846–863.

Poisson's ratio for water-saturated concrete may be higher than 0.17. The correction factor, *T′*, for other values of Poisson's ratio, μ, and given *K/L*, are calculated from the following relationship:

$$T' = T\left[\frac{1 + (0.26\mu + 3.22\mu^2)K/L}{1 + 0.1328\ K/L}\right]$$

where *T* is the value for μ = 0.17 shown in the second column of Table 1 for the given *K/L*.

$$\text{Dynamic } E = DM(n')^2 \tag{2}$$

where:

n' = fundamental longitudinal frequency, Hz, and
D = 5.093 (L/d^2), m^{-1} for a cylinder, or
= 4 (L/bt), m^{-1} for a prism.

10.3 Calculate dynamic modulus of rigidity, *G*, in pascals from the fundamental torsional frequency, mass, and dimensions of the test specimen as follows:

$$\text{Dynamic } G = BM(n'')^2 \tag{3}$$

where:

n'' = fundamental torsional frequency, Hz,
B = $(4LR/A)$, m^{-1},
R = shape factor,
= 1 for a circular cylinder,
= 1.183 for a square cross-section prism,
= $(a/b + b/a)/[4a/b - 2.52(a/b)^2 + 0.21(a/b)^6]$ for a rectangular prism whose cross-sectional dimensions are *a* and *b*, m, with *a* less than *b*, and
A = cross-sectional area of test specimen, m^2.

10.4 Calculate the dynamic Poisson's ratio, the ratio of lateral to longitudinal strain for an isotropic solid, μ, as follows:

$$\mu = (E/2G) - 1 \tag{4}$$

NOTE 13—Values for Poisson's ratio for concrete normally vary between about 0.10 for dry specimens and 0.25 for saturated specimens. Higher values are expected for concrete tested at early ages.

11. Report

11.1 Report the following for each specimen:
11.1.1 Identification number,
11.1.2 Cross-sectional dimensions within 0.1 %,
11.1.3 Length within 0.5 %,
11.1.4 Mass within 0.5 %,
11.1.5 Description of any defects that were present, and
11.1.6 Mode of vibration and corresponding resonant frequency to the nearest 10 Hz.

11.2 If the dynamic Young's modulus of elasticity or dynamic modulus of rigidity are calculated, report to the nearest 0.5 GPa.

11.3 If the dynamic Poisson's ratio is calculated, report to the nearest 0.01.

12. Precision and Bias

12.1 The data used to develop the precision statements were obtained using an earlier inch-pound version of this test method.

12.2 *Precision of Forced Resonance Method*—The following precision statements are for fundamental transverse frequency only, determined on concrete prisms as originally cast. They do not necessarily apply to concrete prisms after they have been subjected to freezing-and-thawing tests. At the present time, data appropriate for determining precision of fundamental torsional and longitudinal frequencies are not available.

12.2.1 *Single-Operator Precision*—Criteria for judging the acceptability of measurements of fundamental transverse frequency obtained by a single operator in a single laboratory on concrete specimens made from the same materials and subjected to the same conditions are given in Table 2. These limits apply over the range of fundamental transverse frequency from 1400 to 3300 Hz. The different specimen sizes represented by the data include the following (the first dimension is the direction of vibration):

76 by 102 by 406 mm
102 by 76 by 406 mm
89 by 114 by 406 mm
76 by 76 by 286 mm
102 by 89 by 406 mm
76 by 76 by 413 mm

NOTE 14—The coefficients of variation for fundamental transverse frequency have been found to be relatively constant over the range of frequencies given for a range of specimen sizes and age or condition of the concrete, within limits.

TABLE 2 Test Results for Single Operator in a Single Laboratory

	Coefficient of Variation, %[A]	Acceptable Range of Two Results, % of Average[A]
Within-batch single specimen	1.0	2.8
Within-batch average of 3 specimens[B]	0.6	1.7
Between-batch, average of 3 specimens per batch	1.0	2.8

[A]These numbers represent, respectively, the 1s % and d2s % limits as described in Practice C 670.
[B]Calculated as described in Practice C 670.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

12.2.2 *Multilaboratory Precision*—The multilaboratory coefficient of variation for averages of three specimens from a single batch of concrete has been found to be 3.9 % for fundamental transverse frequencies over the range from 1400 to 3300 Hz (Note 15). Therefore, two averages of three specimens from the same batch tested in different laboratories should not differ by more than 11.0 % of their common average (see Note 15).

NOTE 15—These numbers represent, respectively, the 1s % and d2s % limits as described in Practice C 670.

12.3 *Precision of Impact Resonance Method*—The precision of this test method has yet to be determined. Experience, however, has shown that, when a frequency analyzer is used, replicate tests on the same specimen result in resonant frequency values that are within ± 1 digital step of each other (Note 16).

NOTE 16—The digital step in the amplitude spectrum equals the sampling frequency divided by number of points in the time domain waveform. For example, for a sampling frequency of 20 kHz (50-μs sample interval) and 1024 points in the waveform, the digital step is 20 000/1024 = 19.5 Hz.

12.4 *Bias*—The bias of either the forced resonance method or the impact resonance method has not been determined because there are no reference samples available.

13. Keywords

13.1 dynamic modulus of rigidity; dynamic Poisson's ratio; dynamic Young's modulus of elasticity; forced resonance; fundamental resonant frequency; impact resonance; nondestructive testing

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 215 – 02, that may impact the use of this test method. (Approved October 1, 2008)

(*1*) Simplified the units for the factors B, C, and D.
(*2*) Clarified that the values of *T* in Table 1 are for different values of Poisson's ratio in 10.1.
(*3*) Added the adjective "dynamic" in 10.4 and deleted 10.4.1.
(*4*) Revised the requirement of a suitable impactor in 6.2.1 so that it is performance based and added a requirement that the manufacturer needs to indicate the maximum resonant frequency that can be excited by the impactor.
(*5*) Added new Note 4 to illustrate an example of a suitable impactor.
(*6*) Revised 8.3.1, 9.3.2, and Fig. 3 to indicate that the point of excitation for the torsional mode should be near an edge of a prismatic specimen.
(*7*) Moved the last sentence of 9.3.1 into new Note 12.
(*8*) Revised 5.1 by adding that the test method can be used to monitor the development of elastic modulus.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 219 – 07a

Standard Terminology Relating to Hydraulic Cement[1]

This standard is issued under the fixed designation C 219; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This terminology defines terms relating to hydraulic cements, their components, characteristics, properties, and the testing thereof. Some terms may have wider application than just to hydraulic cement.

1.2 See individual standards for terms applicable primarily therein, including meanings that may be more restrictive than those given here, and for explanations and descriptions of terms as they apply to those standards.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 294 Descriptive Nomenclature for Constituents of Concrete Aggregates

C 1328 Specification for Plastic (Stucco) Cement

C 1329 Specification for Mortar Cement

2.2 *ACI Standard:*

ACI 116R Cement and Concrete Terminology[3]

3. Significance and Use

3.1 In definitions of cements, ingredients are cited only when they are inherent to the definition, for example portland-pozzolan cement. For ingredients and their quantity limits, if any, that are permitted or prohibited by a specification for a particular cement, see the applicable specification for that cement.

3.2 In definitions of materials including cements, the method of production is included only if it is inherent to the definition.

3.3 Related terms may be found in other terminology documents such as Terminology C 11, Terminology C 51, Terminology C 125, and ACI 116R.

4. Terminology

addition, *n*—a material that is interground or blended in limited amounts into a hydraulic cement during manufacture.

DISCUSSION—Two classes of additions are recognized as defined below.

functional addition, *n*—an addition introduced to modify one or more properties of a hydraulic cement.

air-entraining addition, *n*—a functional addition that will entrain air in mortar or concrete.

processing addition, *n*—an addition introduced to aid in the manufacture or handling, or both, of a hydraulic cement.

air-entraining addition, *n*—see **addition; functional addition; air-entraining addition**

air content, *n*—of freshly mixed mortar the volume of air (and other gases) in mortar, expressed as a percentage of total volume of mortar.

air-entraining hydraulic cement, *n*—a hydraulic cement containing an air-entraining addition in such amount as to cause air to be entrained in mortar within specified limits when measured by the prescribed method.

alkali equivalent, *n*—deprecated term; see **equivalent alkalies**.

aluminous cement, *n*—deprecated term.

anhydrite, *n*—see **calcium sulfate**.

blast-furnace slag, *n*—the nonmetallic product, consisting essentially of silicates and aluminosilicates of calcium and other bases, that is developed in a molten condition simultaneously with iron in a blast furnace.

blended hydraulic cement, *n*—a hydraulic cement consisting of two or more inorganic constituents (at least one of which

[1] This terminology is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.91 on Terminology.

Current edition approved Dec. 1, 2007. Published December 2007. Originally approved in 1948. Last previous edition approved in 2007 as C 219 – 07.

www.technobetar.ir

is not portland cement or portland cement clinker) which separately or in combination contribute to the strength-gaining properties of the cement, (made with or without other constituents, processing additions and functional additions, by intergrinding or other blending).

portland blast-furnace slag cement, n—a hydraulic cement consisting of an intimately interground mixture of portland cement clinker and granulated blast-furnace slag or an intimate and uniform blend of portland cement and fine granulated blast-furnace slag in which the amount of the slag constituent is within specified limits.

portland-pozzolan cement, n—a hydraulic cement consisting of an intimate and uniform blend of portland cement or portland blast-furnace slag cement and fine pozzolan produced by intergrinding portland cement clinker and pozzolan, by blending portland cement or portland blast-furnace slag cement and finely divided pozzolan, or a combination of intergrinding and blending, in which the amount of the pozzolan constituent is within specified limits.

blending, *n—in hydraulic cement manufacture,* a process in which two or more ingredients are combined into an intimate and uniform product of finely divided dry material, as by intergrinding or mixing, or both.

calcium sulfate, *n*—in cement manufacture, a material composed essentially of calcium sulfate in one or more of its hydration states: **anhydrite** ($CaSO_4$), **gypsum** ($CaSO_4 \cdot 2H_2O$), or **calcium sulfate hemihydrate** ($CaSO_4 \cdot ½ H_2O$).

cementitious material, (*hydraulic***),** *n*—an inorganic material or a mixture of inorganic materials that sets and develops strength by chemical reaction with water by formation of hydrates and that is capable of doing so underwater.

cement paste, *n*—an unhardened or hardened mixture of finely divided hydraulic cementious material and water.

early stiffening, *n*—rapid loss of plasticity or rapid development of rigidity in freshly mixed hydraulic cement paste, mortar, or concrete.

false set, n—with little evolution of heat, which can be dispelled by further mixing without the addition of water.

flash set, n—with evolution of considerable heat, which cannot be dispelled by further mixing without the addition of water.

equivalent alkalies, Na_2Oeq**,** *n—in hydraulic cement*, the total of sodium and potassium oxides as calculated from the chemical analysis, and using the formula:
$Na_2Oeq = \% Na_2O + 0.658 \times \% K_2O$.

DISCUSSION—Used to indicate the levels of alkalies in a material when only Na_2O and K_2O are considered. The value, 0.658, is the molecular ratio of Na_2O to K_2O. Alkali equivalent, soda equivalent, and sodium equivalent are deprecated terms.

expansive hydraulic cement, *n*—a hydraulic cement that forms a paste when mixed with water, and increases in volume a controlled amount during the early hardening period occurring after setting.

DISCUSSION—Expansive hydraulic cements are used to compensate for volume decrease due to shrinkage or to induce tensile stress in concrete reinforcement.

false set—see **early stiffening**

flash set—see **early stiffening**

fog room, *n*—a moist room in which the humidity is controlled by atomization of water.

gage length, *n—in cement testing*, the nominal length between the innermost ends of metal studs that are molded into a test specimen with the axis of the stud in each end of the test specimen coincident with the longitudinal axis of the test specimen and with each other.

granulated blast-furnace slag, *n*—the glassy, granular material formed when molten blast-furnace slag is rapidly chilled, as by immersion in water.

gypsum, *n*—see **calcium sulfate**.

hydration, *n*—the chemical reaction between hydraulic cement and water forming new compounds most of which have strength-producing properties.

hydraulic cement, *n*—a cement that sets and hardens by chemical reaction with water and is capable of doing so under water.

hydraulic mortar, *n*—deprecated term; see mortar.

length change, *n—in cement testing*, an increase or decrease in linear dimension due to causes other than applied load, usually measured along the longitudinal axis of a test specimen and expressed as a percentage of a gage length.

lime-saturated water, *n—for curing test specimens*, water containing calcium hydroxide at saturation and in contact with solid calcium hydroxide so that saturation is maintained.

lot, *n*—a quantity of a single material that is considered as a unit, such as that manufactured during a single production run, offered at one time for sale, or offered at one time for inspection, or the contents of one or more transport containers drawn from one or more bins of material from a single production run, sequentially packaged from one or more bins, or a group of samples secured from one of the above.

masonry cement, *n*—a hydraulic cement manufactured for use in mortars for masonry construction or in plasters, or both, which contains a plasticizing material and, possibly, other performance-enhancing addition(s).

moist room, *n*—an enclosed room for storage and curing of paste, mortar, and concrete specimens in which temperature and high relative humidity can be controlled within specified limits.

mortar, *n*—a mixture of finely divided hydraulic cementitious material, fine aggregate, and water in either the unhardened or hardened state; hydraulic mortar.

mortar cement, *n*—a hydraulic cement manufactured for use in masonry mortar designed for specific bond and air content criteria.

DISCUSSION—Mortar cement is similar to masonry cement but must meet bond strength and air content criteria. See Specification C 1329 for limitations.

natural cement, *n*—a hydraulic cement produced by calcining a naturally occurring argillaceous limestone at a temperature below the sintering point and then grinding to a fine powder.

DISCUSSION—Argillaceous limestone is described in Standard C 294.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

normal consistency, *n*—a degree of plasticity of a hydraulic-cement paste that is appropriate for testing as measured by a stipulated method.

DISCUSSION—The result of tests for normal consistency is reported as the mass of water required to achieve this plasticity divided by the mass of hydraulic cement, expressed as a percentage.

plaster, *n*—*hydraulic cement,* a mixture of hydraulic cement, fine aggregate and water that hardens; used for coating surfaces, such as ceilings, walls and partitions.

plastic cement, *n*—a hydraulic cement used in plaster or stucco.

DISCUSSION—See Specification C 1328 for limitations on materials or properties pertaining to cement under that specification.

portland cement, *n*—a hydraulic cement produced by pulverizing clinker, consisting essentially of crystalline hydraulic calcium silicates, and usually containing one or more of the following: water, calcium sulfate, up to 5 % limestone, and processing additions.

portland-cement clinker, *n*—a clinker, partially fused by pyroprocessing, consisting predominantly of crystalline hydraulic calcium silicates.

pozzolan, *n*—a siliceous or siliceous and aluminous material, which in itself possesses little or no cementitious value but will, in finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form cementitious hydrates.

saturated-lime water, *n*—see **lime-saturated water**.

slag cement, *n*—a hydraulic cement consisting predominantly of ground, granulated blast-furnace slag.

stucco, *n*—a hydraulic cement plaster containing fine aggregate, used for coating exterior surfaces.

5. Keywords

5.1 cement terminology; definitions; hydraulic cement terminology; terminology; terms

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this terminology since the last issue, C 219 – 07, that may impact the use of this terminology. (Approved December 1, 2007)

(*1*) Revised the term **lime-saturated water**.

Committee C01 has identified the location of selected changes to this terminology since the last issue, C 219 – 03$^{\epsilon 1}$, that may impact the use of this terminology. (Approved February 1, 2007)

(*1*) Revised the term **equivalent alkalies**.

(*2*) Revised the term **portland cement**.

Designation: C 226 – 07

Standard Specification for Air-Entraining Additions for Use in the Manufacture of Air-Entraining Hydraulic Cement[1]

This standard is issued under the fixed designation C 226; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers the requirements and methods for establishing the suitability of a material for use as an air-entraining addition to be interground with the clinker in the manufacture of air-entraining hydraulic cement conforming to Specifications C 150, C 595, and C 1157.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. (***Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2.2 *ACI Standards:*[5]

ACI 211.1-77 Recommended Practice for Selecting Proportions for Normal and Heavyweight Concrete

3. Materials

3.1 *Cements*:

3.1.1 In cases where it is desired that the proposed air-entraining addition be accepted for general use in portland cement, tests shall be made on six lots of cement ground at cement plants, using commercial grinding equipment. From each of three different samples of clinkers, two lots of cement shall be ground, representing respectively: a Type I portland cement containing not less than 9 % tricalcium aluminate

[1] This specification is under the jurisdiction of ASTM Commitee C01 on Cement and is the direct responsibility of Subcommittee C01.20 on Additions.

Current edition approved June 1, 2007. Published July 2007. Originally approved in 1950. Last previous edition approved in 2002 as C 226 – 02.

www.technobetar.ir

(C_3A), calculated as specified in Table 1 of Specification C 150 and a Type II and a Type III portland cement all conforming to Specification C 150. One lot, the "control" shall be ground without the proposed air-entraining addition; the proposed addition shall be interground with the other lot, using the addition in such amounts as to produce the air/entrainment required in Specification C 150. Not more than two of the three clinkers shall be produced by or ground at the same mill.

3.1.2 In cases where it is desired that the proposed air-entraining addition be limited in use to specific types of cement in specific cement manufacturing plants, either or both less in number than required in 3.1.1, the tests and test procedure shall be as specified in 3.1.1, except that the number of cements to be tested shall be limited to those under specific consideration.

3.1.3 The two companion cements made from any one clinker shall be ground to the same fineness (within 5 m^2/kg when tested in accordance with Test Method C 115) as measured by the turbidimeter test (7.1.3) or (within 10 m^2/kg when tested in accordance with Test Method C 204) as measured by the air permeability apparatus, and the sulfur trioxide (SO_3) content expressed as a percentage of the cement weight and reported to the nearest 0.01 %, shall differ by no more than 0.3 for all types of cement. Each "control" cement shall comply with all of the requirements in the specification applicable to that type of cement, and shall not contain the proposed addition when tested by the method furnished by the producer or seller of the addition.

3.1.4 The percentage of each of the following constituents shall be determined for each lot of cement tested: silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), iron oxide (Fe_2O_3), calcium oxide (CaO), magnesium oxide (MgO), SO_3, ignition loss, insoluble residue, sodium oxide (Na_2O), and potassium oxide (K_2O). There shall also be calculated the potential percentages of the following compounds: tricalcium silicate, dicalcium silicate, tricalcium aluminate, and tetracalcium aluminoferrite. Determinations for the percentage of addition shall be made on the cements containing the addition, using the method proposed therefore by the maker or seller of the addition.

3.2 *Aggregates*:

3.2.1 The fine and coarse aggregates used in the tests shall conform to the requirements of Specification C 33, except that the grading of the aggregates shall conform to the requirements given in Table 1.

TABLE 1 Grading Requirements of Aggregates

Sieve	Percentage Passing
Fine Aggregate	
4.75-mm (No. 4)	100
1.18-mm (No.16)	65 to 75
300-µm (No. 50)	15 to 20
150-µm (No. 100)	2 to 5
Coarse Aggregate	
25.0-mm (1-in.)	100
19.0-mm (¾-in.)	75
12.5-mm (½-in.)	50
9.5-mm (⅜-in.)	25
4.75-mm (No.4)	0

3.2.2 The coarse aggregate shall be carefully separated on the 25.0-mm (1-in.), 19.0-mm (¾-in.), 12.5-mm (½-in.), 9.5-mm (⅜-in.), and 4.75-mm (No. 4) sieves, and then recombined, using equal quantities by weight of each of the resulting four sizes.

3.2.3 The fine and coarse aggregates used in the tests of any two companion cements (that is, a cement containing the addition and the corresponding "control" cement) shall each come from a single lot of such aggregate.

3.3 *Reference Addition*:

3.3.1 The reference addition used in the concrete mixture specified in Section 8, from which specimens will be made for tests for resistance to freezing and thawing as specified in 10.2.3, shall be any one of the four materials (Vinsol resin, Darex, N-TAIR, or Airalon) that have been declared acceptable by ASTM under the former Specifications C 175 – 48 T.

3.3.2 The reference addition to be used will be designated by the person or agency for whom the testing will be performed. If no reference addition is designated, the material known commercially as "Vinsol resin" shall be used. The Vinsol resin used shall be neutralized with 15 percent by mass of sodium hydroxide (NaOH). The air contents of the concrete containing the reference addition and the concrete containing the proposed addition shall agree within 0.5 percentage points.

3.3.3 The reference addition, used as an admixture, is intended for use with control cements only in concrete for freezing-and-thawing tests to establish the durability factor by means of which the concretes containing the addition under test may be evaluated.

3.3.4 *Preparation of Standard Reference Solutions*:

3.3.4.1 Place 50 g (total solids in the case of solution or pastes) of the designated reference addition in 500 mL of freshly distilled water in a 1000-mL flask and mix thoroughly until the solids are completely dissolved or the paste or solution is uniformly diluted. After surface foam has been dissipated, dilute to 1000 mL and mix thoroughly.

3.3.4.2 In the case of Vinsol resin, the neutralized solution shall be made as follows: Dissolve 7.50 g of cp NaOH in 100 mL of distilled water. Add a few drops of this solution to 300 to 350 mL of distilled water contained in a 600-mL beaker. Add 50.00 g of dry, unneutralized Vinsol resin in pulverized form to the beaker and stir until all of the resin is wetted and well dispersed. Then add all of the NaOH solution to this suspension and stir until all of the resin is in solution. Transfer to a measuring flask, dilute to 1000 mL and mix thoroughly. From this stock standard solution prepare a dilute standard solution by diluting 100 mL of the stock solution to 1000 mL.

4. General Requirements

4.1 Air-entraining additions shall conform to the respective requirements prescribed in this specification.

4.2 The trade name, source, and character of the material, and means for the quantitative identification of the proposed addition in the finished cement, shall be furnished by the maker or seller of the addition, and that information shall form a part of the record of tests of the addition.

4.3 Air-entraining additions shall be evaluated by testing cements ground with and without the additions. The cements

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:09:30 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

ground without the additions shall be referred to in this specification as "control" cements.

4.4 An air-entraining addition under this specification, when interground with hydraulic cement, shall produce a cement that complies with the appropriate Specifications C 150, C 595, or C 1157 and when evaluated by the results of tests made according to the procedures herein described, shall also comply with the following requirements as to the effect of the addition on the properties of the cement:

4.4.1 The time of setting of cement containing the addition shall not vary from the time of setting of the respective "control" cement by more than 50 %.

4.4.2 The percentage autoclave expansion for cement containing the addition shall not exceed the percentage autoclave expansion for the corresponding" control" cement by more than 0.1.

4.4.3 The compressive strength of standard mortar cubes made with cement containing the addition shall be not less than 80 % of the compressive strength of similar cubes made with the corresponding "control" cement.

4.4.4 The percentage length change of air-stored mortar bars made with cement containing the addition, based on an initial measurement at the age of 7 days, and expressed as a percentage change in length, shall be not more than 0.01 greater than that of similar mortar bars made with the corresponding "control" cement and similarly tested.

4.4.5 The percentage of air entrained in the concrete made with cement containing the addition shall exceed by at least 2.5 the percentage air in similar concrete prepared with the corresponding "control" cement. (See 3.1.1 for the limitation of air-entraining properties of the "control" cement.)

4.4.6 The compressive strength of the concrete made with cement containing the addition shall be not less than 80 % of the compressive strength of similar concrete made with the corresponding "control" cement.

4.4.7 The flexural strength of concrete made with cement containing the addition shall be not less than 85 % of the flexural strength of corresponding concrete made with the "control" cement.

4.4.8 In the freezing and thawing test, the durability factor of the concrete made with the cement containing the proposed addition shall be not less than 80 % of the durability factor of similar concrete made with the corresponding "control" cement and containing the reference addition as specified in 3.3. (See 11.1.3 for the method of calculating the durability factor.)

5. Sampling Cement

5.1 Samples of the plant-ground cements shall be obtained during grinding. Prior to the commencement of the sampling of a given lot of cement, the mill shall have run for approximately 4 h to establish equilibrium. Notes shall be kept as to the rate and continuity of the feed of the addition, the form in which the addition is used, strength of the solution, and the mill temperature. Fineness of the grinding should be checked during the grinding.

5.2 The quantity of sample shall be not less than 272 kg (600 lb) for the cement containing the proposed addition and for the corresponding control cement.

5.3 As the cement samples are secured, they shall be placed in metal drums provided with gasket-fitted lids. The drums shall be tightly closed at the end of the sampling period. Prior to use, the samples of a given lot of cement shall be well blended to form a uniform, representative composite.

6. Test Methods

6.1 Determine the properties enumerated in this specification in accordance with the methods prescribed in Sections 7-11.

7. Tests on Cement

7.1 Test the cement samples in accordance with the following methods:

7.1.1 *Chemical Analysis of Cement*—Test Methods C 114.

7.1.2 *Determination of Addition in the Finished Cement*—Determine the percentage of the addition in the finished cement by the method furnished by the manufacturer or seller of the proposed addition. The method shall be adequate for the qualitative and quantitative determination of the addition in the finished cement, and shall be fully described in the report of the tests on the addition.

7.1.3 *Fineness of Cement*—Test Method C 115 or C 204.

7.1.4 *Normal Consistency*—Test Method C 187.

7.1.5 *Time of Setting*—Determine the time of setting with the Vicat needle, in accordance with Test Method C 191.

7.1.6 *Autoclave Expansion*—Test Method C 151.

7.1.7 *Air Content of Mortar*—Test Method C 185.

7.1.8 *Compressive Strength of Mortar*—Test Method C 109/C 109M.

7.1.9 *Length Change of Mortar*—For each lot of cement, determine the length change of mortar bars according to Test Method C 596 except, after demolding, cure the specimens in saturated lime water for 6 days (7 days total age) and measure the length of each specimen at 7 days of age. Then, place the specimens in air storage for the remainder of the test period. Obtain a length comparator reading for each specimen at 28 days, 180 days, and 365 days of total age. Report the length change for each bar as a percentage of its length at 7 days of age.

8. Concrete Mixtures

8.1 *Preparation and Weighing*—Prepare all materials used in preparing the concrete mixtures, and make all weighings, as prescribed in Practice C 192/C 192M. Report the amount of mixing water on the basis of saturated surface-dry aggregates.

8.2 *Proportions*—Design one concrete mixture, having an actual cement content of 307 ± 3 kg/m^3 (517± 5 lb/yd^3), and use this mixture in all of the concrete tests specified herein. Adjust the water content of the mixture to provide concrete having a consistency equal to a 64 ± 13-mm (2½ ± ½-in.) slump. Adjust the ratio of fine aggregate to total aggregate to the optimum for concrete to be consolidated by hand-rodding (suggested trial values[6] for the percentage of fine aggregate in the total aggregate, by absolute volume, are shown in Table 2).

[6] Values for concrete without entrained air are based on the ACI Standard Recommended Practice for Selecting Proportions for Normal and Heavyweight Concrete (ACI 211.1-77).

www.technobetar.ir

TABLE 2 Fine Aggregate in Total Aggregate, percent

Coarse Aggregate, Maximum Size 25 mm (1 in.)	Concrete Without Entrained Air	Concrete With Entrained Air
Angular	45	41
Rounded	40	36

8.3 *Mixing of Concrete*—Mix the concrete in accordance with Practice C 192/C 192M except as follows: Hand mixing shall not be permitted. The rated capacity of the mixer shall be not more than twice the size of the batch used. Use a preliminary (buttering) batch of the same proportions as the test batch to coat the mixer and discard it just prior to receiving the batch of the test concrete, which shall be mixed continuously for 2 min following the addition of the mixing water. Do not scrape the mixer after buttering. At the end of the mixing period dump the concrete without scraping from the mixer into a metal wheelbarrow or pan, and then turn with a shovel before making the slump, unit weight, and air determinations, and also before being placed in the test specimen molds.

9. Tests on Plastic Concrete

9.1 Test samples of the plastic concrete in accordance with the following methods:

9.1.1 *Consistency*—Test Method C 143/C 143M.

9.1.2 *Unit Weight and Air Content*—Make a determination of the unit weight, yield, and air content for each batch, in accordance with Test Method C 138/C 138M, except that the air content of the concrete may be determined in accordance with Test Method C 231.

10. Test Specimens of Hardened Concrete

10.1 *Number of Specimens*—Make six test specimens from each condition of concrete to be compared for each test and age. Make test specimens representing each test and each condition of concrete from at least three separate batches. An equal number of specimens for each variable should be made on any given day. When it is impossible to make at least one specimen for each variable on a given day, complete the mixing of the entire series of specimens in as few days as possible and repeat one of the mixes each day as a standard of comparison.

10.2 *Types of Specimens*:

10.2.1 *Compressive Strength*—Compressive strength test specimens shall be 152- by 305-mm (6- by 12-in.) cylinders, and shall be made and cured as prescribed in Practice C 192/C 192M.

10.2.2 *Flexural Strength*—Make and cure flexural strength test specimens as specified in Practice C 192/C 192M, except that the size of the beams shall be 76 by 101 by 406 mm (3 by 4 by 16 in.).

10.2.3 *Resistance to Freezing and Thawing*—Make and cure test specimens for resistance to freezing and thawing as specified in Practice C 192/C 192M, except that the size of the beams shall be 76 by 101 by 406 mm (3 by 4 by 16 in.).

11. Tests on Hardened Concrete

11.1 Test specimens of hardened concrete, as specified in Section 10, in accordance with the following methods, and at the ages herein specified.

11.1.1 *Compressive Strength*—Use Test Method C 39/C 39M, and test specimens at ages of 3, 7, and 28 days, and 3 months, except that for Type III cement a test shall be made also at 1 day.

11.1.2 *Flexural Strength*—Test Method C 293. Test flexural strength specimens at the ages of 3, 7, and 28 days, 3 months, and 1 year, except that for Type III cement a test shall be made also at 1 day.

11.1.3 *Resistance to Freezing and Thawing*—Use Test Method C 666/C 666M, except that the specimens shall be tested at the end of the 28-day curing period.

12. Report

12.1 The report covering the results of the evaluation of a material proposed as an air-entraining addition under this specification shall include the following information:

12.1.1 Trade name, source, and character of the material and means for the quantitative identification of the proposed addition in the finished cement—all as furnished by the manufacturer or seller of the addition.

12.1.2 Identification of the cements as to their type. General geographical location of mills where the test lots of cements were ground. (Company and brand names need not be given.)

12.1.3 Detailed results of all analyses and tests prescribed in this specification, as well as pertinent information required.

12.1.4 Comparison of test results to determine compliance with the requirements prescribed in 4.4.

12.1.5 Name and location of the laboratory or laboratories that made the tests covered by the report.

12.1.6 A statement indicating whether the evaluation was made to establish acceptability of the addition for general use (3.1.1), or whether the evaluation was made to establish acceptability for use with specific types of cement in specific cement mills (3.1.2). In the latter case, the type or types of cement and the brand names and location of mills that are covered by the tests shall be given.

13. Keywords

13.1 addition; air entraining; hydraulic cement

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C 226 – 02, that may impact the use of this specification. (Approved June 1, 2007)

(*1*) Revised 3.1.1 and 3.1.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 227 – 03

Standard Test Method for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar-Bar Method)[1]

This standard is issued under the fixed designation C 227; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the determination of the susceptibility of cement-aggregate combinations to expansive reactions involving hydroxyl ions associated with the alkalies (sodium and potassium) by measurement of the increase (or decrease) in length of mortar bars containing the combination during storage under prescribed conditions of test.

1.2 Alkalies participating in the expansive reactions usually are derived from the cement; under some circumstances they may be derived from other constituents of the concrete or from external sources. Two types of alkali reactivity of aggregates are recognized: *(1)* an alkali-silica reaction involving certain siliceous rocks, minerals, and natural or artificial glasses and *(2)* an alkali-carbonate reaction involving dolomite in certain calcitic dolomites and dolomitic limestones (see Standard C 294). The method is not recommended as a means to detect the latter reaction because expansions produced in the mortar-bar test by the alkali-carbonate reaction (see Test Method C 586) are generally much less than those produced by the alkali-silica reaction for combinations having equally harmful effects in service.

1.3 The values stated in SI units are to be regarded as standard. The non-SI values, shown in parentheses, are for informational purposes only.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Significance and Use

3.1 Data correlating the results of tests performed using this test method with performance of cement-aggregate combinations in concrete in service, results of petrographic examination of aggregates (Guide C 295), and results of tests for potential reactivity of aggregates by chemical methods have been published in Test Method C 289 and should be consulted in connection with the use of results of tests performed using this

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.26 on Chemical Reactions of Materials.

Current edition approved June 10, 2003. Published September 2003. Originally approved in 1950. Last previous edition approved in 1997 as C 227 – 97a.

www.technobetar.ir

test method as the basis for conclusions and recommendations concerning the use of cement-aggregate combinations in concrete.

3.2 The results of tests performed using this method furnish information on the likelihood that a cement-aggregate combination is potentially capable of harmful alkali-silica reactivity with consequent deleterious expansion of concrete. Criteria to determine potential deleterious alkali-silica reactivity of cement-aggregate combinations from the results of this test method have been given in the Appendix of Specification C 33.

3.3 Insignificant expansion may result when potentially deleteriously reactive siliceous rocks are present in comparatively high proportion even when a high-alkali cement is used. This may occur because the alkali-silica reaction products are characterized by an alkali to silica ratio that is so low as to minimize uptake of water and swelling, or because of alkali leaching from the bars (see section on containers). Dolomitic aggregates that are deleteriously affected by the alkali-carbonate reaction when employed as course aggregate in concrete may not produce notable expansion in this test method. Also, significant expansion may occur rarely in the test for reasons other than alkali-aggregate reaction, particularly the presence of sulfates in the aggregate that produce a sulfate attack upon the cement paste, ferrous sulfides (pyrite, marcasite, or pyrrhotite) that oxidize and hydrate with the release of sulfate, and materials such as free lime (CaO) or free magnesia (MgO) in the cement or aggregate that progressively hydrate and carbonate.

3.4 When expansions in excess of those given in the Appendix of Specification C 33 are shown in results of tests performed using this test method, it is strongly recommended that supplementary information be developed to confirm that the expansion is actually due to alkali reactivity. Sources of such supplementary information include: *(1)* petrographic examination of the aggregate to determine if known reactive constituents are present; *(2)* examination of the specimens after tests to identify the products of alkali reactivity; and *(3)* tests of the aggregate for potential reactivity by chemical methods (Test Method C 289).

3.5 When it has been concluded from the results of tests performed using this test method and supplementary information as outlined that a given cement-aggregate combination should be considered potentially deleteriously reactive, additional studies may be appropriate to develop information on the potential reactivity of other combinations containing the same cement with other aggregates, the same aggregate with other cements, or the same cement-aggregate combination with a mineral admixture.

4. Apparatus

4.1 The apparatus shall conform to Specification C 490, except as follows:

4.2 *Sieves*—Square hole, woven-wire cloth sieves, shall conform to Specification E 11.

4.3 *Mixer, Paddle, and Mixing Bowl*— Mixer, paddle, and mixing bowl shall conform to the requirements of Method C 305, except that the clearance between the lower end of the paddle and the bottom of the bowl shall be 5 to 6 mm (0.20 to 0.24 in.) .

4.4 *Tamper and Trowel*—The tamper and trowel shall conform to Test Method C 109/C 109M.

4.5 *Containers*—Covered containers for storing the test specimens shall be constructed of material that is resistant to corrosion under the test conditions. The wall thickness of the container and cover shall be less than 6 mm (3⁄16 in.) to reduce the insulating effect and provide a rapid heat transfer for the initial 14-day test period. The cover shall be constructed in a manner to maintain a tight seal between the cover and top of the container wall (Note 1). The container shall be arranged to provide every surface of each specimen with approximately an equal exposure to an absorbent wicking material. The specimens shall not be in direct contact with the wicking material but every surface shall be within 30 mm (1¼ in.) or less of the the wicking. A typical arrangement of such a container is shown in Fig. 1 (Note 2). The inner sides and the center core of the containers are to be lined with an absorbent material, such as blotting or filter paper, to act as a wick and to ensure that the atmosphere in the container is quickly saturated with water vapor when it is sealed after the specimens are placed therein (Note 2). The wicking liners will extend into the top of the water in the bottom of the container and above the tops of the specimens. Make provisions to support the bars in a vertical position with the lower end of the bars approximately 25 mm (1 in.) above the surface of the water in the containers. The weight of the specimens shall not be supported on the metal gage studs. A supporting rack shall be provided to ensure that the specimens do not touch the wicking material or each other. The supporting rack shall be constructed of brass wire or other material that is resistant to corrosion under the test conditions and shall not act as a vapor barrier but provide free movement of vapors within the container. Provisions shall be made to prevent water from splashing and dripping onto the specimens (Notes 3-5). If required to prevent the growth of mold on the wicking, add a suitable fungicide to the water in the container. The container size and internal arrangement of the specimens and wicking may be varied at the users discretion, providing expansion data for all specimens can be shown to be equivalent to that developed with the container herein described.

NOTE 1—This seal may be achieved by a double wrap of vinyl tape 38 mm (1½ in.) or greater in width, overlaying the lid and container wall along its full circumference.

NOTE 2—A covered container that has been found acceptable for this purpose is sold by the United States Plastic Corp., 1390 Neubrecht Rd., Lima, OH 45801, as a PVC plating, photo, and chemical tank, stock No. 10062, 6-in. diameter x 17 in. high, with cover.

NOTE 3—The shape and spacing of the center wicking material may be maintained during the test by the use of rubber bands or hardware cloth.

NOTE 4—If concern exists for adequately preventing dripping or splashing, the water should be tested for pH and alkali content.

NOTE 5—The container described in 4.5 and in Fig. 1 has been shown to produce large and reproducible expansions with cement-aggregate combinations such as borosilicate glass: high-alkali cement combination called for by ASTM C 441. However, recent work, at a few laboratories, suggests that the same factors that are responsible for the success with the C 441 mixtures, that is, high, constant, uniform internal relative humidity, will, under certain testing regimes permitted by this test method, promote leaching of alkali from the specimens and result in little or no expansion from some known deleteriously alkali-reactive aggregate: high-alkali cement combinations. Each laboratory should evaluate its containers with a known deleteriously alkali-reactive aggregate (not borosilicate glass

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

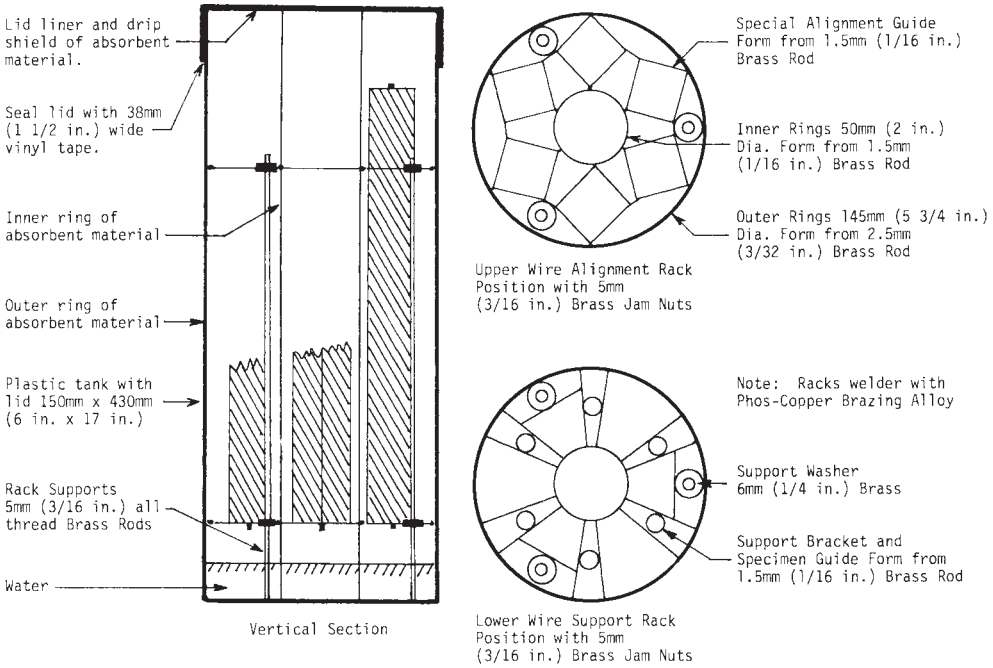

FIG. 1 Diagram of an Acceptable Assembled Container

which releases alkali) and a high-alkali cement, to establish that the expected level of expansion is obtained. If not, try removing the wicking to reduce the condensation and leaching. Minimizing the temperature variation within the storage room and the room in which the bars are read may also reduce condensation on and leaching from the bars.

5. Temperature and Humidity

5.1 The temperature of the molding room and dry materials shall be maintained at not less than 20°C (68°F) and not more than 27.5°C (81.5°F). The temperature of the mixing water, of the moist closet or moist room, and of the room in which the measurements are made shall not vary from 23°C (73.4°F) by more than 2.0°C (3°F).

5.2 The relative humidity of the molding room shall be not less than 50 %. The moist closet or room shall conform to Specification C 511.

5.3 The storage room in which the specimens in containers are stored shall be maintained at a temperature that shall not vary from 38.0°C (100°F) by more than 2.0°C (3°F).

6. Selection and Preparation of Materials

6.1 *Selection of Aggregate*—Materials proposed for use as fine aggregate in concrete shall be processed as described in 6.2 with a minimum of crushing. Materials proposed for use as coarse aggregate in concrete shall be processed by crushing to produce as nearly as practical a graded product from which a sample can be obtained. The sample shall have the grading as prescribed in 6.2 and be representative of the composition of the coarse aggregate as proposed for use.

6.1.1 When a given quarried material is proposed for use, both as coarse and as fine aggregate, it will be tested only by selection of an appropriate sample crushed to the fine aggregate sizes, unless there is reason to expect that the coarser size fractions have a different composition than the finer sizes and that these differences might significantly affect expansion due to reaction with the alkalies in cement. In this case the coarser size fractions should be tested in a manner similar to that employed in testing the fine aggregate sizes.

6.1.2 Coarse aggregate crushed to sand size may give increased expansion, owing to the increased surface exposed upon crushing. Therefore, if coarse aggregate tested by this method produces an excessive amount of expansion, the material shall not be classed as objectionably reactive with alkali unless tests of concrete specimens confirm the findings of the tests of the mortar.

6.2 *Preparation of Aggregate*—Fine aggregate shall be tested in a grading meeting the requirements of the specifications for the project except that any material retained on the 4.75-mm (No. 4) sieve shall be removed. Fine aggregates being tested for reasons other than to determine compliance with individual specifications, and all coarse aggregates to which this method is applied shall be graded in accordance with the requirements prescribed in Table 1. Aggregates in which sufficient quantities of the sizes specified in Table 1 do not exist shall be crushed until the required material has been produced. In the case of aggregates containing insufficient amounts of one or more of the larger sizes listed in Table 1, and if no larger material is available for crushing, the first size in which sufficient material is available shall contain the cumulative percentage of material down to that size as determined from the

TABLE 1 Grading Requirements

Sieve Size		Mass %
Passing	Retained on	
4.75-mm (No. 4)	2.36-mm (No. 8)	10
2.36-mm (No. 8)	1.18-mm (No. 16)	25
1.18-mm (No. 16)	600-µm (No. 30)	25
600-µm (No. 30)	300-µm (No. 50)	25
300-µm (No. 50)	150-µm (No. 100)	15

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:09:33 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

grading specified in Table 1. When such procedures are required, special note shall be made thereof in the test report. After the aggregate has been separated into the various sieve sizes, each size shall be washed with a water spray over the sieve to remove adhering dust and fine particles from the aggregate. The portions retained on the various sieves shall then be dried and, unless used immediately, each such portion shall be stored individually in a clean container provided with a tight-fitting cover.

6.3 *Selection and Preparation of Cement*:

6.3.1 *Job Cement*—When it is desired to evaluate a particular cement-aggregate combination for use in particular work, the cement or cements used shall meet the requirements for the work and shall be from the source or sources expected to be used in the work. If several cements may be used in the work, tests desirably should be made using each of these; in any case, the cement or cements whose alkali content exceeds 0.60 %, calculated as Na_2O, should be used.

6.3.2 *Reference Cements*—When it is desired to evaluate aggregates for general use or to compare aggregates for investigational purposes, the cement used shall be of the highest alkali content representative of the general use intended, or available to the laboratory making the tests. The cement or cements selected should comply with applicable specifications. Additional information of value may be obtained by conducting tests in parallel with cements of different alkali content, different Na_2O:K_2O ratio, or using pozzolans.

6.3.3 *Preparation of Cement*—Cement for use in this test shall be passed through a 850-µm (No. 20) sieve to remove lumps before use.

7. Procedure

7.1 *Preparation of Test Specimens*:

7.1.1 *Number of Specimens*—Make at least four test specimens, two from each of two batches, for each cement-aggregate combination.

7.1.2 *Preparation of Molds*—Prepare the molds in accordance with the requirements of Specification C 490.

7.1.3 *Proportioning of Mortar*—Proportion the dry materials for the test mortar using 1 part of cement to 2.25 parts of graded aggregate by mass. The quantities of dry materials to be mixed at one time in the batch of mortar for making two specimens shall be 300 g of cement and 675 g of aggregate made up by recombining the portions retained on the various sieves (see 6.2) in the grading prescribed in Table 1 or of aggregate in a grading meeting the requirements of the specifications for the project. The amount of mixing water, measured in millimetres, shall be such as to produce a flow of 105 to 120 (as determined in accordance with Test Method C 1437) except that the flow table shall be given 10 drops in approximately 6 s. Express the amount of mixing water used as a percent by mass of the cement.

7.1.4 *Mixing of Mortar*—Mix the mortar in accordance with the requirements of Method C 305.

7.1.5 *Molding of Test Specimens*—Immediately following completion of the flow test return the mortar from the flow table to the mixing bowl. Mix the entire batch for a period of 15 s. Start molding specimens with a total elapsed time of not more than 2 min and 15 s after completion of the original mixing of the mortar batch. Fill the molds with two approximately equal layers, each layer being compacted with the tamper. Work the mortar into the corners, around the gage studs, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, cut off the mortar flush with the top of the mold and smooth the surface with a few strokes of the trowel.

7.1.5.1 When a duplicate batch of mortar is to be made immediately for additional specimens, a second flow test is not required, in which case allow the mortar to stand in the mixing bowl for 90 s and then remixed for 15 s before starting the molding of the specimens.

7.1.6 *Sequence of Making Batches of Mortar*—When more than one cement-aggregate combination is to be tested as part of a single investigation, make the total number of batches of mortar (two per cement-aggregate combination) in random order, except that in no case shall the two batches representing a single cement-aggregate combination be made consecutively. When the making of all of the specimens for a single investigation requires that batches be made on 2 working days, each cement-aggregate combination shall be represented by one batch made on each day, and the order in which the combinations are represented by batches shall be different on the 2 days. When more than 2 days are required, one cement-aggregate combination shall be represented by a batch made on each of the working days.

7.2 *Storage and Measurement of Test Specimens*:

7.2.1 *Initial Storage and Measurement*—After each mold has been filled, place the mold immediately in the moist cabinet or room. The specimens shall remain in the molds for 24 ± 2 h. Then remove them from the molds and, while being protected from loss of moisture, properly identify and measure for initial length. The initial and all subsequent measurements shall be made and recorded to the nearest 0.002 mm (0.0001 in.).

7.2.2 *Subsequent Storage and Measurement*—Stand the specimens on end over, but not in contact with, water in the storage container. Seal and place the container for 12 days in a cabinet or room maintained at a temperature of 38.0 ± 2.0°C (100 ± 3°F). When the specimens are 14 days old measure their length after removal of the container and contents from the storage room or cabinet, and after the container and contents have been stored at 23.0 ± 2.0°C (73.4 ± 3°F) for at least 16 h before opening the container and making the 14-day measurement. Additional measurements shall be made at later ages as required.

7.2.3 Additional information of value may often be obtained by returning the specimens to the 38.0°C (100°F) storage after the 14-day test and making additional measurements at later ages. Measurements at ages of 1, 2, 3, 4, 6, 9, and 12 months and, if necessary, at least every 6 months thereafter are suggested.

7.2.4 After each length measurement specimens may be examined, in the same manner described in Section 9, to provide supplemental information on their condition.

7.2.5 All specimens placed in a given container after the initial length measurement at 24 ± 2 h shall have been made on the same day and shall be placed in the container at the same

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:09:33 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

time so that all specimens in a given container shall be due for measurement at the same time. Each time length measurements are made, clean the container and change the water.

7.2.6 Always place the specimens in the comparator with the same end uppermost and after measurement replace the specimens in the container in inverted position as compared with the previous period.

8. Calculation

8.1 Calculate the difference between the initial length of the specimen and the length at each period of measurement to the nearest 0.001 % of the effective gage length and record as the expansion of the specimen for that period. Report the average of the expansion of the four specimens of a given cement-aggregate combination to the nearest 0.01 % as the expansion for the combination for a given period.

9. Examination at End of Test

9.1 After the final length change measurements have been made, each specimen shall be tested for warping and shall be examined (see Note 6).

9.1.1 *Warping*—The warping, if any, that each specimen has manifested during the test period, shall be determined by placing the specimen on a plane surface and measuring the maximum separation between the specimen and the surface. The specimen shall be placed so that its ends curve down to the reference surface and the measurement made to the nearest 0.3 mm (0.01 in.).

9.1.2 *Examination*—Items to be noted in the examination include:

9.1.2.1 Presence, location, and type of pattern of cracking,

9.1.2.2 Appearance of surfaces, surface mottling, and

9.1.2.3 Surficial deposits or exudations, their nature, thickness and continuity.

NOTE 6—When it is believed that additional features of noteworthy importance are likely to be revealed thereby, a further examination of the interior of the specimen may be made, following Practice C 856. In such cases, the presence of gel-filled pores and fissures, evidence of reaction with aggregate particles of specific types and the nature of such evidence and the properties of the reaction products are among the items to be noted.

10. Report

10.1 Report the following information:

10.1.1 Type and source of aggregate,

10.1.2 Type and source of portland cement,

10.1.3 Alkali content of cement as percent potassium oxide (K_2O), sodium oxide (Na_2O), and calculated sodium oxide (Na_2O) equivalent,

10.1.4 Average length change in percent at each reading of the specimens,

10.1.5 Any relevant information concerning the preparation of aggregates, including the grading of the aggregate when it differs from that given in 6.2,

10.1.6 Any significant features revealed by examination of the specimens during and after test,

10.1.7 Amount of mixing water expressed as percent by mass of cement, and

10.1.8 Type, source, proportions, and chemical analyses, including Na_2O and K_2O, of any pozzolans employed in the tests.

11. Precision and Bias

11.1 Precision shall be considered satisfactory if the differences in the value for percentage expansion of any given specimen in a group from the average value for percentage expansion of the group does not exceed 0.003, except that, if the average expansion exceeds 0.020 %, the repeatability shall be considered satisfactory if the percentage expansion of each specimen molded from the same cement-aggregate combination is within 15 % of the average.

11.2 Interlaboratory test data for the determination of revisions to this section in accordance with Practice C 670 are being evaluated by Subcommittee C09.02.02 and will be included in a later revision of this test method.

12. Keywords

12.1 aggregate; alkali-silica reaction; cement; length change; mortar

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 230/C 230M – 08

Standard Specification for Flow Table for Use in Tests of Hydraulic Cement[1]

This standard is issued under the fixed designation C 230/C 230M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers requirements for the flow table and accessory apparatus (Note 1) used in making flow tests for consistency of mortars in tests of hydraulic cement, such as but not limited to Test Method C 1437.

NOTE 1—To help clarify the design of the flow table and accessory apparatus see the drawing in Fig. 1 [Fig. 2] . This drawing is for informational purposes only.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. It is permissible to use an inch-pound caliper and mold with a SI flow table or a SI caliper and mold with an inch-pound flow table. It is not permissible to mix a SI mold with an inch-pound caliper or an inch-pound mold with a SI caliper.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 1437 Test Method for Flow of Hydraulic Cement Mortar

3. Flow Table and Frame

3.1 The flow table apparatus shall consist of an integrally cast rigid iron frame and a circular rigid table top 10 ± 0.1 in. [255 ± 2.5 mm] in diameter, with a shaft attached perpendicular to the table top by means of a screw thread. The table top and shaft with contact shoulder shall be mounted on a frame in such a manner that it can be raised and dropped vertically through the specified height of 0.500 ± 0.005 in. [12.7± 0.13 mm] for new tables and of 0.500 ± 0.015 in. [12.7 ± 0.38 mm] for tables in use, by means of a rotated cam. The table top shall have a fine machined plane surface, free of blowholes and surface defects. The top shall be scribed with eight equidistant lines 2⅝ in. [68 mm] long, extending from the outside circumference toward the center of the table. Each line shall end with a scribed arc, ¼ in. [6 mm] long, whose center point is the center of the table top with a radius of 2⅜ in. [59.5 mm]. The scribe lines shall be made with a 60° tool to a depth of 0.01 in. [0.25 mm]. The table top shall be of cast brass or bronze having a Rockwell hardness number not less than 25 HRB with an edge thickness of 0.3 in. [7.5 mm], and shall have six integral radial stiffening ribs. The table top and attached shaft shall weigh 9 ± 0.1 lb [4.08 ± 0.05 kg] and the weight shall be symmetrical around the center of the shaft.

3.2 The cam and vertical shaft shall be of medium carbon machinery steel, hardened on the end of the shaft contacting the cam and the tip of the cam contacting the shaft. The shaft shall be straight and the difference between the diameter of the shaft and the diameter of the bore of the frame shall be not less than 0.002 in. [0.05 mm] and not more than 0.003 in. [0.08 mm] for new tables and shall be maintained at 0.002 to 0.010 in. [0.05 to 0.25 mm] for tables in use. The end of the shaft shall not fall upon the cam at the end of the drop, but shall make contact with the cam not less than 120° from the point of drop. The face of the cam shall be a smooth spiraled curve of uniformly increasing radius from ½ to 1¼ in. [13 to 32 mm] in 360° and there shall be no appreciable jar as the shaft comes into contact with the cam. The cam shall be so located and the contact faces of the cam and shaft shall be such that the table does not rotate more than one revolution in 25 drops. The surfaces of the frame and of the table that come into contact at the end of the drop shall be maintained smooth, plane, and horizontal and parallel with the upper surface of the table and shall make continuous contact over a full 360°.

3.3 The supporting frame of the flow table shall be integrally cast of fine-grained, high-grade cast iron. The frame casting shall have three integral stiffening ribs extending the full height of the frame and located 120° apart. The top of the frame shall be chilled to a depth of approximately ¼ in. [6

[1] This specification is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.22 on Workability.

Current edition approved July 1, 2008. Published August 2008. Originally approved in 1949. Last previous edition approved in 2003 as C 230/C 230M – 03.

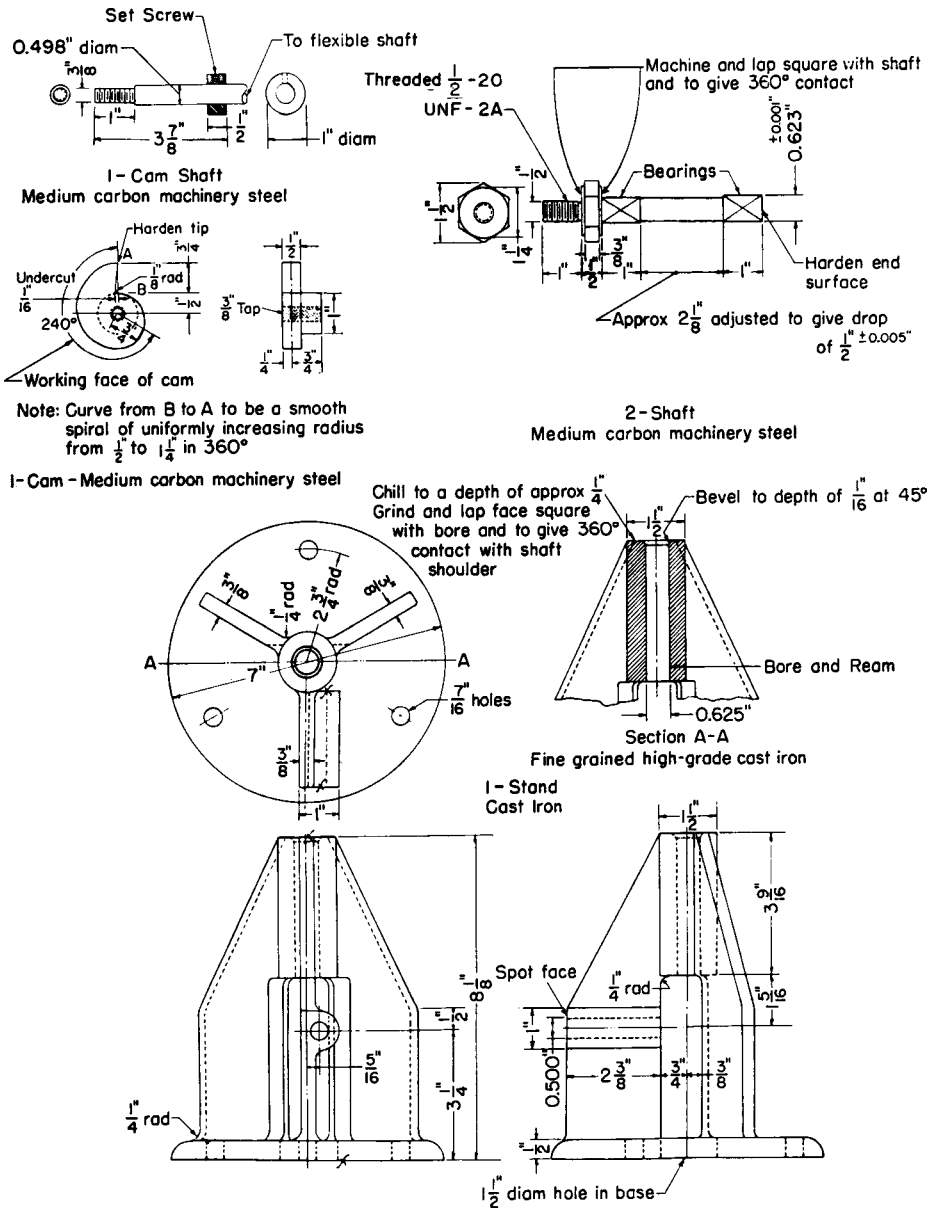

FIG. 1 Flow Table and Accessory Apparatus (Partial) (In./Lb)

mm], and the face shall be ground and lapped square with the bore to give 360° contact with the shaft shoulder. The underside of the base of the frame shall be ground to secure a complete contact with the steel plate beneath.

3.4 The flow table shall be driven by a motor (Note 2), connected to the cam shaft through an enclosed worm gear speed reducer and flexible coupling. The speed of the cam shaft shall be approximately 100 r/min. The motor drive mechanism shall not be fastened or mounted on the table base plate or frame.

NOTE 2—A 1/20-hp [40-W] motor has been found adequate.

3.5 The performance of a flow table shall be considered satisfactory if, in calibration tests, the table gives a flow value that does not differ by more than 5 percentage points from flow values obtained with a suitable calibration material.[3,4] (See Note 3)

[3] Such a material can be obtained from the Cement and Concrete Reference Laboratory at the National Institute of Standards and Technology, Gaithersburg, MD 20899.

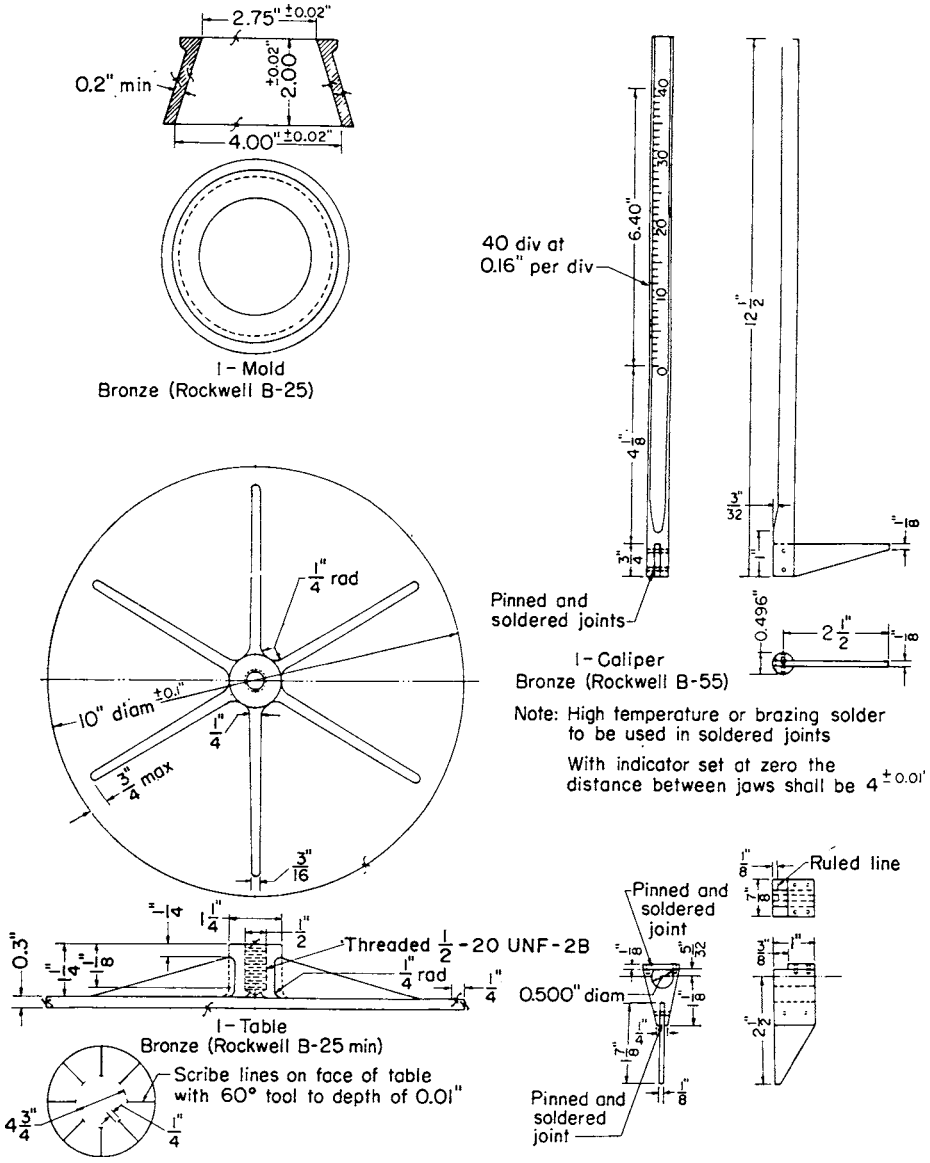

FIG. 1 Flow Table and Accessory Apparatus (Partial) (In./Lb) *(continued)*

NOTE 3—Some causes of and solutions to unsatisfactory performance of the flow table may be found in the section on flow tables in the *ASTM Manual of Cement Testing*.

4. Flow Table Mounting

4.1 The flow table frame shall be tightly bolted to a cast iron or steel plate at least 1 in. [25 mm] thick and 10 in. [250 mm] square. The top surface of this plate shall be machined to a smooth plane surface. The plate shall be anchored to the top of a concrete pedestal by four ½-in. [13-mm] bolts that pass through the plate and are imbedded at least 6 in. [150 mm] in the pedestal. The pedestal shall be cast inverted on the base plate. A positive contact between the base plate and the pedestal shall be obtained at all points. No nuts or other such leveling devices shall be used between the plate and the pedestal. Leveling shall be effected by suitable means under the base of the pedestal.

4.2 The pedestal shall be 10 to 11 in. [250 to 275 mm] square at the top, and 15 to 16 in. [375 to 400 mm] square at the bottom, 25 to 30 in. [625 to 750 mm] in height, and shall be of monolithic construction, cast from concrete weighing at least 140 lb/ft^3 [2240 kg/m ^{3}]. A stable gasket cork padding, ½ in. [13 mm] thick and the same size as the pedestal bottom or four pieces of padding ½ in. [13 mm] thick and approximately 4 in. [100 mm] square, shall be inserted under the pedestal or the four corners, respectively. The flow table shall be checked frequently for levelness of the table top, stability of the pedestal, and tightness of the bolts and nuts in the table base and the pedestal table. (A torque of 20 lb·ft [27 N·m] is recommended when tightening those fastenings.)

4.3 The table top, after the frame has been mounted on the pedestal, shall be level along two diameters at right angles to each other, in both the raised and lowered positions.

5. Flow Table Lubrication

5.1 The vertical shaft of the table shall be kept clean and shall be lightly lubricated (See Note 4) with a light oil

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:09:34 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

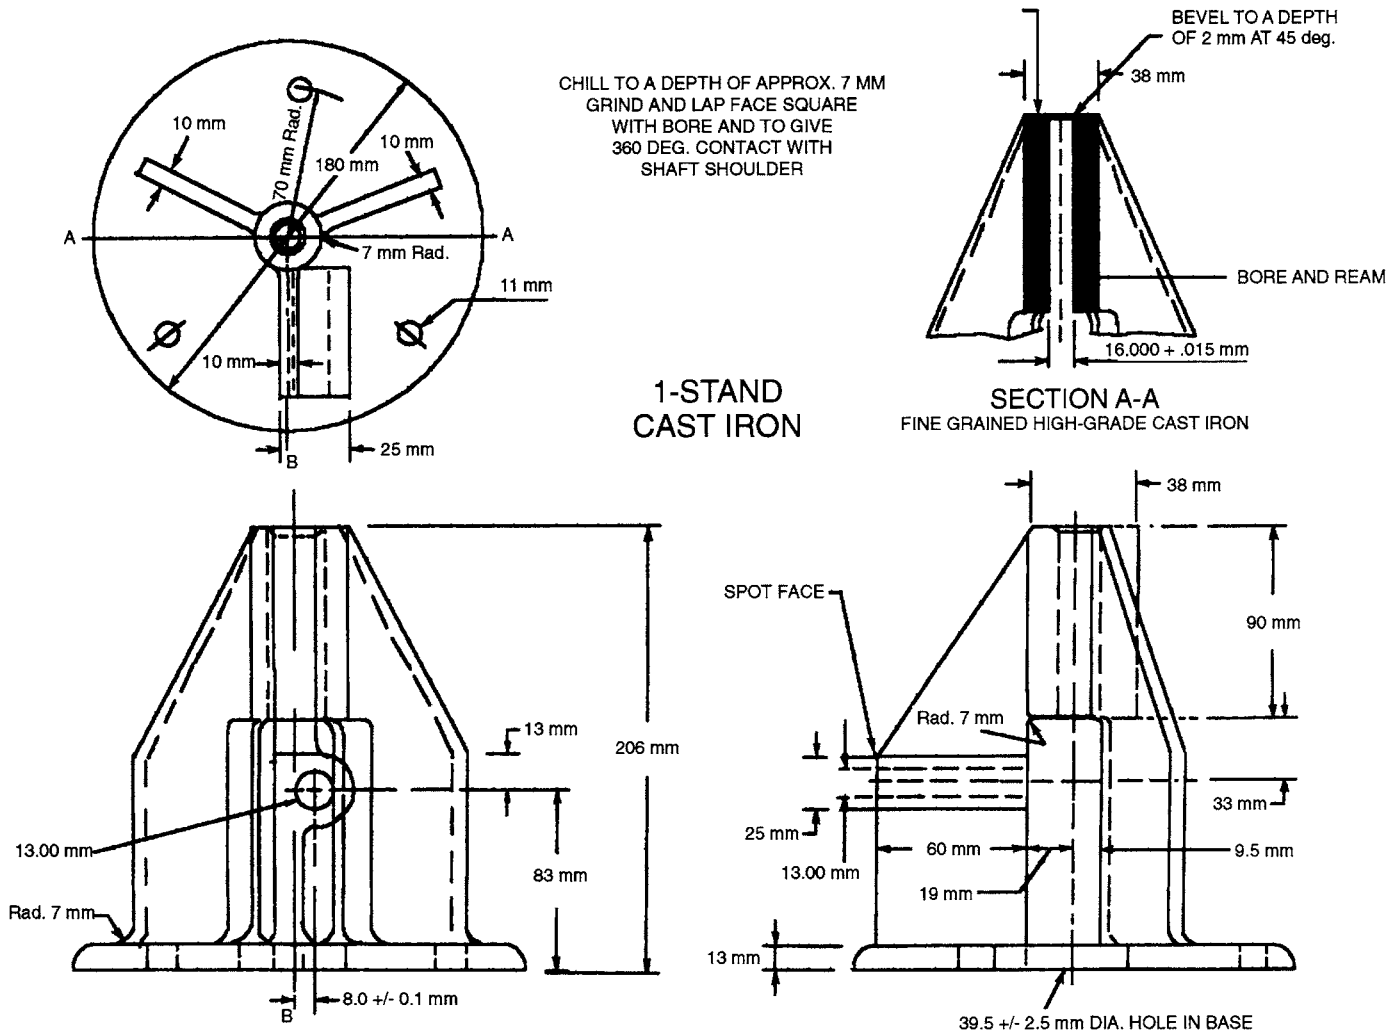

FIG. 2 Flow Table and Accessory Apparatus (Partial) [SI]

(SAE-10). Oil shall not be present between the contact faces of the table top and the supporting frame. Oil on the cam face will lessen wear and promote smoothness of operation. The table should be raised and permitted to drop a dozen or more times just prior to use if it has not been operated for some time.

NOTE 4—It has been demonstrated that an absence of lubrication on the table shaft will significantly reduce the flow reading.

6. Mold and Caliper

6.1 The conical mold for casting the flow specimen shall be of cast bronze or brass. The Rockwell hardness number of the metal shall be not less than 25 HRB. The height of the mold shall be 2.00 ± 0.02 in. [50.0 ± 0.5 mm]. The diameter of the top opening shall be 2.75± 0.02 in. [70.0 ± 0.5 mm] for new molds and 2.75 + 0.05 in. [70.0 + 1.3 mm] and –0.02 in. [–0.5 mm] for molds in use. The diameter of the bottom opening shall be 4.00 ± 0.02 in. [100.0 ± 0.5 mm] for new molds and 4.00 + 0.05 in. [+ 1.3 mm] and –0.02 in. [–0.5 mm] for molds in use. The surfaces of the base and top shall be parallel and at right angles to the vertical axis of the cone. The mold shall have a minimum wall thickness of 0.2 in. [5 mm]. The outside of the top edge of the mold shall be shaped so as to provide an integral collar for convenient lifting of the mold. All surfaces shall be machined to a smooth finish. A circular shield approximately 10 in. [255 mm] in diameter, with a center opening approximately 4 in. [100 mm] in diameter, made of nonabsorbing material not attacked by the cement, shall be used with the flow mold to prevent mortar from spilling on the table top.

6.2 A caliper consisting of one fixed jaw and one jaw movable along a permanent scale shall be provided for measuring the diameter of the mortar after it has been spread by the operation of the table. The scale shall be machine divided into 40 increments with 0.16 in. [4.0 mm] between divisions with major division lines every 5 divisions and the increment number every 10 divisions (Note 5). The construction and accuracy of the caliper shall be such that the distance between the jaws shall be 4 ± 0.01 in. [100 ± 0.25 mm] when the indicator is set at zero.

NOTE 5—The caliper is graduated to indicate one fourth of the actual flow percentage, so that the readings of four measurements on the caliper may be added to give the flow value without the necessity of calculating the average of four individual measurements of the total flow.

Designation: C231/C231M – 09b

Standard Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method[1]

This standard is issued under the fixed designation C231/C231M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers determination of the air content of freshly mixed concrete from observation of the change in volume of concrete with a change in pressure.

1.2 This test method is intended for use with concretes and mortars made with relatively dense aggregates for which the aggregate correction factor can be satisfactorily determined by the technique described in Section 6. It is not applicable to concretes made with lightweight aggregates, air-cooled blast-furnace slag, or aggregates of high porosity. In these cases, Test Method C173/C173M should be used. This test method is also not applicable to nonplastic concrete such as is commonly used in the manufacture of pipe and concrete masonry units.

1.3 The text of this test method references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this standard.

1.4 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C31/C31M Practice for Making and Curing Concrete Test Specimens in the Field

C138/C138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

C143/C143M Test Method for Slump of Hydraulic-Cement Concrete

C172 Practice for Sampling Freshly Mixed Concrete

C173/C173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C192/C192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

E177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods

3. Significance and Use

3.1 This test method covers the determination of the air content of freshly mixed concrete. The test determines the air content of freshly mixed concrete exclusive of any air that may exist inside voids within aggregate particles. For this reason, it is applicable to concrete made with relatively dense aggregate particles and requires determination of the aggregate correction factor (see 6.1 and 9.1).

3.2 This test method and Test Method C138/C138M and C173/C173M provide pressure, gravimetric, and volumetric procedures, respectively, for determining the air content of freshly mixed concrete. The pressure procedure of this test method gives substantially the same air contents as the other two test methods for concretes made with dense aggregates.

3.3 The air content of hardened concrete may be either higher or lower than that determined by this test method. This

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.60 on Testing Fresh Concrete.

Current edition approved Dec. 15, 2009. Published February 2010. Originally approved in 1949. Last previous edition approved in 2009 as C231 – 09a. DOI: 10.1520/C0231_C0231M-09b.

www.technobetar.ir

depends upon the methods and amount of consolidation effort applied to the concrete from which the hardened concrete specimen is taken; uniformity and stability of the air bubbles in the fresh and hardened concrete; accuracy of the microscopic examination, if used; time of comparison; environmental exposure; stage in the delivery, placement and consolidation processes at which the air content of the unhardened concrete is determined, that is, before or after the concrete goes through a pump; and other factors.

4. Apparatus

4.1 *Air Meters*—There are available satisfactory apparatus of two basic operational designs employing the principle of Boyle's law. For purposes of reference herein these are designated Meter Type A and Meter Type B.

4.1.1 *Meter Type A*—An air meter consisting of a measuring bowl and cover assembly (see Fig. 1) conforming to the requirements of 4.2 and 4.3. The operational principle of this meter consists of introducing water to a predetermined height above a sample of concrete of known volume, and the application of a predetermined air pressure over the water. The determination consists of the reduction in volume of the air in the concrete sample by observing the amount the water level is lowered under the applied pressure, the latter amount being calibrated in terms of percent of air in the concrete sample.

4.1.2 *Meter Type B*—An air meter consisting of a measuring bowl and cover assembly (see Fig. 2) conforming to the requirements of 4.2 and 4.3. The operational principle of this meter consists of equalizing a known volume of air at a known pressure in a sealed air chamber with the unknown volume of air in the concrete sample, the dial on the pressure gauge being calibrated in terms of percent air for the observed pressure at which equalization takes place. Working pressures of 50 to 205 kPa [7.5 to 30.0 psi] have been used satisfactorily.

4.2 *Measuring Bowl*—The measuring bowl shall be essentially cylindrical in shape, made of steel, hard metal, or other hard material not readily attacked by the cement paste, having a minimum diameter equal to 0.75 to 1.25 times the height, and a capacity of at least 6.0 L [0.20 ft^3]. It shall be flanged or otherwise constructed to provide for a pressure tight fit between measuring bowl and cover assembly. The interior surfaces of the measuring bowl and surfaces of rims, flanges, and other component fitted parts shall be machined smooth. The measuring bowl and cover assembly shall be sufficiently rigid to limit the expansion factor, *D*, of the apparatus assembly (Annex A1.5) to not more than 0.1 % of air content on the indicator scale when under normal operating pressure.

4.3 *Cover Assembly*:

4.3.1 The cover assembly shall be made of steel, hard metal, or other hard material not readily attacked by the cement paste. It shall be flanged or otherwise constructed to provide for a pressure-tight fit between measuring bowl and cover assembly and shall have machined smooth interior surfaces contoured to provide an air space above the level of the top of the measuring bowl. The cover shall be sufficiently rigid to limit the expansion factor of the apparatus assembly as prescribed in 4.2.

4.3.2 The cover assembly shall be fitted with a means of direct reading of the air content. The cover for the Type A meter shall be fitted with a standpipe, made of a transparent graduated tube or a metal tube of uniform bore with a glass water gauge attached. In the Type B meter, the dial of the pressure gauge shall be calibrated to indicate the percent of air. Graduations shall be provided for a range in air content of at least 8 % readable to 0.1 % as determined by the proper air pressure calibration test.

4.3.3 The cover assembly shall be fitted with air valves, air bleeder valves, and petcocks for bleeding off or through which water may be introduced as necessary for the particular meter design. Suitable means for clamping the cover to the measuring bowl shall be provided to make a pressure-tight seal without entrapping air at the joint between the flanges of the cover and measuring bowl. A suitable hand pump shall be provided with the cover either as an attachment or as an accessory.

4.4 *Calibration Vessel*—A measure having an internal volume equal to a percent of the volume of the measuring bowl corresponding to the approximate percent of air in the concrete to be tested; or, if smaller, it shall be possible to check calibration of the meter indicator at the approximate percent of air in the concrete to be tested by repeated filling of the measure. When the design of the meter requires placing the calibration vessel within the measuring bowl to check calibration, the measure shall be cylindrical in shape.

NOTE 1—A satisfactory calibration vessel to place within the measuring bowl may be machined from No. 16 gauge brass tubing, of a diameter to provide the volume desired, to which a brass disk 13 mm [½ in.] in thickness is soldered to form an end. When design of the meter requires withdrawing of water from the water-filled measuring bowl and cover assembly, to check calibration, the measure may be an integral part of the cover assembly or may be a separate cylindrical measure similar to the above-described cylinder.

4.5 The designs of various available types of air meters are such that they differ in operating techniques; therefore, all of the items described in 4.6-4.16 may not be required. The items required shall be those necessary for use with the particular design of apparatus used to satisfactorily determine air content in accordance with the procedures prescribed herein.

4.6 *Coil Spring or Other Device for Holding Calibration Cylinder in Place*.

4.7 *Spray Tube*—A brass tube of appropriate diameter, which may be an integral part of the cover assembly, or which may be provided separately. It shall be so constructed that when water is added to the container, it is sprayed to the walls of the cover in such a manner as to flow down the sides causing a minimum of disturbance to the concrete.

4.8 *Trowel*—A standard brick mason's trowel.

4.9 *Tamping Rod*—A round, straight steel rod, with a 16 mm [⅝ in.] ± 2 mm [1⁄16 in.] diameter. The length of the tamping rod shall be at least 100 mm [4 in.] greater than the depth of the measuring bowl in which rodding is being performed, but not greater than 600 mm [24 in.] in overall length (See Note 2). The length tolerance for the tamping rod shall be ± 4 mm [⅛ in.]. The rod shall have the tamping end or both ends rounded to a hemispherical tip of the same diameter as the rod.

NOTE 2—A rod length of 400 mm [16 in.] to 600 mm [24 in.] meets the requirements of the following: Practice C31/C31M, Test Method C138/C138M, Test Method C143/C143M, Test Method C173/C173M, and Test Method C231/C231M.

Note: $A_1 = h_1 - h_2$ when measuring bowl contains concrete as shown in this figure; when measuring bowl contains only aggregate and water, $h_1 - h_2 = G$ (aggregate correction factor). $A_1 - G = A$ (entrained air content of concrete)

FIG. 1 Illustration of the Pressure Method for Air Content—Type-A Meter

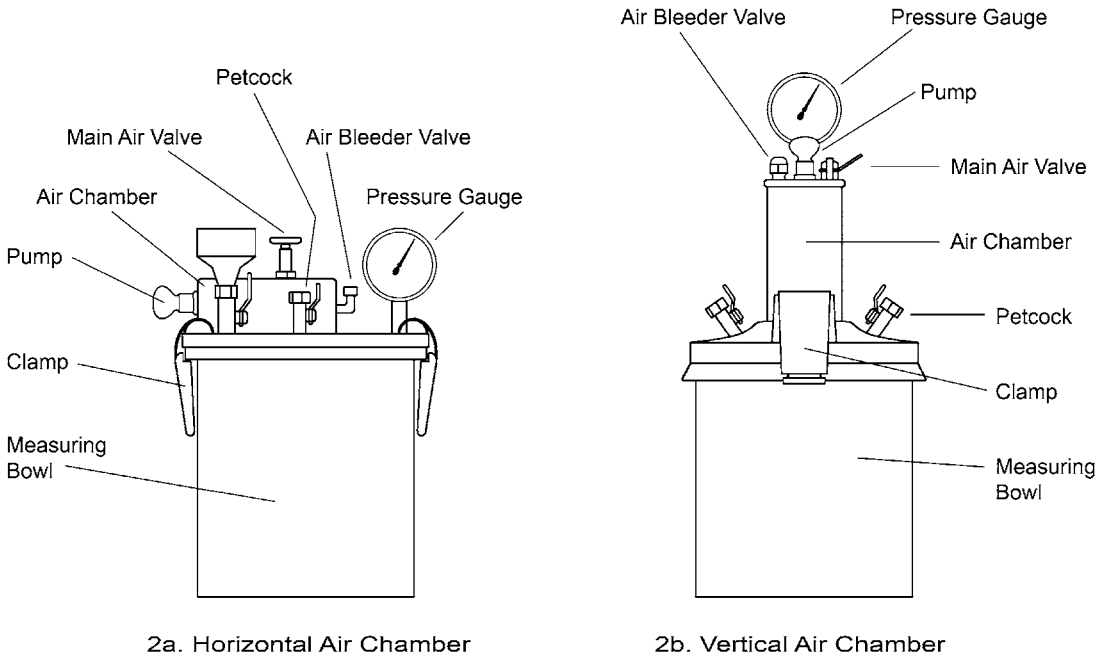

FIG. 2 Schematic Diagram—Type-B Meter

4.10 *Mallet*—A mallet (with a rubber or rawhide head) weighing approximately 0.60 ± 0.25 kg [1.25 ± 0.50 lb] for use with measures of 14 L [0.5 ft^3] or smaller, and a mallet weighing approximately 1.0 ± 0.25 kg [2.25 ± 0.50 lb] for use with measures larger than 14 L [0.5 ft^3].

4.11 *Strike-Off Bar*—A flat straight bar of steel or other suitable metal at least 3 mm [⅛ in.] thick and 20 mm [¾ in.] wide by 300 mm [12 in.] long.

4.12 *Strike-Off Plate*—A flat rectangular metal plate at least 6 mm [¼ in.] thick or a glass or acrylic plate at least 13 mm [½ in.] thick with a length and width at least 50 mm [2 in.] greater than the diameter of the measure with which it is to be used. The edges of the plate shall be straight and smooth within a tolerance of 1.5 mm [1⁄16 in.].

4.13 *Funnel*, with the spout fitting into spray tube.

4.14 *Measure for Water*, having the necessary capacity to fill the indicator with water from the top of the concrete to the zero mark.

4.15 *Vibrator*, as described in Practice C192/C192M.

4.16 *Sieves*, 37.5-mm (1½-in.) with not less than 0.2 m^2 [2 ft^2] of sieving area.

www.technobetar.ir

4.17 *Scoop*—of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the measuring bowl.

5. Calibration of Apparatus

5.1 Make calibration tests in accordance with procedures prescribed in the annex. Rough handling will affect the calibration of both Types A and B meters. Changes in barometric pressure will affect the calibration of Type A meter but not Type B meter. The steps described A1.2-A1.6, as applicable to the meter type under consideration, are prerequisites for the final calibration test to determine the operating pressure, *P*, on the pressure gauge of the Type A meter as described in A1.7, or to determine the accuracy of the graduations indicating air content on the dial face of the pressure gauge of the Type B meter as described in A1.9. The steps in A1.2-A1.6 need be made only once (at the time of initial calibration), or only occasionally to check volume constancy of the calibration cylinder and measuring bowl. The calibration test described in A1.7 and A1.9, as applicable to the meter type being checked, must be made as frequently as necessary and at intervals not to exceed three months to ensure that the proper gauge pressure, *P*, is being used for the Type A meter or that the correct air contents are being indicated on the pressure gauge air content scale for the Type B meter. A change in elevation of more than 180 m [600 ft] from the location at which a Type A meter was last calibrated will require recalibration in accordance with A1.7.

5.2 *Calibration Records*—Information to be maintained in the records shall include determination of expansion factor; size of the calibration vessel used; and the reading of the meter at the calibration test point(s).

6. Determination of Aggregate Correction Factor

6.1 *Procedure*—Determine the aggregate correction factor on a combined sample of fine and coarse aggregate as directed in 6.2 to 6.4. It is determined independently by applying the calibrated pressure to a sample of inundated fine and coarse aggregate in approximately the same moisture condition, amount, and proportions occurring in the concrete sample under test.

6.2 *Aggregate Sample Size*—Calculate the weights of fine and coarse aggregate present in the sample of fresh concrete whose air content is to be determined, as follows:

$$F_s = (S/B) \times F_b \quad (1)$$

$$C_s = (S/B) \times C_b \quad (2)$$

where:

F_s = mass of fine aggregate in concrete sample under test, kg [lb],

S = volume of concrete sample (same as volume of measuring bowl), m^3 [ft^3],

B = volume of concrete produced per batch (Note 3), m^3 [ft^3],

F_b = total mass of fine aggregate in the moisture condition used in batch, kg [lb],

C_s = mass of coarse aggregate in concrete sample under test, kg [lb], and

C_b = total mass of coarse aggregate in the moisture condition used in batch, kg [lb].

NOTE 3—The volume of concrete produced per batch can be determined in accordance with applicable provisions of Test Method C138/C138M.

NOTE 4—The term "weight" is temporarily used in this test method because of established trade usage. The word is used to mean both "force" and "mass," and care must be taken to determine which is meant in each case (SI unit for force = newton and for mass = kilogram).

6.3 *Placement of Aggregate in Measuring Bowl*—Mix representative samples of fine aggregate F_s and coarse aggregate C_s, and place in the measuring bowl filled one-third full with water. Place the mixed aggregate, a small amount at a time, into the measuring bowl; if necessary, add additional water so as to inundate all of the aggregate. Add each scoopful in a manner that will entrap as little air as possible and remove accumulations of foam promptly. Tap the sides of the measuring bowl and lightly rod the upper 25 mm [1 in.] of the aggregate eight to twelve times. Stir after each addition of aggregate to eliminate entrapped air.

6.4 *Aggregate Correction Factor Determination*:

6.4.1 *Initial Procedure for Types A and B Meters*—When all of the aggregate has been placed in the measuring bowl, remove excess foam and keep the aggregate inundated for a period of time approximately equal to the time between introduction of the water into the mixer and the time of performing the test for air content before proceeding with the determination as directed in 6.4.2 or 6.4.3.

6.4.2 *Type A Meter*—Complete the test as described in 8.2.1-8.2.3. The aggregate correction factor, *G*, is equal to $h_1 - h_2$ (see Fig. 1) (Note 5).

6.4.3 *Type B Meter*—Perform the procedures as described in 8.3.1. Remove a volume of water from the assembled and filled apparatus approximately equivalent to the volume of air that would be contained in a typical concrete sample of a size equal to the volume of the measuring bowl. Remove the water in the manner described in A1.9 for the calibration tests. Complete the test as described in 8.3.2. The aggregate correction factor, *G*, is equal to the reading on the air-content scale minus the volume of water removed from the measuring bowl expressed as a percent of the volume of the measuring bowl (see Fig. 1).

NOTE 5—The aggregate correction factor will vary with different aggregates. It can be determined only by test, since apparently it is not directly related to absorption of the particles. The test can be made easily. Ordinarily the factor will remain reasonably constant for given aggregates, but an occasional check test is recommended.

7. Preparation of Concrete Test Sample

7.1 Obtain the sample of freshly mixed concrete in accordance with applicable procedures of Practice C172. If the concrete contains coarse aggregate particles that would be retained on a 50-mm (2-in.) sieve, wet-sieve a sufficient amount of the representative sample over a 37.5-mm (1½-in.) sieve, as described in Practice C172, to yield sufficient material to completely fill the measuring bowl of the size selected for use. Carry out the wet-sieving operation with the minimum

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

practicable disturbance of the mortar. Make no attempt to wipe adhering mortar from coarse aggregate particles retained on the sieve.

8. Procedure for Determining Air Content of Concrete

8.1 *Placement and Consolidation of Sample*:

8.1.1 Prepare the concrete as described in 7.1. Dampen the interior of the measuring bowl and place it on a flat, level, firm surface. Using the scoop described in 4.17, place the concrete in the measuring bowl in the number of layers required by the consolidation method (8.1.2 or 8.1.3). While placing the concrete in the bowl, move the scoop around the perimeter of the bowl opening to ensure an even distribution of the concrete with minimal segregation. Consolidate each layer by the rodding procedure (8.1.2) or by vibration (8.1.3). Strike-off the finally consolidated layer (8.1.4). Rod concretes with a slump greater than 75 mm [3 in.]. Rod or vibrate concrete with a slump of 25 to 75 mm [1 to 3 in.]. Consolidate concretes with a slump less than 25 mm [1 in.] by vibration.

8.1.2 *Rodding*—Place the concrete in the measuring bowl in three layers of approximately equal volume. Rod each layer 25 times uniformly over the cross section with the rounded end of the rod. Rod the bottom layer throughout its depth. In rodding this layer, use care not to damage the bottom of the measuring bowl. For each upper layer, allow the rod to penetrate through the layer being rodded and into the layer below approximately 25 mm [1 in.]. After each layer is rodded, tap the sides of the measuring bowl smartly 10 to 15 times with the mallet to close any voids left by the tamping rod and to release any large bubbles of air that may have been trapped. Add the final layer of concrete in a manner to avoid excessive overfilling (8.1.4).

8.1.3 *Vibration*—Place the concrete in the measuring bowl in two layers of approximately equal volume. Place all of the concrete for each layer before starting vibration of that layer. Consolidate each layer by three insertions of the vibrator evenly distributed over the cross section. Add the final layer in a manner to avoid excessive overfilling (8.1.4). In consolidating each layer, do not allow the vibrator to rest on or touch the measuring bowl. Take care in withdrawing the vibrator to ensure that no air pockets are left in the specimen. Observe a standard duration of vibration for the particular kind of concrete, vibrator, and measuring bowl involved. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator. Continue vibration until the concrete is properly consolidated. Never continue vibration long enough to cause escape of froth from the sample.

NOTE 6—Overvibration may cause segregation and loss of intentionally entrained air. Usually, sufficient vibration has been applied as soon as the surface of the concrete becomes relatively smooth and has a glazed appearance.

8.1.4 *Strike Off*—After consolidation of the concrete, strike off the top surface by sliding the strike-off bar across the top flange or rim of the measuring bowl with a sawing motion until the bowl is just level full. On completion of consolidation, the measuring bowl must not contain an excess or deficiency of concrete. Removal of 3 mm [⅛ in.] during strike off is optimum. When a strike-off plate is used, strike off concrete as prescribed in Test Method C138/C138M.

NOTE 7—A small quantity of representative concrete may be added to correct a deficiency. If the measure contains a great excess, remove a representative portion of concrete with a trowel or scoop before the measure is struck off.

NOTE 8—The use of the strike-off plate on cast aluminum or other relatively soft metal air meter bases may cause rapid wear of the rim and require frequent maintenance, calibration, and ultimately, replacement.

8.1.5 *Application of Test Method*—Any portion of the test method not specifically designated as pertaining to Type A or Type B meter shall apply to both types.

8.2 *Procedure—Type A Meter*:

8.2.1 *Preparation for Test*—Thoroughly clean the flanges or rims of the measuring bowl and of the cover assembly so that when the cover is clamped in place a pressure-tight seal will be obtained. Assemble the apparatus and add water over the concrete by means of the tube until it rises to about the halfway mark in the standpipe. Incline the apparatus assembly about 0.5 rad [30°] from vertical and, using the bottom of the measuring bowl as a pivot, describe several complete circles with the upper end of the column, simultaneously tapping the cover lightly to remove any entrapped air bubbles above the concrete sample. Return the apparatus assembly to a vertical position and fill the water column slightly above the zero mark, while lightly tapping the sides of the measuring bowl. Bring the water level to the zero mark of the graduated tube before closing the vent at the top of the water column (see Fig. 1 A).

NOTE 9—Some Type A meters have a calibrated starting fill mark above the zero mark. Generally, this starting mark should not be used since, as noted in 8.2.3, the apparent air content is the difference between the water level reading H, at pressure P and the water level h_2 at zero pressure after release of pressure P.

8.2.2 The internal surface of the cover assembly shall be kept clean and free from oil or grease; the surface shall be wet to prevent adherence of air bubbles that might be difficult to dislodge after assembly of the apparatus.

8.2.3 *Test Procedure*—Apply more than the desired test pressure, P, (about 1.4 kPa [0.2 psi] more) to the concrete by means of the small hand pump. To relieve local restraints, tap the sides of the measuring bowl sharply and, when the pressure gauge indicates the exact test pressure, P, as determined in accordance with A1.7, read the water level, h_1, and record to the nearest division or half-division on the graduated precision-bore tube or gauge glass of the standpipe (see Fig. 1 B). For extremely harsh mixes tap the measuring bowl vigorously until further tapping produces no change in the indicated air content. Gradually release the air pressure through the vent at the top of the water column and tap the sides of the measuring bowl lightly for about 1 min. Record the water level, h_2, to the nearest division or half-division (see Fig. 1 C). Calculate the apparent air content as follows:

$$A_1 = h_1 - h_2 \tag{3}$$

where:

A_1 = apparent air content,
h_1 = water level reading at pressure, P (see Note 10), and
h_2 = water level reading at zero pressure after release of pressure, P.

8.2.4 *Check Test*—Repeat the steps described in 8.2.3 without adding water to reestablish the water level at the zero mark.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:09:36 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

The two consecutive determinations of apparent air content should check within 0.2 % of air and shall be averaged to give the value A_1 to be used in calculating the air content, A_s, in accordance with Section 9.

8.2.5 In the event the air content exceeds the range of the meter when it is operated at the normal test pressure P, reduce the test pressure to the alternative test pressure P_1 and repeat the steps outlined in 8.2.2 and 8.2.3.

NOTE 10—See A1.7 for exact calibration procedures. An approximate value of the alternative pressure, P_1, such that the apparent air content will equal twice the meter reading can be computed from the following relationship:

$$P_1 = P_a P/(2P_a + P) \quad (4)$$

where:

P_1 = alternative test pressure, kPa or [psi],
P_a = atmospheric pressure, kPa or [psi], (approximately 100 kPa [14.7 psi] but will vary with altitude and weather conditions), and
P = normal test or operating gauge pressure, kPa or [psi].

8.3 *Procedure—Type B Meter*:

8.3.1 *Preparation for Test*—Thoroughly clean the flanges or rims of the measuring bowl and the cover assembly so that when the cover is clamped in place a pressure-tight seal will be obtained. Assemble the apparatus. Close the main air valve between the air chamber and the measuring bowl and open both petcocks on the holes through the cover. Using a rubber syringe, inject water through one petcock until water emerges from the opposite petcock. Jar the meter gently until all air is expelled from this same petcock.

8.3.2 *Test Procedure*—Close the air bleeder valve on the air chamber and pump air into the air chamber until the gauge hand is on the initial pressure line. Allow a few seconds for the compressed air to cool to normal temperature. Stabilize the gauge hand at the initial pressure line by pumping or bleeding-off air as necessary, tapping the gauge lightly by hand. Close both petcocks on the holes through the cover. Open the main air valve between the air chamber and the measuring bowl. Tap the sides of the measuring bowl smartly with the mallet to relieve local restraints. Lightly tap the pressure gauge by hand to stabilize the gauge hand. Read the percentage of air on the dial of the pressure gauge. Release the main air valve. Failure to close the main air valve before releasing the pressure from either the container or the air chamber will result in water being drawn into the air chamber, thus introducing error in subsequent measurements. In the event water enters the air chamber, it must be bled from the air chamber through the air bleeder valve followed by several strokes of the pump to blow out the last traces of water. Release the pressure by opening both petcocks (Fig. 2) before removing the cover.

9. Calculation

9.1 *Air Content of Sample Tested*—Calculate the air content of the concrete in the measuring bowl as follows:

$$A_s = A_1 - G \quad (5)$$

where:

A_s = air content of the sample tested, %,
A_1 = apparent air content of the sample tested, % (see 8.2.3 and 8.3.2), and
G = aggregate correction factor, % (Section 6).

9.2 *Air Content of Full Mixture*—When the sample tested represents that portion of the mixture that is obtained by wet sieving to remove aggregate particles larger than a 37.5-mm (1½-in.) sieve, the air content of the full mixture is calculated as follows:

$$A_t = 100\,A_s V_c/(100\,V_t - A_s V_a) \quad (6)$$

where: (Note 11):

A_t = air content of the full mixture, %,
V_c = absolute volume of the ingredients of the mixture passing a 37.5-mm (1½-in.) sieve, airfree, as determined from the original batch weights, m^3 [ft^3],
V_t = absolute volume of all ingredients of the mixture, airfree, m^3 [ft^3], and
V_a = absolute volume of the aggregate in the mixture coarser than a 37.5-mm (1½-in.) sieve, as determined from original batch weights, m^3 [ft^3].

9.3 *Air Content of the Mortar Fraction*—When it is desired to know the air content of the mortar fraction of the mixture, calculate it as follows:

$$A_m = 100\,A_s\,V_c/[100\,V_m + A_s(V_c - V_m)] \quad (7)$$

where: (Note 11):

A_m = air content of the mortar fraction, %, and
V_m = absolute volume of the ingredients of the mortar fraction of the mixture, airfree, m^3 [ft^3].

NOTE 11—The values for use in Eq 6 and Eq 7 are most conveniently obtained from data on the concrete mixture tabulated as follows for a batch of any size:

		Absolute Volume, m^3 [ft^3]	
Cement			
Water		V_m	V_c
Fine aggregate			
Coarse aggregate (4.75-mm (No. 4) to 37.5-mm (1½-in.))			
Coarse aggregate (37.5-mm (1½-in.))		V_a	
Total		V_t	

10. Report

10.1 Report the following information:

10.1.1 The air content of the concrete sample to the nearest 0.1 % after subtracting the aggregate correction factor, unless the gauge reading of the meter exceeds 8 %, in which case the corrected reading shall be reported to the nearest ½ scale division on the dial.

10.1.2 The date and time of the test.

10.1.3 When requested, and when the absolute volume of the ingredients of the mortar fraction of the mixture can be determined, the air content of the mortar fraction of the mixture to the nearest ¼ %.

11. Precision and Bias

11.1 *Precision*:

11.1.1 *Single-Operator Precision*—The single-operator standard deviation cannot be established because the sampling

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:09:36 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

requirements for this test, as established in Practice C172, do not allow a single operator time to conduct more than one test on a sample.

11.1.2 *Multilaboratory Precision*—The multilaboratory standard deviation has not been established.

11.1.3 *Multioperator Precision*—The multioperator standard deviation of a single test result has been found to be 0.28 % air by volume of concrete for Type A air meters as long as the air content does not exceed 7 %. Therefore results of two tests properly conducted by different operators but on the same material should not differ by more than 0.8 % air by volume of concrete (see Practice E177, Note 12 and Note 13).

NOTE 12—These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C670. The precision statements are based on the variations in tests on three different concretes, each tested by eleven different operators.[4]

NOTE 13—The precision of this test method using Type B air meters has not been determined.

11.2 *Bias*—This test method has no bias because the air content of freshly mixed concrete can only be defined in terms of the test methods.

Frohnsdorff and B. Horner, National Institute for Standards and Technology, Gaithersburg, MD 20899, formerly National Bureau of Standards, Washington, DC 20234.

ANNEX

(Mandatory Information)

A1. CALIBRATION OF APPARATUS

A1.1 Calibration tests shall be performed in accordance with the following procedures as applicable to the meter type being employed.

A1.2 *Calibration of the Calibration Vessel*—Determine accurately the weight of water, w, required to fill the calibration vessel, using a scale accurate to 0.1 % of the weight of the vessel filled with water. This step shall be performed for Type A and B meters.

A1.3 *Calibration of the Measuring Bowl*—Determine the weight of water, W, required to fill the measuring bowl, using a scale accurate to 0.1 % of the weight of the measuring bowl filled with water. Slide a glass plate carefully over the flange of the measuring bowl in a manner to ensure that the measuring bowl is completely filled with water. A thin film of cup grease smeared on the flange of the measuring bowl will make a watertight joint between the glass plate and the top of the measuring bowl. This step shall be performed for Type A and B meters.

A1.4 *Effective Volume of the Calibration Vessel, R*—The constant R represents the effective volume of the calibration vessel expressed as a percentage of the volume of the measuring bowl.

A1.4.1 For meter Types A, calculate R as follows (Note A1.1):

$$R = 0.98\ w/W \tag{A1.1}$$

where:

w = weight of water required to fill the calibration vessel, and
W = weight of water required to fill the measuring bowl.

NOTE A1.1—The factor 0.98 is used to correct for the reduction in the volume of air in the calibration vessel when it is compressed by a depth of water equal to the depth of the measuring bowl. This factor is approximately 0.98 for a 200-mm [8-in.] deep measuring bowl at sea level. Its value decreases to approximately 0.975 at 1500 m [5000 ft] above sea level and 0.970 at 4000 m [13 000 ft] above sea level. The value of this constant will decrease by about 0.01 for each 100-mm [4-in.] increase in measuring bowl depth. The depth of the measuring bowl and atmospheric pressure do not affect the effective volume of the calibration vessel for meter Types B.

A1.4.2 For meter Types B calculate R as follows (Note A1.1):

$$R = w/W \tag{A1.2}$$

A1.5 *Determination of, or Check of, Allowance for Expansion Factor, D*:

A1.5.1 For meter assemblies of Type A determine the expansion factor, D (Note A1.2) by filling the apparatus with water only (making certain that all entrapped air has been removed and the water level is exactly on the zero mark (Note A1.3) and applying an air pressure approximately equal to the operating pressure, P, determined by the calibration test described in A1.7. The amount the water column lowers will be the equivalent expansion factor, D, for that particular apparatus and pressure (Note A1.5).

NOTE A1.2—Although the measuring bowl, cover, and clamping mechanism of the apparatus must of necessity be sturdily constructed so

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:09:36 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

that it will be pressure-tight, the application of internal pressure will result in a small increase in volume. This expansion will not affect the test results because, with the procedure described in Sections 6 and 8, the amount of expansion is the same for the test for air in concrete as for the test for aggregate correction factor on combined fine and coarse aggregates, and is thereby automatically cancelled. However, it does enter into the calibration test to determine the air pressure to be used in testing fresh concrete.

NOTE A1.3—The water columns on some meters of Type-A design are marked with an initial water level and a zero mark, the difference between the two marks being the allowance for the expansion factor. This allowance should be checked in the same manner as for meters not so marked and in such a case, the expansion factor should be omitted in computing the calibration readings in A1.7.

NOTE A1.4—It will be sufficiently accurate for this purpose to use an approximate value for P determined by making a preliminary calibration test as described in A1.7 except that an approximate value for the calibration factor, K, should be used. For this test $K = 0.98R$ which is the same as Eq A1.2 except that the expansion reading, D, as yet unknown, is assumed to be zero.

A1.5.2 For meters of Type B design, the allowance for the expansion factor, D, is included in the difference between the initial pressure indicated on the pressure gauge and the zero percent mark on the air-content scale on the pressure gauge. This allowance shall be checked by filling the apparatus with water (making certain that all entrapped air has been removed), pumping air into the air chamber until the gauge hand is stabilized at the indicated initial pressure line, and then releasing the air to the measuring bowl (Note A1.5). If the initial pressure line is correctly positioned, the gauge should read zero percent. The initial pressure line shall be adjusted if two or more determinations show the same variation from zero percent and the test repeated to check the adjusted initial pressure line.

NOTE A1.5—This procedure may be accomplished in conjunction with the calibration test described in A1.9.

A1.6 *Calibration Reading, K*—The calibration reading, K, is the final meter reading to be obtained when the meter is operated at the correct calibration pressure.

A1.6.1 For meter Types A, the calibration reading, K, is as follows:

$$K = R + D \tag{A1.3}$$

where:

R = effective volume of the calibration vessel (A1.4.1), and

D = expansion factor (A1.5.1, Note A1.6).

A1.6.2 For meter Types B the calibration reading, K, equals the effective volume of the calibration vessel (A1.4.2) as follows:

$$K = R \tag{A1.4}$$

NOTE A1.6—If the water column indicator is graduated to include an initial water level and a zero mark, the difference between the two marks being equivalent to the expansion factor, the term D shall be omitted from Eq A1.3.

A1.7 *Calibration Test to Determine Operating Pressure, P, on Pressure Gauge, Type A Meter*—If the rim of the calibration cylinder contains no recesses or projections, fit it with three or more spacers equally spaced around the circumference. Invert the cylinder and place it at the center of the dry bottom of the measuring bowl. The spacers will provide an opening for flow of water into the calibration cylinder when pressure is applied. Secure the inverted cylinder against displacement and carefully lower the cover assembly. After the cover is clamped in place, carefully adjust the apparatus assembly to a vertical position and add water at air temperature, by means of the tube and funnel, until it rises above the zero mark on the standpipe. Close the vent and pump air into the apparatus to the approximate operating pressure. Incline the assembly about 0.5 rad [30°] from vertical and, using the bottom of the measuring bowl as a pivot, describe several complete circles with the upper end of the standpipe, simultaneously tapping the cover and sides of the measuring bowl lightly to remove any entrapped air adhering to the inner surfaces of the apparatus. Return the apparatus to a vertical position, gradually release the pressure (to avoid loss of air from the calibration vessel), and open the vent. Bring the water level exactly to the zero mark by bleeding water through the petcock in the top of the conical cover. After closing the vent, apply pressure until the water level has dropped an amount equivalent to about 0.1 to 0.2 % of air more than the value of the calibration reading, K, determined as described in A1.6. To relieve local restraints, lightly tap the sides of the measuring bowl, and when the water level is exactly at the value of the calibration reading, K, read the pressure, P, indicated by the gauge and record to the nearest 700 Pa [0.1 psi]. Gradually release the pressure and open the vent to determine whether the water level returns to the zero mark when the sides of the measuring bowl are tapped lightly (failure to do so indicates loss of air from the calibration vessel or loss of water due to a leak in the assembly). If the water levels fails to return to within 0.05 % air of the zero mark and no leakage beyond a few drops of water is found, some air probably was lost from the calibration cylinder. In this case, repeat the calibration procedure step by step from the beginning of this paragraph. If the leakage is more than a few drops of water, tighten the leaking joint before repeating the calibration procedure. Check the indicated pressure reading promptly by bringing the water level exactly to the zero mark, closing the vent, and applying the pressure, P, just determined. Tap the gauge lightly with a finger. When the gauge indicates the exact pressure, P, the water column should read the value of the calibration factor, K, used in the first pressure application within about 0.05 % of air.

A1.7.1 The apparatus assembly must not be moved from the vertical position until pressure has been applied, which will force water about one third of the way up into the calibration cylinder. Any loss of air from this cylinder will nullify the calibration.

A1.8 *Calibration Test to Determine Alternative Operating Pressure P_1—Meter Type A*—The range of air contents which can be measured with a given meter can be doubled by determining an alternative operating pressure P_1 such that the meter reads half of the calibration reading, K, (Eq A1.3). Exact calibration will require determination of the expansion factor at the reduced pressure in A1.5. For most purposes the change in expansion factor can be disregarded and the alternative operating pressure determined during the determination of the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:09:36 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

regular operating pressure in A1.7.

A1.9 *Calibration Test to Check the Air Content Graduations on the Pressure Gauge, Type B Meter*—Fill the measuring bowl with water as described in A1.3. Screw the short piece of tubing or pipe furnished with the apparatus into the threaded petcock hole on the underside of the cover assembly. Assemble the apparatus. Close the main air valve between the air chamber and the measuring bowl and open the two petcocks on holes through the cover assembly. Add water through the petcock on the cover assembly having the extension below until all air is expelled from the second petcock. Pump air into the air chamber until the pressure reaches the indicated initial pressure line. Allow a few seconds for the compressed air to cool to normal temperature. Stabilize the gauge hand at the initial pressure line by pumping or bleeding off air as necessary, tapping the gauge lightly. Close the petcock not provided with the tube or pipe extension on the under side of the cover. Remove water from the assembly to the calibrating vessel controlling the flow, depending on the particular meter design, by opening the petcock provided with the tube or pipe extension and cracking the main air valve between the air chamber and the measuring bowl, or by opening the main air valve and using the petcock to control flow. Perform the calibration at an air content which is within the normal range of use. If the calibration vessel (A1.2) has a capacity within the normal range of use, remove exactly that amount of water. With some meters the calibrating vessel is quite small and it will be necessary to remove several times that volume to obtain an air content within the normal range of use. In this instance, carefully collect the water in an auxiliary container and determine the amount removed by weighing to the nearest 0.1 %. Calculate the correct air content, *R*, by using Eq A1.2. Release the air from the apparatus at the petcock not used for filling the calibration vessel and if the apparatus employs an auxiliary tube for filling the calibration container, open the petcock to which the tube is connected to drain the tube back into the measuring bowl (see A1.7.1). At this point of procedure the measuring bowl contains the percentage of air determined by the calibration test of the calibrating vessel. Pump air into the air chamber until the pressure reaches the initial pressure line marked on the pressure gauge, close both petcocks in the cover assembly, and then open the main air valve between the air chamber and the measuring bowl. The indicated air content on the pressure gauge dial should correspond to the percentage of air determined to be in the measuring bowl. If two or more determinations show the same variation from the correct air content, the dial hand shall be reset to the correct air content and the test repeated until the gauge reading corresponds to the calibrated air content within 0.1 %. If the dial hand was reset to obtain the correct air content, recheck the initial pressure mark as in A1.5.2. If a new initial pressure reading is required, repeat the calibration to check the accuracy of the graduation on the pressure gauge described earlier in this section. If difficulty is encountered in obtaining consistent readings, check for leaks, for the presence of water inside the air chamber (see Fig. 2), or the presence of air bubbles clinging to the inside surfaces of the meter from the use of cool aerated water. In this latter instance use deaerated water which can be obtained by cooling hot water to room temperature.

NOTE A1.7—If the calibrating vessel is an integral part of the cover assembly, the petcock used in filling the vessel should be closed immediately after filling the calibration vessel and not opened until the test is complete.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C231 – 09a, that may impact the use of this test method. (Approved December 15, 2009)

(*1*) Revised the standard as a dual units test method with SI units first and inch-pound units in brackets.

Committee C09 has identified the location of selected changes to this test method since the last issue, C231 – 09, that may impact the use of this test method. (Approved July 1, 2009)

(*1*) Revised 4.4.

Committee C09 has identified the location of selected changes to this test method since the last issue, C231 – 08c, that may impact the use of this test method. (Approved June 1, 2009)

(*1*) Revised 4.9 to alter tamping rod requirements.
(*2*) Added Note 2 describing acceptable tamping rod length.
(*3*) Revised 8.1.2 to alter wording of tamping rod use.

Designation: C 232/C 232M – 09

Standard Test Methods for Bleeding of Concrete[1]

This standard is issued under the fixed designation C 232/C 232M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 These test methods cover the determination of the relative quantity of mixing water that will bleed from a sample of freshly mixed concrete. Two test methods, that differ primarily in the degree of vibration to which the concrete sample is subjected, are included.

1.2 The two test methods are not expected to yield the same test results when samples of concrete from the same batch are tested by each method. When various concretes are to be compared, all the tests must be conducted using the same method, and if the batches are of similar unit weight, the sample masses shall not differ by more than 1 kg [2 lb].

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure).[2]

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C 138/C 138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

C 172 Practice for Sampling Freshly Mixed Concrete

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Significance and Use

3.1 This test method provides procedures to be used for determining the effect of variables of composition, treatment, environment, or other factors in the bleeding of concrete. It is also permitted to be used to determine the conformance of a product or treatment with a requirement relating to its effect on bleeding of concrete.

3.2 *Method A*—For a sample consolidated by rodding only and tested without further disturbance, thus simulating conditions in which the concrete, after placement, is not subjected to intermittent vibration.

3.3 *Method B*—For a sample consolidated by vibration and tested with further intermittent periods of vibration, thus simulating conditions in which concrete, after being placed, is subjected to intermittent vibration.

TEST METHOD A—SAMPLE CONSOLIDATED BY TAMPING

4. Apparatus

4.1 *Container*—A cylindrical container of approximately 14-L [½-ft^3] capacity, having an inside diameter of 255 ± 5 mm [10 ± ¼ in.] and an inside height of 280 ± 5 mm [11 ± ¼ in.]. The container shall be made of metal having a thickness of 2.67 to 3.40 mm [0.105 to 0.134 in.] and shall be externally reinforced around the top with a 2.67 to 3.40 mm [0.105 to 0.134 in.] metal band, 40 mm [1½ in.] wide. The inside shall be smooth and free of corrosion, coatings, or lubricants.

4.2 *Scale*, of sufficient capacity to determine the mass of the load required with an accuracy of 0.5 %. Balances or scales shall be calibrated at least annually or whenever there is reason to question the accuracy of the equipment. Equipment not in operating condition or out of tolerance shall be marked as such and taken out of service until corrected.

[1] These test methods are under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and are the direct responsibility of Subcommittee C09.60 on Testing Fresh Concrete.

Current edition approved June 1, 2009. Published July 2009. Originally approved in 1949. Last previous edition approved in 2007 as C 232 – 07.

www.technobetar.ir

4.3 *Pipet*, or similar instrument, for drawing off free water from the surface of the test specimen.

4.4 *Glass Graduate*, 100-mL capacity for collecting and measuring the quantity of water withdrawn.

4.5 *Tamping Rod*—A round, straight steel rod, 16 mm [⅝ in.] in diameter and approximately 610 mm [24 in.] in length, having the tamping end rounded to a hemispherical tip, the diameter of which is 16 mm [⅝ in.].

4.6 The apparatus listed in 4.7, 4.8, and 4.9 are required if the procedure of measuring the amount of bleeding water recovered is one involving weighing, evaporation, and re-weighing.

4.7 *Metal Beaker (Optional)*—A 1000-mL metal beaker for collecting the decanted supernatant water and sludge.

4.8 *Balance (Optional)*—A balance sensitive to 1 g for determining the mass of the decanted water and sludge.

4.9 *Hot Plate (Optional)*—A small electric hot plate or other source of heat for evaporating decanted water.

5. Test Specimen

5.1 For concrete made in the laboratory, prepare as described in Practice C 192/C 192M. For concrete made in the field, sample the concrete as described in Practice C 172. The apparatus described in this test method is permitted to be used with samples of concrete containing any size of aggregate graded up to and including a nominal maximum size of 50 mm [2 in.]. Concrete containing aggregate larger than 50 mm [2 in.] in nominal maximum size shall be wet sieved over a 3.75 mm [1½-in.] sieve and the test performed on a portion of the sample that passes through the sieve.

5.2 Fill the container with the concrete in accordance with Test Method C 138/C 138M except that the container shall be filled to a height of 254 ± 3 mm [10 ± ⅛ in.]. Level the top surface of the concrete to a reasonably smooth surface by a minimum amount of troweling.

6. Procedure

6.1 During the test, maintain the ambient temperature between 18 and 24 °C [65 and 75 °F]. Immediately after troweling the surface of the specimen, record the time and determine the mass of the container and its contents. Place the specimen and container on a level platform or floor free of noticeable vibration and cover the container to prevent evaporation of the bleed water. Keep the cover in place throughout the test, except when drawing off the water. Draw off (with pipet or similar instrument) the water that has accumulated on the surface at 10-min intervals during the first 40 min and at 30-min intervals thereafter until cessation of bleeding, recording the time of last observation. To facilitate the collection of bleeding water, tilt the specimen carefully by placing a block approximately 50 mm [2 in.] thick under one side of the container 2 min prior to each time the water is withdrawn. After the water is removed, return the container to a level position without jarring. After each withdrawal, transfer the water to a 100-mL graduated cylinder. Record the accumulated quantity of water after each transfer. When only the total volume of bleeding is desired to be determined, the periodic removal procedure shall be omitted and the entire amount removed in a single operation. If it is desired to determine the mass of the bleeding water and to exclude the material present other than the water, carefully decant the contents of the cylinder into a metal beaker. Determine the mass and record the mass of the beaker and its contents. Dry the beaker and its contents to constant mass and record the final mass. The difference between the two masses, D, is equal to the mass of the bleeding water. The mass of the sludge shall also be obtained, if desired, by initially determining the tare mass of the beaker.

7. Calculation

7.1 Calculate the volume of bleeding water per unit area of surface, V, as follows:

$$V = V_1/A \quad (1)$$

where:

V_1 = volume of bleeding water measured during the selected time interval, mL, and

A = area of exposed concrete, cm^2.

The comparative rate of bleeding shall be determined as the test progresses by comparing the volume of bleeding water for each equal time interval.

7.2 Calculate the accumulated bleeding water, expressed as a percentage of the net mixing water contained within the test specimen, as follows:

$$C = (w/W) \times S \quad (2)$$

$$\text{Bleeding, } \% = (D/C) \times 100$$

where:

C = mass of the water in the test specimen, g,

W = total mass of the batch, kg,

w = net mixing water (the total amount of water minus the water absorbed by the aggregates), kg,

S = mass of the sample, g, and

D = mass of the bleeding water, g, or total volume withdrawn from the test specimen in cubic centimeters multiplied by 1 g/cm^3.

TEST METHOD B—SAMPLE CONSOLIDATED BY VIBRATION

8. Apparatus

8.1 *Vibrating Platform*—A platform shall be provided upon which the filled container shall be mounted. The platform shall be equipped with a suitable device so that intermittent periods of vibration of reproducible duration, frequency, and amplitudes will be imparted to the specimen container as prescribed by Section 8 (see Fig. 1). Suitable vibration will be provided if there is bolted to the platform a 93W [⅛-hp] electric motor, to the shaft of which a small eccentric whose mass is approximately 110 g [0.24 lb] is attached by means of a setscrew. The eccentric shall be fabricated from cold-rolled stock in accordance with the details and dimensions shown in Fig. 2. The hole through the eccentric is 13.5 mm [34/64 in.] or an appropriate size to accommodate the motor shaft. The platform shall be supported on rubber supports resting on a concrete slab. The concrete slab shall be separated from the floor by a layer of cork as shown in Fig. 2.

www.technobetar.ir

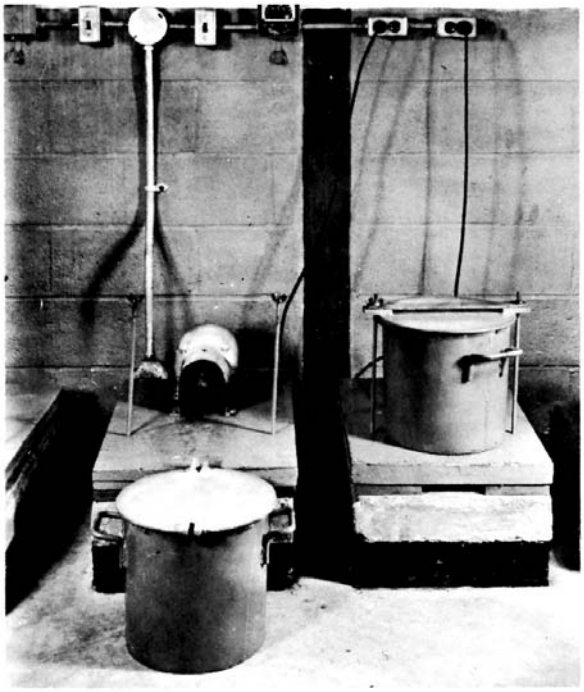

FIG. 1 Vibrating Platform and Timer

8.2 *Timer*—A timing device, by means of which the periods of vibration provided to the platform and specimen in accordance with the provisions of Section 8 is permitted to be regulated.

8.3 *Container*—A steel container 290 mm [11½ in.] in diameter at the top, 280 mm [11 in.] in diameter at the bottom, and 285 mm [11⅛ in.] high shall be provided. A steel container cover shall also be provided. The container and cover shall conform with the details given in Fig. 3.

8.3.1 The remainder of the apparatus is identical with that given for Method A.

9. Vibrating Cycle

9.1 The vibrating cycle shall be as follows: Power on for 3 s, power off 30 s. However, due to the coasting of the motor after the power is turned off, the period of perceptible vibration is approximately 7 s.

10. Test Specimen

10.1 The sample shall be prepared as described for Method A.

10.2 The sample shall be placed in the container to a depth equal to approximately one half the average diameter of the container. The size of the test sample can best be regulated by mass; a sample with a mass of 20 ± 0.5 kg [45 ± 1 lb] usually meets the requirements for the apparatus described herein.

11. Procedure

11.1 *Consolidation of Test Specimen*—Consolidate the sample in the container by means of vibration of only that duration required to effect the desired degree of compaction. Sufficient vibration has been applied as soon as the surface of the concrete has become relatively smooth. Stop the consolidating procedure immediately upon the first appearance of free water segregating from the concrete as indicated by the development of a water sheen on its surface. For some unusually wet or plastic mixtures, no consolidating effort will be needed beyond that supplied by placing the sample in the container and handling the container during the operations of determining the mass and placing it on the platform for test.

11.2 *Intermittent Vibration*—Place the cover on the container and the container on the vibrating platform. Clamp the container and cover down tightly. Note and record the time, and start the motor. Continue intermittent vibration for 1 h.

11.3 *Determination of Bleeding Water*—The intermittent periods of vibrations do not permit the determination of bleeding water at a number of different time intervals. Determine the total volume of bleeding water as described for Method A.

12. Calculation

12.1 Calculate the percentage bleeding water as described for Method A.

13. Report

13.1 Concrete mixture proportions,

13.2 Source and identification of each material used,

13.3 Method used for collection of the bleeding data (A or B),

13.4 The volume of bleeding water per unit area of surface, and the accumulated bleeding water, expressed as a percentage of the net mixing water contained within the test specimen, and

13.5 Elapsed time required for cessation of bleeding.

14. Precision and Bias

14.1 *Precision*:

14.1.1 *Method A*—Data are not available to evaluate the precision of Method A directly. However, there is reason to believe that the precision for Method A is at least as good as that for Method B. The values given for Method B shall be used as maximum precision limits for Method A.

14.1.2 *Method B*—The single operator-day-multibatch standard deviation (1s) has been found to be 0.71 % for a bleeding range from 0 to 10 %, 1.06 % for a bleeding range from 10 to 20 %, and 1.77 % for more than 20 %. Therefore, results of two properly conducted tests by the same operator on the same day on different batches of the same mixture are not expected to differ by more than 2.0 % (d2s) for a bleeding range from 0 to 10 %, 3.0 % for a range from 10 to 20 %, and 5.0 % for more than 20 %. (See Note 1.)

NOTE 1—These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

14.2 *Bias*—The test methods have no bias because the values determined can be defined only in terms of the test methods.

15. Keywords

15.1 bleeding; concrete, bleeding of

Designation: C 233 – 07

Standard Test Method for Air-Entraining Admixtures for Concrete[1]

This standard is issued under the fixed designation C 233; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the testing of materials proposed for use as air-entraining admixtures in the field.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this test method references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

D 1193 Specification for Reagent Water

E 70 Test Method for pH of Aqueous Solutions With the Glass Electrode

2.2 *ACI Standards:*

ACI 211.1 Recommended Practice for Selecting Proportions for Normal, Heavyweight, and Mass Concrete[3]

3. Significance and Use

3.1 This test method is used to develop data for comparison with the requirements of Specification C 260. These tests are based on arbitrary stipulations permitting highly standardized testing in the laboratory, and are not intended to simulate actual job conditions.

4. Materials

4.1 *Cement*—The cement used in any series of tests shall be either the cement proposed for specific work in accordance with 4.4, a Type I or Type II cement conforming to Specification C 150, or a blend of two or more cements, in equal parts. Each cement of the blend shall conform to the requirements of either Type I or Type II, Specification C 150. If a blend of cements is used, it shall be a combination which produces an

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

Current edition approved July 15, 2007. Published August 2007. Originally approved in 1949. Last previous edition approved in 2004 as C 233 – 04.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

air content of less than 10 % when tested in accordance with Test Method C 185 (Note 4).

4.2 *Aggregates*—Except when tests are made in accordance with 4.4, using the aggregates proposed for specific work, the fine and coarse aggregates used in any series of tests shall come from single lots of well-graded, sound materials that conform to the requirements of Specification C 33, except that the grading of the aggregates shall conform to the following requirements:

4.2.1 *Fine Aggregate Grading*—The fine aggregate shall meet the requirements for the fine aggregate in Specification C 33.

4.2.2 *Coarse Aggregate Grading*—The coarse aggregate grading shall meet the Size 57 grading requirements of Specification C 33.

NOTE 1—Take care in loading and delivery to avoid segregation.

4.2.3 The coarse aggregate used for the reference concrete and test concretes shall be essentially the same. Provide sufficient coarse aggregate for the reference concrete, the test concrete, and for the grading analysis. Concrete consists of one reference concrete and as many test admixture-containing concretes as are intended to be compared.

4.2.3.1 Prepare required quantities of coarse aggregate as follows: Fill tared containers, one for sieve analysis, one for a batch of reference concrete, and one for a batch of test concrete, to the required mass from the aggregate stockpile (See Note 2). Accomplish this by placing equal quantities into each container, successively, and repeat the procedure until all the containers have their required mass (See Note 2).

NOTE 2—See the Appendix of Practice D 75, Sampling from Stockpiles, and the section on Sampling Aggregates in the Manual of Aggregate and Concrete Testing[4] for guidance on procedures for sampling from stockpiles.

4.2.4 Perform sieve analysis on the coarse aggregate sample prepared in 4.2.3.1 by Test Method C 136. Discard any set for which the sample does not comply with Size 57. Average test results for samples that comply with Size 57 for each sieve size. Discard any set for which the sample deviates from this average by more than the amount shown in column 3. Continue the process of preparation, testing and averaging until sufficient sets of aggregate within tolerance are obtained.

[4] Manual of Aggregate and Concrete Testing, *Annual Book of ASTM Standards* , Vol 04.02.

Sieve	Specification C 33, No. 57 Percent Passing	Maximum variation from average/passing
37.5-mm	100	00
25.0-mm	95 to 100	1.0
12.5-mm	25 to 60	4.0
4.75-mm	0 to 10	4.0
2.36-mm	0 to 5	1.0

NOTE 3—All of the results required for demonstrating compliance under this specification are dependent on the uniformity of the aggregate samples prepared and used. Careful, skilled and well-supervised work is essential.

4.3 *Reference Admixture*—For this test method, unless otherwise requested by the purchaser, the reference admixture used in the concrete mixture specified in Section 4 shall be "neutralized Vinsol resin."[5]

4.4 *Materials for Tests for Specific Uses*—When it is desired to test an air-entraining admixture for use in specific work, the cement and aggregates used shall be representative of those proposed for use in the work, and the concrete mixtures shall be designed to have the cement content specified for use in the work (Note 4). If the maximum size of coarse aggregate is greater than 25.0 mm (1 in.), the freshly mixed concrete shall be screened over a 25.0-mm (1-in.) sieve prior to fabricating the test specimens in accordance with the wet sieving procedure described in Practice C 172.

4.5 *Preparation and Weighing*—All materials shall be prepared and all weighings shall be made as prescribed in Practice C 192/C 192M.

NOTE 4—It is recommended that whenever practicable, tests be made in accordance with 4.4 using the cement and pozzolanic or chemical admixtures, if any, proposed for specific work.

5. Concrete Mixtures

5.1 *Proportions*—Using ACI 211.1, all concrete shall be proportioned to conform to the following requirements:

5.1.1 The cement content shall be 307 ± 3 kg/m^3 (517 ± 5 lb/yd^3) except when tests are being made for specific uses (see 4.4).

5.1.2 The first trial mixture shall contain the amount of coarse aggregate shown in Table 6.3.6 of ACI 211.1 for the maximum size of aggregate and for the fineness modulus of the sand being used.

[5] The sole source of supply of Vinsol resin known to the committee at this time is Hercules Inc., Wilmington, DE. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend. Neutralization may be accomplished by treating 100 parts of the Vinsol resin with 9 to 15 parts of NaOH by weight. In an aqueous solution, the ratio of reagent water (See Specification D 1193) to the resinate shall not exceed 12:1 by weight.

NOTE 5—The volumes of coarse aggregate recommended in ACI 211.1 are intended to ensure workable mixtures with the least favorable combinations of aggregate likely to be used. It is suggested, therefore, that for a closer approximation of the proportions required for this test, the recommended values in ACI 211.1 be multiplied by 1.07 for the first trial mixture.

5.1.3 The air content used in the computation of proportions for all concrete shall be 5.5 % except where the admixture under test is for use in specific work (see 4.4). In this case the air content used in selecting proportions shall be the median of the range to be permitted in the work. If lightweight aggregates are to be used in specific work, the unit weight of concrete used in selecting proportions shall be the median of the range permitted in the work.

5.1.4 The water content and sand content shall be adjusted to obtain a slump of 90 ± 15 mm (3½ ± ½ in.). The workability of the concrete mixture shall be suitable for consolidation by hand rodding and the concrete mixture shall have the minimum water content possible. These conditions shall be achieved by final adjustments in the proportion of fine aggregate to total aggregate, in the amount of total aggregate, or both, while maintaining the yield and slump in the required ranges.

5.2 *Conditions*—Concrete mixtures shall be prepared both with the air-entraining admixture under test and with the reference admixture. The admixtures shall be added in the amounts necessary to produce the air content selected in accordance with 5.1.3 within a tolerance of ±0.5 % of the volume of concrete.

6. Mixing

6.1 Machine mix the concrete as prescribed in Practice C 192/C 192M.

7. Tests and Properties of Freshly Mixed Concrete

7.1 Test samples of freshly mixed concrete from at least three separate batches for each condition of concrete in accordance with the following methods and the minimum number of tests shall be as prescribed in Table 1.

7.1.1 *Slump*—Test Method C 143/C 143M.

7.1.2 *Air Content*—Test Method C 231. When lightweight aggregates, air-cooled blast furnace slag, or aggregates of high porosity, for which the aggregate correction factor defined in Test Method C 231 exceeds 0.5 %, are used under the provisions of 4.4, use Test Method C 173/C 173M.

7.1.3 *Bleeding*—Test Methods C 232.

7.1.4 *Time of Setting*—Test Method C 403/C 403M, except that the temperature of each of the ingredients of the concrete mixtures, just prior to mixing, and the temperature at which the time of setting specimens are stored during the test period shall be 23.0± 2 °C (73 ± 3 °F).

8. Preparation of Test Specimens

8.1 Specimens for test of hardened concrete, representing each test and age of test and each condition of concrete being compared, shall be made from at least three separate batches, and the minimum number of specimens shall be as prescribed in Table 1. On a given day at least one specimen shall be made for each test and age of test from each condition of concrete except that at least two specimens for the freezing and thawing test shall be made from each condition of concrete. The preparation of all specimens shall be completed in three days of mixing.

8.2 *Manifestly Faulty Specimens*—Each group of specimens representing a given test or a given age of test, including tests of freshly mixed concrete, shall be examined visually before or during the test, or both, whichever is appropriate. Discard any specimen found to be manifestly faulty by such examination without testing. Visually examine all specimens representing a given test at a given age after testing, and should any specimen be found to be manifestly faulty, the test results thereof shall be disregarded. Should more than one specimen representing a given test at a given age be found manifestly faulty, either before or after testing, the entire test shall be disregarded and repeated. The test result reported shall be the average of the individual test results of the specimens tested or, in the event that one specimen or one result has been discarded, it shall be the average of the test results of the remaining specimens.

9. Test Specimens of Hardened Concrete

9.1 *Number of Specimens*—Make six or more test specimens for the freezing and thawing test and three or more test specimens for each other type of test and age of test specified in Table 1 for each condition of concrete to be compared.

TABLE 1 Types and Minimum Number of Specimens and Tests

Test	Number of Types of Specimens[A]	Number of Test Ages	Number of Conditions of Concrete[B]	Minimum Number of Specimens
Slump	1	1	2	[C]
Air content	1	1	2	[C]
Bleeding	1	1	2	6
Time of setting	1	[D]	2	6
Compressive strength	1	3	2	18
Flexural strength[E]	1	3	2	18
Freezing and thawing	1	1	2	12[F]
Length change[E]	1	1	2	6

[A] See Section 7 and 9.2.
[B] See 4.2.
[C] Determined on each batch of concrete mixed.
[D] See 7.1.4.
[E] Optional tests, see 10.1.5.
[F] Specimens for duplicate tests from each batch.

www.technobetar.ir

9.2 *Types of Specimens*—Prepare specimens made from concrete with and without the air-entraining admixture under test in accordance with the following:

9.2.1 *Compressive Strength*—Make and cure test specimens in accordance with Practice C 192/C 192M.

9.2.2 *Flexural Strength*—Make and cure test specimens in accordance with Practice C 192/C 192M.

9.2.3 *Resistance to Freezing and Thawing*—Test specimens shall consist of prisms made and cured in accordance with the applicable requirement of Practice C 192/C 192M. Test specimen dimensions shall be as required by Test Method C 666/C 666M. Make one set of specimens from the concrete mixture containing the air-entraining admixture under test and from the reference concrete mixture, the air content of each mixture being as specified in 5.2.

9.2.4 *Length Change*—Make and cure test specimens in accordance with Test Method C 157/C 157M. The moist-curing period, including the period in the molds, shall be 14 days.

10. Tests on Hardened Concrete

10.1 Test specimens of hardened concrete in accordance with the following test methods:

10.1.1 *Compressive Strength*—Test Method C 39/C 39M. Test specimens at ages of 3, 7, and 28 days. Calculate the compressive strength of the concrete containing the admixture under test as a percentage of the compressive strength of the reference concrete as follows:

10.1.1.1 Divide the average compressive strength of the specimens made from the concrete containing the admixture under test at a given age of test by the average compressive strength of the specimens made from the reference concrete at the same age of test and multiply the quotient by 100.

10.1.2 *Flexural Strength*—Test Method C 78. Test specimens at ages 3, 7, and 28 days. Calculate the flexural strength of the concrete containing the admixture under test as a percentage of the flexural strength of the reference concrete as follows:

10.1.2.1 Divide the average flexural strength of the specimens made from the concrete containing the admixture under test at a given age of test by the average flexural strength of the specimens made from the reference concrete at the same age of test, and multiply the quotient by 100.

10.1.3 *Resistance to Freezing and Thawing*—Procedure A of Test Method C 666/C 666M. Place specimens under test at the age of 14 days.

10.1.4 *Length Change*—Test Method C 157/C 157M. The drying period shall be 14 days.

10.1.5 The flexural strength and length change tests are applicable only when specifically required by the purchaser.

11. Check Tests for Uniformity

11.1 The check tests enumerated in Specification C 260 in the section on Optional Uniformity Requirements shall be determined as follows:

11.1.1 *pH*—The pH of liquid air-entraining admixtures shall be determined in accordance with Test Method E 70. Non-liquid admixtures shall be prepared in solution to determine pH. Unless there is reason to do otherwise, dissolve the material in reagent water in the proportions specified for job use as shown on the package or in other manufacturer's instructions. The temperature of the check test sample shall be within ± 1 °C (± 2 °F) of that for the acceptance sample and preferably in the range of 21 to 27 °C (70 to 80 °F).

11.1.2 *Air Content of Mortar*—Using the same amounts of successive lots of air-entraining admixtures with the same cement, determine the air contents of mortars in accordance with Test Method C 185. The air-entraining admixture shall be combined with the mixing water prior to the start of the mixing procedure. The determinations for both the check test sample and acceptance sample shall be made on the same day.

12. Procedure for Residue by Oven Drying

12.1 Determine the mass of an aluminum dish (about 57 mm diameter, 15 mm height, and about 1 g in weight) to the nearest 0.0001 g. Using a pipet, evenly distribute 1 ml of the liquid air entraining admixture in the dish, and weigh to the nearest 0.0001 g. Place the weighing dish in a drying oven (12.2). Dry for 25 ± 2 min at 125 ± 1 °C. At the end of the drying period transfer the weighing dish to a desiccator, cool to room temperature, and weigh to the nearest 0.0001 g.

12.2 The drying oven shall be either a forced circulation type or one with provision for free access of air. There shall be precise control of temperature and time of drying so that the degree of volatilization of the material other than water from sample to sample will not vary.

12.3 *Calculation*:

12.3.1 Record the following weights:

M_1 = mass of weighing dish and admixture prior to heating,
M_2 = mass of empty weighing dish,
M_3 = $M_1 - M_2$ = mass of sample,
M_4 = mass of weighing dish and dried residue, and
M_5 = $M_4 - M_2$ = mass of dried residue.

12.3.2 Calculate the residue by using the following equation:

$$\text{Residue by oven drying (\% by mass)} = (M_5 \times 100)/M_3 \quad (1)$$

13. Report

13.1 Report the following information:

13.1.1 Results of the tests specified in this method as compared with the requirements of Specification C 260,

13.1.2 Brand name, manufacturer's name and lot number, character of the material, and quantity represented by the sample of the admixture under test,

13.1.3 Brand name, manufacturer's name, and other data on the reference admixture,

13.1.4 Brand name, manufacturer's name, type, and test data on the portland cement or cements used,

13.1.5 Description of, and test data on the fine and coarse aggregates used,

13.1.6 Detailed data on the concrete mixtures used, including amounts and proportions of admixtures used, actual cement factors, water-cement ratios, ratios of fine to total aggregate, consistency, and air content.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

13.1.7 In reporting on check tests for uniformity, report both the initial and current air contents of mortar for the acceptance sample, and the air content of the check test sample, all as determined by Test Method C 185.

14. Precision and Bias [6]

14.1 *Precision*:

14.1.1 The single-laboratory coefficient of variation of residue by oven drying has been found to be 0.79 %. Therefore, the results of two properly conducted tests on the same material in the same laboratory are not expected to differ by more than 2.24 % of their average.[7]

NOTE 6—As an example, two tests conducted on the same material yield residues by oven drying of 6.14 % and 6.04 %, respectively. The average of these two measurements is 6.09 %. The acceptable range of results is then 2.24 % of 6.09 % or ±0.136 %. As the difference between 6.14 % and 6.04 % is 0.10 % the results are within the acceptable range.

14.1.2 The multilaboratory coefficient of variation of residue by oven drying has been found to be 2.35 %. Therefore, the results of two properly conducted tests on the same material in different laboratories are not expected to differ by more than 6.65 % of their average.[7]

14.1.3 Other procedures referenced in this test method use results obtained from other ASTM test methods listed in Section 2. These documents are to be referred to for their respective precision statements.

14.2 *Bias*—Since there is no accepted reference material suitable for determining the bias of this test method, no statement on bias is made.

15. Keywords

15.1 air content; air-entraining admixture; cement; concrete; pH; residue; specific gravity

[6] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1005.

[7] These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 233 – 04, that may impact the use of this test method. (Approved July 15, 2007)

(*1*) Revised 4.2.2, 4.2.3, 4.2.3.1, and 4.2.4.

(*2*) Added new Note 2 and renumbered subsequent notes.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 260 – 06

Standard Specification for Air-Entraining Admixtures for Concrete[1]

This standard is issued under the fixed designation C 260; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers materials proposed for use as air-entraining admixtures to be added to concrete mixtures in the field.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 The text of this specification references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 183 Practice for Sampling and the Amount of Testing of Hydraulic Cement

C 185 Test Method for Air Content of Hydraulic Cement Mortar

C 233 Test Method for Air-Entraining Admixtures for Concrete

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *air-entraining admixture*, *n—for the purpose of this specification*, a material that is used as an ingredient of concrete, added to the batch immediately before or during its mixing, for the purpose of entraining air.

4. General Requirements

4.1 At the request of the purchaser, the manufacturer shall state in writing that the air-entraining admixture supplied for use in the work is essentially identical in concentration, composition, and performance to the air-entraining admixture tested under this specification.

NOTE 1—It is recommended that, whenever practicable, tests with the air-entraining admixture be made using all of the ingredients of the concrete proposed for the specific work, because the effect produced by the air-entraining admixture may vary with the properties of the other ingredients of the concrete.

4.2 Requirements for establishing compositional or chemical equivalence of a subsequent lot relative to a previous lot that was subjected to quality tests and found to comply with the requirements of 5.1 shall be determined if agreed upon by the purchaser and the manufacturer. At the request of the purchaser, the manufacturer shall recommend appropriate test procedures, such as infrared spectrophotometry (I.R.), pH value and solids content, for establishing the equivalence of materials from different lots or different portions of the same lot.

NOTE 2—Ultraviolet light absorption (UV) of solutions and infrared spectroscopy of dried residues have been found to be valuable for these purposes. The specific procedures to be employed and the criteria to establish equivalence should be stipulated with due regard to the composition and properties of the sample.

4.3 At the request of the purchaser, the manufacturer shall state in writing the chloride content of the air-entraining admixture and whether or not chloride was added during its manufacture.

NOTE 3—Admixtures that contain chlorides may accelerate corrosion of embedded metals.

5. Optional Uniformity Requirements

5.1 A series of two or more samples from a manufacturing lot will be considered sufficiently uniform to be properly composited into a single sample for quality testing provided they do not differ more than the amounts indicated in 5.4.

5.2 A subsequent sample or composite sample shall be considered in compliance with these requirements, so long as they differ from the original sample, tested to the requirements of 6.1, by no more than the amounts listed in 5.4, and provided that any additional optional, appropriate tests, such as infrared spectroscopy and ultraviolet light absorption, referred to in 4.2, also meet pre-agreed requirements.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

Current edition approved Aug. 1, 2006. Published August 2006. Originally approved in 1950. Last previous edition approved in 2001 as C 260 – 01.

www.technobetar.ir

5.3 Determinations of uniformity shall be made in accordance with the procedures given in the sections "Check Tests for Uniformity" and "Procedure for Residue by Oven Drying" of Test Method C 233.

5.4 Allowable differences in results of uniformity determinations shall not exceed the following amounts:

5.4.1 The manufacturer shall provide an acceptable range of pH not to exceed a range of 3.0. The pH of samples tested shall fall within this range.

5.4.2 The air content in percent of Test Method C 185 mortars prepared from successive lots shall not differ by more than 2.0 from that for the acceptance sample.

5.4.3 The manufacturer shall provide acceptable limits of residue content not to exceed ±12 % of the midpoint of the limits. The residue content of samples tested shall fall within these limits (Note 4).

NOTE 4—As an example, an admixture may commonly be produced with residue content ranging from 5.0 to 6.5 %. The manufacturer would provide acceptable limits of 5.06 to 6.44 %, representing ±12 % of the midpoint of the limits which is 5.75 %.

6. Performance Requirements

6.1 The air-entraining admixture shall conform to the requirements in Table 1.

6.1.1 *Resistance to Freezing and Thawing*—The relative durability factor of concrete containing the admixture under test shall be not less than 80. The relative durability factor shall be calculated as follows:

TABLE 1 Physical Requirements[A]

Air-Entraining Admixtures	
Time of setting, allowable deviation from control, h:min:	
Initial: not more than	1:15 earlier nor 1:15 later
Final: not more than	1:15 earlier nor 1:15 later
Compressive strength, min, % of control:	
3 days	90
7 days	90
28 days	90
Flexural strength, min, % of control:[B]	
3 days	90
7 days	90
28 days	90
Length change, max shrinkage (alternative requirements):[B,C]	
Percent of control	120
Increase over control, percentage points[D]	0.006
Relative durability factor, min	80
Bleeding of the net amount of mixing water, max percent over control[E]	2

[A] The values in the table include allowance for normal variation in test results. The object of the 90 % compressive strength requirement for air entraining admixtures is to require a level of performance comparable to that of the reference concrete.

[B] Applicable only when required by the purchaser.

[C] Alternative requirements, see 6.1.2, "percent of control" limit applies when the length change of the control is 0.030 % or greater, "increase over control" limit applies when the length change of the control is less than 0.030 %.

[D] Applicable when shrinkage of control concrete is less than 0.030 %.

[E] Bleeding is computed as a percentage of the net amount of mixing water in each concrete. The net mixing water is the water in excess of that present as absorbed water in the aggregates. For example, a test concrete mixture that contains 4.65 kg of net mix water and produces 0.29 kg of bleed water would have 6.24 % bleed water by mass of net mixing water. If a control mixture produces 7.05 % bleed water, the change in bleeding between the test and control concrete mixtures would be – 0.81 percentage points.

$$DF \text{ (or } DF_1) = PN/300 \quad (1)$$

$$RDF = (DF/DF_1) \times 100$$

where:

DF = durability factor of the concrete containing the admixture under test,

DF_1 = durability factor of the concrete containing the reference admixture,

P = relative dynamic modulus of elasticity in percentage of the dynamic modulus of elasticity at zero cycles (values of P will be 60 or greater),

N = number of cycles at which P reaches 60 %, or 300 if P does not reach 60 % prior to the end of the test (300 cycles), and

RDF = relative durability factor.

6.1.2 *Length Change*—After 14 days of drying, the length change of the concrete containing the test admixture shall not be more than 120 % of that of the concrete containing the reference admixture. When, after 14 days of drying, the length change of the reference concrete is less than 0.030 %, the length change of the concrete containing the test admixture shall not be more than 0.006 percentage points greater than that of the reference concrete.

7. Sampling

7.1 Opportunity shall be provided the purchaser for careful sampling and inspection, either at the point of manufacture or at the site of the work, as specified by the purchaser.

7.2 Samples shall be either "grab" or "composite" samples, as specified or required by this specification. A grab sample is one obtained in a single operation. A composite sample is one obtained by combining three or more grab samples.

7.3 For the purpose of this specification, it is recognized that samples will be taken for the two following reasons:

7.3.1 *Quality Tests*—A sample taken for the purpose of evaluating the quality of a source or lot of admixture will be required to meet all the applicable requirements of this specification. Samples used to determine conformance with the requirements of this specification shall be composites of grab samples taken from sufficient locations to ensure that the composite sample will be representative of the lot.
