7.3.2 *Uniformity Tests*—A sample taken for the purpose of evaluating the uniformity of a single lot or of different lots from the same source will generally be subjected to a limited number of tests as the result of agreement between the purchaser and manufacturer (see Section 4). Such samples shall be composite samples from individual lots when different lots from the same source are being compared. When the uniformity of a single lot is being determined, grab samples shall be used.

7.4 *Liquid Air-Entraining Admixtures*—Liquid admixtures shall be agitated thoroughly immediately prior to sampling. Grab samples taken for quality or uniformity tests shall represent not more than 9500 L (2500 gal) of admixture and shall have a volume of at least 1 L (1 qt). A minimum of three grab samples shall be taken. Composite samples shall be prepared by thoroughly mixing the grab samples selected and the resultant mixture sampled to provide at least 4 L (1 gal) for

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

quality tests. Grab samples shall be taken from different locations well distributed throughout the quantity to be represented.

7.4.1 Admixtures in bulk storage tanks shall be sampled equally from the upper, intermediate, and lower levels by means of drain cocks in the sides of the tanks or a weighted sampling bottle fitted with a stopper that can be removed after the bottle is lowered to the desired depth.

7.4.2 Samples shall be packaged in impermeable, airtight containers that are resistant to attack by the admixture.

7.5 *Nonliquid Air-Entraining Admixtures*—Grab samples taken for quality or uniformity tests shall represent not more than 2 metric tons (2 tons) of admixture and shall have a mass of at least 1 kg (2 lb). A minimum of four grab samples shall be taken. Composite samples shall be prepared by thoroughly mixing the grab samples selected and the resultant mixture sampled to provide at least 2.5 kg (5 lb) for the composite sample. Grab samples shall be taken from different locations well distributed throughout the quantity to be represented.

7.5.1 Samples of packaged admixtures shall be obtained by means of a tube sampler as described in Practice C 183.

7.5.2 Samples shall be packaged in moisture-proof, airtight containers.

7.6 Samples shall be thoroughly mixed before testing to assure uniformity. When recommended by the manufacturer, the entire sample of a nonliquid admixture shall be dissolved in water prior to testing.

8. Test Methods

8.1 Determine the properties enumerated in Section 6 in accordance with Test Method C 233. It is recommended that, whenever practicable, tests be made in accordance with the section on Materials for Tests for Specific Uses in Test Method C 233, using the cement proposed for the specific work.

9. Rejection

9.1 The air-entraining admixture shall be rejected if the purchaser desires when it fails to meet any of the applicable requirements of this specification.

9.2 After completion of tests, an admixture stored at the point of manufacture for more than 6 months prior to shipment, or an admixture in local storage in the hands of a seller for more than 6 months, shall be retested before use when requested by the purchaser. It shall be rejected, if the purchaser desires, when it fails to conform to any of the applicable requirements of this specification.

9.3 Packages or containers varying more than 5 % from the specified weight or volume shall be rejected if the purchaser desires. If the average weight or volume of 50 packages or containers taken at random is less than that specified, the entire shipment shall be rejected if the purchaser desires.

10. Packaging and Marking

10.1 The proprietary name of the air-entraining admixture and the net quantity in pounds or gallons (kilograms or litres) shall be plainly indicated on the packages or containers in which the admixture is delivered. Similar information shall be provided in the shipping advices accompanying packaged or bulk shipments of admixtures.

11. Keywords

11.1 air content; air entraining admixtures; cement; concrete; pH, residue; specific gravity

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 260 – 01, that may impact the use of this specification. (Approved August 1, 2006)

(*1*) Revised 5.4.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 265 – 08

Standard Test Method for Water-Extractable Sulfate in Hydrated Hydraulic Cement Mortar[1]

This standard is issued under the fixed designation C 265; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the measurement of water-extractable SO_3 in hardened hydraulic cement mortar. This measurement is assumed to represent unreacted, available sulfate remaining in the mortar.

1.1.1 **Warning—**Fresh hydraulic cementious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 Values in SI units were obtained by measurement in SI units or by appropriate conversion using the Rules for Conversion and Rounding given in IEEE/ASTM SI-10 Standard of measurements made in other units.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 114 Test Methods for Chemical Analysis of Hydraulic Cement

C 150 Specification for Portland Cement

C 219 Terminology Relating to Hydraulic Cement

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 563 Test Method for Approximation of Optimum SO_3 in Hydraulic Cement Using Compressive Strength

C 595 Specification for Blended Hydraulic Cements

C 778 Specification for Standard Sand

C 1157 Performance Specification for Hydraulic Cement

D 1193 Specification for Reagent Water

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

IEEE/ASTM SI-10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Terminology

3.1 *Definitions*—The terms used in this test method are defined in accordance with Terminology C 219.

4. Significance and Use

4.1 Excess soluble sulfate ions in hardened cement can result in reduced durability. This test method is intended to show whether calcium sulfate has been used in cement in such amount to leave excess soluble sulfate in hardened mortar. The test method is used to establish compliance in Specification C 595 for those cements in which optimized SO_3 exceeds the table limit. This test method also can provide useful information on other hydraulic cements, such as those specified in Specifications C 150 and C 1157.

4.2 When this test method is used in conjunction with Test Method C 563, use the appropriate age of test specimens (24 h, 3 days, or 7 days) to coincide with the age of specimens used in Test Method C 563.

5. Apparatus

5.1 *Sieve*—A 2.36-mm (No.8) sieve conforming to Specification E 11.

5.2 *Mixer, Bowl, and Paddle*—An electrically driven mechanical mixer equipped with a paddle and bowl, as specified in the Apparatus section of Practice C 305.

5.3 *Polyethylene Containers*—Watertight polyethylene bags of 1-L (1-qt) capacity or approximately 360-mm (14-in.) sheet material, made using polyethylene at least 0.10-mm (0.004-in.) in thickness.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.28 on Sulfate Content

Current edition approved May 1, 2008. Published June 2008. Originally approved in 1951. Last previous edition approved in 2006 as C 265 – 06.

www.technobetar.ir

5.4 *Mortar and Pestle*—A mortar of 1.5-L (1½-qt) size, and a pestle, both of which shall be iron or porcelain.

5.5 *Water Bath*—A water bath thermostatically controlled at 23.0 ± 0.15 °C .

6. Reagents and Materials

6.1 *Mixing Water*—Reagent water conforming to the numerical limits of Type II of Specification D 1193.

6.2 *Graded Sand*—Sand conforming to the requirements for graded sand in Specification C 778.

7. Temperature and Relative Humidity

7.1 Maintain the temperature of the molding room at 23.0 ± 2.0 °C . Adjust the temperature of the dry materials and the mixing water, prior to mixing, so that the temperature of the mortar, immediately upon completion of mixing is 23 ± 1 °C .

7.2 Maintain the relative humidity of the laboratory so that it is not less than 50 %.

8. Preparation of Test Mortar

8.1 Proportion the mortar in accordance with the instructions for a six-cube batch given in the section on Composition of Mortars of Test Method C 109/C 109M, except use a water-cementious material ratio of 0.5, by mass. Mix mechanically in accordance with Procedure for Mixing Mortars of Practice C 305.

8.2 Split the batch immediately after mixing then place approximately 450 g of mortar in each of the two polyethylene containers. Obtain the temperature of each portion to ensure that it is within the range 23 ± 1 °C . If bags are used, twist the neck of each and seal with a rubber band; double the neck over and seal with a second band. If sheets are used to contain the samples, gather the corners and edges to make a bag and seal in similar manner.

9. Storage of Test Mortar

9.1 Immediately immerse both containers in the water bath maintained at (23.0 ± 0.15 °C) .

10. Preparation of Cement Extract

10.1 At 24 ± ¼ h, 3 days ± 1 h, or 7 days ± 3 h, after the instant the cement and water were mixed together, remove the containers successively from the water bath, pulverizing each sample in turn with the pestle in the mortar as rapidly as possible. Immediately upon removal from the water bath treat each sample individually as follows: First pulverize approximately one third of the specimen until most of it passes the 2.36-mm (No. 8) sieve. Return the coarse residue to the mortar and grind another one third of the specimen as before. Repeat the process until the entire specimen is pulverized to pass the 2.36-mm (No. 8) sieve. Place 400 g of the pulverized material in a 600-mL beaker and add 100 mL of water at a temperature of 23.0 ± 0.6 °C . Quickly mix to uniform consistency with a spatula; then stir mechanically for 2 min. Use a stirrer of such a type and speed that all particles of the slurry are suspended, with no settling and no appreciable increase of the temperature of the slurry occurs.

10.2 Filter the slurry on a dry No. 2A Büchner funnel with the aid of suction using a dry 90-mm, medium, ashless paper. Complete filtration within a period of 2 min. Filter again, whether the filtrate is turbid or not, using a new dry filter paper without suction.

11. Analysis of the Extract

11.1 Transfer 50.0 mL of the clear extract by means of a 50-mL pipet to a 400-mL beaker, dilute with distilled water to about 250 mL, and add 5 mL of concentrated hydrochloric acid (HCl, sp gr 1.19). Heat to boiling, and proceed in accordance with the sulfur trioxide determination section of Test Methods C 114. Perform a blank on the reagents in use in the analysis.

11.1.1 After the $BaCl_2$ solution is added in accordance with the sulfur trioxide determination section of Test Methods C 114, boil the solution vigorously for 15 min.

11.2 When the amount of filtrate is insufficient to provide a 50-mL aliquot, use 25 mL of the extract and a factor twice that given in Section 12.

12. Calculation and Report

12.1 Calculate the SO_3 content to the nearest 0.01 g/L of solution, as follows:

$$SO_3, g/L = W \times 6.86 \quad (1)$$

where:

W = grams of barium sulfate ($BaSO_4$) precipitated.

12.2 Report the average of the two determinations.

12.3 Report the age of the test specimens.

13. Precision and Bias

13.1 *Precision*—The single-operator (within-laboratory) standard deviation for testing at 24 h has been found to be 0.077 g/L SO_3 throughout the range of 0.20 to 0.85 g/L SO_3. Therefore, results of two properly conducted tests at 24 h by the same operator on water-extractable SO_3 in hardened hydraulic cement mortars of the same material should not differ from each other by more than 0.22 g/L SO_3. The multi-laboratory (between-laboratory) standard deviation for testing at 24 h has been found to be 0.137g/L SO_3 throughout the range of 0.20 to 0.85 g/L SO_3. Therefore, results of two properly conducted tests at 24 h on the same material, from two different laboratories on water-extractable SO_3 in hardened hydraulic cement mortars should not differ from each other by more than 0.39 g/L SO_3.

13.2 *Bias*—No justifiable statement can be made on the bias of the procedure in this test method for measuring the water-extractable SO_3 in hardened hydraulic cement mortars, because no reference samples are available.

14. Keywords

14.1 hydraulic cement; optimum sulfate content; sulfate; sulfate content

Designation: C 266 – 08

Standard Test Method for Time of Setting of Hydraulic-Cement Paste by Gillmore Needles[1]

This standard is issued under the fixed designation C 266; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the time of setting of hydraulic-cement paste by means of the Gillmore needles.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning: Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 min. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 151 Test Method for Autoclave Expansion of Hydraulic Cement

C 183 Practice for Sampling and the Amount of Testing of Hydraulic Cement

C 187 Test Method for Normal Consistency of Hydraulic Cement

C 219 Terminology Relating to Hydraulic Cement

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

D 1193 Specification for Reagent Water

3. Terminology

3.1 Refer to Terminology C 219 for definitions of terms.

4. Summary of Test Method

4.1 Sufficient water is added to the cement that is being tested to produce a paste of normal consistency. A specimen is molded from this paste and is tested for time of setting by means of the Gillmore initial and final needles. The initial time of setting is the time elapsed between initial contact of cement and water and the time when the Gillmore Initial needle does not leave a complete circular impression in the paste surface. The final time of setting is the time elapsed between initial contact of cement and water and the time when the Gillmore Final needle does not leave a complete circular impression in the paste surface.

5. Significance and Use

5.1 The purpose of this test method is to establish whether a cement complies with a specification limit on Gillmore time of setting.

6. Apparatus

6.1 *Flat Trowel*, having a sharpened straight-edged steel blade 100 to 150 mm in length. The edges when placed on a plane surface shall not depart from straightness by more than 1 mm.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.30 on Time of Set

Current edition approved June 1, 2008. Published July 2008. Originally approved in 1951. Last previous edition approved in 2007 as C 266 – 07.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

6.2 *Mixer, Bowl, Paddle, and Scraper*, conforming to the requirements of Practice C 305.

6.3 *Glass Graduates*, 200 or 250 mL capacity, conforming to the requirements of Specification C 1005.

6.4 *Mass Determining Devices*, conforming to the requirements of Specification C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

6.5 *Plane Non-absorptive Plates*, 100 mm ± 5 mm square, of similar planeness, corrosivity, and absorptivity to that of glass (see Test Method C 187 Fig. 1, item H).

6.6 *Gillmore Needles*, conforming to the following requirements:

6.6.1 The initial time of setting needle shall have a mass of 0.250 ± 0.001 lb (113.4 ± 0.5 g) and a tip diameter of 0.084 ± 0.002 in. (2.12 ± 0.05 mm).

6.6.2 The final time of setting needle shall have a mass of 1.000 ± 0.001 lb (453.6 ± 0.5 g) and a tip diameter of 0.042 ± 0.002 in. (1.06 ± 0.05 mm).

6.6.3 The needle tips shall be cylindrical for a distance of 0.189 ± 0.020 in. (4.8 ± 0.5 mm). The needle ends shall be plane and at right angles to the axis of the rod and shall be maintained in a clean condition (See Note 1).

6.7 Inspect and document Section 6 apparatus for conformance to the requirements of this test method at least every 2 ½ years.

NOTE 1—The Gillmore needles should preferably be mounted as shown in Fig. 1 (b).

7. Reagents

7.1 *Mixing Water*—Potable water is satisfactory for routine tests. For all referee and cooperative tests, reagent water conforming to the requirements of Specification D 1193 for Type III or Type IV grade of reagent water shall be used.

8. Sampling

8.1 When the test is part of acceptance testing, sample the cement in accordance with Practice C 183.

9. Conditioning

9.1 Maintain the temperature of the room, dry materials, paddle, bowl, and plane non-absorptive plates at 23.0 ± 3.0 °C. Maintain the temperature of the mixing water at 23.0 ± 2.0 °C.

9.2 Maintain the relative humidity of the mixing room at not less than 50%.

9.3 The moist cabinet or moist room shall conform to the requirements of Specification C 511.

10. Procedure

10.1 *Preparation of Cement Paste*:

Obtain the cement paste used for determination of the time of setting from one of the following methods:

10.1.1 Prepare a new batch of paste by mixing 650 g of cement with the percentage of mixing water required for normal consistency (Test Method C 187), following the procedure described in Practice C 305.

10.1.2 At the option of the tester, use the paste remaining from the batch used for the autoclave expansion specimen (Test Method C 151) or from the normal consistency determination (Test Method C 187).

10.2 *Molding Test Specimen*—From the cement paste prepared as described in 10.1, make a pat with a flat top and the sides tapering to a thin edge on a plane non-absorptive plate, conforming to the dimensions and tolerances in Fig. 1 (a). In molding the pat, flatten the cement paste first on the plate and then form the pat by drawing the trowel from the outer edge toward the center, then flattening the top. After making, place the pat in the moist cabinet or moist room and allow it to remain there except when the determinations of time of setting are being made.

10.3 *Time of Setting Determination*—Determine the time of setting by holding the needle in a vertical position and lightly applying it to the surface of the pat.

10.3.1 Using the Initial Gillmore needle, determine the Gillmore Initial time of setting end point to be the first penetration measurement that does not mark the specimen surface with a complete circular impression. Verify Initial set by obtaining two additional penetration measurements on different areas of the specimen surface. Verification measurements must be obtained within 90 s of the first "initial set" measurement. The elapsed time, in minutes, between the time of contact of cement and mixing water and the end point determined above is the Gillmore initial time of setting.

10.3.2 Using the Final Gillmore needle, determine the Gillmore Final time of setting end point to be the first penetration measurement that does not mark the specimen surface with a complete circular impression. Verify Final set by obtaining two additional penetration measurements on different areas of the specimen surface. Verification measurements must be obtained within 90 s of the first "final set" measurement. The elapsed time, in minutes, between the time of contact of cement and mixing water and the end point determined above is the Gillmore final time of setting.

11. Report

11.1 Report the time of setting, to the nearest 5 min, as follows:

Initial Time of Setting, Gillmore	__ min
Final Time of Setting, Gillmore	__min

12. Precision and Bias

12.1 Precision, Gillmore Initial Time of Setting on samples testing between 100 and 341 min. (See Note 2)

12.1.1 The single-operator (within laboratory) standard deviation has been found to be 16 min (1s), therefore, results of two properly conducted tests by the same operator on samples of the same cement should not differ from each other by more than 44 min (d2s) (1s and d2s are defined in Practice C 670).

12.1.2 The multi-laboratory standard deviation has been found to be 28 min (1s), therefore, results of two properly conducted tests from two different laboratories should not differ from each other by more than 78 min (d2s).

12.2 Precision, Gillmore Final Time of Setting on samples testing between 239 and 561 min (See Note 2).

www.technobetar.ir

12.2.1 The single-operator (within laboratory) standard deviation has been found to be 22 min (1s), therefore, results of two properly conducted tests by the same operator on samples of the same cement should not differ from each other by more than 62 min (d2s).

12.2.2 The multi-laboratory standard deviation has been found to be 46 min (1s), therefore, results of two properly conducted tests from two different laboratories on samples of the same cement should not differ by more than 129 min (d2s).

12.3 Bias

12.3.1 Since an acceptable reference material suitable for determining any bias of this method does not exist, no statement on bias is being made.

NOTE 2—This data is based upon CCRL Portland cement round robin test samples 47 to 138 and CCRL Masonry cement round robin test samples 1 to 46.

13. Keywords

13.1 gillmore needles; hydraulic cement paste; time of setting

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 266 – 07, that may impact the use of this test method. (Approved June 1, 2008)

(*1*) Revised 4.1, 6.1, 6.4, and 9.2.

(*2*) Revised the units statement in 1.2 and reversed the order of units throughout the standard editorially to comply with ASTM Form and Style.

Committee C01 has identified the location of selected changes to this test method since the last issue, C 266 – 04, that may impact the use of this test method. (Approved July 15, 2007)

(*1*) Added new 6.7.

Designation: C 289 – 07

Standard Test Method for Potential Alkali-Silica Reactivity of Aggregates (Chemical Method)[1]

This standard is issued under the fixed designation C 289; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers chemical determination of the potential reactivity of an aggregate with alkalies in portland-cement concrete as indicated by the amount of reaction during 24 h at 80 °C between 1 *N* sodium hydroxide solution and aggregate that has been crushed and sieved to pass a 300-µm sieve and be retained on a 150-µm sieve.

1.2 The values stated in SI units are to be regarded as standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* A specific precautionary statement is given in 5.7.1.

2.2 *American Chemical Society Documents:*

Reagent Chemicals, American Chemical Society Specifications

NOTE 1—For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

3. Significance and Use

3.1 When this test method is used to evaluate the potential reactivity of siliceous components in the aggregate with alkalies in hydraulic-cement concrete, it must be used in combination with other methods. Do not use the results of tests by this test method as the sole basis for acceptance or rejection for sources with regard to ASR.

3.2 Reactions between a sodium hydroxide solution and siliceous components in the aggregate have been shown to correlate with the performance of some aggregates in concrete structures. The results from this test method can be obtained quickly, and, while not completely reliable in all cases, they can provide useful data.

3.3 This test method can be employed as a quality control tool to periodically check samples from an existing source with an acceptable service history.

4. Apparatus

4.1 *Scales*—The scales and weights used for weighing materials shall conform to the requirements prescribed in Specification C 1005.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.26 on Chemical Reactions.

Current edition approved Nov. 1, 2007. Published December 2007. Originally approved in 1952. Last previous edition approved in 2003 as C 289 – 03.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

4.2 *Balances*—The analytical balance and weights used for determining dissolved silica by the gravimetric method shall conform to the requirements prescribed in Test Methods C 114.

4.3 *Crushing and Grinding Equipment*—A small jaw crusher and disk pulverizer or other suitable equipment capable of crushing and grinding aggregate to pass a 300-µm sieve.

4.4 *Sieves*:

4.4.1 300-µm and 150-µm square-hole, woven wire-cloth sieves conforming to Specification E 11.

4.4.2 A 4.75-mm (No. 4) sieve.

4.5 *Containers*—Reaction containers of 50 to 75-mL capacity, made of corrosion-resistant steel or other corrosion-resistant material, and fitted with airtight covers. A container that has been found suitable is shown in Fig. 1. Other containers, made of corrosion-resistant material such as polyethylene, may be suitable. Such suitability can be demonstrated by a change in the alkalinity of the sodium hydroxide solution (R_c, Section on Reduction in Alkalinity) when used alone as a blank in the container in question, of less than 10 mmol/L.

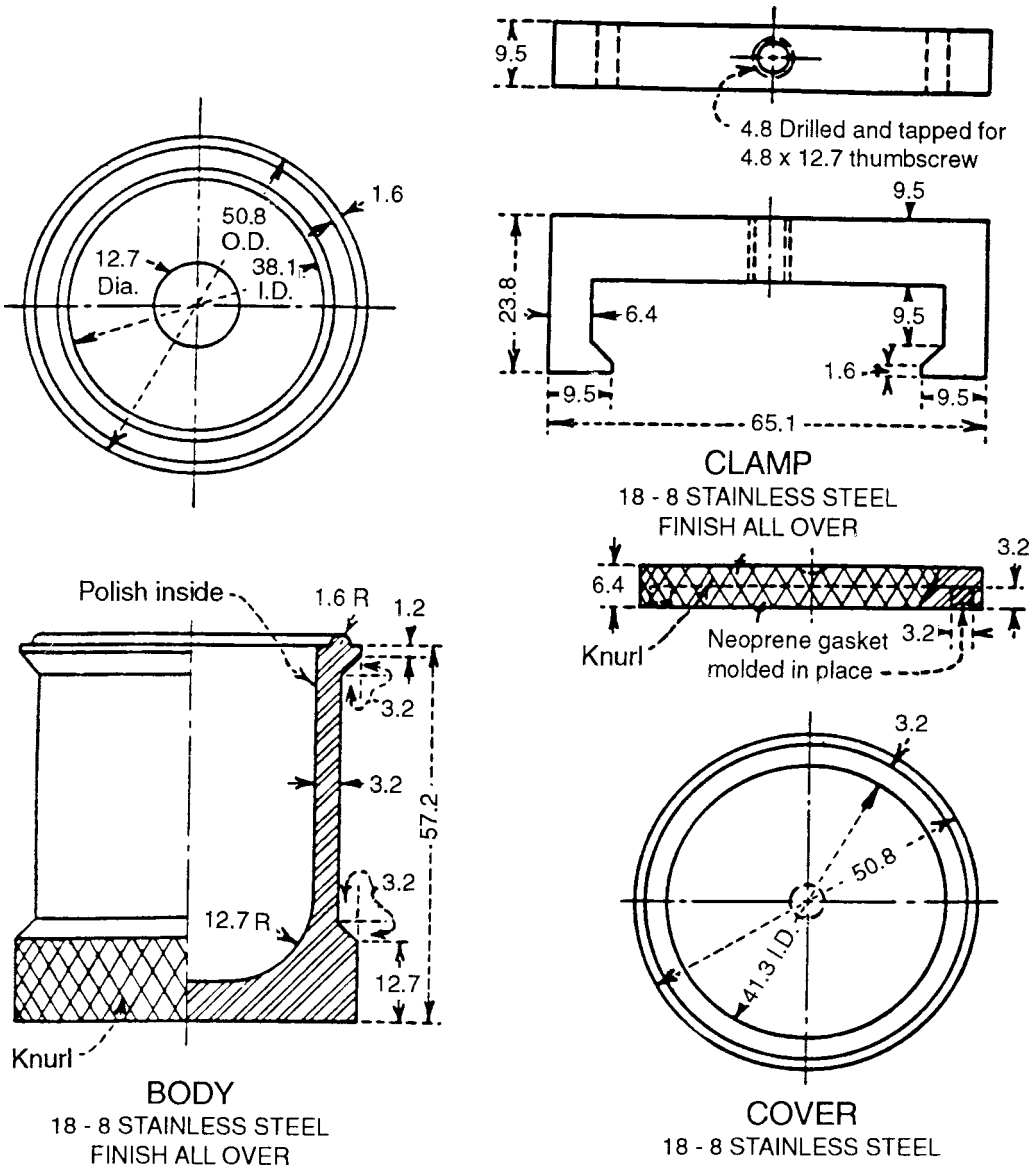
4.6 *Constant-Temperature Bath*—A liquid bath capable of maintaining a temperature of 80 ± 1 °C for 24 h.

4.7 *Spectrophotometer or Photometer*—A spectrophotometer or photoelectric photometer capable of measuring the transmission of light at a constant wavelength of approximately 410 nm (see Practice E 60).

4.8 *Glassware*—All glass apparatus and vessels should be carefully selected to meet the particular requirements for each operation. Standard volumetric flasks, burets, and pipets should be of precision grade.

5. Reagents

5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, all reagents shall conform to Reagent Chemicals, American Chemical Society



NOTE 1—All dimensions are in mm.

FIG. 1 Reaction Container

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Specifications. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type IV of Specification D 1193.

5.3 *Ammonium Molybdate Solution*—Dissolve 10 g of ammonium molybdate ($(NH_4)_6\ Mo_7O_{24}\cdot 4H_2O$) in 100 mL of water. If the solution is not clear, filter through a fine-texture paper. Store the solution in a polyethylene container (see Note 2).

5.4 *Hydrochloric Acid (1.19 kg/L)*—Concentrated hydrochloric acid (HCl). Store the solution in a chemically resistant glass or suitable plastic container (see Note 2).

5.5 *Hydrochloric Acid, Standard* (0.05 *N*)—Prepare approximately 0.05 *N* HCl and standardize to ±0.0001 *N*. Store the solution in a chemically resistant glass or suitable plastic container (see Note 2).

5.6 *Hydrochloric Acid (1 + 1)*—Mix equal volumes of concentrated HCl (1.19 kg/L) and water. Store the solution in a chemically resistant glass or suitable plastic container (see Note 2).

5.7 *Hydrofluoric Acid (approximately 50 % HF)*—Concentrated hydrofluoric acid. Store in a polyethylene bottle (see Note 2).

5.7.1 **Warning—**Before using HF, review (*1*) the safety precautions for using HF, (*2*) first aid for burns, and (*3*) the emergency response to spills, as described in the manufacturer's Material Safety Data Sheet or other reliable safety literature. HF can cause very severe burns and injury to unprotected skin and eyes. Suitable personal protective equipment should always be used. These should include full-face shields, rubber aprons, and gloves impervious to HF. Gloves should be checked periodically for pin holes.

5.8 *Oxalic Acid Solution*—Dissolve 10 g of oxalic acid dihydrate in 100 mL of water. Store the solution in a chemically resistant glass or suitable plastic container (see Note 2).

5.9 *Phenolphthalein Indicator Solution*—Dissolve 1 g of phenolphthalein in 100 mL of ethanol (1 + 1). Store the solution in a chemically resistant glass or suitable plastic container (see Note 2).

5.10 *Silica Standard Solution*—Prepare a standard silica solution containing approximately 10 mmol of silica (SiO_2)/L by dissolving sodium metasilicate in water. Store the solution in a polyethylene bottle. Use a 100-mL aliquot of the solution to determine its SiO_2 content by the procedure described in 8.2. Do not use a standard silica solution older than 1 year, since dissolved ionic silica in such a solution slowly polymerizes, causing spuriously low photometric readings (see Note 2).

5.11 *Sodium Hydroxide, Standard Solution* (1.000 ± 0.010 *N*)—Prepare a 1.000 ± 0.010 *N* sodium hydroxide (NaOH) solution and standardize to ±0.001 *N*. Store the solution in a polyethylene bottle (Note 2). Protect the dry reagent and solution from contamination by carbon dioxide.

5.12 *Sulfuric Acid (sp gr 1.84)*—Concentrated sulfuric acid (H_2SO_4). Store the solution in a chemically resistant glass container (see Note 2).

NOTE 2—In selecting the container, take care to ensure that the reagent will not be modified by reaction with the material composing the container, including pigments or other additives, or by transpiration of phases through the walls of the container. Containers with wall thickness not less than 0.51 mm and composed of high-density polyethylene meeting the requirements of Specification D 1248, for materials of Type III, Class A, are suitable.

6. Selection and Preparation of Test Samples

6.1 The test can be used for either fine or coarse aggregate, and when the fine and coarse aggregate are of the same material it can be used for the total aggregate.

6.2 Obtain the aggregate sample in accordance with Practice D 75. Use the sample sizes given in Table number 1 of Practice D 75.

6.2.1 For samples of aggregate with a nominal maximum size less than 19.0 mm, split the sample in half in accordance with Practice C 702. Crush one half as described in 6.2.3. Retain the other half for further testing if desired.

6.2.2 For samples of aggregate with a nominal maximum size 19.0 mm or larger, mix and quarter the sample in accordance with Practice C 702. Crush one quarter as described in 6.2.3. Retain the other three quarters of the sample for further testing if desired.

6.2.3 Crush the sample in a jaw-crusher using small portions at a time, retaining all fractions, until the sample passes a 4.75-mm (No. 4) sieve. Reduce the crushed sample to 300 ± 5 g by splitting in accordance with Practice C 702.

6.3 Sieve the 300-g sample, discarding all material that passes the 150-µm (No. 100) sieve. Crush or grind the sample in small portions using a disk pulverizer, rotary mill (rotating-puck) device, or mortar and pestle. To minimize the production of material passing the 150-µm (No.100) sieve, use several passes of the portion through the equipment, removing material passing the 300-µm (No. 50) sieve before regrinding the remainder. If the amount of material retained on the 150-µm (No. 100) sieve is less than 100 g after pulverizing the entire 300-g sample, discard the sample and pulverize a new 300-g sample (Note 3).

NOTE 3—An over-pulverized sample may not produce the correct chemical test results. A properly pulverized sample will have about 110 to 150 g of material remaining on the 150-µm (No. 100) sieve after washing.

6.4 To ensure that all material finer than the 150-µm sieve has been removed, wash the sample over a 150-µm sieve. Do not wash more than 100 g over a 203-mm diameter sieve at one time. Dry the washed sample at 105 ± 5 °C for 20 ± 4 h. Cool the sample and again sieve on the 150-µm sieve. If inspection of the sample indicates the presence of silty or clayey coatings on particles, repeat the washing and drying procedure, and sieve as before over the 150-µm sieve. Reserve the portion retained on the 150-µm sieve for the test sample.

7. Reaction Procedure

7.1 Weigh out three representative 25.00 ± 0.05-g portions of the dry 150-µm to 300-µm test sample prepared in accordance with Section 6. Place one portion in each of the three of the reaction containers, and add by means of a pipet, 25 mL of the 1.000 *N* NaOH solution. To a fourth reaction container, by means of a pipet, add 25 mL of the same NaOH solution to

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:45 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

serve as a blank. Seal the four containers and gently swirl them to liberate trapped air.

7.2 Immediately after the containers have been sealed, place them in a liquid bath maintained at 80 ± 1.0 °C. After 24 ± ¼ h, remove the containers from the bath and cool them, for 15 ± 2 min, under running tap water having a temperature below 30 °C.

7.3 Immediately after the containers have been cooled, open them and filter the solution from the aggregate residue. Use a porcelain Gooch crucible (see Note 4) with a disk of rapid, analytical-grade filter paper cut to fit the bottom of the crucible, setting the crucible in a rubber crucible holder in a funnel. Place a dry test tube, 35 to 50-mL capacity, in the filter flask to collect the filtrate, and seat the funnel in the neck of the filter flask. With the aspirator in operation or the vacuum line open, decant a small quantity of the solution onto the filter paper so it will seat properly in the crucible. Without stirring the contents of the container, decant the remaining free liquid into the crucible. When the decantation of the liquid has been completed, discontinue the vacuum and transfer the solids remaining in the container to the crucible and pack in place with the aid of a stainless-steel spatula. Then apply and adjust the vacuum to approximately 51 kPa. Continue the filtration until further filtration yields filtrate at the approximate rate of 1 drop every 10 s; reserve the filtrate for further tests. Record the total amount of time during which the vacuum is applied as the filtration time; make every effort to achieve an equal filtration time for all samples in a set, by uniformity of procedure in the assembly of the filtration apparatus and the packing of the solids in the crucible.

NOTE 4—Coors Size No. 4 Gooch crucibles, or equivalent, have been found satisfactory for this purpose.

7.4 Filter the blank according to the procedure described in 7.3. Apply the vacuum for a length of time equal to the average filtration time for the three specimens.

7.5 Immediately following the completion of filtration, stir the filtrate to assure homogeneity, then take by pipet an aliquot of 10 mL of the filtrate and dilute with water to 200 mL in a volumetric flask. Reserve this diluted solution for the determination of the dissolved SiO_2 and the reduction in alkalinity.

7.6 If the diluted filtrate is not to be analyzed within 4 h following completion of the filtration, transfer the solution to a clean, dry polyethylene container and close the container by means of a stopper or tight-fitting cap or lid.

8. Analysis of Filtrate

8.1 Measure dissolved silica using either the gravimetric method (See 8.2) or the photometric method (See 8.3) and measure reduction in alkalinity (See 8.4).

8.2 Dissolved Silica by the Gravimetric Method

8.2.1 *Procedure*:

8.2.1.1 Transfer by pipet 100 mL of the dilute solution (7.5) to an evaporating dish, preferably of platinum for speed in evaporation, add 5 to 10 mL of HCl (1.19 kg/L), and evaporate to dryness on a steam bath. Without heating the residue further, treat it with 5 to 10 mL of HCl (1.19 kg/L) and then an equal amount of water, or at once pour 10 to 20 mL of HCl (1 + 1) upon the residue. Cover the dish and digest for 10 min on the steam bath or a hot plate. Dilute the solution with an equal volume of hot water, filter immediately through quantitative-grade, low–ash filter paper, and wash the separated silica (SiO_2) thoroughly with hot water (see Note 5) and reserve the residue.

NOTE 5—The washing of the SiO_2 precipitates can be made more effective by using hot HCl (1 + 99) and then completing the washing with hot water.

8.2.1.2 Again evaporate the filtrate to dryness, baking the residue in an oven for 1 h at 105 to 110 °C. Take up the residue with 10 to 15 mL of HCl (1 + 1) and heat on the bath or hot plate. Dilute the solution with an equal volume of hot water and catch and wash the small amount of SiO_2 it contains on another filter paper. This second evaporation is necessary only when determining the concentration of the standard sodium metasilicate solution in 5.10. For the other test solutions, it can be eliminated.

8.2.1.3 Transfer the papers containing the residue (8.2.1.1 and 8.2.1.2) to a platinum crucible (see Note 6). Dry and ignite the papers, first at a low heat until the carbon of the filter paper is completely consumed without inflaming, and finally at 1100 to 1200 °C until the mass remains constant.

NOTE 6—The mass of the empty crucible may be determined if one wishes to know the magnitude of impurities in the residue of SiO_2.

8.2.1.4 Treat the SiO_2 thus obtained, which will contain small amounts of impurities, in the crucible with a few drops of water, about 10 mL of HF, and one drop of H_2SO_4, and evaporate cautiously to dryness on the steam bath. Finally, heat the small residue at 1050 to 1100 °C for 1 to 2 min, cool, and determine the mass. The difference between this determination and that previously obtained represents the amount of SiO_2.

8.2.2 *Calculation*:

Calculate the SiO_2 concentration of the NaOH solution filtered from the aggregate material, as follows:

$$S_c = 3330 \times W \quad (1)$$

where:

S_c = concentration of SiO_2 in mmol/L in the original filtrate, and

W = grams of SiO_2 found in 100 mL of the dilute solution.

8.3 Dissolved Silica by the Photometric Method

8.3.1 *Application*:

This method is applicable to the determination of crystalloidal (noncolloidal) silica (see Note 7) in all aqueous solutions except those with excessive color interferences (tannin and so forth), but it will not determine total silica. The method is particularly applicable to rapid control analysis of crystalloidal silica below 10 ppm.

NOTE 7—Crystalloidal (noncolloidal) silica reacts with molybdate ion in acid solution (optimum pH 1.2 to 1.5) to form a greenish yellow silico-molybdate color complex the intensity of which is approximately proportional to the silica concentration of the solution, but does not follow Beer's law perfectly.

8.3.2 *Preparation of Calibration Curve*:

8.3.2.1 Prepare a series of solutions of known silica concentration varying from 0.0 to 0.5 mmol/L by diluting portions of the stock solution of sodium silicate (5.10). Transfer the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:45 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

portions of sodium silicate solution to 100-mL volumetric flasks about half filled with water.

8.3.2.2 Add 2 mL of the ammonium molybdate solution and 1 mL of HCl (1 + 1), and agitate by swirling the flask. Allow the solution to stand for 15 min at room temperature. Add 1.5 ± 0.2 mL of the oxalic acid solution, fill the flask to the mark with water, and mix thoroughly. Allow the solution to stand for 5.0 ± 0.1 min. Read the transmittance of the various solutions on the photometer at 410 nm, in comparison with that of water.

8.3.2.3 Prepare a calibration curve by plotting the percent transmittance or absorbance readings against the known concentrations of silica in each solution.

8.3.3 *Determination of Dissolved Silica*:

8.3.3.1 Transfer by pipet a 10-mL aliquot of the dilute solution to a 100-mL volumetric flask half filled with water and proceed as directed in 8.3.2.2 and 8.3.2.3. Read the concentration of silica in the solution directly from the previously prepared calibration curve correlating transmission of light of this wave length with silica concentration. If the transmittance is below 30 % or above 50 %, a smaller or larger aliquot of the diluted solution shall be used.

8.3.4 *Calculation*:

8.3.4.1 Calculate the SiO_2 concentration of the NaOH solution filtered from the aggregate material, as follows:

$$S_c = 20 \times (100/V) \times C \quad (2)$$

where:

S_c = concentration of SiO_2, mmol/L in the original filtrate,
C = concentration of silica in the solution measured in the photometer, mmol/L, and
V = millilitres of dilute solution used from 7.5.

8.4 Reduction in Alkalinity

8.4.1 *Procedure*:

Transfer by pipet a 20-mL aliquot of the dilute solution (7.5) to a 125-mL Erlenmeyer flask, add 2 or 3 drops of phenolphthalein solution, and titrate with 0.05-*N* HCl to the phenolphthalein end point.

8.4.2 *Calculation*:

Calculate the reduction in alkalinity as follows:

$$R_c = (20N/V_1)(V_3 - V_2) \times 1000 \quad (3)$$

where:

R_c = the reduction in alkalinity, mmol/L,
N = normality of the HCl used for the titration,
V_1 = millilitres of dilute solution used from 7.5,
V_2 = millilitres of HCl used to attain the phenolphthalein end point in the test sample, and
V_3 = millilitres of HCl used to attain the phenolphthalein end point in the blank.

9. Precision and Bias

9.1 *Precision*—Information concerning the precision of this test method is being investigated and will be published when the proper data have been obtained and analyzed as prescribed in Practice C 670.

9.2 Preliminary data on precision indicate that the test results may be considered satisfactory if none of the three values of R_c (and of S_c) differs from the average of the three by more than the following amounts: (*1*) when the average is 100 mmol or less, 12 mmol/L, and (*2*) when the average is more than 100 mmol/L, 12 %.

9.3 *Bias*—Since there is no accepted reference material suitable for determining the bias of this test method, no statement on bias is made.

10. Keywords

10.1 aggregate reactivity; alkali; alkali-silica reactivity; concrete aggregates

APPENDIX

(Nonmandatory Information)

X1. INTERPRETATION OF RESULTS

X1.1 Correlations between data obtained by this method, expansion of mortar bars containing high-alkali cement, petrographic examinations of aggregates, and performance of aggregates in concrete structures have been published **(1-7).**[3] On the basis of these data, the solid curve shown in Fig. X1.1 has been established. A potentially deleterious degree of alkali reactivity is indicated if any of the three R_c, S_c points lie on the deleterious side of the curve in Fig. X1.1. However, potentially deleterious aggregates represented by points lying above the dashed line in Fig. X1.1 may give relatively low expansions in mortar or concrete even though they are extremely reactive with alkalies. These aggregates should be considered to indicate a potentially deleterious degree of reactivity until the innocuous character of the aggregate is demonstrated by service records or by supplementary tests in accordance with the provisions of Test Methods C 227, C 1260, or C 1293, as applicable. The additional test method(s) should be selected based on the mineralogical characteristics of the aggregate. It is recommended that these mineralogical properties be determined with a petrographic examination in accordance with the provisions of Guide C 295.

X1.2 Results of this test may not be correct for aggregates containing carbonates of calcium, magnesium, or ferrous iron, such as calcite, dolomite, magnesite, or siderite; or silicates of magnesium such as antigorite (serpentine) **(6,7)**. The error

[3] The boldface numbers in parentheses refer to the references appearing at the end of this test method.

www.technobetar.ir

introduced by calcium carbonate is not significant unless S_c and R_c values indicate the potential reactivity is marginal. Examinations of the aggregate in accordance with Guide C 295, can be used to determine the presence of minerals of this type.

X1.3 It is recommended that interpretations based upon this method be correlated with Guide C 295 and service records of the aggregate. The results of this test do not predict the late-slow silica-silicate reactivity in concrete that may result with aggregates containing strained or micro-granulated quartz, or aggregates composed of metagraywacke, meta-siltstone, meta-quartz, and similar rocks.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 289 – 03, that may impact the use of this test method. (Approved November 1, 2007)

(*1*) Reorganized the test method, moving old Sections 8–13 into new Section 8.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 293 – 07

Standard Test Method for Flexural Strength of Concrete (Using Simple Beam With Center-Point Loading)[1]

This standard is issued under the fixed designation C 293; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers determination of the flexural strength of concrete specimens by the use of a simple beam with center-point loading. It is not an alternative to Test Method C 78.

1.2 The values stated in inch-pound units are to be regarded as standard. The SI equivalent of inch-pound units has been rounded where necessary for practical application.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 78 Test Method for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 617 Practice for Capping Cylindrical Concrete Specimens

C 1077 Practice for Laboratories Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation

E 4 Practices for Force Verification of Testing Machines

3. Significance and Use

3.1 This test method is used to determine the modulus of rupture of specimens prepared and cured in accordance with Practices C 31 or C 192. The strength determined will vary where there are differences in specimen size, preparation, moisture condition, or curing.

3.2 The results of this test method may be used to determine compliance with specifications or as a basis for proportioning, mixing and placement operations. This test method produces values of flexural strength significantly higher than Test Method C 78 (Note 1).

NOTE 1—The testing laboratory performing this test method may be evaluated in accordance with Practice C 1077.

4. Apparatus

4.1 The testing machine shall conform to the requirements of the sections on Basis of Verification, Corrections, and Time Interval Between Verifications of Practices E 4. Hand operated testing machines having pumps that do not provide a continuous loading to failure in one stroke are not permitted. Motorized pumps or hand operated positive displacement pumps having sufficient volume in one continuous stroke to complete a test without requiring replenishment are permitted and shall be capable of applying loads at a uniform rate without shock or interruption.

4.2 *Loading Apparatus*—The mechanism by which forces are applied to the specimen shall employ a load-applying block and two specimen support blocks. It shall ensure that all forces are applied perpendicular to the face of the specimen without eccentricity. A diagram of an apparatus that accomplishes this purpose is shown in Fig. 1.

4.2.1 All apparatus for making center-point loading flexure tests shall be similar to Fig. 1 and maintain the span length and central position of the load-applying block with respect to the support blocks constant within ±0.05 in. (±1.3 mm).

4.2.2 Reactions shall be parallel to the direction of the applied load at all times during the test, and the ratio of the horizontal distance between the point of load application and nearest reaction to the depth of the beam shall be 1.5 ± 2 %.

4.2.3 The load-applying and support blocks shall not be more than 2½ in. (64 mm) high, measured from the center or the axis of pivot, and shall extend at least across the full width of the specimen. Each hardened bearing surface in contact with the specimen shall not depart from a plane by more than 0.002 in. (0.05 mm) and shall be a portion of a cylinder, the axis of

NOTE 1—Apparatus may be used inverted.

FIG. 1 Diagrammatic View of a Suitable Apparatus for Flexure Test of Concrete by Center-Point Loading Method.

which is coincidental with either the axis of the rod or center of the ball, whichever the block is pivoted upon. The angle subtended by the curved surface of each block shall be at least 45° (0.79 rad). The load-applying and support blocks shall be maintained in a vertical position and in contact with the rod or ball by means of spring-loaded screws that hold them in contact with the pivot rod or ball. The rod in the center load-applying block in Fig. 1 may be omitted when a spherically seated bearing block is used.

5. Test Specimen

5.1 The test specimen shall conform to all requirements of Practice C 31 or C 192 applicable to beam specimens and shall have a test span within 2 % of being three times its depth as tested. The sides of the specimen shall be at right angles with the top and bottom. All surfaces shall be smooth and free of scars, indentations, holes, or inscribed identification marks.

6. Procedure

6.1 Flexural tests of moist-cured specimens shall be made as soon as practical after removal from moist storage. Surface drying of the specimen results in a reduction in the measured modulus of rupture.

6.2 Turn the test specimen on its side with respect to its position as molded and center it on the support blocks. Center the loading system in relation to the applied force. Bring the load-applying block in contact with the surface of the specimen at the center and apply a load of between 3 and 6 % of the estimated ultimate load. Using 0.004 in. (0.10 mm) and 0.015 in. (0.38 mm) leaf-type feeler gages, determine whether any gap between the specimen and the load-applying or support blocks is greater or less than each of the gages over a length of 1 in. (25 mm) or more. Grind, cap, or use leather shims on the specimen contact surface to eliminate any gap in excess of 0.004 in. (0.10 mm). Leather shims shall be of uniform ¼ in. (6.4 mm) thickness, 1 to 2 in. (25 to 50 mm) in width, and shall extend across the full width of the specimen. Gaps in excess of 0.015 in. (0.38 mm) shall be eliminated only by capping or grinding. Grinding of lateral surfaces shall be minimized inasmuch as grinding may change the physical characteristics of the specimens. Capping shall be in accordance with Practice C 617.

6.3 Load the specimen continuously and without shock. The load shall be applied at a constant rate to the breaking point. Apply the load so that the maximum stress on the tension face increases at a rate between 125 and 175 psi/min (0.9 and 1.2 MPa/min). The loading rate is computed using:

$$r = 2Sbd^2/3L \quad (1)$$

where:

r = loading rate, lb/min (N/min),
S = rate of increase in the maximum stress on the tension face, psi/min (MPa/min),
b = average width of the specimen as oriented for testing, in. (mm),
d = average depth of the specimen as oriented for testing, in. (mm), and
L = span length, in. (mm).

7. Measurement of Specimens After Test

7.1 To determine the dimensions of the specimen section for use in calculating modulus of rupture, take measurements across one of the fractured faces after testing. The width and depth are measured with the specimen as oriented for testing. For each dimension, take one measurement at each edge and one at the center of the cross section. Use the three measurements for each direction to determine the average width and the average depth. Take all measurements to the nearest 0.05 in. (1 mm). If the fracture occurs at a capped section, include the cap thickness in the measurement.

8. Calculation

8.1 Calculate the modulus of rupture as follows:

$$R = 3\,PL/2bd^2 \quad (2)$$

where:

R = modulus of rupture, psi, or MPa,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 18:48:44 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

P = maximum applied load indicated by the testing machine, lbf, or N,
L = span length, in., or mm,
b = average width of specimen, at the fracture, in., or mm, and
d = average depth of specimen, at the fracture, in., or mm.

NOTE 2—The weight of the beam is not included in the above calculation.

9. Report

9.1 Report the following information:
9.1.1 Identification number,
9.1.2 Average width to the nearest 0.05 in. (1 mm), at the fracture,
9.1.3 Average depth to the nearest 0.05 in. (1 mm), at the fracture,
9.1.4 Span length in inches (or millimetres),
9.1.5 Maximum applied load in pounds-force (or newtons),
9.1.6 Modulus of rupture calculated to the nearest 5 psi (0.05 MPa),
9.1.7 Record of curing and apparent moisture condition of the specimens at the time of test,
9.1.8 If specimens were capped, ground, or if leather shims were used,
9.1.9 Defects in specimens, and
9.1.10 Age of specimens.

10. Precision and Bias

10.1 *Precision*—The coefficient of variation of test results has been observed to be dependent on the strength level of the beams.[3] The single operator coefficient of variation has been found to be 4.4 %. Therefore, results of two properly conducted tests by the same operator on beams made from the same batch sample should not differ from each other by more than 12 %. The multilaboratory coefficient of variation has been found to be 5.3 %. Therefore, results of two different laboratories on beams made from the same batch sample should not differ from each other by more than 15 %.

10.2 *Bias*—Since there is no accepted standard for determining bias in this test method, no statement on bias is made.

11. Keywords

11.1 beams; concrete; flexural strength testing; modulus of rupture

[3] See "Improved Concrete Quality Control Procedures Using Third Point Loading" by P. M. Carrasquillo and R. L. Carrasquillo, Research Report 119-1F, Project 3-9-87-1119, Center For Transportation Research, The University of Texas at Austin, November 1987, for information as to the relationship of strength and variability under center point loading.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 293 – 02, that may impact the use of this test method.

(*1*) Revised 5.1.
(*2*) Revised 6.3.
(*3*) Revised 7.1.

Designation: C 293 – 07

Standard Test Method for Flexural Strength of Concrete (Using Simple Beam With Center-Point Loading)[1]

This standard is issued under the fixed designation C 293; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers determination of the flexural strength of concrete specimens by the use of a simple beam with center-point loading. It is not an alternative to Test Method C 78.

1.2 The values stated in inch-pound units are to be regarded as standard. The SI equivalent of inch-pound units has been rounded where necessary for practical application.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 617 Practice for Capping Cylindrical Concrete Specimens

C 1077 Practice for Laboratories Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation

E 4 Practices for Force Verification of Testing Machines

3. Significance and Use

3.1 This test method is used to determine the modulus of rupture of specimens prepared and cured in accordance with Practices C 31 or C 192. The strength determined will vary where there are differences in specimen size, preparation, moisture condition, or curing.

3.2 The results of this test method may be used to determine compliance with specifications or as a basis for proportioning, mixing and placement operations. This test method produces values of flexural strength significantly higher than Test Method C 78 (Note 1).

NOTE 1—The testing laboratory performing this test method may be evaluated in accordance with Practice C 1077.

4. Apparatus

4.1 The testing machine shall conform to the requirements of the sections on Basis of Verification, Corrections, and Time Interval Between Verifications of Practices E 4. Hand operated testing machines having pumps that do not provide a continuous loading to failure in one stroke are not permitted. Motorized pumps or hand operated positive displacement pumps having sufficient volume in one continuous stroke to complete a test without requiring replenishment are permitted and shall be capable of applying loads at a uniform rate without shock or interruption.

4.2 *Loading Apparatus*—The mechanism by which forces are applied to the specimen shall employ a load-applying block and two specimen support blocks. It shall ensure that all forces are applied perpendicular to the face of the specimen without eccentricity. A diagram of an apparatus that accomplishes this purpose is shown in Fig. 1.

4.2.1 All apparatus for making center-point loading flexure tests shall be similar to Fig. 1 and maintain the span length and central position of the load-applying block with respect to the support blocks constant within ±0.05 in. (±1.3 mm).

4.2.2 Reactions shall be parallel to the direction of the applied load at all times during the test, and the ratio of the horizontal distance between the point of load application and nearest reaction to the depth of the beam shall be 1.5 ± 2 %.

4.2.3 The load-applying and support blocks shall not be more than 2½ in. (64 mm) high, measured from the center or the axis of pivot, and shall extend at least across the full width of the specimen. Each hardened bearing surface in contact with the specimen shall not depart from a plane by more than 0.002 in. (0.05 mm) and shall be a portion of a cylinder, the axis of

NOTE 1—Apparatus may be used inverted.

FIG. 1 Diagrammatic View of a Suitable Apparatus for Flexure Test of Concrete by Center-Point Loading Method.

which is coincidental with either the axis of the rod or center of the ball, whichever the block is pivoted upon. The angle subtended by the curved surface of each block shall be at least 45° (0.79 rad). The load-applying and support blocks shall be maintained in a vertical position and in contact with the rod or ball by means of spring-loaded screws that hold them in contact with the pivot rod or ball. The rod in the center load-applying block in Fig. 1 may be omitted when a spherically seated bearing block is used.

5. Test Specimen

5.1 The test specimen shall conform to all requirements of Practice C 31 or C 192 applicable to beam specimens and shall have a test span within 2 % of being three times its depth as tested. The sides of the specimen shall be at right angles with the top and bottom. All surfaces shall be smooth and free of scars, indentations, holes, or inscribed identification marks.

6. Procedure

6.1 Flexural tests of moist-cured specimens shall be made as soon as practical after removal from moist storage. Surface drying of the specimen results in a reduction in the measured modulus of rupture.

6.2 Turn the test specimen on its side with respect to its position as molded and center it on the support blocks. Center the loading system in relation to the applied force. Bring the load-applying block in contact with the surface of the specimen at the center and apply a load of between 3 and 6 % of the estimated ultimate load. Using 0.004 in. (0.10 mm) and 0.015 in. (0.38 mm) leaf-type feeler gages, determine whether any gap between the specimen and the load-applying or support blocks is greater or less than each of the gages over a length of 1 in. (25 mm) or more. Grind, cap, or use leather shims on the specimen contact surface to eliminate any gap in excess of 0.004 in. (0.10 mm). Leather shims shall be of uniform ¼ in. (6.4 mm) thickness, 1 to 2 in. (25 to 50 mm) in width, and shall extend across the full width of the specimen. Gaps in excess of 0.015 in. (0.38 mm) shall be eliminated only by capping or grinding. Grinding of lateral surfaces shall be minimized inasmuch as grinding may change the physical characteristics of the specimens. Capping shall be in accordance with Practice C 617.

6.3 Load the specimen continuously and without shock. The load shall be applied at a constant rate to the breaking point. Apply the load so that the maximum stress on the tension face increases at a rate between 125 and 175 psi/min (0.9 and 1.2 MPa/min). The loading rate is computed using:

$$r = 2Sbd^2/3L \quad (1)$$

where:

r = loading rate, lb/min (N/min),
S = rate of increase in the maximum stress on the tension face, psi/min (MPa/min),
b = average width of the specimen as oriented for testing, in. (mm),
d = average depth of the specimen as oriented for testing, in. (mm), and
L = span length, in. (mm).

7. Measurement of Specimens After Test

7.1 To determine the dimensions of the specimen section for use in calculating modulus of rupture, take measurements across one of the fractured faces after testing. The width and depth are measured with the specimen as oriented for testing. For each dimension, take one measurement at each edge and one at the center of the cross section. Use the three measurements for each direction to determine the average width and the average depth. Take all measurements to the nearest 0.05 in. (1 mm). If the fracture occurs at a capped section, include the cap thickness in the measurement.

8. Calculation

8.1 Calculate the modulus of rupture as follows:

$$R = 3\,PL/2bd^2 \quad (2)$$

where:

R = modulus of rupture, psi, or MPa,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:47 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

P = maximum applied load indicated by the testing machine, lbf, or N,
L = span length, in., or mm,
b = average width of specimen, at the fracture, in., or mm, and
d = average depth of specimen, at the fracture, in., or mm.

NOTE 2—The weight of the beam is not included in the above calculation.

9. Report

9.1 Report the following information:
9.1.1 Identification number,
9.1.2 Average width to the nearest 0.05 in. (1 mm), at the fracture,
9.1.3 Average depth to the nearest 0.05 in. (1 mm), at the fracture,
9.1.4 Span length in inches (or millimetres),
9.1.5 Maximum applied load in pounds-force (or newtons),
9.1.6 Modulus of rupture calculated to the nearest 5 psi (0.05 MPa),
9.1.7 Record of curing and apparent moisture condition of the specimens at the time of test,
9.1.8 If specimens were capped, ground, or if leather shims were used,
9.1.9 Defects in specimens, and
9.1.10 Age of specimens.

10. Precision and Bias

10.1 *Precision*—The coefficient of variation of test results has been observed to be dependent on the strength level of the beams.[3] The single operator coefficient of variation has been found to be 4.4 %. Therefore, results of two properly conducted tests by the same operator on beams made from the same batch sample should not differ from each other by more than 12 %. The multilaboratory coefficient of variation has been found to be 5.3 %. Therefore, results of two different laboratories on beams made from the same batch sample should not differ from each other by more than 15 %.

10.2 *Bias*—Since there is no accepted standard for determining bias in this test method, no statement on bias is made.

11. Keywords

11.1 beams; concrete; flexural strength testing; modulus of rupture

[3] See "Improved Concrete Quality Control Procedures Using Third Point Loading" by P. M. Carrasquillo and R. L. Carrasquillo, Research Report 119-1F, Project 3-9-87-1119, Center For Transportation Research, The University of Texas at Austin, November 1987, for information as to the relationship of strength and variability under center point loading.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 293 – 02, that may impact the use of this test method.

Designation: C 294 – 05

Standard Descriptive Nomenclature for Constituents of Concrete Aggregates[1]

This standard is issued under the fixed designation C 294; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This descriptive nomenclature provides brief descriptions of some of the more commonly occurring, or more important, natural and artificial materials of which mineral aggregates are composed. The descriptions provide a basis for understanding these terms as applied to concrete aggregates. When appropriate, brief observations regarding the potential effects of using the natural and artificial materials in concrete are discussed.

NOTE 1—These descriptions characterize minerals and rocks as they occur in nature and blast-furnace slag or lightweight aggregates that are prepared by the alteration of the structure and composition of natural material. Information about lightweight aggregates are given in Specifications C 330, C 331, and C 332.

1.2 This standard does not include descriptions of constituents of aggregates used in radiation shielding concrete. See Descriptive Nonmenclature C 638.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 227 Test Method for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar Bar Method)

C 289 Test Method for Potential Alkali-Silica Reactivity of Aggregates (Chemical Method)

C 330 Specification for Lightweight Aggregates for Structural Concrete

C 331 Specification for Lightweight Aggregates for Concrete Masonry Units

C 332 Specification for Lightweight Aggregates for Insulating Concrete

C 638 Descriptive Nonmenclature of Constituents of Aggregates for Radiation-Shielding Concrete

3. Significance and Use

3.1 This descriptive nomenclature provides information on terms commonly applied to concrete aggregates. This standard is intended to assist in understanding the meaning and significance of the terms.

3.2 Many of the materials described frequently occur in particles that do not display all the characteristics given in the descriptions, and most of the described rocks grade from varieties meeting one description to varieties meeting another with all intermediate stages being found.

3.3 The accurate identification of rocks and minerals can, in many cases, be made only by a qualified geologist, mineralogist, or petrographer using the apparatus and procedures of these sciences. Reference to these descriptions may, however, serve to indicate or prevent gross errors in identification. Identification of the constituent materials in an aggregate may assist in characterizing its engineering properties, but identification alone cannot provide the sole basis for predicting behavior of aggregates in service. Aggregates of any type or combination of types may perform well or poorly in service depending upon the exposure to which the concrete is subjected, the physical and chemical properties of the matrix in which they are embedded, their physical condition at the time they are used, and other factors. Constituents that may occur only in minor amounts in the aggregate may or may not decisively influence its performance. Information about concrete aggregate performance in concrete has been published by ASTM.[3]

CONSTITUENTS OF NATURAL MINERAL AGGREGATES

4. Classes and Types

4.1 The materials found as constituents of natural mineral aggregates are minerals and rocks.

4.2 Minerals are naturally occurring inorganic substances of more or less definite chemical composition and usually of a specific crystalline structure. The physical nature of the rock-forming minerals and aspects of crystal chemistry determine the important physical and chemical properties of natural

[1] This descriptive nomenclature is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.65 on Petrography.

Current edition approved Jan. 1, 2005. Published January 2005. Originally approved in 1952. Last previous edition approved in 2004 as C 294 – 04.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

mineral aggregates. Certain assemblages of rock-forming minerals possess desirable qualities for use as aggregates in cementitious materials.

4.2.1 Minerals are characterized by their crystallographic, physical, and optical properties and their chemical composition. The crystallographic properties of minerals may be determined by x-ray diffraction and optical properties (**1-6**). The physical properties of minerals include but are not limited to crystal habit, cleavage, parting, fracture, hardness, specific gravity, luster, color, streak, magnetism, luminescence, and pyroelectricity (**7**). The optical properties of minerals include but are not limited to refractive index, birefringence, optic sign, pleochroism, and sign of elongation (**2-5**). Methods to determine the chemical composition of minerals include but are not limited to optical properties (**5**), flame photometry (**7,8**), chemical spot tests (**9,10**), various staining techniques (**11**), x-ray fluorescence, and electron microscopy (**12-14**).

4.2.2 Different minerals may have the same chemical composition but different crystallographic and physical properties. Such sets of minerals are known as polymorphs. Distinguishing between some polymorphs can be important for determining the suitability of aggregates for use in cementitious materials.

4.3 Rocks are classified according to origin into three major divisions: igneous, sedimentary, and metamorphic. These three major groups are subdivided into types according to mineral and chemical composition, texture, and internal structure. Most rocks are composed of several minerals but some are composed of only one mineral. Certain examples of the rock quartzite are composed exclusively of the mineral quartz, and certain limestones are composed exclusively of the mineral calcite. Individual sand grains frequently are composed of particles of rock, but they may be composed of a single mineral, particularly in the finer sizes.

4.3.1 Igneous rocks form from molten matter either at or below the earth's surface.

4.3.2 Sedimentary rocks form near the earth's surface by the accumulation and consolidation of the products of weathering and erosion of existing rocks, or by direct chemical precipitation. Sedimentary rocks may form from pre-existing igneous, metamorphic, or sedimentary rocks.

4.3.3 Metamorphic rocks form from pre-existing igneous, sedimentary, or metamorphic rocks by the action of heat or pressure or both.

5. Silica Minerals

5.1 *Quartz*—a very common hard mineral composed of silica (SiO_2). It will scratch glass and is not scratched by a knife. When pure it is colorless with a glassy (vitreous) luster and a shell-like (conchoidal) fracture. It lacks a visible cleavage (the ability to break in definite directions along even planes) and, when present in massive rocks such as granite, it usually has no characteristic shape. It is resistant to weathering and is therefore an important constituent of many sand and gravel deposits and many sandstones. It is also abundant in many light-colored igneous and metamorphic rocks. Some strained, or intensely fractured (granulated), and microcrystalline quartz may be potentially deleteriously reactive with the alkalies in the hydraulic cement paste.

5.2 *Opal*—a hydrous form of silica ($SiO_2 \cdot nH_2O$) which occurs without characteristic external form or internal crystalline arrangement as determined by ordinary visible light methods. When X-ray diffraction methods are used, opal may show some evidences of internal crystalline arrangement. Opal has a variable water content, generally ranging from 3 to 9 %. The specific gravity and hardness are always less than those of quartz. The color is variable and the luster is resinous to glassy. It is usually found in sedimentary rocks, especially some cherts, and is the principal constituent of diatomite. It is also found as a secondary material filling cavities and fissures in igneous rocks and may occur as a coating on gravel and sand. The recognition of opal in aggregates is important because it is potentially deleteriously reactive with the alkalies in hydraulic cement paste or with the alkalies from other sources, such as aggregates containing zeolites, and ground water.

5.3 *Chalcedony*—chalcedony has been considered both as a distinct mineral and a variety of quartz. It is frequently composed of a mixture of microscopic fibers of quartz with a large number of submicroscopic pores filled with water and air. The properties of chalcedony are intermediate between those of opal and quartz, from which it can sometimes be distinguished only by laboratory tests. It frequently occurs as a constituent of the rock chert and is potentially deleteriously reactive with the alkalies in hydraulic cement paste.

5.4 *Tridymite and cristobalite*—high temperature crystalline forms of silica (SiO_2) sometimes found in volcanic rocks. They are metastable at ordinary temperatures and pressures. They are rare minerals in aggregates except in areas where volcanic rocks are abundant. A type of cristobalite is a common constituent of opal. Tridymite and cristobalite are potentially deleteriously reactive with the alkalies in hydraulic cement paste.

6. Feldspars

6.1 The minerals of the feldspar group are the most abundant rock-forming minerals in the crust of the earth. They are important constituents of all three major rock groups, igneous, sedimentary, and metamorphic. Since all feldspars have good cleavages in two directions, particles of feldspar usually show several smooth surfaces. Frequently, the smooth cleavage surfaces show fine parallel lines. All feldspars are slightly less hard than, and can be scratched by, quartz and will, when fresh, easily scratch a penny. The various members of the group are differentiated by chemical composition and crystallographic properties. The feldspars *orthoclase, sanidine*, and *microcline* are potassium aluminum silicates, and are frequently referred to as *potassium feldspars*. The *plagioclase* feldspars include those that are sodium aluminum silicates and calcium aluminum silicates, or both sodium and calcium aluminum silicates. This group, frequently referred to as the "soda-lime" group, includes a continuous series, of varying chemical composition and optical properties, from *albite*, the sodium aluminum feldspar, to *anorthite*, the calcium aluminum feldspar, with intermediate members of the series designated *oligoclase, andesine, labradorite*, and *bytownite*. Potassium feldspars and sodium-rich plagioclase feldspars occur typically in igneous rocks such as granites and rhyolites, whereas, plagioclase

www.technobetar.ir

feldspars of higher calcium content are found in igneous rocks of lower silica content such as diorite, gabbro, andesite, and basalt.

7. Ferromagnesian Minerals

7.1 Many igneous and metamorphic rocks contain dark green to black minerals that are generally silicates of iron or magnesium, or of both. They include the minerals of the amphibole, pyroxene, and olivine groups. The most common amphibole mineral is hornblende; the most common pyroxene mineral is augite; and the most common olivine mineral is forsterite. Dark mica, such as biotite and phlogopite, are also considered ferromagnesian minerals. The amphibole and pyroxene minerals are brown to green to black and generally occur as prismatic units. Olivine is usually olive green, glassy in appearance, and usually altered. Biotite has excellent cleavage and can be easily cleaved into thin flakes and plates. These minerals can be found as components of a variety of rocks, and in sands and gravels. Olivine is found only in dark igneous rocks where quartz is not present, and in sands and gravels close to the olivine source.

8. Micaceous Minerals

8.1 Micaceous minerals have perfect cleavage in one direction and can be easily split into thin flakes. The mica minerals of the muscovite group are colorless to light green; of the biotite group, dark brown to black or dark green; of the lepidolite group, white to pink and red or yellow; and of the chlorite group, shades of green. Another mica, phlogopite, is similar to biotite, commonly has a pearl-like luster and bronze color, and less commonly is brownish red, green, or yellow. The mica minerals are common and occur in igneous, sedimentary, and metamorphic rocks, and are common as minor to trace components in many sands and gravels. The muscovite, biotite, lepidolite, and phlogopite minerals cleave into flakes and plates that are elastic; the chlorite minerals, by comparison, form inelastic flakes and plates. Vermiculite (a mica-like mineral) forms by the alteration of other micas and is brown and has a bronze luster.

8.2 Because micaceous materials have a high surface area, they can influence the properties of freshly mixed and hardened concrete. Aggregates with a high mica content can reduce workability and increase the water demand of the concrete (**15**). The shape and perfect cleavage of micaceous minerals may result in a poor bond to the cementitious paste (**16**).

9. Clay Minerals

9.1 The term "clay" refers to natural material composed of particles in a specific size range less than 2 μm (0.002 mm). Mineralogically, clay refers to a group of layered silicate minerals including the clay-micas (illites), the kaolin group, very finely divided chlorites, and the swelling clays—smectite including montmorillonites. Members of several groups, particularly micas, chlorites, and vermiculites, occur both in the clay-size range and in larger sizes. Some clays are made up of alternating layers of two or more clay groups. Random, regular, or both types of interlayering are known. If smectite is a significant constituent in such mixtures, then fairly large volume changes may occur with wetting and drying.

9.2 Clay minerals are hydrous aluminum, magnesium, and iron silicates that may contain calcium, magnesium, potassium, sodium, and other exchangeable cations. They are formed by alteration and weathering of other silicates and volcanic glass. The clay minerals are major constituents of clays and shales. They are found disseminated in carbonate rocks as seams and pockets and in altered and weathered igneous and metamorphic rocks. Clays may also be found as matrix, void fillings, and cementing material in sandstones and other sedimentary rocks.

9.3 Most aggregate particles composed of, or containing, large proportions of clay minerals are soft and, because of the large internal surface area of the constituents, they are porous. Some of these aggregates will disintegrate when wetted. Rocks in which the cementing matrix is principally clay, such as clay-bonded sandstones, and rocks in which swelling clay minerals (smectite) are present as a continuous phase or matrix, such as in some altered volcanics, may slake in water or may disintegrate in the concrete mixer. Rocks of this type are unsuitable for use as aggregates. Rocks having these properties less well developed will abrade considerably during mixing, releasing clay, and raising the water requirement of the concrete containing them. When such rocks are present in hardened concrete, the concrete will manifest greater volume change on wetting and drying than similar concrete containing non-swelling aggregate.

10. Zeolites

10.1 The zeolite minerals are a large group of hydrated aluminum silicates of the alkali and alkaline earth elements which are soft and usually white or light colored. They are formed as a secondary filling in cavities or fissures in igneous rocks, or within the rock itself as a product of hydrothermal alteration of original minerals, especially feldspars. Some zeolites, particularly *heulandite, natrolite*, and *laumontite*, reportedly produce deleterious effects in concrete, the first two having been reported to raise the alkali content in concrete by releasing alkalies through cation exchange and thus increasing alkali reactivity when alkali-reactive aggregate constituents are present. Laumontite and its partially dehydrated variety *leonhardite* are notable for their substantial volume change with wetting and drying. Both are found in rocks such as quartz diorites and some sandstones.

11. Carbonate Minerals

11.1 The most common carbonate mineral is *calcite* (calcium carbonate, $CaCO_3$). The mineral *dolomite* consists of calcium carbonate and magnesium carbonate ($CaCO_3 \cdot MgCO_3$ or $CaMg(CO_3)_2$) in equivalent molecular amounts, which are 54.27 and 45.73 by mass %, respectively. Both calcite and dolomite are relatively soft, the hardness of calcite being 3 and that of dolomite 3½ to 4 on the Mohs scale, and are readily scratched by a knife blade. They have rhombohedral cleavage, which results in their breaking into fragments with smooth parallelogram shaped sides. Calcite is soluble with vigorous effervescence in cold dilute hydrochloric acid; dolomite is soluble with slow effervescence in cold dilute hydrochloric acid and with vigorous effervescence if the acid or the sample is heated or if the sample is pulverized.

www.technobetar.ir

12. Sulfate Minerals

12.1 Carbonate rocks and shales may contain sulfates as impurities. The most abundant sulfate mineral is *gypsum* (hydrous calcium sulfate; $CaSO_4 \cdot 2H_2O$); *anhydrite* (anhydrous calcium sulfate, $CaSO_4$) is less common. Gypsum is usually white or colorless and characterized by a perfect cleavage along one plane and by its softness, representing hardness of 2 on the Mohs scale; it is readily scratched by the fingernail. Gypsum may form a whitish pulverulent or crystalline coating on sand and gravel. It is slightly soluble in water.

12.2 Anhydrite resembles dolomite in hand specimen but has three cleavages at right angles; it is less soluble in hydrochloric acid than dolomite, does not effervesce and is slightly soluble in water. Anhydrite is harder than gypsum. Gypsum and anhydrite occurring in aggregates can cause sulfate attack in concrete and mortar.

13. Iron Sulfide Minerals

13.1 The sulfides of iron, *pyrite, marcasite*, and *pyrrhotite* are frequently found in natural aggregates. Pyrite is found in igneous, sedimentary, and metamorphic rocks; marcasite is much less common and is found mainly in sedimentary rocks; pyrrhotite is less common but may be found in many types of igneous and metamorphic rocks. Pyrite is brass yellow, and pyrrhotite bronze brown, and both have a metallic luster. Marcasite is also metallic but lighter in color and finely divided iron sulfides are soot black. Pyrite is often found in cubic crystals. Marcasite readily oxidizes with the liberation of sulfuric acid and formation of iron oxides, hydroxides, and, to a much smaller extent, sulfates; pyrite and pyrrhotite do so less readily. Marcasite and certain forms of pyrite and pyrrhotite are reactive in mortar and concrete, producing a brown stain accompanied by a volume increase that has been reported as one source of popouts in concrete. Reactive forms of iron sulfides may be recognized by immersion in saturated lime water (calcium hydroxide solution); upon exposure to air the reactive varieties produce a brown coating within a few minutes.

14. Iron Oxide Minerals, Anhydrous and Hydrous

14.1 There are two common iron oxide minerals: (*1*) Black, magnetic: *magnetite* (Fe_3O_4), and (*2*) red or reddish when powdered: *hematite* (Fe_2O_3); and one common hydrous oxide mineral, brown or yellowish: *goethite* (FeO(OH)). Another common iron-bearing mineral is black, weakly magnetic, *ilmenite* ($FeTiO_3$). Magnetite and ilmenite are important accessory minerals in many dark igneous rocks and are common detrital minerals in sediments. Hematite is frequently found as an accessory mineral in reddish rocks. Limonite, the brown weathering product of iron-bearing minerals, is a field name for several varieties of hydrous iron oxide minerals including goethite; it frequently contains adsorbed water, and various impurities such as colloidal or crystalline silica, clay minerals, and organic matter. The presence of substantial amounts of soft iron-oxide minerals in concrete aggregate can color concrete various shades of yellow or brown. Very minor amounts of iron minerals color many rocks, such as ferruginous sandstones, shales, clay-ironstones, and granites. Magnetite, ilmenite, and hematite ores are used as heavy aggregates.

DESCRIPTIONS OF IGNEOUS ROCKS

15. General

15.1 Igneous rocks are those formed by cooling from a molten rock mass (magma). They may be divided into two classes: (*1*) plutonic, or intrusive, that have cooled slowly within the earth; and (*2*) volcanic, or extrusive, that formed from quickly cooled lavas. Plutonic rocks have grain sizes greater than approximately 1 mm, and are classified as coarse- or medium-grained. Volcanic rocks have grain sizes less than approximately 1 mm, and are classified as fine-grained. Volcanic rocks frequently contain glass. Both plutonic and volcanic rocks may consist of porphyries, that are characterized by the presence of large mineral grains in a fine-grained or glassy groundmass. This is the result of sharp changes in rate of cooling or other physico-chemical conditions during solidification of the melt.

15.2 Igneous rocks are usually classified and named on the basis of their texture, internal structure, and their mineral composition which in turn depends to a large extent on their chemical composition. Rocks in the plutonic class generally have chemical equivalents in the volcanic class.

16. Plutonic Rocks

16.1 *Granite*—granite is a medium- to coarse-grained, light-colored rock characterized by the presence of potassium feldspar with lesser amounts of plagioclase feldspars and quartz. The characteristic potassium feldspars are orthoclase or microcline, or both; the common plagioclase feldspars are albite and oligoclase. Feldspars are more abundant than quartz. Dark-colored mica (biotite) is usually present, and light-colored mica (muscovite) is frequently present. Other dark-colored ferromagnesian minerals, especially hornblende, may be present in amounts less than those of the light-colored constituents. *Quartz-monzonite* and *granodiorite* are rocks similar to granite, but they contain more plagioclase feldspar than potassium feldspar.

16.2 *Syenite*—syenite is a medium- to coarse-grained, light-colored rock composed essentially of alkali feldspars, namely microcline, orthoclase, or albite. Quartz is generally absent. Dark ferromagnesian minerals such as hornblende, biotite, or pyroxene are usually present.

16.3 *Diorite*—diorite is a medium- to coarse-grained rock composed essentially of plagioclase feldspar and one or more ferromagnesian minerals such as hornblende, biotite, or pyroxene. The plagioclase is intermediate in composition, usually of the variety andesine, and is more abundant than the ferromagnesian minerals. Diorite usually is darker in color than granite or syenite and lighter than gabbro. If quartz is present, the rock is called *quartz diorite.*

16.4 *Gabbro*—gabbro is a medium- to coarse-grained, dark-colored rock consisting essentially of ferromagnesian minerals and plagioclase feldspar. The ferromagnesian minerals may be pyroxenes, amphiboles, or both. The plagioclase is one of the calcium-rich varieties, namely labradorite, bytownite, or anorthite. Ferromagnesian minerals are usually more abundant than feldspar. *Diabase* (in European usage *dolerite*) is a rock of similar composition to gabbro and basalt but is intermediate in mode of origin, usually occurring in smaller intrusions than

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

gabbro, and having a medium to fine-grained texture. The terms "trap" or "trap rock" are collective terms for dark-colored, medium- to fine-grained igneous rocks especially diabase and basalt.

16.5 *Peridotite*—peridotite is composed of olivine and pyroxene. Rocks composed almost entirely of pyroxene are known as *pyroxenites*, and those composed of olivine as *dunites.* Rocks of these types are relatively rare but their metamorphosed equivalent, serpentinite, is more common.

16.6 *Pegmatite*—extremely coarse-grained varieties of igneous rocks are known as pegmatites. These are *usually* light-colored and are most frequently equivalent to granite or syenite in mineral composition.

17. Fine-Grained and Glassy Extrusive Igneous Rocks

17.1 *Volcanic Rock*—volcanic or extrusive rocks are the fine-grained equivalents of the coarse-and-medium-grained plutonic rocks. Equivalent types have similar chemical compositions and may contain the same minerals. Volcanic rocks commonly are so fine-grained that the individual mineral grains usually are not visible to the naked eye. Porphyritic textures are common, and the rocks may be partially or wholly glassy or non-crystalline. The glassy portion of a partially glassy rock usually has a higher silica content than the crystalline portion. Some volcanic or extrusive rocks may not be distinguishable in texture and structure from plutonic or intrusive rocks that originated at shallow depth.

17.2 *Glassy Volcanic Rocks*—These rocks are of particular significance because they contain, or may contain, high silica glass that is alkali-reactive, and secondary minerals that are alkali-reactive or release alkalies into concrete. The high silica glasses, generally classed as those containing more than 55 % silica, are known to be alkali-reactive, whereas the low-silica glasses are not. Among igneous rocks that contain, or may contain, high silica glass are: obsidian, pumice, trachyte, rhyolite, scoria, dacite, basalt, andesite, and perlite. Aggregates containing these rocks include crushed parent rock where the aggregate is constituted totally of the rock, or as varying percentages in gravels and sands. Glassy rocks, particularly the more siliceous ones, are potentially deleteriously reactive with the alkalies in hydraulic cement paste.

17.3 *Volcanic Glass*—igneous rocks composed wholly of glass are named on the basis of their texture and internal structure. A dense dark natural glass of high silica content is called *obsidian*, while lighter colored finely vesicular glassy froth filled with elongated, tubular bubbles is called *pumice.* Dark-colored coarsely vesicular types containing more or less spherical bubbles are called *scoria.* Pumices are usually silica-rich (corresponding to rhyolites or dacites), whereas scorias usually are more basic (corresponding to basalts). A high-silica glassy lava with an onion-like structure and a pearly luster, containing 2 to 5 % water, is called *perlite.* When heated quickly to the softening temperature, perlite puffs to become an artificial pumice. Glass with up to 10 % water and with a dull resinous luster is called *pitchstone*.

17.4 *Felsite*—light-colored, very fine-grained igneous rocks are collectively known as felsites. The felsite group includes *rhyolite, dacite, andesite*, and *trachyte*, which are the equivalents of granite, quartz diorite, diorite, and syenite, respectively. These rocks are usually light colored but they may be gray, green, dark red, or black. When they are microcrystalline or contain natural glass, rhyolites, dacites, and andesites are potentially deleteriously reactive with the alkalies in hydraulic cement paste.

17.5 *Basalt*—fine-grained extrusive equivalent of gabbro and diabase. When basalt contains natural glass, the glass is generally lower in silica content than that of the lighter-colored extrusive rocks and hence is not deleteriously reactive with the alkalies in hydraulic cement paste; however, exceptions have been noted in the literature with respect to the alkali reactivity of basaltic glasses.

17.6 Vesicles and other voids in volcanic rocks may contain alkali-reactive forms of silica such as opal, cristobalite, tridymite, and various varieties of microcrystalline quartz. Additionally, zeolitic minerals can release alkalies and thus increase the alkalies in the paste.

DESCRIPTIONS OF SEDIMENTARY ROCKS

18. General

18.1 Sedimentary rocks are stratified rocks usually laid down under water, although they can also be formed by wind and glacial action. Sediments may be composed of particles of preexisting rocks derived by mechanical agencies or they may be of chemical or organic origin. The sediments are usually indurated by cementation or compaction during geologic time, although the degree of consolidation may vary widely.

18.2 *Gravel, sand, silt*, and *clay* form the group of unconsolidated sediments. Although the distinction between these four members is made on the basis of their particle size, a general trend in the composition occurs. Gravel and, to a lesser degree, coarse sands usually consist of rock fragments; fine sands and silt consist predominantly of mineral grains; and clay exclusively of mineral grains, largely of the group of clay minerals. All types of rocks and minerals may be represented in unconsolidated sediments.

19. Conglomerates, Sandstones, and Quartzites

19.1 These rocks consist of particles of *sand* or *gravel*, or both, with or without interstitial and cementing material. If the particles include a considerable proportion of gravel, the rock is a *conglomerate*. If the particles are in the sand sizes, that is, less than 2 mm but more than 0.06 mm in major diameter, the rock is a *sandstone* or a *quartzite*. If the rock breaks around the sand grains, it is a sandstone; if the grains are largely quartz and the rock breaks through the grains, it is quartzite. Conglomerates, and sandstones are sedimentary rocks but quartzites may be sedimentary (*orthoquartzites*) or metamorphic (*metaquartzites*). The cementing or interstitial materials of sandstones may be quartz, opal, calcite, dolomite, clay, iron oxides, or other materials. These may influence the quality of a sandstone as concrete aggregate. If the nature of the cementing material is known, the rock name may include a reference to it, such as *opal-bonded sandstone* or *ferruginous conglomerate.* Opal-containing rocks may be potentially deleteriously reactive with alkalies in the hydraulic cement paste.

19.2 *Graywackes and subgraywackes*—gray to greenish gray sandstones containing angular quartz and feldspar grains,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:48 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

and sand-sized rock fragments in an abundant matrix resembling claystone, shale, argillite, or slate. Graywackes grade into subgraywackes, the most common sandstones of the geologic column.

19.3 *Arkose*—coarse-grained sandstone derived from granite, containing conspicuous amounts of feldspar.

20. Claystones, Shales, Argillites, and Siltstones

20.1 These very fine-grained rocks are composed of, or derived by erosion of sedimentary *silts* and *clays*, or of any type of rock that contained clay. When relatively soft and massive, they are known as *claystones*, or *siltstones*, depending on the size of the majority of the particles of which they are composed. Siltstones consist predominantly of silt-sized particles (0.0625 to 0.002 mm in diameter) and are intermediate rocks between claystones and sandstones. When the claystones are harder and platy or fissile, they are known as *shales*. Claystones and shales may be gray, black, reddish, or green and may contain some carbonate minerals (calcareous shales). A massive, firmly indurated fine-grained argillaceous rock consisting of quartz, feldspar, and micaceous minerals is known as *argillite.* Argillites do not slake in water as some shales do. As an aid in distinguishing these fine-grained sediments from fine-grained, foliated metamorphic rocks such as slates and phyllites, it may be noted that the cleavage surfaces of shales are generally dull and earthy while those of slates are more lustrous. Phyllite has a glossier luster resembling a silky sheen. Clay ironstone concretions are generally nodular particles consisting of mixtures of clay minerals and iron oxides. They are commonly hard and range in color from red-brown to purplish brown to orange-brown to orange to yellow. They are commonly concentric and may contain soft cores of clay minerals.

20.2 Clay ironstones may cause popouts in concrete subject to freezing and thawing while saturated with water. Aggregates containing abundant shale may be detrimental to concrete because they can produce high shrinkage, but not all shales are harmful. Some shales and siltstones may cause popouts and scaling in concrete subject to freezing and thawing while saturated with water (**15**,**17**). Some argillites, siltstones, and shales are alkali-silica reactive and may cause popouts (**18**,**19**).

20.3 Although aggregates which are volumetrically unstable in wetting and drying are not confined to any class of rock, they do share some common characteristics. If there is a matrix or continuous phase, it is usually physically weak and consists of material of high specific surface, frequently including clay. However, no general relation has been demonstrated between clay content or type of clay and large volume change upon wetting and drying. Volumetrically unstable aggregates do not have mineral grains of high modulus interlocked in a continuous rigid structure capable of resisting volume change.

20.4 Aggregates having high elastic modulus and low volume change from the wet to the dry condition contribute to the volume stability of concrete by restraining the volume change of the cement paste. In a relatively few cases, aggregates have been demonstrated to contribute to unsatisfactory performance of concrete because they have relatively large volume change from the wet to the dry condition combined with relatively low modulus of elasticity. On drying, such aggregates shrink away from the surrounding cement paste and consequently fail to restrain its volume change with change in moisture content.

21. Carbonate Rocks

21.1 *Limestones*, the most widespread of carbonate rocks. They range from pure limestones consisting of the mineral calcite to pure *dolomites* (dolostones) consisting of the mineral dolomite. Usually they contain both minerals in various proportions. If 50 to 90 % is the mineral dolomite, the rock is called *calcitic dolomite*. The term "magnesium limestone" is sometimes applied to dolomitic limestones and calcitic dolomites but it is ambiguous and its use should be avoided. Most carbonate rocks contain some noncarbonate impurities such as quartz, chert, clay minerals, organic matter, gypsum, and sulfides. Carbonate rocks containing 10 to 50 % sand are *arenaceous* (or *sandy*) *limestones* (or *dolomites*); those containing 10 to 50 % clay are *argillaceous* (or *clayey* or *shaly*) *limestones* (or *dolomites*). *Marl* is a clayey limestone which is fine-grained and commonly soft. Chalk is fine-textured, very soft, porous, and somewhat friable limestone, composed chiefly of particles of microorganisms. Micrite is very fine-textured chemically precipitated carbonate or a mechanical ooze of carbonate particles, usually 0.001 to 0.003 mm in size. The term "limerock" is not recommended.

21.2 The reaction of the dolomite in certain carbonate rocks with alkalies in portland cement paste has been found to be associated with deleterious expansion of concrete containing such rocks as coarse aggregate. Carbonate rocks capable of such reaction possess a characteristic texture and composition. The characteristic microscopic texture is that in which relatively large crystals of dolomite (rhombs) are scattered in a finer-grained matrix of micritic calcite and clay. The characteristic composition is that in which the carbonate portion consists of substantial amounts of both dolomite and calcite, and the acid-insoluble residue contains a significant amount of clay. Except in certain areas, such rocks are of relatively infrequent occurrence and seldom make up a significant proportion of the material present in a deposit of rock being considered for use in making aggregate for concrete.

22. Chert

22.1 *Chert*—the general term for a group of variously colored, very fine-grained (aphanitic), siliceous rocks composed of microcrystalline or cryptocrystalline quartz, chalcedony, or opal, either singly or in combinations of varying proportions. Identification of the form or forms of silica requires careful determination of optical properties, absolute specific gravity, loss on ignition, or a combination of these characteristics. Dense cherts are very tough, with a waxy to greasy luster, and are usually gray, brown, white, or red, and less frequently, green, black or blue. Porous varieties are usually lighter in color, frequently off-white, or stained yellowish, brownish, or reddish, firm to very weak, and grade to tripoli. Ferruginous, dense, red, and in some cases, dense, yellow, brown, or green chert is sometimes called *jasper.* Dense black or gray chert is sometimes called *flint.* A very dense, even textured, light gray to white chert, composed mostly of microcrystalline to cryptocrystalline quartz, is called *novaculite.* Chert is hard (scratches glass, but is not scratched

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:48 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

by a knife blade) and has a conchoidal (shell-like) fracture in the dense varieties, and a more splintery fracture in the porous varieties. Chert occurs most frequently as nodules, lenses, or interstitial material, in limestone and dolomite formations, as extensively bedded deposits, and as components of sand and gravel. Most cherts have been found to be alkali-silica reactive to some degree when tested with high-alkali cement, or in the quick chemical test (Test Method C 289). In the absence of information to the contrary, all chert should be regarded as potentially deleteriously reactive with the alkalies in hydraulic cement paste. The degree of alkali-silica reactivity, and whether a given chert will produce a deleterious degree of expansion in concrete, are complex functions of several factors. The degree of the alkali-silica reactivity and whether a given chert will produce a deleterious degree of expansion in concrete are complex functions of several factors. Among them are: the mineralogic composition and internal structure of the chert; the amount of the chert as a proportion of the aggregates; the particle-size distribution; the alkali content of the cement; and the cement content of the concrete. However, opaline cherts may produce deleterious expansion of mortar or concrete when present in very small proportions (less than 5 % by mass of the aggregate). Cherts that are porous may be susceptible to freezing and thawing deterioration in concrete and may cause popouts or cracking of the concrete surface above the chert particle.

DESCRIPTIONS OF METAMORPHIC ROCKS

23. General

23.1 Metamorphic rocks form from igneous, sedimentary, or pre-existing metamorphic rocks in response to changes in chemical and physical conditions occurring within the earth's crust after formation of the original rock. The changes may be textural, structural, or mineralogic and may be accompanied by changes in chemical composition. The rocks are dense and may be massive but are more frequently foliated (laminated or layered) and tend to break into platy particles. Rocks formed from argillaceous rocks by dynamic metamorphism usually split easily along one plane independent of original bedding; this feature is designated "platy cleavage." The mineral composition is very variable depending in part on the degree of metamorphism and in part on the composition of the original rock.

23.2 Most of the metamorphic rocks may derive either from igneous or sedimentary rocks but a few, such as marbles and slates, originate only from sediments.

23.3 Phyllites, slates, metaquartzites, gneisses, schists, mylonite, and other rocks containing low temperature silica and silicate minerals and highly strained or microcrystalline quartz are potentially deleteriously reactive with alkalies in the hydraulic cement paste.

24. Metamorphic Rocks

24.1 *Marble*—a recrystallized medium- to coarse-grained carbonate rock composed of calcite or dolomite, or calcite and dolomite. The original impurities are present in the form of new minerals, such as micas, amphiboles, pyroxenes, and graphite.

24.2 *Metaquartzite*—a granular rock consisting essentially of recrystallized quartz. Its strength and resistance to weathering derive from the interlocking of the quartz grains.

24.3 *Slate*—a fine-grained metamorphic rock that is distinctly laminated and tends to split into thin parallel layers. The mineral composition usually cannot be determined with the unaided eye.

24.4 *Phyllite*—a fine-grained thinly layered rock. Minerals, such as micas and chlorite, are noticeable and impart a silky sheen to the surface of schistosity. Phyllites are intermediate between slates and schists in grain size and mineral composition. They derive from argillaceous sedimentary rocks or fine-grained extrusive igneous rocks, such as felsites.

24.5 *Schist*—a highly layered rock tending to split into nearly parallel planes (schistose) in which the grain is coarse enough to permit identification of the principal minerals. Schists are subdivided into varieties on the basis of the most prominent mineral present in addition to quartz or to quartz and feldspars; for instance, *mica schist. Greenschist* is a green schistose rock whose color is due to abundance of one or more of the green minerals, chlorite or amphibole, and is commonly derived from altered volcanic rock.

24.6 *Amphibolite*—a medium- to coarse-grained dark-colored rock composed mainly of hornblende and plagioclase feldspar. Its schistosity, which is due to parallel alignment of hornblende grains, is commonly less obvious than in typical schists.

24.7 *Hornfels*—equigranular, massive, and usually tough rock produced by complete recrystallization of sedimentary, igneous, or metamorphic rocks through thermal metamorphism sometimes with the addition of components of molten rock. Their mineral compositions vary widely.

24.8 *Gneiss*—one of the most common metamorphic rocks, usually formed from igneous or sedimentary rocks by a higher degree of metamorphism than the schists. It is characterized by a layered or foliated structure resulting from approximately parallel lenses and bands of platy minerals, usually micas, or prisms, usually amphiboles, and of granular minerals, usually quartz and feldspars. All intermediate varieties between gneiss and schist, and between gneiss and granite are often found in the same areas in which well-defined gneisses occur.

24.9 *Serpentinite*—a relatively soft, light to dark green to almost black rock formed usually from silica-poor igneous rocks, such as pyroxenites, peridotites, and dunites. It may contain some of the original pyroxene or olivine but is largely composed of softer hydrous ferromagnesian minerals of the serpentine group. Very soft talc-like material is often present in serpentinite.

CONSTITUENTS OF ARTIFICIAL AGGREGATES

25. General

25.1 Artificial aggregates are aggregates resulting from reconstitution of natural materials, other than by physical processes, such as crushing and screening, or from physical or mechanical processing of pre-existing artificial materials to produce aggregates for new work. Examples of reconstitution processes are: (1) heat treatment, such as heating, sintering, calcination, or partial or complete fusion of volcanic rocks,

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

clay, shale, or slate, with resulting mechanical disruption, vitrification, recrystallization, bloating, or combinations of these phenomena in production of lightweight aggregates, and (2) formation of new materials as a consequence of industrial processes, such as slag produced simultaneously with iron in a blast furnace. An example of mechanical processing of pre-existing artificial material is the recovery of hardened concrete from constructions to produce aggregate.

26. Artificial Aggregate

26.1 *Cinders (industrial)*—the agglomerated residue from combustion of coal or coke in an industrial furnace. Specifications may place limitations on content of combustible residues, sulfides, and sulfate. Undesirable sulfur compounds can be reduced by leaching during storage in stockpiles.

26.1.1 Industrial cinders are highly porous and variable in firmness, friability, particle shape, and surface texture. The matrix is a mixture of siliceous glass and finely divided residues of original silt, fine sand, and calcined clay minerals. Particles of unburned coal and coke may be present. Original laminations of sandstone or siltstone occurring in the coal will be represented by compact particles within the product. Such particles and unburned coal and coke may produce unsoundness in concrete.

26.2 *Blast-furnace slag*—the nonmetallic product, consisting essentially of silicates and aluminosilicates of calcium and other bases, that is developed in a molten condition simultaneously with iron in a blast furnace (as described in Terminology C 125). The glass phase of normal blast-furnace slag is not deleteriously reactive with alkalies in concrete.

NOTE 2—Steel furnace slag, unlike blast furnace slag, should not be used as aggregate for hydraulic cement concrete.

26.2.1 *Air-Cooled Blast-Furnace Slag*—the material resulting from solidification of molten blast-furnace slag under atmospheric conditions. Subsequent cooling may be accelerated by application of water to the solidified surface. Such slags are more or less crystallized, the crystals ranging from submicroscopic to several millimetres in size. More than 20 compounds have been identified in air-cooled slag but even well crystallized slag rarely contains more than five compounds. The most typical crystalline constituent is melilite, a compound of variable composition between akermanite ($2CaO \cdot MgO \cdot 2SiO_2$) and gehlenite ($2CaO \cdot Al_2O_3 \cdot SiO_2$). Calcium sulfide (CaS) is almost always present in small proportion.

26.2.1.1 Potentially deleterious constituents include iron sulfides that may produce unsightly staining of concrete or may result in formation of gypsum (calcium sulfate dihydrate, $CaSO_4 \cdot 2H_2O$) by weathering. Use of very old slag with high alumina cement may cause ettringite formation and concrete expansion. Rare chemical anomalies may cause inversion of β-dicalcium silicate to γ-dicalcium silicate with accompanying 10 % increase in volume, resulting in "dusting" or "blowing" of slag. Such inversion while cooling the slag allows removal of the disintegrated material by screening during the production of aggregate. Slower inversion may produce weak and friable particles that are unsuitable as constituents of concrete aggregate; this is determinable by appropriate tests.

26.2.2 *Granulated Blast-Furnace Slag*—the glassy, granular material formed when molten blast-furnace slag is rapidly chilled as by immersion in water. In the jet process, the steam of molten slag is disrupted by a high-pressure water jet and the water/slag mixture is separated by screening. Dry-granulated slag is produced by a mechanical device that breaks the stream of molten slag by impact into small particles which then are quenched by water and air.

26.2.3 *Lightweight Blast-Furnace Slag*—the foamed product formed when molten slag is expanded by applying a limited amount of water, typically less than that required for granulation, so that a relatively dry, cellular, lumpy product results. Aggregate is produced by crushing and screening the clinker. (see 26.2.2).

26.3 *Expanded Shale, Clay, and Slate*—aggregates produced by heating prepared materials of these types to a range of temperature between incipient and complete fusion with accompanying expansion (bloating) that occurs with formation and expansion of entrapped gases. The aggregate may be prepared by prior crushing and screening of the raw materials and fired with or without admixtures, with iron oxides, or carbonaceous materials, crushing and screening of the fired product, or by processing of pellets produced by any of several methods. Other processes involve production of light-weight aggregate by burning of mixtures of coal and shale, clays, or other materials in moving grates exposed to heated gas flow.

26.3.1 Expansion and vesiculation of clays, shales, and slates occurs during firing in the range from about 1650°C (3000°F) to 1700°C (3100°F), but the results obtained for a particular material depend upon the rate of heating, the temperature attained in the feed, the composition of the kiln atmosphere, residency in the kiln, and other factors. Expansion and vesiculation requires *(1)* presence of one or more substances that release gas after fusion has developed sufficient molten material to prevent its escape, and *(2)* the molten material be of sufficient viscosity to retain the expanding gas. The viscosity of the melt is determined to a large extent by the bulk chemical composition of the raw material as defined by proportions of SiO_2 and Al_2O_3 and the total of calcium, magnesium, ferrous iron, ferric iron, and alkalies. Increasing alumina content tends to increase refractory quality of the feed and decreases vesiculation.

26.3.2 Gas is released by several processes. The most significant reaction apparently is partial reduction of ferric oxide with release of oxygen. The ferric oxide is furnished by limonite or hematite in the raw feed or by decomposition of original iron-bearing minerals, most notably clays, micas, and clay-like minerals.

26.3.3 The internal structure or fabric of the clay, shale, or slate is significant in the expansion process. Most beneficial is a dense, relatively impervious fabric that resists shrinkage during heating and retards release of vapors and gases before fusion effects a seal in the particles. The fabric is especially important in firing of carbonaceous clays and shales inasmuch as a porous, open fabric permits ready burning out of the carbon, whereas a dense fabric retards oxidation by the kiln atmosphere and retains CO and CO_2 produced by reaction with

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

interstitial water or with water or oxygen released by hydrated compounds or hydroxylated silicates.

26.3.4 The most promising sources of lightweight aggregate are shales and clays containing illite, beidellite, members of the montmorillonite (smectite) clays, and vermiculitechlorite. These minerals approximate the composition that has been found to yield a melt of optimum viscosity. Compared to members of the kaolin group, they contain lesser proportions of alumina and moderate proportions of alkalies and alkaline earths, which serve as fluxes in the firing process.

26.3.5 The matrix of expanded clays, shales, and slates is composed of an intimate intermingling of siliceous glass and residues of granular minerals. Decomposition of calcium and magnesium carbonates produces free lime, free magnesia, or both compounds, which may cause expansion or popouts in concrete constructions or products unless the aggregate is water- or steam-cured prior to use. Laminations or seams of sandstone or siltstone that were constituents of the geologic formation at the source will occur as individual particles or as portions of vesiculated particles in the aggregate. They may display efflorescence and may include free lime or magnesia when originally carbonaceous. The glass phase of expanded clays, shales, and slates may be alkali reactive but expansion of concrete from this cause has not been observed because any siliceous gels that are generated are accommodated within the abundant air-filled cavities that characterize the expanded particles.

26.4 *Diatomite (sintered)*—lightweight aggregate produced by crushing and screening of diatomaceous earth or shales, spraying with oil, and firing in a rotary kiln. The main constituents are opaline skeletons of diatoms together with variable proportions of siliceous glass produced by the firing process. Other constituents are fine sand, silt, clay, and finely divided volcanic glass.

26.4.1 Some sintered diatomites used as aggregate for concrete produce significant expansion with both low- and high-alkali cements.

26.5 *Vermiculite (exfoliated)*—a micaceous mineral caused to expand and exfoliate by rapid heating as a result of release of combined water. The final volume of the particles can be as much as 30 times the original size. However, the degree of expansion, elasticity, brittleness, and fragility of the particles varies widely, depending upon mineralogic composition of the vermiculite, crystal size, purity, and conditions of firing.

26.5.1 Bodies of vermiculite ore may grade at the margins to hydrobiotite and biotite mica and become intermingled with varying proportions of granular or other non-micaceous minerals.

26.6 *Perlite (expanded)*—rhyolitic volcanic glass having a relatively high water content and a perlitic structure that has been heated sufficiently to cause it to break into small, expanded particles. The product usually is produced only in fine aggregate sizes and used in products for insulating purposes.

26.6.1 Expanded perlite varies in particle shape, surface texture, friability, and content of dense volcanic rock particles and individual crystals. Typical expanded perlite is potentially alkali reactive although significant expansion may not occur because of porosity of the particles. Laboratory tests show that certain perlites produce significant expansion of mortar stored and tested in accordance with Test Method C 227 with either low- or high-alkali cements. Such volume change will not necessarily cause structural distress if appropriately accommodated in the design of structures or products.

26.7 Recycled concrete-hardened hydraulic-cement concrete that has been processed for use as concrete aggregate. Extensive evaluations in several countries have shown that use of recycled concrete as aggregate in new concrete is feasible and may become routine. Approval of an available source of concrete for recycling as aggregate should include two stages, namely, *(1)* planning the examination of the constructions to be demolished and *(2)* selection of procedures that should be included in evaluation of the aggregate that can be obtained economically for the intended new work. The following relationships are of especial significance:

26.7.1 The potential compressive strength of concrete containing recycled concrete as aggregate is controlled largely by the compressive strength of the concrete to be recycled, provided the fine aggregate is crushed rock or natural sand of suitable quality.

26.7.2 A substantial reduction in potential compressive strength may result when the conventional fine aggregate is replaced in whole or in part by fine aggregate derived from the recycled concrete. Hansen[4] concludes that all material smaller than 2 mm in recycled concrete should be screened and wasted.

26.7.3 Use of recycled concrete decreases workability of fresh concrete at given water content, increases water requirements for given consistency, increases drying shrinkage at given water content, and reduces modulus of elasticity at given water-cement ratio. The effects are greatest when the recycled concrete is used as both coarse and fine aggregate.

26.7.4 Freezing and thawing resistance of the new concrete relates to many factors, including the properties of the recycled concrete in terms of compressive strength, parameters of the air-void system, and frost resistance of the aggregate included in the recycled concrete as well as the parameters of the air-void system and other qualities of the cementitious matrix of the new concrete.

26.7.5 Chemical admixtures, air-entraining admixtures, and mineral admixtures included in the recycled concrete will not modify significantly the properties of the fresh or hardened, new concrete, except insofar as they modify the conditions enumerated in 26.7.1-26.7.4. High concentrations of water-soluble chloride ion in the recycled concrete may contribute to accelerated corrosion of steel embedments in the new concrete.

26.7.6 Prospective sources of recycled concrete may be unsound or have been rendered unsound in service, such as presence of physically unsound or chemically reactive aggregate, deterioration by aggressive chemical attack or leaching, damage by fire or service at high temperature, and so on.

26.7.7 Significance of contaminants in the recycled concrete should be analyzed in relation to the anticipated service, such

as presence of noxious, toxic, or radioactive substances; presence of bituminous materials that may impair air entrainment; appreciable concentrations of organic materials that my produce excessive air entrainment; inclusion of metallic embedments that may cause rust staining or blistering of surfaces; and excessive fragments of glass, including bottle glass, that are expected to produce harmful effects of alkali-silica reaction.

Designation: C 295 – 08

Standard Guide for Petrographic Examination of Aggregates for Concrete[1]

This standard is issued under the fixed designation C 295; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This guide outlines procedures for the petrographic examination of samples representative of materials proposed for use as aggregates in cementitious mixtures or as raw materials for use in production of such aggregates. This guide is based on Ref (**1**).[2]

1.2 This guide outlines the extent to which petrographic techniques should be used, the selection of properties that should be looked for, and the manner in which such techniques may be employed in the examination of samples of aggregates for concrete.

1.3 The rock and mineral names given in Descriptive Nomenclature C 294 should be used, insofar as they are appropriate, in reports prepared in accordance with this guide.

1.4 The values stated in SI units are to be regarded as the standard. The values given in parentheses are mathematical conversions to inch-pound units that are provided for information purposes only and are not considered standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

3. Qualifications of Petrographers

3.1 All petrographic examinations of aggregate for use in concrete as described in this guide should be performed by a petrographer with at least 5 years experience in petrographic examination of concrete or concrete-making materials. The petrographer should have completed college-level course work pertaining to basic geology, mineralogy, petrography, and optical mineralogy or have obtained equivalent knowledge through experience and on-the-job training. Completion of course work in concrete materials is also advantageous. The petrographer should have experience evaluating the effects of aggregates on the physical and chemical properties of hardened concrete. Identification of individual minerals in aggregate particles, classification of rock types, and categorizing the physical and chemical properties of rocks and minerals should also be included in the petrographer's experience. The petrographer should have expertise to properly use the equipment and apparatus described in Section 6 and provide detailed interpretations of the petrographic examination. If the petrographer does not meet these qualifications, the individual may perform such examinations under the technical direction of a full-time supervising petrographer who meets these qualifications. A resume of the professional experience and education of the petrographer shall be available.

3.1.1 Licensing, certification, or other accreditation by a governmental agency or other organization stating the individual is a professional geologist should not, by itself, constitute sufficient qualification for examination of aggregates for concrete.

[1] This guide is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.65 on Petrography.

Current edition approved July 1, 2008. Published December 2008. Originally approved in 1954. Last previous edition approved in 2003 as C 295 – 03.

4. Summary of Method

4.1 The specific procedures employed in the petrographic examination of any sample will depend to a large extent on the purpose of the examination and the nature of the sample. In most cases the examination will require the use of optical microscopy. Complete petrographic examinations for particular purposes and to investigate particular problems may require examination of aggregates or of selected constituents by means of additional procedures, such as X-ray diffraction (XRD) analysis, differential thermal analysis (DTA), infrared spectroscopy, or other scanning electron microscopy (SEM) energy-dispersive x-ray analysis (EDX). In some instances, such procedures are more rapid and more definitive than are microscopical methods.

4.2 Identification of the constituents of a sample is usually a necessary step towards recognition of the properties that may be expected to influence the behavior of the material in its intended use, but identification is not an end in itself. The value of any petrographic examination will depend to a large extent on the representativeness of the samples examined, the completeness and accuracy of the information provided to the petrographer concerning the source and proposed use of the material, and the petrographer's ability to correlate these data with the findings of the examination.

4.3 This guide does not attempt to describe the techniques of petrographic work since it is assumed that the guide will be used by persons who are qualified by education and experience to employ such techniques for the recognition of the characteristic properties of rocks and minerals and to describe and classify the constituents of an aggregate sample. In some cases, the petrographer will have had experience adequate to provide detailed interpretation of the results. In others, the interpretation will be made in part by engineers or others qualified to relate the observations to the questions to be answered.

5. Significance and Use

5.1 Petrographic examinations are made for the following purposes:

5.1.1 To determine the physical and chemical characteristics of the material that may be observed by petrographic methods and that have a bearing on the performance of the material in its intended use.

5.1.2 To describe and classify the constituents of the sample,

5.1.3 To determine the relative amounts of the constituents of the sample that are essential for proper evaluation of the sample when the constituents differ significantly in properties that have a bearing on the performance of the material in its intended use, and

5.1.4 To compare samples of aggregate from new sources with samples of aggregate from one or more sources, for which test data or performance records are available.

5.2 This guide may be used by a petrographer employed directly by those for whom the examination is made. The employer should tell the petrographer, in as much detail as necessary, the purposes and objectives of the examination, the kind of information needed, and the extent of examination desired. Pertinent background information, including results of prior testing, should be made available. The petrographer's advice and judgment should be sought regarding the extent of the examination.

5.3 This guide may form the basis for establishing arrangements between a purchaser of consulting petrographic service and the petrographer. In such a case, the purchaser and the consultant should together determine the kind, extent, and objectives of the examination and analyses to be made, and should record their agreement in writing. The agreement may stipulate specific determinations to be made, observations to be reported, funds to be obligated, or a combination of these or other conditions.

5.4 Petrographic examination of aggregate considered for use in hydraulic-cement concrete is one aspect of the evaluation of aggregate, but petrographic examination is also used for many other purposes. Petrographic examinations provide identification of types and varieties of rocks present in potential aggregates. However, as noted above, identification of every rock and mineral present in an aggregate source is not required.

5.5 The petrographic examination should establish whether the aggregate contains chemically unstable minerals such as soluble sulfates, unstable sulfides that may form sulfuric acid or create distress in concrete exposed to high temperatures during service, or volumetrically unstable materials such as smectites (formerly known as the montmorillonite-saponite group of minerals or swelling clays). Specifications may limit the quartz content of aggregates for use in concrete that may be subject to high temperature (purposefully or accidentally) because of the conversion to beta-quartz at 573 °C (1063 °F), with accompanying volume increase.

5.6 Petrographic examination should identify the portion of each coarse aggregate that is composed of weathered or otherwise altered particles and the extent of that weathering or alteration, whether it is severe, moderate, or slight, and should determine the proportion of each rock type in each condition. If the concrete in which the aggregate may be used will be exposed to freezing and thawing in a critically saturated condition, finely porous and highly weathered or otherwise altered rocks should be identified because they will be especially susceptible to damage by freezing and thawing and will cause the aggregate portion of the concrete to fail in freezing and thawing. This will ultimately destroy the concrete because such aggregates cannot be protected by adequately air-entrained mortar. Finely porous aggregates near the concrete surface are also likely to form popouts, which are blemishes on pavements and walls.

5.7 Petrographic examinations may also be used to determine the proportions of cubic, spherical, ellipsoidal, pyramidal, tabular, flat, and elongated particles in an aggregate sample or samples. Flat, elongated, and thin chip-like particles in aggregate increase the mixing water requirement and hence decrease concrete strength.

5.8 Petrographic examination should identify and call attention to potentially alkali-silica reactive and alkali-carbonate reactive constituents, determine such constituents quantitatively, and recommend additional tests to confirm or refute the presence in significant amounts of aggregate constituents capable of alkali reaction in concrete. See Specification C 33.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Alkali-silica reactive constituents found in aggregates include: opal, chalcedony, cristobalite, tridymite, highly strained quartz, microcrystalline quartz, volcanic glass, and synthetic siliceous glass. Aggregate materials containing these constituents include: glassy to cryptocrystalline intermediate to acidic volcanic rocks, some argillites, phyllites, graywacke, gneiss, schist, gneissic granite, vein quartz, quartzite, sandstone, and chert. Criteria are available for identifying the minerals in the list above by their optical properties or by XRD (**2**),(**3**). Criteria are available for identifying rocks by their mineral composition and texture (**4**). Examination in both reflected and transmitted light may be necessary to provide data for these identifications. X-ray microanalysis using energy-dispersive x-ray spectrometers with scanning electron microscopy (SEM/EDX) or wavelength-dispersive x-ray spectrometers in electron microprobes (EMPA/WDX) may provide useful information on the chemical composition of minerals and rocks. Potentially deleterious alkali-carbonate reactive rocks are usually calcareous dolomites or dolomitic limestones with clayey insoluble residues. Some dolomites essentially free of clay and some very fine-grained limestones free of clay and with minor insoluble residue, mostly quartz, are also capable of some alkali-carbonate reactions, however, such reactions are not necessarily deleterious.

5.9 Petrographic examination may be directed specifically at the possible presence of contaminants in aggregates, such as synthetic glass, cinders, clinker, or coal ash, magnesium oxide, calcium oxide, or both, gypsum, soil, hydrocarbons, chemicals that may affect the setting behavior of concrete or the properties of the aggregate, animal excrement, plants or rotten vegetation, and any other contaminant that may prove undesirable in concrete.

5.10 These objectives, for which this guide was prepared, will have been attained if those involved with the evaluation of aggregate materials for use in concrete construction have reasonable assurance that the petrographic examination results wherever and whenever obtained may confidently be compared.

6. Apparatus and Supplies

6.1 The apparatus and supplies listed as follows comprise a selection that will permit the use of the procedures described in this guide. All specific items listed have been used, in connection with the performance of petrographic examinations, by the procedures described herein; it is not, however, intended to imply that other items cannot be substituted to serve similar functions. Whenever possible the selection of particular apparatus and supplies should be left to the judgment of the petrographer who is to perform the work so that the items obtained will be those with the use of which the petrographer has the greatest experience and familiarity. The minimum equipment regarded as essential to the making of petrographic examinations of aggregate samples are those items, or equivalent apparatus or supplies that will serve the same purpose, that are indicated by asterisks in the lists given as follows.

6.1.1 *Apparatus and Supplies for Preparation of Specimens*:

6.1.1.1 *Rock-Cutting Saw*, * preferably with 350-mm or larger diamond blade, and automatic feed.

6.1.1.2 *Horizontal Grinding Wheel*, * preferably 400 mm in diameter.

6.1.1.3 *Polishing Wheel*, preferably 200 to 300 mm in diameter.

6.1.1.4 *Abrasives** , Silicon carbide grit No. 100 (122 μm), 220 (63 μm), 320 (31 μm), 600 (16 μm), and 800 (12 μm); alumina M-305 (5 μm).[4]

6.1.1.5 *Geologist's Pick or Hammer*.

6.1.1.6 *Microscope Slides**, clear, noncorrosive, 25 by 45 mm in size.

6.1.1.7 *Mounting Medium for Powder Mounts** —Canada balsam, neutral, in xylene; suitable low-viscosity epoxy resins; or Lakeside 70.

6.1.1.8 *Xylene**.

6.1.1.9 *Mounting Medium**, suitable for mounting rock slices for thin sections.

6.1.1.10 *Laboratory Oven**.

6.1.1.11 *Plate-Glass Squares**, about 300 mm on an edge for thin-section grinding.

6.1.1.12 *Sample Splitter* with pans.*

6.1.1.13 *Micro Cover Glasses*, * noncorrosive, square, 12 to 18 mm, 25 mm, etc.

6.1.1.14 *Plattner Mortar*.

6.1.2 *Apparatus and Supplies for Examination of Specimens*:

6.1.2.1 *Petrographic Microscope**, with mechanical stage; oculars and objective lenses that will allow magnifications of up to 600 x, and objective-centering devices; full- and quarter-wave compensators; quartz wedge; micrometer eyepiece; Bertrand lens.

6.1.2.2 *Microscope Lamps**

6.1.2.3 *Stereoscopic Microscope**, with objectives and oculars to give final magnifications from about 6× to about 150×.

6.1.2.4 *Magnet**, preferably Alnico, or an electromagnet.

6.1.2.5 *Needleholder and Points**.

6.1.2.6 *Dropping Bottle*, 60-mL capacity.

6.1.2.7 *Petri Culture Dishes*.

6.1.2.8 *Forceps*, smooth, straightpointed.

6.1.2.9 *Lens Paper.**

6.1.2.10 *Immersion Media**, $n = 1.410$ to $n = 1.785$ in steps of no more than 0.005.

6.1.2.11 *Counter*.

6.1.2.12 *Photomicrographic Camera* and accessories.

6.2 The items under Apparatus and Supplies include those used to make thin sections. Semiautomatic thin section machines are available, and there are several thin-section makers who advertise in *Geotimes*, the *American Mineralogist*, and other mineralogical or geological journals. Laboratories may find it reasonable to buy a thin-section machine or use a commercial thin-section maker. Remotely located laboratories have more need to be able to make their own thin sections.

6.3 It is necessary that facilities be available to the petrographer to check the index of refraction of the immersion media. If accurate identification of materials is to be attempted, as for example the differentiation of quartz and chalcedony, or the

[4] The values given in micrometres are the approximate average grain size of commercial silicon carbide grit in the designated size classification.

www.technobetar.ir

differentiation of basic from intermediate volcanic glass, the indices of refraction of the media need to be known with accuracy. Media will not be stable for very long periods of time and are subject to considerable variation due to temperature change. In laboratories not provided with close temperature control, it is often necessary to recalibrate immersion media several times during the course of a single day when accurate identifications are required. The equipment needed for checking immersion media consists of an Abbé refractometer. The refractometer should be equipped with compensating prisms to read indices for sodium light from white light, or it should be used with a sodium arc lamp.

6.4 A laboratory that undertakes any considerable amount of petrographic work should be provided with facilities to make photomicrographic records of such features as cannot adequately be described in words. For illustrations of typical apparatus, reference may be made to Ref **(1)** and manufacturers of microscopes equipped with cameras and photomacrographic equipment may be consulted. Much useful guidance regarding photomicrography, especially using reflected light, is found in Guide E 883.

7. Sampling

7.1 Samples for petrographic examination should be taken by or under the direct supervision of a geologist familiar with the requirements for random sampling of aggregates for concrete and in general following the requirements of Practice D 75. Information on the exact location from which the sample was taken, the geology of the site, and other pertinent data should be submitted with the sample. The amount of material actually studied in the petrographic examination will be determined by the nature of the examination to be made and the nature of the material to be examined, as discussed below.

7.1.1 *Undeveloped quarries* should be sampled by means of cores drilled through the entire depth expected to be exploited. Drilling of such cores should be in a direction that is essentially perpendicular to the dominant structural feature of the rock. Massive material may be sampled by "NX" (53-mm (2⅛-in.) diameter) cores. Thinly bedded or complex material should be represented by cores not less than 100 mm (4 in.) in diameter. There should be an adequate number of cores to cover the limits of the deposit proposed for the project. The entire footage of the recovered core should be included in the sample and accurate data given as to elevations, depths, and core losses.

7.1.2 *Operating quarries and operating sand and gravel deposits*, in which stock piles of the material produced are available, should be represented by not less than 45 kg (100 lb) or 300 pieces, whichever is larger, of each size of material to be examined. Samples from stock piles should be composed of representative portions of larger samples collected with due consideration given to segregation in the piles.

7.1.3 *Exposed faces of nonproducing quarries*, where stock piles of processed material are not available, should be represented by not less than 2 kg (4 lb) from each distinctive stratum or bed, with no piece having a mass less than 0.5 kg (1 lb), or by a drilled core as described above.

7.1.4 *Undeveloped sand and gravel deposits* should be sampled by means of test pits dug to the anticipated depth of future economic production. Samples should consist of not less than the quantities of material indicated in Table 1, selected so as to be representative of the deposits.

NATURAL GRAVEL AND SAND

8. Procedure

8.1 *Selection of Samples for Examination*—Samples of gravel and natural sand for petrographic examination should be dry sieved in accordance with Method C 136 to provide samples of each sieve size. In the case of sands an additional portion should then be tested in accordance with Test Method C 117, with the wash water being saved and removed by drying in order to provide a sample of the material passing the 75-µm (No. 200) sieve (See Specification E 11). The results of the sieve analysis of each sample made in accordance with Method C 136 should be provided to the petrographer making the examination and used in calculating results of the petrographic examination. Each sieve fraction should be examined separately, starting with the largest size available. Rocks are more easily recognized in larger pieces; the breakdown of a heterogeneous type present in the larger sizes may have provided particles of several apparently different types in the smaller sizes. Some important and easily confused types may be recognizable using the stereoscopic microscope if they are first recognized and separated in the larger sizes, but may require examination using the petrographic microscope if they are first encountered in the smaller sizes.

8.2 The number of particles of each sieve fraction to be examined will be fixed by the required precision of determination of the less abundant constituents. Assuming that the field sampling and laboratory sampling procedures are accurate and reliable, the number of particles examined, identified, and counted in each sieve fraction will depend on the required accuracy of the estimate of constituents present in small quantities. The numbers given in this method are minimal. They are based on experience and on statistical considerations **(5, 6)**. It is believed that at least 150 particles of each sieve fraction should be identified and counted in order to obtain reliable results. Precise determinations of small quantities of an important constituent will require counts of larger numbers of particles. If the sample of a sieve fraction contains many more particles than need to be identified, the sample shall be reduced in accordance with one of the procedures in Practice C 702, so as to contain a proper number of particles for examination.

TABLE 1 Minimum Sizes for Samples from Undeveloped Sand and Gravel Deposits

Sieve Size	Quantity		
	kg	(lb)	Pieces
Larger than 150-mm (6-in.)	...	...	[A]
75 to 150-mm (3 to 6-in.)	...	...	300[A]
37.5 to 75-mm (1½ to 3-in.)	180	(400)	...
19.0 to 37.5-mm (¾ to 1½-in.)	90	(200)	...
4.75 to 19.0-mm (No. 4 to ¾-in.)	45	(100)	...
Finer than 4.75-mm (No. 4)[B]	23	(50)	...

[A] Not less than one piece from each apparent type of rock.
[B] Fine aggregate.

www.technobetar.ir

9. Procedure for Examination of Natural Gravel

9.1 *Coatings*—The particles should be examined to establish whether exterior coatings are present. If coatings are present, it should be determined whether the coatings consist of materials likely to be deleterious in concrete (opal, gypsum, easily soluble salts, organic matter). It should also be determined qualitatively how firmly the coatings are bonded to the particles.

9.2 *Rock Types*—The sieve fraction should be sorted into rock types by visual examination. If all or most of the groups present are types easily identifiable in hand specimen by examination of a natural or broken surface, and by scratch and acid tests, no further identification may be needed. Fine-grained rocks that cannot be identified macroscopically or that may consist of or contain constituents known to be deleterious in concrete should be checked by examination with the stereoscopic microscope. If they cannot be identified by that means, they should be examined by means of the petrographic microscope. The amount of work done in identifying fine-grained rocks should be adapted to the information needed about the particular sample. Careful examination of one size of a sample, or study of information from previous examination of samples from the same source, will usually reveal the amount of additional detailed microscopical work required to obtain information adequate for the purpose. In some instances, petrographic methods other than microscopy, such as X-ray diffraction, may be required or might most rapidly serve to identify fine-grained rock materials.

9.3 *Condition*—The separated groups belonging to each rock type should be examined to determine whether a further separation by physical condition is necessary. If all of the particles of a rock type are in a similar condition, that fact should be noted. More frequently, particles in several degrees of weathering will be found in a group. They should be sorted into categories based on condition and on the expectation of comparable behavior in concrete. The types of categories intended are: (*1*) fresh, dense; (*2*) moderately weathered; (*3*) very weathered; or (*1*) dense; (*2*) porous (or porous and friable). It usually is not practicable to recognize more than three conditions per rock type, and one or two may be sufficient. An important constituent present in larger quantities may sometimes require separation into four groups by condition. The conspicuous example is chert when it is the major constituent of a gravel sample. It may be present as dense, unfractured chert; as vuggy chert; as porous chert; and as dense but highly fractured chert. The determination of which of these four conditions characterizes a particle may be expected to have an important influence on prediction of the behavior of the particle in concrete.

9.4 *Record*:

9.4.1 Notes should be taken during the examination. Each rock type should be described; the relevant features may include the following:

9.4.1.1 Particle shape,

9.4.1.2 Particle surface texture,

9.4.1.3 Grain size,

9.4.1.4 Internal structure, including observations of pore space, packing of grains, cementation of grains,

9.4.1.5 Color,

9.4.1.6 Mineral composition,

9.4.1.7 Significant heterogeneities,

9.4.1.8 General physical condition of the rock type in the sample,

9.4.1.9 Coatings or incrustations, and

9.4.1.10 Presence of constituents known to cause deleterious chemical reaction in concrete.

9.4.2 Particle counts should be recorded so that tables can be made for inclusion in the report. When the examination has been completed, the notes should contain enough information to permit the preparation of tables and descriptions. Tables should be prepared showing the composition and condition of the samples by sieve fractions, and the weighted average composition, based on the grading of the sample as received and on the distribution of constituents by sieve fractions. Descriptions of constituent groups should be prepared containing the relevant features among those enumerated in the preceding list.

10. Procedure for Examination of Natural Sand

10.1 The procedure for the examination of natural sand is similar to that for the examination of gravel, with the modifications necessitated by the differences in particle size.

10.1.1 *Sizes Coarser than 600 μm (No. 30)*—Each sieve fraction present that is coarser than the 600-μm (No. 30) sieve should be reduced in accordance with one of the procedures in Practice C 702 until a split or splits containing at least 150 particles are obtained. The reduced sample of each sieve fraction should be examined, and its constituents identified and counted, using the stereoscopic microscope. It is convenient to spread out the sample in a flat-bottom glass dish such as a Petri dish and manipulate the grains with a forceps and dissecting needle. The identification of grains in the coarser sand sizes is often easier when the grains are just submerged in water. The submergence lessens reflection from the outer surfaces and may show diagnostic features that cannot be seen when the grains are dry. There are exceptions to this generalization. Where identification is difficult, the examination includes examination of the natural surface (dry and wet), examination of a broken surface (dry and wet), and scratch and acid tests. Only after all of these steps have been taken and the grain is still unidentified should the petrographer resort to the petrographic microscope. Grains that cannot be identified using the stereoscopic microscope, or that are suspected of consisting of or containing substances known to react deleteriously in concrete, should be set aside to be examined with the petrographic microscope. If the question of reaction with alkalies is important in the examination of the sample, certain additions to the procedure are indicated. If the coarser sand sizes contain fine-grained, possibly glassy igneous rocks, several typical particles of each variety of such rocks should be selected for a more thorough examination. The petrographer should determine the presence or absence of glass by crushing typical grains and examining them in immersion media, using the petrographic microscope. In difficult or especially important cases, it may be necessary to break suspected grains and to make immersion mounts of part of the grain and a thin section of another part. Where the sand contains chert and the potential

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

reactivity of the chert is an important consideration, a number of chert particles from the fractions retained on the 600-µm (No. 30) sieve should be set aside for determinations of the index of refraction. Methylene blue staining techniques may be useful in identifying the presence of smectite (**7**).

10.1.2 *Sizes Finer than 600 µm (No. 30)*—The sieve fractions finer than the 600-µm (No. 30) sieve should each be reduced in a sample splitter or by quartering to about 4 or 5 g (Note 1). These splits should be further reduced on a miniature sample splitter or by coning and quartering with a spatula on a clean sheet of paper. The examination may be conducted as described previously for the coarser sizes. As required, the petrographic microscope should be used. For this purpose, a representative portion of each reduced split should be mounted in immersion oil on a clean glass slide and covered with a clean cover glass. No entirely satisfactory method of reducing a split to a predetermined number of grains is known. The reduced split can be sampled by spreading it in a thin layer on glass or clean paper, dragging the end of a dissecting needle moistened in immersion oil through the sample and transferring the grains that adhere to the needle to a drop of immersion oil on a clean slide. If this is done carefully, a fairly representative sample will be obtained. If the dissecting needle is made of magnetized steel, a concentration of magnetic minerals may result. It is usually necessary to make several mounts of the 300-µm (No. 50) and 150-µm (No. 100) sieve fractions to obtain at least 150 grains of each. The refractive index of the immersion oil should be selected to make the identification of the important constituents as easy and as definite as possible. The use of an immersion oil with an index of or just below the lower index of quartz (1.544) is recommended. The slide should be mounted on a petrographic microscope equipped with a mechanical stage. Several traverses should be made, and each grain that passes under the intersection of the cross hairs should be identified and counted. Care should be taken to move the slide on the north-south adjustment between traverses so that no grain will be counted twice. Each sieve fraction passing the 600-µm (No. 30) and retained on the 75-µm (No. 200) sieve should be examined. Ordinarily, the material passing the 75-µm (No. 200) sieve is mounted on a slide following the procedure described above, examined by means of the petrographic microscope, and its composition estimated. If an unusually large amount of this size is present, or if it contains constituents that may be expected to have an important effect on the suitability of the aggregate for the intended use, it should be counted. In this event, it is suggested that the fraction passing the 75-µm (No. 200) sieve be washed over the 45-µm (No. 325) sieve before being counted.

NOTE 1—The volume will usually be less than a level teaspoonful. In some gradings the fractions retained on the 150-µm (No. 100) and 75-µm (No. 200) sieves may be present in such small amounts that reduction is unnecessary.

10.1.3 Grain thin sections using an epoxy as mounting medium also may be useful in classifying particles passing the 300-µm (No. 50) sieve.

DRILLED CORE, LEDGE ROCK, CRUSHED STONE, AND MANUFACTURED SAND

11. Procedure for Examination of Drilled Core

11.1 Each core should be examined and a log prepared showing length of core recovered, core loss and location; location and spacing of fractures and parting planes; lithologic type or types; alternation of types; physical condition and variations in condition; toughness, hardness (**8**), coherence; obvious porosity; grain size, texture, variations in grain size and texture; type or types of breakage; and presence of constituents capable of deleterious reaction in concrete. If the size of the core permits, the probability that the rock will make aggregate of the required maximum size should be considered. If the surface of the core being examined is wetted, it is usually easier to recognize significant features and changes in lithology. Most of the information usually required can be obtained by careful visual examination, scratch and acid tests, and hitting the core with a hammer. In the case of fine-grained rocks, it may be necessary to examine parts of the core, using the stereoscopic microscope, or to prepare thin sections of selected portions. Some considerations and procedures are more applicable to particular rock types than to others. Ordinarily, the layered rocks considered for concrete aggregate will be limestone, and occasionally metamorphic rocks, such as phyllite, gneiss, or schist. One of the most important questions arising in the examination of limestone is that of the presence, type, and distribution of argillaceous impurities. Limestones that contain intercalated thin beds of soft shale may make suitable sources of aggregate if the shale is so distributed that it does not prevent manufacture of the required maximum size, and if the shale can be eliminated or reduced in processing. Where argillaceous impurities are present, it should be determined whether they actually consist of clay minerals or of other minerals in clay sizes. If they do consist of clay minerals, it should be established whether the clay minerals include smectites (**9**). X-ray diffraction analysis is especially valuable in identification and quantitative determination of clay minerals. Methylene blue staining techniques (**7**) are useful in identifying smectite. In the examination of fine-grained igneous rocks, particular attention should be directed to the nature of the groundmass. This examination should include determination of the presence or absence of opal, chalcedony, natural glass, and swelling clays; if any of these are found the amount should be estimated; if natural glass is found the type should be determined.

12. Procedure for Examination of Ledge Rock

12.1 The procedure used in examination should be the same as for core samples to the extent that the spacing of samples and size of the individual pieces allow. If the sample consists of a relatively large quantity of broken stone produced by blasting, it is desirable to inspect the whole sample, estimate the relative abundance of rock types or varieties present, and sample each type before further processing. Subsequent procedure should be the same as given below for crushed stone.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

13. Procedure for Examination of Crushed Stone

13.1 The procedure for examination of crushed stone should be similar to that for core, except that necessary quantitative data should be obtained by particle counts of the separated sieve fractions obtained as described in the section on Natural Gravel and Sand.

14. Procedure for Examination of Manufactured Sand

14.1 The examination procedure should be similar to that for natural sand, with particular emphasis on the amount and extent of fracturing and the amount and nature of rock dust developed by the milling operations. If a sample of the rock from which the sand was produced is available, examination of it will provide useful information.

CALCULATION AND REPORT

15. Calculation

15.1 Calculate the composition of each sieve fraction of a heterogeneous sample and the weighted average composition of the whole sample as follows:

15.1.1 Express the composition of each sieve fraction by summing the total number of particles of that fraction counted, and calculating each constituent in each condition as a percentage of the total amount (as number of particles in percent, in each sieve fraction). It is convenient to calculate and record the percentages to tenths at this stage. An example of these calculations is given in the upper half of Table 2.

15.1.2 Obtain the percentage by mass of the sieve fraction in the whole sample (individual percentages retained on consecutive sieves) from the grading of the sample as determined by Method C 136.

15.1.3 By multiplying the percentage of the constituent in the sieve fraction, determined as described above by the percentage of the sieve fraction in the whole sample, obtained as described above, calculate the percentage in the whole sample of that constituent in that size (weighted percentage of constituents in sieve fraction, Table 2). It is convenient to calculate and record these percentages to tenths.

15.1.4 By adding the weighted percentages of each constituent in each sieve fraction, obtain the weighted percentage of each constituent in the whole sample (see under weighted composition of sample in Table 2).

15.1.5 Construct a table to show the composition of each sieve fraction and the weighted composition of the whole sample. Report values to the nearest whole number. Report constituents amounting to 0.5 % or less of a sieve fraction or of the whole sample as traces. Table 3 is an example constructed

TABLE 2 Calculation of Results of Particle Counts[A]

Individual Percentage Retained on Sieve	Composition of Fractions Retained on Sieves Shown Below							
	19.0-mm (¾-in.)		12.5-mm (½-in.)		9.5-mm (⅜-in.)		4.75-mm (No. 4)	
	17.4		32.6		29.5		20.5	
Constituents[B]	Number of Particles	%	Number of Particles	%	Number of Particles	%	Number of Particles	%

Total in sieve fraction	17.4	32.6	29.5	20.5	
Total in sample, condition 1					48.5
Total in sample, condition 2					31.4
Total in sample, condition 3					20.1

[A] This table indicates a convenient method of setting up a work sheet for recording results and calculations. The results developed here are entered in the form indicated by Table number 3. Table number 3 is included in the petrographic report. Table number 2 is not.

[B] Letters (A, B, C) refer to the various constituents found, subscript numbers (1, 2, 3) refer to the various conditions in which each constituent has been found, such as relative degree of weathering.

[C] The recommendation concerning the number of particles to be counted has been met; the selection of 500 particles per fraction for the example is to illustrate the calculation; it is not intended to suggest that a predetermined number of particles per fraction should be selected.

Weighted average, condition 2					...	32	...	...
Weighted average, condition 3					...	...	20	...

[A] For other forms of presentation of results of petrographic analysis, see Table numbers 1- 4 in **(10)**.

[B] Based on count of 500 particles in each sieve fraction. (The number of particles of each sieve fraction counted should be shown in the report and this may conveniently be done as a footnote to the table.)

[C] Based on grading of the sample as received, and on the distribution of constituents by sieve fractions shown at the left above. (If the petrographic report forms part of a complete investigation of the sample, including a report of the grading, the grading need not be shown. If the petrographic report is to be submitted alone, the grading of the sample should be included with it.)

from the data obtained in Table 2. As a convention, the total in each sieve fraction and the total in the whole sample shall each be 100 % without the traces. Difficulties in abiding by this convention can usually be avoided by grouping minor constituents of little engineering importance. It is preferable to tabulate constituents known to react deleteriously in concrete so that their distribution will be apparent from inspection of the table, even though the amount in the whole sample or in any fraction is very small.

16. Report

16.1 The report of the petrographic examination should summarize the essential data needed to identify the sample as to source and proposed use, and include a description giving the essential data on composition and properties of the material as revealed by the examination. The report should record the test procedures employed, and give a description of the nature and features of each important constituent of the sample, accompanied by such tables and photographs as may be required. The findings and conclusions should be expressed in terms likely to be intelligible to those who must make decisions as to the suitability of a material for use as concrete aggregate.

16.2 When the sample has been found to possess properties or constituents that are known to have specific unfavorable effects in concrete, those properties or constituents should be described qualitatively and, to the extent practicable, quantitatively. The unfavorable effects that may be expected to ensue in concrete should be mentioned. When appropriate, it should be stated that a given sample was not found to contain any undesirable features. When such is the case it may also be appropriate, especially if the report of the petrographic examination is not accompanied by reports of results of physical and chemical tests for which numerical limits may be applicable, to add that the material appears acceptable for use provided the applicable acceptance tests are made and the results are within the appropriate limits. The report should not, however, contain conclusions other than those based upon the finding of the examination unless the additional data to support such conclusions are included in or with the petrographic report and the petrographer has been authorized to analyze the other relevant nonpetrographic data.

16.3 The petrographic report should include recommendations regarding any additional petrographic, chemical, physical, or geological investigations that may be required to evaluate adverse properties that are indicated by the petrographic examination that has been performed. Supplementary petrographic investigations might include qualitative or quantitative analysis of the aggregate or of selected portions thereof by X-ray diffraction, differential thermal methods, or other procedures that are directed to identification and description of the constituents of the aggregate.

17. Precision and Bias

17.1 Those test methods that are used in connection with this guide that have been standardized in ASTM are subject to having precision and bias sections. Those that have not been standardized will each be provided with such a section, if and when standardized. None of the nonstandardized procedures mentioned for optional use in this practice are used in ways that lend themselves to the preparation of precision and bias statements.

18. Keywords

18.1 aggregate; analysis; composition; crushed rock; crushed stone; examination; ledge rock; manufacture sand; natural sand; petrography; quarry

Designation: C 305 – 06

American Association State
Highway and Transportation Officials Standard
AASHTO No.: T162

Standard Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency[1]

This standard is issued under the fixed designation C 305; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers the mechanical mixing of hydraulic cement pastes and mortars of plastic consistency.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 778 Specification for Standard Sand

3. Significance and Use

3.1 This practice is intended for use in the mechanical mixing of pastes and mortars for the testing of hydraulic cements.

4. Apparatus

4.1 *Mixer*—The mixer shall be an electrically driven mechanical mixer of the epicyclic type, which imparts both a planetary and a revolving motion to the mixer paddle. The mixer shall have a minimum of two speeds, controlled by definite mechanical means. (Rheostat adjustment of speed will not be acceptable.) The first, or slow speed shall revolve the paddle at a rate of 140 ± 5 r/min, with a planetary motion of approximately 62 r/min. The second speed shall revolve the paddle at a rate of 285 ± 10 r/min, with a planetary motion of approximately 125 r/min. The electric motor shall be at least 124 W (⅙ hp). The mixer shall be equipped with either an adjustment screw which is an integral part of the mixer or a clearance adjustment bracket such as the one shown in Fig. 1 (Note 1) to provide clearance between the lower end of the paddle and the bottom of the bowl that is not greater than 2.5 mm but not less than 0.8 mm (Note 2) when the bowl is in the mixing position.

NOTE 1—When the bracket is in the proper position beneath the motor housing, the lugs are to the front and facing upward and the heads of the adjustment screws are to the rear and facing downward in the path of the sliding frame that holds the bowl. It is intended that the bracket be fastened at the front housing connection by inserting replacement screws on an appropriate size upward through the opening in each lug and into the existing threaded holes in the bottom of the motor housing. The original stops for the sliding frame are to be filed down if they prevent the frame from coming in contact with the adjustment screws.

NOTE 2—This is the approximate diameter of a grain of 20-30 sand as described in Specification C 778.

4.2 *Paddle*—The paddle shall be readily removable, made of stainless steel, and shall conform to the basic design shown in Fig. 2. The dimensions of the paddle shall be such that when in the mixing position the paddle outline conforms to the contour of the bowl used with the mixer, and the clearance between corresponding points on the edge of the paddle and the side of the bowl in the position of closest approach shall be approximately 4.0 mm but not less than 0.8 mm.

4.3 *Mixing Bowl*—The removable mixing bowl shall have a nominal capacity of 4.73 L, shall be of the general shape and comply with the limiting dimensions shown in Fig. 3, and shall be made of stainless steel. The bowl shall be so equipped that it will be positively held in the mixing apparatus in a fixed position during the mixing procedure. There shall be provided a lid, made of a nonabsorbing material not attacked by the cement.

4.4 *Scraper*—The scraper shall consist of a semirigid rubber blade attached to a handle about 150 mm long. The blade shall be about 75 mm long, 50 mm wide, and tapered to a thin edge about 2 mm thick.

NOTE 3—A kitchen tool known as a plate and bowl scraper conforms to these requirements.

4.5 *Supplementary Apparatus*—The balances, weights, glass graduates, and any other supplementary apparatus used in measuring and preparing the mortar materials prior to mixing

[1] This practice is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.22 on Workability.

Current edition approved Aug. 1, 2006. Published August 2006. Originally approved in 1953. Last previous edition approved in 1999 as C 305 – 99$^{\epsilon 1}$.

Plate and Bushings—Brass
Screws and Nuts—Steel
All Dimensions in mm

FIG. 1 Clearance Adjustment Bracket

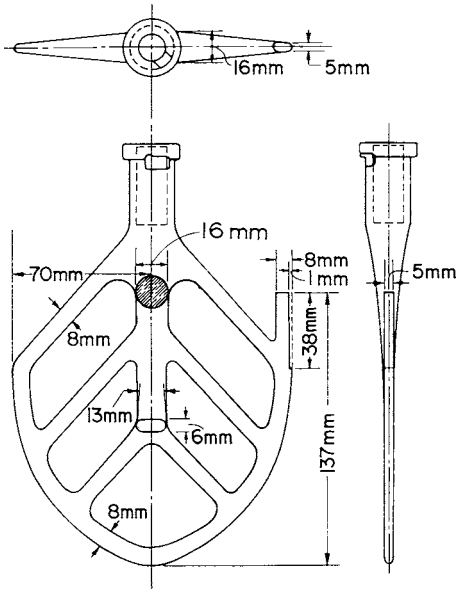

FIG. 2 Paddle

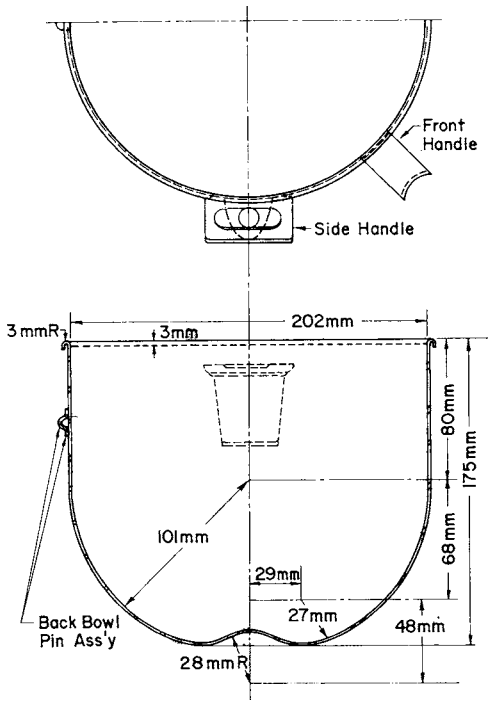

FIG. 3 Mixing Bowl

shall conform to the respective requirements for such apparatus as specified in the method for the particular test for which the mortar is being prepared.

5. Temperature and Humidity

5.1 The temperature of the room shall be maintained between 20 and 27.5 °C (68 and 81.5 °F), and the temperature of the dry materials, paddle, and bowl shall be within the above range at the time of test. The temperature of the mixing water shall not vary from 23 °C (73.4 °F) by more than ±1.7 °C (3 °F).

5.2 The relative humidity of the laboratory shall be not less than 50 %.

6. Materials, Proportioning, and Consistency

6.1 The materials and their proportions and quantities shall conform to the requirements contained in the particular method for which the paste or mortar is being prepared.

7. Procedure for Mixing Pastes

7.1 Place the dry paddle and the dry bowl in the mixing position in the mixer. Then introduce the materials for a batch into the bowl and mix in the following manner:

7.1.1 Place all the mixing water in the bowl.

7.1.2 Add the cement to the water and allow 30 s for the absorption of the water.

7.1.3 Start the mixer and mix at slow speed (140 ± 5 r/min) for 30 s.

7.1.4 Stop the mixer for 15 s and during this time scrape down into the batch any paste that may have collected on sides of the bowl.

7.1.5 Start the mixer at medium speed (285 ± 10 r/min) and mix for 60 s.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8. Procedure for Mixing Mortars

8.1 Place the dry paddle and the dry bowl in the mixing position in the mixer. Then introduce the materials for a batch into the bowl and mix in the following manner:

8.1.1 Place all the mixing water in the bowl.

8.1.2 Add the cement to the water; then start the mixer and mix at the slow speed (140 ± 5 r/min) for 30 s.

8.1.3 Add the entire quantity of sand slowly over a 30-s period, while mixing at slow speed.

8.1.4 Stop the mixer, change to medium speed (285 ± 10 r/min), and mix for 30 s.

8.1.5 Stop the mixer and let the mortar stand for 90 s. During the first 15 s of this interval, quickly scrape down into the batch any mortar that may have collected on the side of the bowl; then for the remainder of this interval, close the mixer enclosure or cover the bowl with the lid.

8.1.6 Finish by mixing for 60 s at medium speed (285± 10 r/min).

8.1.7 In any case requiring a remixing interval, any mortar adhering to the side of the bowl shall be quickly scraped down into the batch with the scraper prior to remixing.

Warning—The clearances between the paddle and the bowl specified in this practice are suitable when using mortar made with standard sand as described in Specification C 778. To permit the mixer to operate freely and to avoid serious damage to the paddle and bowl when coarser aggregates are used, it may be necessary to set the clearance adjustment bracket to provide greater clearances than those specified in 4.1.

For additional useful information on details of cement test methods, reference may be made to the "Manual of Cement Testing," which appears in the *Annual Book of ASTM Standards*, Vol 04.01.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this practice since the last issue, C 503 – 99$^{\epsilon 1}$, that may impact the use of this practice. (Approved August 1, 2006)

(*1*) Deleted current reference to Hobart N50A mixer because references to individual manufacturers are reserved for instances where a single manufacturer supplies the referred equipment.

(*2*) Revised 7.1.5.

(*3*) Revised 8.1.5.

(*4*) Revised 8.1.6.

Designation: C 309 – 07

Standard Specification for Liquid Membrane-Forming Compounds for Curing Concrete[1]

This standard is issued under the fixed designation C 309; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers liquid membrane-forming compounds suitable for application to concrete surfaces to reduce the loss of water during the early-hardening period. White-pigmented membrane-forming compounds serve the additional purpose of reducing the temperature rise in concrete exposed to radiation from the sun. The membrane-forming compounds covered by this specification are suitable for use as curing media for fresh concrete, and may also be used for further curing of concrete after removal of forms or after initial moist curing.

NOTE 1—This specification addresses only those properties listed in Sections 5 through 8. Membrane-forming compounds with special properties including better water retention, minimum solids content, resistance to ultraviolet radiation, acid and alkali resistance and non-interference with adhesives are described in Specification C 1315.

NOTE 2—Solutions of silicate salts are chemically reactive in concrete rather than membrane-forming; therefore, they do not meet the intent of this specification.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are provided for informational purposes only.

1.3 The following precautionary caveat pertains only to the test methods portion, Section 10, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

1.5 This is a performance specification. The allowable composition of products covered by this specification is limited by various local, regional, and national regulations. Issues related to air quality (solvent emission), worker exposure, and other hazards are not addressed here. It is the responsibility of the producers and users of these materials to comply with pertinent regulations.

Warning—Some VOC exempt solvents used to meet the regulations are extremely flammable with low auto ignition temperatures and rapid evaporation rates. Consult the manufacturer's product information sheet for important application and safety information.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 156 Test Method for Water Retention by Liquid Membrane-Forming Curing Compounds for Concrete

C 1315 Specification for Liquid Membrane-Forming Compounds Having Special Properties for Curing and Sealing Concrete

D 869 Test Method for Evaluating Degree of Settling of Paint

D 883 Terminology Relating to Plastics

D 1309 Test Method for Settling Properties of Traffic Paints During Storage

D 2369 Test Method for Volatile Content of Coatings

E 1347 Test Method for Color and Color-Difference Measurement by Tristimulus Colorimetry

3. Classification

3.1 The following types of liquid membrane-forming compounds are included:

3.1.1 *Type 1*—Clear or translucent without dye,

3.1.2 *Type 1-D*—Clear or translucent with fugitive dye, and

3.1.3 *Type 2*—White pigmented.

3.2 The solids dissolved in the vehicle shall be one of the following classes:

3.2.1 *Class A*—No restrictions,

3.2.2 *Class B*—Must be a resin as defined in Terminology D 883.

NOTE 3—Permanent colors other than white, or other special attributes,

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.22 on Materials Applied to New Concrete Surfaces.

Current edition approved June 1, 2007. Published July 2007. Originally approved in 1953. Last previous edition approved in 2006 as C 309 – 06.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

are beyond the scope of this specification and are subject to negotiation between the purchaser and the supplier.

4. Ordering Information

4.1 The purchaser shall include the following information in the purchase order when applicable:

4.1.1 Type of liquid membrane-forming compound and class of solids to be furnished, and

4.1.2 Rate of application to be used to determine conformance to this specification. If not specified, the liquid membrane-forming material shall be applied at a rate of 5.0 m^2/L (200 ft^2/gal) for testing purposes.

NOTE 4—The application rate used for testing may, or may not, be the same as the rate to be used for field application. Many agencies use the same rate for field application on relatively smooth surfaces as the rate used for testing, while requiring a substantially greater field application rate on deeply textured surfaces.

4.1.3 The intended method of application (for example, spraying, brushing, or by roller). If not specified, the material shall be of a sprayable consistency.

4.1.4 Maximum permissible volatile organic compound (VOC) content if required by applicable regulations.

5. General Requirements

5.1 Liquid membrane-forming compound Types 1 and 1-D shall be clear or translucent. Membrane-forming compounds with a fugitive dye (Type 1-D) shall be readily distinguishable upon the concrete surface for at least 4 h after application but shall become inconspicuous within 7 days after application if exposed to direct sunlight.

NOTE 5—No laboratory test for the fugitive characteristic of the color in dyed (Type 1-D) compounds is provided in this specification. The disappearance of these colors is strongly dependent on the nature of the exposure and the rate of application of the compounds.

5.2 Type 2 liquid membrane-forming compounds shall consist of finely-divided white pigment and vehicle, ready-mixed for immediate use as is. The membrane-forming compound shall present a uniform white appearance when applied uniformly to a new concrete surface at the specified rate of application.

5.3 Liquid membrane-forming compounds shall be of such a consistency that they can be readily applied by spraying, or by brushing or rolling, when specified, to a uniform coating at temperatures above 4 °C (40 °F).

NOTE 6—For uniform application in the field on vertical concrete surfaces, the specified rate of application may be achieved by two coats applied at an interval of approximately 1 h.

5.4 Liquid membrane-forming compounds shall adhere to freshly placed concrete that has stiffened or set sufficiently to resist marring during application, and to damp, hardened concrete, and shall form a continuous film when applied at the specified rate of application.

5.5 Liquid membrane-forming compounds shall not react deleteriously with concrete. Deleterious reactions are detected by scratching the surface of a mortar specimen (used for the water-retention test) with a knife or screwdriver, not less than 72 h after application, and comparing with the surface hardness similarly determined of a similar specimen that has been moist-cured for approximately half as long. Any softening of the liquid membrane-forming compound-treated surface indicated by such a comparison shall be considered sufficient cause for rejection of the compound.

NOTE 7—Testing for deleterious reactions need only be done for curing compounds of a new or unknown composition.

5.6 Liquid membrane-forming compounds shall be storable for at least 6 months without deterioration, except compounds of the water-emulsion type will not be expected to resist freezing. Type 2 liquid membrane-forming compounds shall not settle out excessively or cake in the container, and shall be capable of being mixed to a uniform consistency by moderate stirring or agitation. When tested for long-term settling, as stated in 10.4, the compound shall have a rating of not less than four.

6. Water Retention Properties

6.1 Liquid membrane-forming compounds, when tested in accordance with 10.1, shall restrict the loss of water to not more than 0.55 kg/m^2 in 72 h.

7. Reflectance Properties

7.1 Type 2 liquid membrane-forming compounds, when tested in accordance with 10.2, shall exhibit a daylight reflectance of not less than 60 %.

8. Drying Time Requirement

8.1 Liquid membrane-forming compounds, when tested in accordance with 10.3, shall dry to touch in not more than 4 h.

9. Sampling

9.1 Samples shall be taken either at the plant or warehouse prior to delivery, or at the point of delivery, at the option of the purchaser. If sampling is done prior to shipment, the inspector representing the purchaser shall have free access to the materials being sampled and shall be afforded all reasonable facilities for inspection and sampling.

9.2 Shake or thoroughly stir liquid membrane-forming compounds before taking a sample. Take one sample for each lot, batch, or other unit of production in a shipment. If the liquid membrane-forming compound is in mixing tanks or vats, one third of the sample shall represent the material coming from the tank at the beginning of the filling operation, one third shall represent the material coming at the middle of the filling operation, and one third shall represent the material coming at the end of the filling operation. If the liquid membrane-forming compound to be sampled is in containers, obtain a sample by taking a portion out of a number of containers equal in number to the next integer larger than the cube root of the total number of containers in the lot.

9.3 Seal all of the filled containers represented by the sample to prevent leakage, substitution, or dilution. The sampling agency shall mark each container represented by the sample with a suitable identification mark for later identification and correlation.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10. Test Methods

10.1 *Water Retention Test*—Using the application rate specified by the purchaser, or 5.0 m^2/L (200 ft^2/gal) if no rate is specified, test for water retention using Test Method C 156.

10.2 *Reflectance Test*—For Type 2 compounds, on completion of the water retention test, determine the daylight reflectance of the specimens in accordance with Test Method E 1347.

NOTE 8—Daylight reflectance is total luminous reflectance factor, CIE tristimulus value Y for CIE 1931 (2°) standard observer and CIE standard illuminant C or D56.

10.3 *Drying Time Test*:

10.3.1 *Scope*—This test method is used to determine the length of time for a liquid membrane-forming curing compound to dry to the touch and develop into a film that will not track off the concrete.

10.3.2 *Significance and Use*—The ability of a liquid membrane-forming curing compound to dry in a suitable length of time ensures the user of the ability to perform other tasks on the concrete, such as sawing joints, and so forth, without lifting the membrane from the concrete by tracking.

10.3.3 *Procedure*—Apply the membrane-forming compound to a fresh mortar specimen at the specified rate of application and expose it to air at 23 ± 2 °C (73.4 ± 3.6 °F), 50 ± 10 % relative humidity, and at an air velocity of approximately 183 m/min (600 ft/min) horizontally across the surface of the test specimen. Test the film with the finger using moderate pressure. Consider the film to be dry when the soft tacky condition no longer exists and the film feels firm.

10.3.4 *Precision and Bias*—The precision for this procedure is still being determined. The value of drying time can be defined only in terms of a test method; therefore, no statement of bias is being made.

10.4 *Long-Term Settling Test*—Use Test Method D 1309 for routine testing. In the case of dispute, use Test Method D 869.

10.5 *Nonvolatile Content Test*—Test in accordance with Test Method D 2369.

11. Packaging and Package Marking

11.1 The liquid membrane-forming compound shall be delivered in the manufacturer's original, clean, sealed containers. Each container shall be legibly marked with the name of the manufacturer, the trade name of the liquid membrane-forming compound, the type of liquid membrane-forming compound and class of solids, the nominal percentage of nonvolatile material, and the manufacturer's batch or lot number (Note 9). The manufacturer will assign batch or lot numbers to the quantity of membrane-forming compound mixed, sampled, and tested as a single lot. The manufacturer shall exercise care in filling the containers so that all are equally representative of the compound produced.

NOTE 9—The listing of the nominal percentage of nonvolatile material by the manufacturer, and the reporting of this information on the identification accompanying the sample, will assist the testing agency in determining whether the compound in the containers was adequately stirred and the sample is reasonably representative of the membrane-forming compound produced. Type 2 membrane-forming compounds are especially prone to separation due to settling of the pigment.

12. Keywords

12.1 concrete curing; liquid membrane-forming compounds for curing concrete

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 309 – 06, that may impact the use of this specification. (Approved June 1, 2007)

(*1*) Added new paragraph 1.5.

(*2*) Deleted old 5.7, 10.6, 10.7, and Footnote 3.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 309 – 03, that may impact the use of this specification. (Approved June 1, 2006)

(*1*) Added new Note 1 and renumbered subsequent notes.

Designation: C 309 – 07

Standard Specification for Liquid Membrane-Forming Compounds for Curing Concrete[1]

This standard is issued under the fixed designation C 309; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers liquid membrane-forming compounds suitable for application to concrete surfaces to reduce the loss of water during the early-hardening period. White-pigmented membrane-forming compounds serve the additional purpose of reducing the temperature rise in concrete exposed to radiation from the sun. The membrane-forming compounds covered by this specification are suitable for use as curing media for fresh concrete, and may also be used for further curing of concrete after removal of forms or after initial moist curing.

NOTE 1—This specification addresses only those properties listed in Sections 5 through 8. Membrane-forming compounds with special properties including better water retention, minimum solids content, resistance to ultraviolet radiation, acid and alkali resistance and non-interference with adhesives are described in Specification C 1315.

NOTE 2—Solutions of silicate salts are chemically reactive in concrete rather than membrane-forming; therefore, they do not meet the intent of this specification.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are provided for informational purposes only.

1.3 The following precautionary caveat pertains only to the test methods portion, Section 10, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

1.5 This is a performance specification. The allowable composition of products covered by this specification is limited by various local, regional, and national regulations. Issues related to air quality (solvent emission), worker exposure, and other hazards are not addressed here. It is the responsibility of the producers and users of these materials to comply with pertinent regulations.

Warning—Some VOC exempt solvents used to meet the regulations are extremely flammable with low auto ignition temperatures and rapid evaporation rates. Consult the manufacturer's product information sheet for important application and safety information.

C 156 Test Method for Water Retention by Liquid Membrane-Forming Curing Compounds for Concrete

C 1315 Specification for Liquid Membrane-Forming Compounds Having Special Properties for Curing and Sealing Concrete

D 869 Test Method for Evaluating Degree of Settling of Paint

D 883 Terminology Relating to Plastics

D 1309 Test Method for Settling Properties of Traffic Paints During Storage

D 2369 Test Method for Volatile Content of Coatings

E 1347 Test Method for Color and Color-Difference Measurement by Tristimulus Colorimetry

3. Classification

3.1 The following types of liquid membrane-forming compounds are included:

3.1.1 *Type 1*—Clear or translucent without dye,

3.1.2 *Type 1-D*—Clear or translucent with fugitive dye, and

3.1.3 *Type 2*—White pigmented.

3.2 The solids dissolved in the vehicle shall be one of the following classes:

3.2.1 *Class A*—No restrictions,

3.2.2 *Class B*—Must be a resin as defined in Terminology D 883.

NOTE 3—Permanent colors other than white, or other special attributes,

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.22 on Materials Applied to New Concrete Surfaces.

Current edition approved June 1, 2007. Published July 2007. Originally approved in 1953. Last previous edition approved in 2006 as C 309 – 06.

www.technobetar.ir

are beyond the scope of this specification and are subject to negotiation between the purchaser and the supplier.

4. Ordering Information

4.1 The purchaser shall include the following information in the purchase order when applicable:

4.1.1 Type of liquid membrane-forming compound and class of solids to be furnished, and

4.1.2 Rate of application to be used to determine conformance to this specification. If not specified, the liquid membrane-forming material shall be applied at a rate of 5.0 m^2/L (200 ft^2/gal) for testing purposes.

NOTE 4—The application rate used for testing may, or may not, be the same as the rate to be used for field application. Many agencies use the same rate for field application on relatively smooth surfaces as the rate used for testing, while requiring a substantially greater field application rate on deeply textured surfaces.

4.1.3 The intended method of application (for example, spraying, brushing, or by roller). If not specified, the material shall be of a sprayable consistency.

4.1.4 Maximum permissible volatile organic compound (VOC) content if required by applicable regulations.

5. General Requirements

5.1 Liquid membrane-forming compound Types 1 and 1-D shall be clear or translucent. Membrane-forming compounds with a fugitive dye (Type 1-D) shall be readily distinguishable upon the concrete surface for at least 4 h after application but shall become inconspicuous within 7 days after application if exposed to direct sunlight.

NOTE 5—No laboratory test for the fugitive characteristic of the color in dyed (Type 1-D) compounds is provided in this specification. The disappearance of these colors is strongly dependent on the nature of the exposure and the rate of application of the compounds.

5.2 Type 2 liquid membrane-forming compounds shall consist of finely-divided white pigment and vehicle, ready-mixed for immediate use as is. The membrane-forming compound shall present a uniform white appearance when applied uniformly to a new concrete surface at the specified rate of application.

5.3 Liquid membrane-forming compounds shall be of such a consistency that they can be readily applied by spraying, or by brushing or rolling, when specified, to a uniform coating at temperatures above 4 °C (40 °F).

NOTE 6—For uniform application in the field on vertical concrete surfaces, the specified rate of application may be achieved by two coats applied at an interval of approximately 1 h.

5.4 Liquid membrane-forming compounds shall adhere to freshly placed concrete that has stiffened or set sufficiently to resist marring during application, and to damp, hardened concrete, and shall form a continuous film when applied at the specified rate of application.

5.5 Liquid membrane-forming compounds shall not react deleteriously with concrete. Deleterious reactions are detected by scratching the surface of a mortar specimen (used for the water-retention test) with a knife or screwdriver, not less than 72 h after application, and comparing with the surface hardness similarly determined of a similar specimen that has been moist-cured for approximately half as long. Any softening of the liquid membrane-forming compound-treated surface indicated by such a comparison shall be considered sufficient cause for rejection of the compound.

NOTE 7—Testing for deleterious reactions need only be done for curing compounds of a new or unknown composition.

5.6 Liquid membrane-forming compounds shall be storable for at least 6 months without deterioration, except compounds of the water-emulsion type will not be expected to resist freezing. Type 2 liquid membrane-forming compounds shall not settle out excessively or cake in the container, and shall be capable of being mixed to a uniform consistency by moderate stirring or agitation. When tested for long-term settling, as stated in 10.4, the compound shall have a rating of not less than four.

6. Water Retention Properties

6.1 Liquid membrane-forming compounds, when tested in accordance with 10.1, shall restrict the loss of water to not more than 0.55 kg/m^2 in 72 h.

7. Reflectance Properties

7.1 Type 2 liquid membrane-forming compounds, when tested in accordance with 10.2, shall exhibit a daylight reflectance of not less than 60 %.

8. Drying Time Requirement

8.1 Liquid membrane-forming compounds, when tested in accordance with 10.3, shall dry to touch in not more than 4 h.

9. Sampling

9.1 Samples shall be taken either at the plant or warehouse prior to delivery, or at the point of delivery, at the option of the purchaser. If sampling is done prior to shipment, the inspector representing the purchaser shall have free access to the materials being sampled and shall be afforded all reasonable facilities for inspection and sampling.

9.2 Shake or thoroughly stir liquid membrane-forming compounds before taking a sample. Take one sample for each lot, batch, or other unit of production in a shipment. If the liquid membrane-forming compound is in mixing tanks or vats, one third of the sample shall represent the material coming from the tank at the beginning of the filling operation, one third shall represent the material coming at the middle of the filling operation, and one third shall represent the material coming at the end of the filling operation. If the liquid membrane-forming compound to be sampled is in containers, obtain a sample by taking a portion out of a number of containers equal in number to the next integer larger than the cube root of the total number of containers in the lot.

9.3 Seal all of the filled containers represented by the sample to prevent leakage, substitution, or dilution. The sampling agency shall mark each container represented by the sample with a suitable identification mark for later identification and correlation.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:11:01 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10. Test Methods

10.1 *Water Retention Test*—Using the application rate specified by the purchaser, or 5.0 m^2/L (200 ft^2/gal) if no rate is specified, test for water retention using Test Method C 156.

10.2 *Reflectance Test*—For Type 2 compounds, on completion of the water retention test, determine the daylight reflectance of the specimens in accordance with Test Method E 1347.

NOTE 8—Daylight reflectance is total luminous reflectance factor, CIE tristimulus value Y for CIE 1931 (2°) standard observer and CIE standard illuminant C or D56.

10.3 *Drying Time Test*:

10.3.1 *Scope*—This test method is used to determine the length of time for a liquid membrane-forming curing compound to dry to the touch and develop into a film that will not track off the concrete.

10.3.2 *Significance and Use*—The ability of a liquid membrane-forming curing compound to dry in a suitable length of time ensures the user of the ability to perform other tasks on the concrete, such as sawing joints, and so forth, without lifting the membrane from the concrete by tracking.

10.3.3 *Procedure*—Apply the membrane-forming compound to a fresh mortar specimen at the specified rate of application and expose it to air at 23 ± 2 °C (73.4 ± 3.6 °F), 50 ± 10 % relative humidity, and at an air velocity of approximately 183 m/min (600 ft/min) horizontally across the surface of the test specimen. Test the film with the finger using moderate pressure. Consider the film to be dry when the soft tacky condition no longer exists and the film feels firm.

10.3.4 *Precision and Bias*—The precision for this procedure is still being determined. The value of drying time can be defined only in terms of a test method; therefore, no statement of bias is being made.

10.4 *Long-Term Settling Test*—Use Test Method D 1309 for routine testing. In the case of dispute, use Test Method D 869.

10.5 *Nonvolatile Content Test*—Test in accordance with Test Method D 2369.

11. Packaging and Package Marking

11.1 The liquid membrane-forming compound shall be delivered in the manufacturer's original, clean, sealed containers. Each container shall be legibly marked with the name of the manufacturer, the trade name of the liquid membrane-forming compound, the type of liquid membrane-forming compound and class of solids, the nominal percentage of nonvolatile material, and the manufacturer's batch or lot number (Note 9). The manufacturer will assign batch or lot numbers to the quantity of membrane-forming compound mixed, sampled, and tested as a single lot. The manufacturer shall exercise care in filling the containers so that all are equally representative of the compound produced.

NOTE 9—The listing of the nominal percentage of nonvolatile material by the manufacturer, and the reporting of this information on the identification accompanying the sample, will assist the testing agency in determining whether the compound in the containers was adequately stirred and the sample is reasonably representative of the membrane-forming compound produced. Type 2 membrane-forming compounds are especially prone to separation due to settling of the pigment.

12. Keywords

12.1 concrete curing; liquid membrane-forming compounds for curing concrete

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 309 – 06, that may impact the use of this specification. (Approved June 1, 2007)

(*1*) Added new paragraph 1.5.

(*2*) Deleted old 5.7, 10.6, 10.7, and Footnote 3.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 309 – 03, that may impact the use of this specification. (Approved June 1, 2006)

(*1*) Added new Note 1 and renumbered subsequent notes.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 311 – 07

Standard Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete[1]

This standard is issued under the fixed designation C 311; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 These test methods cover procedures for sampling and testing fly ash and raw or calcined pozzolans for use in portland-cement concrete.

1.2 The procedures appear in the following order:

	Sections
Sampling	7
CHEMICAL ANALYSIS	
Reagents and apparatus	10
Moisture content	11 and 12
Loss on ignition	13 and 14
Silicon dioxide, aluminum oxide, iron oxide, calcium oxide, magnesium oxide, sulfur trioxide, sodium oxide and potassium oxide	15
Available alkali	16 and 17
Ammonia	18
PHYSICAL TESTS	
Density	19
Fineness	20
Increase of drying shrinkage of mortar bars	21-23
Soundness	24
Air-entrainment of mortar	25 and 26
Strength activity index with portland cement	27-30
Water requirement	31
Effectiveness of Fly Ash or Natural Pozzolan in Controlling Alkali-Silica Reactions	32
Effectiveness of Fly Ash or Natural Pozzolan in Contributing to Sulfate Resistance	34

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.5 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this standard.

D 4326 Test Method for Major and Minor Elements in Coal and Coke Ash By X-Ray Fluorescence

2.2 *ACI Document:*[3]

ACI 201.2R Guide to Durable Concrete

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *composite sample*—a sample that is constructed by combining equal portions of grab or regular samples.

3.1.2 *established source*—a source for which at least six months of continuous production quality assurance records from a test frequency required for a new source are available, sampled at the source.

3.1.3 *grab sample*—a sample that is taken in a single operation from a conveyor delivering to bulk storage, from bags, or from a bulk shipment. Such a sample may, or may not, reflect the composition or physical properties of a single lot of fly ash or natural pozzolan. This type of sample can be used to characterize small amounts of material.

3.1.4 *jobsite or new source*—a source for which less than six months of production records are available, sampled at the source.

3.1.5 *lot*—specific quantity of fly ash or natural pozzolan offered for inspection at any one time. A lot may be one storage bin or the contents of one or more transport units representing material drawn from the same storage bin.

3.1.6 *regular sample*—a sample that is constructed by combining equal portions of grab samples that were taken at predetermined times or locations from any single lot of material.

4. Significance and Use

4.1 These test methods are used to develop data for comparison with the requirements of Specification C 618. These test methods are based on standardized testing in the laboratory and are not intended to simulate job conditions.

4.1.1 *Strength Activity Index*—The test for strength activity index is used to determine whether fly ash or natural pozzolan results in an acceptable level of strength development when used with hydraulic cement in concrete. Since the test is performed with mortar, the results may not provide a direct correlation of how the fly ash or natural pozzolan will contribute to strength in concrete.

4.1.2 *Chemical Tests*— The chemical component determinations and the limits placed on each do not predict the performance of a fly ash or natural pozzolan with hydraulic cement in concrete, but collectively help describe composition and uniformity of the material.

5. Materials

5.1 *Graded Standard Sand*—The sand used for making test specimens for the activity index with lime or portland cement shall be natural silica sand conforming to the requirements for graded standard sand in Specification C 778.

NOTE 1—*Segregation of Graded Sand*—The graded standard sand should be handled in such a manner as to prevent segregation, since variations in the grading of the sand cause variations in the consistency of the mortar. In emptying bins or sacks, care should be exercised to prevent the formation of mounds of sand or craters in the sand, down the slopes of which the coarser particles will roll. Bins should be of sufficient size to permit these precautions. Devices for drawing the sand from bins by gravity should not be used.

5.2 *Hydrated Lime*— The hydrated lime used in the tests shall be reagent-grade calcium hydroxide, 95 % minimum calculated as $Ca(OH)_2$(Note 2), and have a minimum fineness of 2500 m^2/kg as determined in accordance with Test Method C 204.

NOTE 2—The calcium hydroxide should be protected from exposure to carbon dioxide. Material remaining in an opened container after a test should not be used for subsequent tests.

5.3 *Portland Cement*— The portland cement used in the Strength Activity Index with Portland Cement test shall comply with the requirements of Specification C 150 and have a minimum compressive strength of 35 MPa (5000 psi) at 28 days and total alkalies ($Na_2O + 0.658\ K_2O$) not less than 0.50 % nor more than 0.80 %.

5.3.1 The use of a locally available portland cement in the Strength Activity Index or a project cement that does not meet the requirements of the section on Materials is permitted when the variations from the requirements of the section on Materials are reported and when the use of such portland cement is requested.

6. Sample Type and Size

6.1 Grab samples and regular samples shall have a mass of at least 2 kg (4 lb).

6.2 Grab samples or regular samples taken at prescribed intervals over a period of time (see Table 1), may be combined to form a composite sample representative of the fly ash or natural pozzolan produced during that period of time.

6.3 Composite samples shall have a mass of at least 4 kg (8 lb).

6.4 The sampling shall be done by, or under the direction of, a responsible representative of the purchaser.

7. Sampling Procedure

7.1 The fly ash or natural pozzolan may be sampled by any one of the following methods:

7.1.1 *From Bulk Storage at Point of Discharge or from Rail Cars and Road Tankers*—A sample may be taken by siphon

TABLE 1 Minimum Sampling and Testing Frequency[A]

Test	Sample Type	Jobsite or New Source[B]	Established Source[B]
Moisture content Loss on ignition Fineness	Regular	Daily or each 90 Mg[C] (100 Tons)	Daily or each 360 Mg[C] (400 Tons)
Density and the other tests in Specification C 618, Tables 1 and 2	Composite	Monthly or each 1 800 Mg[C] (2 000 Tons)	Monthly or each 2 900 Mg[C] (3 200 Tons)

[A] It should be noted that the minimum test frequency given in Table 1 is not necessarily the frequency needed for quality control programs on some fly ash or natural pozzolans.

[B] For definitions, refer to the Terminology section.

[C] Whichever comes first.

[3] Available from American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333-9094, http://www.aci-int.org.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

tube during loading or by sampling tube from each loaded car or tanker. If the load is sampled at the point of discharge into the rail car or tanker, the top surface shall be removed to a depth of at least 200 mm (8 in.) before sampling. The sample shall be identified with at least the date and shipment number.

7.1.2 *From Bags in Storage*—The regular sample shall comprise increments of equal size taken by sampling tube from three bags selected at random from one lot of bagged material. The sample shall be identified with date and lot number.

7.1.3 *From Conveyor Delivering to Bulk Storage*—Take one sample of 2 kg (4 lb) or more of the material passing over the conveyor. This may be secured by taking the entire test sample in a single operation, known as the grab sample method, or by combining several equal portions taken at regular intervals, known as the regular sample method. Automatic samplers may be used to obtain samples.

7.2 Samples shall be treated as described in Section 8.

NOTE 3—Some methods of loading or delivery of fly ash or natural pozzolan, particularly from an airstream or conveyor belt, may create stratification or segregation in the material stream. Sampling techniques must be designed to ensure that the sample is representative of the material shipped.

8. Preparation and Storage of Samples

8.1 Prepare composite samples for the tests required in Section 9, by arranging all grab or regular samples into groups covering the period or quantity to be represented by the sample. Take equal portions from each, sufficient to produce a composite sample large enough for the tests required. Mix the composite sample thoroughly.

8.2 Samples shall be stored in clean, airtight containers identified with the source and lot or period of time represented. Untested portions of the sample shall be retained for at least one month after all test results have been reported.

9. Testing Frequency

9.1 *General*—When required, the purchaser shall specify the amount of testing for available alkalies, reactivity with cement alkalies, drying shrinkage, and air-entrainment. Make all other tests on regular or composite samples chosen as specified in Table 1.

CHEMICAL ANALYSIS

10. General

10.1 All apparatus, reagents and techniques shall comply with the requirements of Test Methods C 114.

10.2 *Purity of Water*— Unless otherwise indicated, references to water shall be understood to mean distilled water or water of equal purity.

MOISTURE CONTENT

11. Procedure

11.1 Dry a weighed sample, as received, to constant weight in an oven at 105 to 110 °C (221 to 230 °F).

12. Calculation

12.1 Calculate the percentage of moisture to the nearest 0.1 %, as follows:

$$\text{Moisture content, \%} = (A/B) \times 100 \quad (1)$$

where:

A = mass loss during drying, and
B = mass as received.

LOSS ON IGNITION

13. Procedure

13.1 Determine loss on ignition in accordance with the procedures outlined in Test Methods C 114, except that the material remaining from the determination of moisture content shall be ignited to constant mass in an uncovered porcelain, not platinum, crucible at 750 ± 50 °C (1382 ± 190 °F).

14. Calculation

14.1 Calculate the percentage of loss on ignition to the nearest 0.1, as follows:

$$\text{Loss on ignition, \%} = (A/B) \times 100 \quad (2)$$

where:

A = loss in mass between 105 and 750 °C (221 and 1382 °F),
B = mass of moisture-free sample used.

SILICON DIOXIDE, ALUMINUM OXIDE, IRON OXIDE, CALCIUM OXIDE, MAGNESIUM OXIDE, SULFUR TRIOXIDE, SODIUM OXIDE AND POTASSIUM OXIDE

15. Procedure

15.1 Determine the percentages of these oxides as required in accordance with the applicable sections of Test Methods C 114 for materials having an insoluble residue greater than 1 % (Note 4). Analysts performing sodium oxide and potassium oxide determinations shall observe the precautions outlined in the applicable section of Performance Specification C 1157 (refer to the section on Test Methods). Most pozzolans dissolve completely in lithium borate fluxes.

NOTE 4—Rapid and instrumental methods may be employed similar to those in Test Methods C 114 and D 4326.

AVAILABLE ALKALI

16. Procedure

16.1 Weigh 5.0 g of the sample and 2.0 g of hydrated lime on a piece of weighing paper, carefully mix using a metal spatula, and transfer to a small plastic vial of approximately 25-mL capacity. Add 10.0 mL of water to this mixture, seal the vial by securing the cap or lid to the vial with tape (Note 5), blend by shaking until the mixture is uniform, and store at 38 ± 2 °C.

NOTE 5—To ensure that moisture loss from the paste does not occur, place the sealed vial in a sealable container (such as a small sample or mason jar), add sufficient water to cover the bottom of the container, and seal.

16.2 Open the vial at the age of 28 days and transfer the contents to a 250-mL casserole. Break up and grind the cake with a pestle, adding a small amount of water, if necessary, so that a uniform slurry containing no lumps is obtained (Note 6). Add sufficient water to make the total volume 200 mL. Let

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

stand 1 h at room temperature with frequent stirring. Filter through a medium-textured filter paper onto a 500-mL volumetric flask. Wash thoroughly with hot water (eight to ten times).

NOTE 6—At times it may be necessary to break the vial and peel off the plastic from the solid cake. In such cases, care should be exercised to avoid the loss of material and to remove all solid material from the fragments of the vial. If the cake is too hard to break up and grind in the casserole, a mortar should be used.

16.3 Neutralize the filtrate with dilute HCl (1 + 3), using 1 to 2 drops of phenolphthalein solution as the indicator. Add exactly 5 mL of dilute HCl (1 + 3) in excess. Cool the solution to room temperature and fill the flask to the mark with distilled water. Determine the amount of sodium and potassium oxides in the solution using the flame photometric procedure, described in Test Methods C 114, except that the standard solutions shall be made up to contain 8 mL of calcium chloride ($CaCl_2$) stock solution per litre of standard solution, and the solution as prepared shall be used in place of the solution of cement.

NOTE 7—The standard solutions made up with 8 mL of calcium chloride ($CaCl_2$) stock solution contain the equivalent of 504 ppm of CaO. Tests have shown that this amount closely approximates the amount of calcium dissolved in the test solution.

17. Calculation and Report

17.1 Calculate the results as weight percent of the original sample material. Report as equivalent percentage of sodium oxide (Na_2O), calculated as follows:

$$\text{Equivalent } Na_2O, \% = Na_2O, \% + 0.658 \times K_2O, \% \quad (3)$$

AMMONIA

18. Procedure

18.1 Weigh 1.00 g of the fly ash sample into a 125 mL Erlenmeyer flask. Add 100 mL of ammonia-free water. Place a neoprene rubber stopper on the flask and swirl the contents to thoroughly mix the sample and the water.

18.2 Filter the mixture using a medium-textured filter paper and save the filtrate for the ammonia determination.

18.3 Determine the concentration of ammonia in the filtrate in accordance with the procedures outlined in Test Methods D 1426, Method A–Direct Nesslerization or Method B–Selective Ion Electrode.

18.4 Calculate the ammonia concentration of the fly ash as follows:

$$Ammonia, mg/kg = N_W \times V_W / W_{fa} \quad (4)$$

where:

N_W = ammonia concentration of the water extract determined by Test Methods D 1426, mg/L,
V_W = volume of water used for extracting ammonia from the fly ash sample, mL, and
W_{fa} = Mass of fly ash sample used in the test, g.

PHYSICAL TESTS

DENSITY

19. Procedure

19.1 Determine the density of the sample in accordance with the procedure described in Test Method C 188, except use about 50 g of fly ash or natural pozzolan instead of approximately 64 g of cement as recommended in Test Method C 188.

FINENESS, AMOUNT RETAINED WHEN WET-SIEVED ON A 45-μm (NO. 325) SIEVE

20. Procedure

20.1 Determine the amount of the sample retained when wet-sieved on a 45-μm (No. 325) sieve, in accordance with Test Method C 430, with the following exceptions.

20.1.1 Calibrate the 45-μm (No. 325) sieve using a cement standard (SRM 114). Calculate the sieve correction factors as follows:

$$CF = std - obs \quad (5)$$

where:

CF = the sieve correction factor, %, (include a negative sign when appropriate),
std = the certified residue value for the SRM, %, and
obs = the observed residue value for the SRM, %.

20.1.2 Calculate the fineness of the fly ash or natural pozzolan to the nearest 0.1 % as follows:

$$R_C = R_S + CF \quad (6)$$

where:

R_C = corrected sieve residue, %,
R_S = observed residue for the test sample, %, and
CF = the sieve correction factor, %.

If the residue retained for the test sample is equal to zero ($R_S = 0$), then the sieve correction factor shall not be added to the test result to calculate the corrected sieve residue. In such cases, the corrected fineness shall be reported as zero.

NOTE 8—Test Method C 430 has been adopted for testing fly ash fineness. However, certain requirements, such as cleaning of sieves and interpretation of the test results, are sometimes not appropriate for fly ashes.

20.2 Numerical examples for calibrating a fineness sieve and calculating the corrected fineness.

20.2.1 Calibrating a fineness sieve (NIST standard reference material SRM 114p was used in this example):

Certified residue retained on a 45−*μm sieve*
= 8.24 % (*obtained from standard certificate*)

Measured residue retained on a 45−*μm sieve*
= 7.12 % (*measured in the laboratory*)

Correction factor (*CF*) = *standard value* (*std*) – *observed value* (*obs*)
= 8.24 – 7.12
= 1.12 %

20.2.2 Calculating a corrected fineness value for a calibrated sieve (fly ash A was used in this example):

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Amount of fly ash A retained on the sieve: R_s
= 15.2 % (*expressed as a % of sample mass*)

Corrected sieve residue for fly ash A: $R_c = R_s + CF$
= 15.2 + 1.12
= 16.3 %

INCREASE OF DRYING SHRINKAGE OF MORTAR BARS

21. Test Specimen

21.1 Prepare test specimens in accordance with the procedures described in Test Method C 157/C 157M, except mold three mortar bars from both the control mix and the test mix using the following proportions:

	Control Mix	Test Mix
Portland cement, g	500	500
Fly ash or natural pozzolan, g	None	125
Graded standard sand, g	1375	1250
Water	sufficient to produce a flow of 100 to 115 %	

22. Procedure

22.1 Cure and measure the test specimens in accordance with Test Method C 157/C 157M, except that the moist-curing period (including the period in the molds) shall be 7 days, and the comparator reading at the age of 24 ± ½ h shall be omitted. Immediately after taking the comparator reading at the end of the 7-day moist-curing period, store the specimens in accordance with Test Method C 157/C 157M, and after 28 days of air storage, take a comparator reading for the specimens in accordance with Test Method C 157/C 157M.

23. Calculation and Report

23.1 Calculate the increase in drying shrinkage of the mortar bars, S_i, as follows:

$$S_i = S_t - S_c \quad (7)$$

where:

S_t = average drying shrinkage of the test specimens calculated as follows, and
S_c = average drying shrinkage of the control specimens calculated as follows:

$$S = \frac{[\text{initial CRD} - \text{CRD}] \times 100}{G} \quad (8)$$

where:

S = drying shrinkage of test or control specimens, %,
initial CRD = difference between the comparator reading of the specimen and the reference bar at 7 days of moist curing,
CRD = difference between the comparator reading of the specimen and the reference bar at 28 days of drying, and
G = the gage length of the specimens 250 mm (10 in.).

23.2 Report the results to the nearest 0.01. If the average drying shrinkage of the control specimens is larger than the average drying shrinkage of the test specimens, prefix a minus sign to the increase of drying shrinkage of mortar bars reported.

SOUNDNESS

24. Procedure

24.1 Conduct the soundness test in accordance with Test Method C 151, except that the specimens shall be molded from a paste composed of 25 parts by weight of fly ash or natural pozzolan and 100 parts by weight of a portland cement conforming to Specification C 150.

AIR-ENTRAINMENT OF MORTAR

25. Procedure

25.1 Using portland cement conforming to the requirements for Type I or Type II of Specification C 150, prepare a test mixture in accordance with Test Method C 185, using the following proportions:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

	Test Mix
Portland cement, g	300
Fly ash or natural pozzolan	75
20–30 standard sand, g	1125
Water, mL, sufficient to give a flow of 80 to 95	Y
Neutralized Vinsol resin solution, mL,[A] sufficient to produce an air content of 18 ± 3 %	Z

[A] The amount of Vinsol resin solution used shall be considered as part of the mixing water.

25.2 The neutralized Vinsol resin solution used in this section on Air-Entrainment of Mortar shall be either a commercial neutralized Vinsol resin solution or a neutralized Vinsol resin solution prepared in accordance with Specification C 226. If it is necessary to dilute either of these solutions, use distilled or demineralized water. (Note 9.)

NOTE 9—Dissolved minerals in drinking water may precipitate Vinsol resin solutions and greatly diminish its air-entraining characteristics.

25.3 Prepare two test mixtures with sufficient neutralized Vinsol resin to produce an air content of 15 to 18 % in the first mix and 18 to 21 % in the second mix. Then, determine by interpolation the amount of Vinsol resin, expressed as weight percent of the cement, required to produce an air content of 18 %.

26. Calculation

26.1 Calculate the air content of the test mixtures as follows:

$$\text{Air content, volume } \% = 100[1-(W_a/W_c)] \quad (9)$$

$$W_a = W/400 \quad (10)$$

$$W_c = \frac{300+1125+75+(300 \times P \times 0.01)}{\left[\left(\frac{300}{3.15}\right)+\left(\frac{1125}{2.65}\right)+\left(\frac{75}{D}\right)+\left(\frac{300 \times P \times 0.01}{1}\right)\right]} \quad (11)$$

where:

W_a = actual weight per unit of volume of mortar as determined by Test Method C 185, g/mL,
W = weight of the specified 400 mL of mortar (see Test Method C 185), g,
W_c = theoretical weight per unit of volume, calculated on an air-free basis and using the values for density and quantities of the materials in the mix, g/mL,
P = percentage of mixing water plus Vinsol resin solution based on weight of cement, and
D = density of fly ash or natural pozzolan in the mixture, Mg/m^3.

STRENGTH ACTIVITY INDEX WITH PORTLAND CEMENT

27. Specimens

27.1 Mold the specimens from a control mixture and from a test mixture in accordance with Test Method C 109/C 109M. The portland cement used in the Strength Activity Index test shall comply with the requirements of Specification C 150 and with the alkali and strength limits given in the section on Materials. In the test mixture, replace 20 % of the mass of the amount of cement used in the control mixture by the same mass of the test sample. Make six-cube batches as follows:

27.1.1 Control Mixture:

500 g of portland cement
1375 g of graded standard sand
242 mL of water

27.1.2 Test Mixture:

400 g of portland cement
100 g of test sample
1375 g of graded standard sand
mL of water required for flow ± 5 of control mixture

27.2 *Number of Specimens*:

27.2.1 Since Specification C 618 specifies that "meeting the 7 day or 28 day Strength Activity Index will indicate specification compliance" only one age might be required. At the option of the producer or the user after preparing six-cube batches, only three cubes of control and test mixtures need to be molded for either 7 or 28 day testing.

28. Storage of Specimens

28.1 After molding, place the specimens and molds (on the base plates) in the moist room or closet at 23.0 ± 2.0 °C (73.4 ± 3 °F) for 20 to 24 h. While in the moist room or closet, protect the surface from dripping water. Remove the molds from the moist room or closet and remove the cubes from the molds. Place and store the cubes in saturated lime water as specified in Test Method C 109/C 109M.

NOTE 10—Take care to ensure against zones of stratification or pockets of variation in temperature in the curing chamber.

29. Compressive Strength Test

29.1 Determine the compressive strength, as specified in Test Method C 109/C 109M, of three specimens of the control mixture and three specimens of the test mixture at ages of 7 days, or 28 days, or both, depending upon how many specimens were molded as prescribed in the section on Number of Specimens.

30. Calculation

30.1 Calculate the strength activity index with portland cement as follows:

Strength activity index with portland cement =

$$(A/B) \times 100 \quad (11)$$

where:

A = average compressive strength of test mixture cubes, MPa (psi), and
B = average compressive strength of control mix cubes, MPa (psi).

WATER REQUIREMENT

31. Calculation

31.1 Calculate the water requirement for the Strength Activity Index with Portland Cement as follows:

Water requirement, percentage of control =

$$(Y/242 \times 100) \quad (12)$$

where:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Y = water required for the test mixture to be ±5 of control flow.

EFFECTIVENESS OF FLY ASH OR NATURAL POZZOLAN IN CONTROLLING ALKALI SILICA-REACTIONS (SEE Appendix X1)

32. Procedure

32.1 Determine expansion of mortar made with a fly ash or natural pozzolan and a test cement as a percent of expansion of mortar made with low alkali cement in accordance with Test Method C 441 as modified in the following paragraphs:

32.1.1 *Control Mixture*— The control mixture will be made as required in Test Method C 441 except that the control cement shall have an alkali content (as equivalent Na_2O) less than 0.60 % (Note 11).

NOTE 11—Generally, the control cement should have an alkali content as equivalent Na_2O between 0.50 and 0.60 %. However, lower alkali control cement may be used, if desired, to demonstrate equivalence.

32.1.2 *Test Mixture Using Fly Ash or Natural Pozzolan*— The combined quantity of cement plus fly ash or natural pozzolan shall total 400 g (see Appendix X1). Use 900 g of borosilicate glass aggregate and sufficient mixing water to produce a flow between 100 and 115 % as determined in accordance with Test Method C 1437. The cement used in the test mixture shall have an alkali content greater than that of the cement in the control mixture (Note 12).

NOTE 12—Generally, this test cement will have an alkali content equal to or higher than that used in the job.

32.1.3 Store and measure specimens as required in Test Method C 227. Measure length of specimens at ages of 1 and 14 days.

33. Report

33.1 Include in the report for each test mixture comparison made:

33.1.1 The 14 day expansion of the test mixture as a percent of the control mixture at that age,

33.1.2 The identification and chemical analysis of the fly ash or natural pozzolan,

33.1.3 The mass percentage of fly ash or natural pozzolan based on the total mass of cement plus fly ash or natural pozzolan in the test mixture, and

33.1.4 The alkali content of control and test mixture cements as equivalent alkali ($Na_2O + 0.658\ K_2O$).

EFFECTIVENESS OF FLY ASH OR NATURAL POZZOLAN IN CONTRIBUTING TO SULFATE RESISTANCE

34. Procedure

34.1 Compare the length change of mortar bars with absolute expansion limits or compare the length change of mortar bars made with a control cement with the length change of mortar bars made with fly ash or natural pozzolan and a test cement, in accordance with Test Method C 1012, as modified in the following paragraphs. Results shall be evaluated using absolute limits (Procedure A) or the relative expansion limits (Procedure B) in Specification C 618, Table 2A.

34.2 *Control Mixture for Procedure A*—A control mixture is not mandatory since performance measured using Procedure A is based on maximum expansion of the test mixture. If a control mixture is made for Procedure A then proportion it as required in Test Method C 1012 using a cement meeting the requirements of Specification C 150, Type II or Type V.

34.3 *Test Mixture Using Fly Ash or Natural Pozzolan for Procedure A*—Make the combined quantity of cement plus fly ash or natural pozzolan, by mass, the same as the total cement content of the control mixture described in the Making Mortars section of Test Method C 1012. The proportion of fly ash or natural pozzolan may be varied using from 15 % to 50 %, by mass, of the total cement plus fly ash or natural pozzolan. Any type of portland cement may be used to prepare test mixtures.

34.4 *Control Mixture for Procedure B*—Make the control mixture for Procedure B as required in Test Method C 1012 with the cement that is proposed for use in the project or a cement that through performance or definition (Specification C 150, Section 1) is expected to give satisfactory results (or a cement for which the contribution to sulfate resistance is known and is satisfactory).

NOTE 13—The control cement should be chosen to give sulfate resistance for the expected level of sulfate exposure. Experience has shown that Type II cements are often used for moderate levels of exposure. Type V cement is commonly used for severe exposures (see X2.2 of Appendix X2).

34.5 *Test Mixture for Using Fly Ash or Natural Pozzolan for Procedure B*—Make the combined quantity of cement plus fly ash or natural pozzolan, by mass, the same as the total cement used in the control mixture. The proportion of fly ash or natural pozzolan may be varied from 15 % to 50 % of the total cement plus fly ash or natural pozzolan by mass. Any type of portland cement may be used to prepare test mixtures.

34.6 For either Procedure A or B, store and measure specimens as required in Test Method C 1012 for at least 6 months.

NOTE 14—Evaluation of the sulfate resistance of cementitious materials for use in certain situations or critical structures may require longer periods of storage and additional length measurements. Refer to Test Method C 1012 for guidance on this matter.

35. Report

35.1 In addition to the information required in Test Method C 1012, report the following information for each mixture comparison made:

35.2 For Procedure A, the age and expansion as a specific amount,

35.3 For Procedure B, the age and expansion as a percent of the control mixture at that age,

35.4 The identification and chemical analysis including C_3A content of the cements used in both the control and test mixtures,

35.5 The identification and chemical analysis of the fly ash or natural pozzolan used in the test mixtures,

35.6 The mass percentages of the fly ash or natural pozzolan based on the total mass of cement plus fly ash or natural pozzolan in the test mixture.

TABLE 2 Within and Between Lab Precision Estimates for C 114 Methods Applied to the Analysis of Fly Ash[A]

Oxide	1s		d2s	
	W/L	B/L	W/L	B/L
SiO_2	0.62	0.86	1.75	2.45
Al_2O_3	1.46	2.29	4.12	6.48
Fe_2O_3				
<2 %	0.12	0.11	0.34	0.31
≥2 %	0.12	0.25	0.34	0.71
CaO	0.63	0.74	1.79	2.09
MgO	0.20	0.21	0.55	0.61
SO_3	0.10	0.16	0.28	0.45
Moisture	0.05	0.06	0.15	0.17
LOI	0.09	0.12	0.25	0.35

[A]The four values for SO_3 were editorially corrected to reflect updated research reports associated with this standard.

PRECISION AND BIAS

36. Precision and Bias

36.1 *Strength Activity Index Test*:

36.1.1 Precision was determined from two interlaboratory studies involving two Class C fly ashes, two Class F fly ashes, and one Class N pozzolan. Participating laboratories numbered 12 and 7 in the two studies.[4]

36.1.2 The single-operator standard deviation for the Strength Activity Index test has been found to be 3.7 % (1s). This does not appear to vary either with material or with test age, over the range of 7 to 28 days. Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 10.5 % (d2s) of the average of the two results.

36.1.3 The multilaboratory standard deviation for the Strength Activity Index test has been found to be 4.5 % (1s). This does not appear to vary either with material or with test age, over the range of 7 to 28 days. Therefore, results of two properly conducted tests in different laboratories on the same material should not differ by more than 12.7 % (d2s) of the average of the two results.

36.1.4 Since there is no accepted reference material suitable for determining the bias for this procedure, no statement on bias is being made.

36.2 *Chemical Analysis*:

36.2.1 Precision and bias estimates for the test methods in C 114 when applied to the analysis of pozzolans were calculated from an interlaboratory study involving 7 laboratories each analyzing 4 NIST SRM fly ashes. A research report describing the results of this study is available from ASTM.[5]

36.2.2 *Precision*—Within-laboratory (W/L) and between-laboratory (B/L) estimates of standard deviation and estimates of maximum differences expected between duplicate determinations in 95 % of comparisons[6] are summarized in Table 2.

36.2.3 *Bias*—Statistically significant bias was found in the determination of CaO and MgO. CaO determinations averaged 0.46 % higher than the value certified for the SRM. MgO determinations averaged 0.19 % higher than the value certified for the SRM.

36.3 *Ammonia*:

36.3.1 Precision of Method A (Direct Nesslerization) – The single-laboratory coefficient of variation (repeatability) has been found to be 9.2 % (1s %). The reproducibility of this test method is being determined and will be available on or before July 2010.

36.3.2 Precision of Method B (Selective Ion Electrode) – The single-laboratory coefficient of variation (repeatability) has been found to be 7.4 % (1s %). The reproducibility of this test method is being determined and will be available on or before July 2010.

36.3.3 *Bias*—Since there is no accepted reference material suitable for determining the bias for these procedures, no statement on bias is being made.

37. Keywords

37.1 fly ash; natural pozzolan

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1001.

[5] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1008.

[6] These values represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

APPENDIXES

(Nonmandatory Information)

X1. COMMENTARY ON SECTION 32

X1.1 Test procedures in Section 32 are designed to determine the effectiveness of fly ash, or natural pozzolan, in preventing excessive expansion resulting from a reaction between certain aggregates and alkalies in portland-cement mixtures. Tests are made in accordance with Test Method C 441 using:

X1.1.1 400 g of portland cement or a combined total of cement plus fly ash or natural pozzolan of 400 g,

X1.1.2 900 g of borosilicate glass, and

X1.1.3 Sufficient water to obtain a flow of 100 to 115 %.

X1.2 The control mixture is made with a low-alkali portland cement. The test mixture, made of a test percentage of the fly ash or natural pozzolan, can be made with the same cement or any other cement having an equivalent alkali content greater than 0.60 %.

X1.3 *Interpretation of Results*—The fly ash or natural pozzolan should be considered "effective" when used at

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:10:59 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

percentages equal to or greater than the percentages used in the test mixture with cements having alkali contents that do not exceed by more than 0.05 percentage points the alkali content of the cement used in the test mixture.

X1.4 *Selection of the Percentage of Fly Ash or Natural Pozzolan*—It may be necessary to make test mixtures with several percentages of fly ash or natural pozzolan to determine the minimum amount necessary to be considered "effective" in reducing expansion to the level produced by the "control" low-alkali cement. The minimum amount of fly ash or natural pozzolan should be 15 % by weight of cementitious material.

X1.5 *Selection of the Alkali Content of the Cement Used in the Test Mixture*—In some instances it may not be necessary to demonstrate that the fly ash or natural pozzolan will reduce expansion, but rather that it will not increase expansion. In this instance the test and control mixtures should be made with the same low alkali cement used in the control mixture to better delineate any increase in expansion. The fly ash or natural pozzolan percentage used may need to be sufficiently high to demonstrate that the percentage exceeds the pessimum if such pessimum exists for the combination.

X1.6 *Selection of the Low Alkali Control Cement*—The test procedure in this test method and requirements in Specification C 618 are designed to measure the relative effectiveness of the fly ash or natural pozzolan in reducing expansion due to alkali-silica reactions. The effectiveness is a function of both the alkali content of the cement used in the test mixture and the percentage of fly ash or natural pozzolan. The higher the alkali content of the test mixture cement and the lower the percentage of fly ash or natural pozzolan used, the more effective the fly ash or natural pozzolan. This test procedure and the 100 % criterion of Specification C 618 can be used as a guide to enhance field performance of job mixtures if it is assumed that use of the low alkali control cement will prevent excessive expansion in service with materials proposed for use in the job. This is the situation when the aggregates proposed for use contain rapidly reactive constituents but do not exceed 0.05 % expansion in three months or 0.10 % expansion in six months when tested with the control cement in Test Method C 227. In such instances the control cement used in this test method should have an alkali content as required to control the expansive reactions of the aggregates being used, for example in the 0.50 to 0.60 % range. See the appendix to Specification C 33.

X1.6.1 Certain reactive aggregates have been identified which produce deleterious expansion after many years of service when used with cements with equivalent alkali contents well below 0.60 %. Often these reactive aggregates do not produce expansions in Test Method C 227 exceeding those discussed in the appendix of Specification C 33 until a much later age, perhaps one or two years. In such instances the use of a control cement with an alkali content significantly less than 0.60 % is appropriate.

X2. COMMENTARY ON SECTION 34

X2.1 The test procedures in Section 34 are designed to evaluate the performance of particular fly ashes or natural pozzolans in contributing to the resistance or durability of concrete in a sulfate environment. Tests are made on mortars in accordance with Test Method C 1012.

X2.2 The control mixture should be made with a cement that by performance or definition (Specification C 150, Section 1.1) is expected to give satisfactory results for the anticipated level of sulfate exposure. ACI 201.2R recommends Type II cement when the sulfate content, expressed as SO_4, is 0.10 to 0.20 percent in soils or 150 to 1500 ppm in waters. ACI 201.2R recommends Type V cements when the sulfate content, expressed as SO_4, is 0.20 to 2.0 % in soils, or 1500 to 10 000 ppm in waters. The test mixtures for both procedures may be made with varying percentages of fly ash or natural pozzolan. Test mixtures can use cements with equal or higher or lower C_3A contents that might not have given satisfactory results when used alone.

X2.3 *Interpretation of Results*—The absolute expansion limits used in Procedure A make it difficult to ascertain how the addition of fly ash or natural pozzolan influences sulfate resistance. However, as referenced in Test Method C 1012, research has indicated that mortars meeting the expansion criteria will perform adequately. Under Procedure B, the fly ash or natural pozzolan will be considered to be able to contribute to sulfate resistance if the expansion of the test mixture does not exceed that of the control mixture at an exposure time of at least 6 months. It is recommended that the proportion of fly ash or natural pozzolan used in the test mixture be the same one proposed for use in the project ± 2 %, and that the C_3A content of the project cement be equal to, or less than, that which was used in the test mixtures. See Appendix X1, Technical Background, Test Method C 1012.

X2.4 *Selection of the Percentage of Fly Ash or Natural Pozzolan*—It may be necessary to make test mixtures with several percentages of fly ash or natural pozzolan to determine the amount necessary to obtain adequate resistance to different concentrations of sulfates. Percentages used in a project should be within 2 % of those that are successful in the test mixtures or should be between two percentages that are successful.

Designation: C 317/C 317M – 00 (Reapproved 2005)

Standard Specification for Gypsum Concrete[1]

This standard is issued under the fixed designation C 317/C 317M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers mill-mixed gypsum concrete, consisting essentially of calcined gypsum and suitable aggregate, requiring the addition of water only at the job site. Gypsum concrete is intended for use in the construction of poured-in-place roof decks or slabs. Two classes, based on the compressive strength and density, are covered.

1.2 The values stated in either inch-pound units or SI units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 28 Specification for Gypsum Plasters

C 35 Specification for Inorganic Aggregates for Use in Gypsum Plaster

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete

3. Terminology

3.1 Definitions of terms shall be in accordance with Terminology C 11.

4. Materials and Manufacture

4.1 Gypsum concrete shall consist of calcined gypsum to which is added aggregates, wood chips, or wood shavings in proportion to meet the applicable requirements of this specification.

4.2 *Calcined Gypsum*—Specification C 28.

4.3 *Aggregates*—Specification C 35.

4.4 *Wood Chips or Wood Shavings*, shall be dry wood, uniform and clean in appearance, passing a 1-in. [25-mm] sieve, and not more than 1/16 in. [1.5 mm] thick.

5. Physical Properties

5.1 *Setting Time*—Gypsum concrete shall set in not less than 20 min and not more than 90 min.

5.2 *Compressive Strength*—Gypsum concrete shall have the following compressive strength for the respective classes:

Class	Compressive Strength, min, psi [MPa]
A	500 [3.5]
B	1000 [7.0]

5.3 *Density*—Gypsum concrete, Class A, shall have a density of not more than 60 lb/ft^3[960 kg/m^3].

6. Sampling

6.1 Randomly select at least 1 % of the packages, but not less than five packages. Take samples from both the outer portion and the center of each package. Mix the samples so obtained to provide a composite sample of not less than 15 lb [6.5 kg]. Immediately place the sample in a clean, dry, airtight container for delivery to the laboratory.

7. Test Methods

7.1 Determine the physical properties of gypsum concrete in accordance with Test Methods C 472.

7.1.1 Determine the setting time by the Vicat method.

8. Inspection

8.1 Inspection of the gypsum concrete shall be agreed upon between the purchaser and the supplier as part of the purchase agreement.

9. Rejection

9.1 Rejection of gypsum concrete that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved May 1, 2005. Published June 2005. Originally approved in 1953. Last previous edition approved in 2000 as C 317 – 00.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

rejection shall contain a statement documenting how the gypsum concrete has failed to conform to the requirements of this specification.

10. Certification

10.1 When specified in the purchase agreement, a producer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

11. Packaging and Marking

11.1 Gypsum concrete shall be shipped dry and free of lumps.

11.2 When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

11.2.1 Name of the manufacturer or the seller,

11.2.2 Brand,

11.2.3 Description, and

11.2.4 Net and gross weight of the package.

12. Keywords

12.1 aggregates; calcined gypsum; gypsum; gypsum concrete

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 317/C 317M – 98, that may impact the use of this specification. (Approved August 10, 2000)

(*1*) The designation was changed to a dual inch-pound/SI standard.

(*2*) Paragraph 1.2 was revised to designate a dual inch-pound/SI standard.

(*3*) Paragraphs 4.4, 5.2, 5.3, and 6.1 were revised to reflect a metric conversion.

(*4*) All SI units were placed in brackets.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 318/C 318M – 00 (Reapproved 2005)

Standard Specification for Gypsum Formboard[1]

This standard is issued under the fixed designation C 318/C 318M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers the minimum requirements for gypsum formboard designed for use as a permanent form for poured-in-place reinforced gypsum concrete roof decks.

1.2 The values stated in either inch-pound units or SI (metric) are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be used independent of the other. Values from the two systems shall not be combined.

1.3 The text of this standard references notes which provide explanatory material. These notes shall not be considered requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 473 Test Methods for Physical Testing of Gypsum Panel Products

C 1264 Specification for Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling and Storage of Gypsum Board

G 21 Practice for Determining Resistance of Synthetic Polymeric Materials to Fungi

3. Terminology

3.1 *Definitions*—Definitions of terms used in this standard shall be in accordance with Terminology C 11.

4. Materials and Manufacture

4.1 Gypsum formboard shall consist of a noncombustible core, essentially gypsum, containing not more than 15 % by weight of fiber, either mineral or organic, synthetic or natural.

4.2 The face surface shall be specifically treated to resist fungus growth.

5. Physical Properties

5.1 Specimens shall be tested in accordance with Test Methods C 473.

NOTE 1—Since this product is laid between subpurlins without mechanical attachment, a nail pull requirement is not specified for this gypsum panel product.

5.1.1 Specimens shall be taken from the samples obtained in accordance with Specification C 1264.

5.1.2 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

	Bearing Edges Across Fiber of Surfacing, lbf [N]	Bearing Edges Parallel Fiber of Surfacing, Face, lbf [N]	Bearing Edges Parallel Fiber of Surfacing, Back, lbf [N]
Method A	160 [715]	60 [270]	40 [180]
Method B	157 [700]	56 [250]	36 [160]

5.1.3 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. (mm)	Humidified Deflection, Eighths of an in. (mm)
½ [12.7]	10 [32]

5.1.4 *Core, End, and Edge Hardness*—The specimens shall have an average hardness of 15 lbf [65 N] when tested by Method A and 11 lbf [50 N] when tested by Method B.

5.1.5 *Resistance to Fungi*—The specimens shall obtain a rating not more than 1 (one) when judged in accordance with Practice G 21, paragraph 9.3, (Observation for Visible Effects).

6. Dimensions and Tolerances

6.1 Specimens shall be taken from the samples obtained in accordance with Section 8.

6.2 Thickness, width, length, and end squareness shall be determined in accordance with Test Methods C 473.

6.2.1 *Thickness*—The nominal thickness shall be ½ in. [12.7 mm] with tolerances in the nominal thickness of ±1/64 in. [0.4 mm] with local variations of ±1/32 in. [0.8 mm] from the nominal thickness.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 Specifications and Test Methods for Gypsum Products.

Current edition approved May 1, 2005. Published June 2005. Originally approved in 1953. Last previous edition approved in 2000 as C 318/C 318M – 00.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

6.2.2 *Width*—The nominal width shall be 32 in. [813 mm] with a tolerance of ⅛ in. [3 mm] over the specified width, and ¼ in. [6 mm] under the specified width.

6.2.3 *Length*—The nominal length of gypsum formboard shall conform to the purlin spacing of multiples thereof, with tolerances of ±¼ in. [6 mm] from the nominal length.

6.2.4 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

6.3 *Edges and Ends*—The edges and ends shall be square (90 ± 10°), straight, and solid.

7. Finish and Appearance

7.1 The surfaces of gypsum formboard shall be true and free from imperfections that would render it unfit for use with or without decoration.

8. Sampling, Inspection, Rejection, Certification, Packaging and Package Marking, Shipping, Handling and Storage

8.1 The sampling, inspection, rejection, certification, packaging and package marking, shipping, handling and storage shall be conducted in accordance with Specification C 1264.

9. Keywords

9.1 gypsum; gypsum concrete; gypsum formboard; gypsum panel product; roof decks

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 318/C 318M – 96, that may impact the use of this specification. (Approved July 10, 2000)

(*1*) SI values in paragraphs 5.1.2 and 5.1.4 were rationalized to the nearest 5N.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Designation: C330/C330M – 09

Standard Specification for Lightweight Aggregates for Structural Concrete[1]

This standard is issued under the fixed designation C330/C330M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers lightweight aggregates intended for use in structural concrete in which prime considerations are reducing the density while maintaining the compressive strength of the concrete. Procedures covered in this specification are not intended for job control of concrete.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.2.1 With regard to other units of measure, the values stated in inch-pound units are to be regarded as standard.

1.3 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

NOTE 1—This specification is regarded as adequate to ensure satisfactory lightweight aggregates for most concrete. It is recognized that it may be either more or less restrictive than needed for some conditions and for special purposes, such as fire resistance, fill, and concrete constructions, the use of which is based on load tests rather than conventional design procedures.

2. Referenced Documents

C666/C666M Test Method for Resistance of Concrete to Rapid Freezing and Thawing

C702 Practice for Reducing Samples of Aggregate to Testing Size

D75 Practice for Sampling Aggregates

2.2 *ACI Standards:*

ACI 211.2 Standard Practices for Selecting Proportions for Structural Lightweight Concrete [3]

3. Aggregate Types

3.1 Two general types of lightweight aggregates are covered by this specification, as follows:

3.1.1 Aggregates prepared by expanding, pelletizing, or sintering products such as blast-furnace slag, clay, diatomite, fly ash, shale, or slate, and

3.1.2 Aggregates prepared by processing natural materials, such as pumice, scoria, or tuff.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.21 on Lightweight Aggregates and Concrete.

Current edition approved Dec. 15, 2009. Published February 2010. Originally approved in 1953. Last previous edition approved in 2005 as C330–05. DOI: 10.1520/C0330_C0330M-09.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

3.2 The aggregates shall be composed predominately of lightweight-cellular and granular inorganic material.

4. Chemical Composition

4.1 Lightweight aggregates shall not contain excessive amounts of deleterious substances, as determined by the following limits:

4.1.1 *Organic Impurities (Test Method C40)*—Lightweight aggregates that, upon being subjected to test for organic impurities, produce a color darker than the standard shall be rejected, unless it is demonstrated that the discoloration is due to small quantities of materials not harmful to the concrete.

4.1.2 *Staining (Test Method C641)*—An aggregate producing a stain index of 60 or higher shall be rejected when the deposited stain is found upon chemical analysis to contain an iron content, expressed as Fe_2O_3 equal to or greater than 1.5 mg/200 g of sample.

4.1.3 *Loss on Ignition (Test Methods C114)*—The loss on ignition of lightweight aggregates shall not exceed 5 %.

NOTE 2—Some aggregates may contain carbonates or water of hydration that contribute to loss on ignition but may not affect the quality of the product. Therefore, when evaluating an aggregate, consideration should be given to the material characteristics that cause the ignition loss.

5. Physical Properties

5.1 Lightweight aggregate under test shall meet the following requirements:

5.1.1 *Clay Lumps and Friable Particles*—The total amount of clay lumps and friable particles shall not exceed 2 % by dry mass.

5.1.2 *Grading*—The grading shall conform to the requirements shown in Table 1.

NOTE 3—The surfaces of pyro-processed lightweight aggregate particles finer than 75 µm (No. 200) sieves are not deleterious and may be moderately pozzolanic.

5.1.3 *Uniformity of Grading*—To ensure reasonable uniformity in the grading of successive shipments of lightweight aggregate, fineness modulus shall be determined on samples taken from shipments at intervals stipulated by the purchaser. If the fineness modulus of the aggregate in any shipment differs by more than 7 % from that of the sample submitted for acceptance tests, the aggregate in the shipment shall be rejected, unless the supplier demonstrates that it will produce concrete of the required characteristics.

5.1.4 *Loose Bulk Density (Test Method C29/C29M)*—The dry loose bulk density of lightweight aggregates shall conform to the requirements shown in Table 2 using a 14 L [½ cubic foot] measure.

5.1.5 *Uniformity of Loose Bulk Density*—The dry loose bulk density of lightweight aggregate shipments sampled and tested, shall not differ by more than 10 % from that of the sample submitted for acceptance tests, and shall not exceed the limits in Table 2.

5.1.6 *Density Factor*—When specified, the density factor shall be determined in accordance with 8.10.

5.2 Concrete specimens containing lightweight aggregate under test shall meet the following requirements:

5.2.1 *Compressive Strength (Test Method C39/C39M), Density (Test Method C567), and Splitting Tensile Strength (Test Method C496/C496M)* —Compressive strength and density shall be an average of three specimens and the splitting tensile strength shall be the average of eight specimens. It shall be possible to produce structural concrete using the lightweight aggregates under test, so that from the same batch of concrete one or more of the compressive strength requirements and splitting tensile strength requirements in Table 3 will be satisfied without exceeding the corresponding maximum density values.

NOTE 4—Intermediate values for strength and corresponding density values shall be established by interpolation. Materials that do not meet the minimum average splitting tensile strength requirement may be used provided the design is modified to compensate for the lower value.

5.2.2 *Natural Aggregates*— Natural aggregates, when used to replace part, or all, of the lightweight-aggregates shall comply with the applicable requirements of Specification C33. The test report shall record the proportion of all ingredients and the characteristics of the natural aggregates to ensure compliance with these minimum requirements.

5.2.3 *Drying Shrinkage*— The drying shrinkage of concrete specimens prepared, cured, and tested in accordance with 8.4 shall not exceed 0.07 %.

5.2.4 *Popouts*—Concrete specimens prepared in accordance with 8.4 and 8.5, and tested in accordance with Test Method C151 shall show no surface popouts.

5.2.5 *Resistance to Freezing and Thawing*—When required, the aggregate supplier shall demonstrate by test or proven field performance that the lightweight aggregate when used in

TABLE 1 Grading Requirements for Lightweight Aggregate for Structural Concrete

Nominal Size Designation	Percentages (Mass) Passing Sieves Having Square Openings									
	25.0 mm (1 in.)	19.0 mm (¾ in.)	12.5 mm (½ in.)	9.5 mm (⅜ in.)	4.75 mm (No. 4)	2.36 mm (No. 8)	1.18 mm (No. 16)	300 µm (No. 50)	150 µm (No. 100)	75 µm (No. 200)
Fine aggregate:

TABLE 2 Maximum Dry Loose Bulk Density Requirements of Lightweight Aggregates for Structural Concrete

Size Designation	Maximum Dry Loose Bulk Density kg/m³ [lb/ft³]
Fine aggregate	1120 [70]
Coarse aggregate	880 [55]
Combined fine and coarse aggregate	1040 [65]

TABLE 3 Compressive Strength and Splitting Tensile Strength Requirements

Calculated Equilibrium Density max, kg/m³ [lb/ft³]	Average 28-day Splitting Tensile Strength, min, MPa [psi]	Average 28-day Compressive Strength, min, MPa [psi]
All Lightweight Aggregate		
1760 [110]	2.2 [320]	28 [4000]
1680 [105]	2.1 [300]	21 [3000]
1600 [100]	2.0 [290]	17 [2500]
Combination of Normal Weight and Lightweight Aggregates		
1840 [115]	2.3 [330]	28 [4000]
1760 [110]	2.1 [310]	21 [3000]
1680 [105]	2.1 [300]	17 [2500]

concrete, had the necessary resistance to freezing and thawing to perform satisfactorily in its intended use.

6. Sampling

6.1 Sample lightweight aggregates in accordance with Practice D75.

6.2 Reduce sample to test sizes in accordance with Practice C702.

7. Number of Tests

7.1 *Tests on Aggregates*—One representative sample is required for each test for organic impurities, staining, loss on ignition, grading, bulk density, and clay lumps.

7.2 *Tests on Concrete*—At least three specimens are required for each of the following tests of concrete: compressive strength, shrinkage, density, resistance to freezing and thawing, and presence of popout materials. At least eight concrete specimens are required for splitting tensile strength tests.

8. Test Methods

8.1 *Compressive Strength (Test Method C39/C39M)*—Make test specimens in accordance with Practice C192/C192M and Practice C31/C31M. Unless otherwise specified, cure specimens in accordance with Practice C192/C192M or Practice C31/C31M, until the time of test. When specified, an alternative curing method is allowed. The alternative method shall be in accordance with Practice C192/C192M or the standard curing procedure in Practice C31/C31M for the first 7 days, after which the specimens shall be removed from moist curing and stored at 23 ± 2 °C [73.5 ± 3.5 °F] with a relative humidity of 50 ± 5 % until the time of test.

8.2 *Splitting Tensile Strength*—Make 152 by 305 mm [6 by 12 in.] cylindrical test specimens in accordance with Practice C192/C192M, cure, and test in accordance with Test Method C496/C496M.

8.3 *Density of Concrete (Test Method C567)*—Follow the procedures in Test Method C567.

8.4 *Shrinkage of Concrete (Test Method C157/C157M)*—Follow the procedures of Test Method C157/C157M with the following exceptions:

8.4.1 Prepare the concrete mixture using 335 kg of cement/m³ [564 lb/yd³], admixture (if any), and with an air content of 6 ± 1 %. Adjust the water content so as to produce a slump of 50 to 100 mm [2 to 4 in.]. Thoroughly consolidate the concrete in steel molds not smaller than 50 by 50 mm [2 by 2 in.] nor larger than 100 by 100 [4 by 4 in.] in cross section, and long enough to provide a 250 mm [10 in.] gauge length. The surface of the concrete shall be steel troweled.

8.4.2 *Curing*—To prevent evaporation of water from the unhardened concrete, cover the specimen with a nonabsorptive, nonreactive plate or sheet of tough, durable, impervious plastic or wet burlap. When wet burlap is used for covering, the burlap must be kept wet until the specimens are removed from the molds (see Note 5). Remove specimens from the molds not less than 20 nor more than 48 h after casting and store in a moist room maintained at 23 ± 2 °C [73.5 ± 3.5 °F] with a relative humidity of not less than 95 %. At the age of 7 days, remove the specimens from the moist room, measure for length, and store in a curing cabinet maintained at 37.8 ± 1.1 °C [100 ± 2 °F] with a relative humidity of 32 ± 2 %.

NOTE 5—Placing a sheet of plastic over the burlap will facilitate keeping it wet.

NOTE 6—The air immediately above a saturated solution of magnesium chloride ($MgCl_2$) at 37.8 °C [100 °F] is approximately 32 % relative humidity.

8.4.3 *Report*—After storage in the cabinet for 28 days, remove each specimen and within 15 s, determine its change in length to the nearest 0.01 % of the effective gauge length. Report the change in length as the drying shrinkage of the specimen; report the average drying shrinkage of the specimens as the drying shrinkage of the concrete.

8.5 *Test for Popout Materials*—Prepare concrete specimens for the test for popout materials as described in method for preparation of samples for shrinkage of concrete. Cure and autoclave the specimens in accordance with Test Method C151. Visually inspect the autoclaved specimens for the number of popouts that have developed on the surface. Report the number of popouts per specimen.

8.6 *Test for Freezing and Thawing*— Make freezing and thawing tests of concrete, when required, in accordance with Test Method C666/C666M, with the following modification to the section on Test Specimens and on Procedure. Unless otherwise specified, remove the lightweight aggregate concrete specimens from moist curing at an age of 14 days and allow to dry in air for another 14 days exposed to a relative humidity of 50 ± 5 % and a temperature of 23 ± 2 °C [73.5 ± 3.5 °F]. Then submerge the specimens in water for 24 hours, prior to the freezing and thawing test.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.7 *Grading (Test Method* C136*)*—Follow the procedures of Test Method C136, except that the mass of the test sample for fine aggregate shall be in accordance with Table 4. The test sample for coarse aggregate shall consist of 2830 cm^3 [0.1 ft^3] or more of the material used for the determination of bulk density. Mechanical sieving of aggregate shall be for 5 minutes.

8.8 *Bulk Density (Loose) (Test Method* C29/C29M*)*—The aggregate shall be tested in an oven dry condition utilizing the shoveling procedure.

TABLE 4 Mass of Sieve Test Sample for Fine Lightweight Aggregates

Nominal Bulk Density (Loose) of Aggregate		Mass of Test Sample, g
kg/m^3	lb/ft^3	
80–240	5–15	50
240–400	15–25	100
400–560	25–35	150
560–720	35–45	200
720–880	45–55	250
880– 1040	55–65	300
1040–1120	65–70	350

8.9 *Clay Lumps and Friable Particles in Aggregate*, shall be in accordance with Test Method C142.

8.10 *Density Factor*—Determine the Density ("Specific Gravity") Factor in accordance with ACI 211.2.

9. Rejection

9.1 Material that fails to conform to the requirements of this specification shall be subject to rejection. The reason for rejection shall be reported to the producer or supplier promptly and in writing.

10. Certification

10.1 When specified in the purchase order or contract, a producer's or supplier's certification shall be furnished to the purchaser that the material was sampled and tested in accordance with this specification and has been found to meet the requirements. When specified in the purchase order or contract, a report of the test results shall be furnished.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C330–05, that may impact the use of this specification. (Approved December 15, 2009)

(*1*) Revised 8.4.3.

(*2*) Moved the tabular information from 5.2.1 into new Table 3 and renumbered subsequent tables.

Designation: C 331 – 05

Standard Specification for Lightweight Aggregates for Concrete Masonry Units[1]

This standard is issued under the fixed designation C 331; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers lightweight aggregates intended for use in concrete masonry units when a prime consideration is to reduce the density of the units.

1.2 The values stated in SI units are to be regarded as the standard. The values shown in parentheses are for information purposes only.

1.3 The text of this specification references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 29/C 29M Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate

C 40 Test Method for Organic Impurities in Fine Aggregates for Concrete

C 114 Test Methods for Chemical Analysis of Hydraulic Cement

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 142 Test Method for Clay Lumps and Friable Particles in Aggregates

C 151 Test Method for Autoclave Expansion of Hydraulic Cement

C 157/C 157M Test Method for Length Change of Hardened Hydraulic-Cement Mortar and Concrete

C 641 Test Method for Iron Staining Materials in Lightweight Concrete Aggregates

C 702 Practice for Reducing Samples of Aggregate to Testing Size

C 1262 Test Method for Evaluating the Freeze-Thaw Durability of Manufactured Concrete Masonry Units and Related Concrete Units

D 75 Practice for Sampling Aggregates

3. Aggregate Types

3.1 Three general types of lightweight aggregates are covered by this specification, as follows:

3.1.1 Aggregates prepared by expanding, pelletizing, or sintering products such as blast-furnace slag, clay, diatomite, fly ash, shale, or slate, and

3.1.2 Aggregates prepared by processing natural materials, such as pumice, scoria, or tuff, and

3.1.3 Aggregates consisting of end products of coal or coke combustion.

3.2 The aggregates shall be composed predominately of lightweight-cellular and granular inorganic material.

4. Chemical Composition

4.1 Lightweight aggregates shall not contain excessive amounts of deleterious substances, as determined by the following limits:

4.1.1 *Organic Impurities (Test Method C 40)*—Lightweight aggregates subjected to the test for organic impurities that produce a color darker than the standard shall be rejected, unless it is demonstrated that the discoloration is due to small quantities of materials not harmful to the concrete.

4.1.2 *Staining (Test Method C 641)*—An aggregate producing a stain index of 60 or higher shall be rejected when the deposited stain is found upon chemical analysis to contain an iron content, expressed as Fe_2O_3 equal to or greater than 1.5 mg/200 g of sample.

4.1.3 *Loss on Ignition (Test Methods C 114)*—Loss on ignition of aggregates, consisting of end products of coal or coke combustion, shall not exceed 12 %. Loss on ignition of other aggregates shall not exceed 5 %.

NOTE 1—Some aggregates may contain carbonates or water of hydration that contribute to loss on ignition but may not affect the quality of the product. Therefore, when evaluating an aggregate, consideration should be given to the material characteristics that cause the ignition loss.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.21 on Lightweight Aggregates and Concrete.

Current edition approved Dec. 15, 2005. Published January 2006. Originally approved in 1953. Last previous edition approved in 2004 as C 331–04.

5. Physical Properties

5.1 Lightweight aggregate under test shall meet the following requirements:

5.1.1 *Clay Lumps and Friable Particles*— The amount of clay lumps and friable particles shall not exceed 2 % by dry mass.

5.1.2 *Grading*—Aggregate grading shall be by mutual agreement between interested parties. See Appendix X1 for aggregate grading guidance.

5.1.3 *Uniformity of Grading*—To ensure reasonable uniformity in the gradation of successive shipments of lightweight aggregate, fineness modulus shall be determined on samples taken from shipments at intervals stipulated by the purchaser. If the fineness modulus of the aggregate in any shipment differs by more than 7 % from that of the sample submitted for acceptance tests, the aggregate in the shipment shall be rejected, unless the supplier demonstrated that it will produce concrete of the required characteristics.

5.1.4 *Loose Bulk Density (Test Method C 29/C 29M)*—The loose bulk density of lightweight aggregates shall conform to the requirements in Table 1 using a 14 L (½ cubic foot) measure.

5.1.5 *Uniformity of Loose Bulk Density*— The dry loose bulk density of lightweight aggregate shipments sampled and tested shall not differ by more than ±50 kg/m^3 (3 lb/ft^3) or 7 %, whichever is greater, from that of the sample submitted for acceptance tests, and shall not exceed the limits in Table 1.

5.2 Concrete specimens containing lightweight aggregate under test shall meet the following requirements:

5.2.1 *Popouts*—Concrete specimens prepared and tested in accordance with 8.1 shall show no surface popouts.

5.2.2 *Resistance to Freezing and Thawing*— When required, the aggregate supplier shall demonstrate by test or proven field performance that the lightweight aggregate when used in manufactured concrete masonry units and related concrete units has the necessary resistance to freezing and thawing to perform satisfactorily in its intended use.

NOTE 2—Methods are available to evaluate the performance of manufactured concrete masonry products made with lightweight aggregates. For example, Test Method C 1262 includes procedures for evaluating manufactured concrete masonry units and related concrete units, but does not include criteria for determining compliance. Care should be used in evaluating the results of Test Method C 1262 or any other method since the results are affected by other characteristics of the concrete mixture in addition to the characteristics of the lightweight aggregate, including, but not limited to the following: cement content, cement type, admixtures, and water content.

TABLE 1 Maximum Bulk Density (Dry Loose) Requirements of Lightweight Aggregates for Concrete Masonry Units

Nominal Size Designation	Maximum Dry Loose Bulk Density kg/m^3(lb/ft^3)
Fine aggregate 4.75 mm (No. 4) to 0	1120 (70)
Coarse aggregate 9.5 to 2.36 mm (⅜ in. to No. 8)	880 (55)
Combined fine and coarse aggregate	1040 (65)

5.2.3 *Drying Shrinkage*—Drying shrinkage of concrete specimens prepared and tested in accordance with 8.6 shall not exceed 0.10 %.

6. Sampling

6.1 Sample lightweight aggregates in accordance with Practice D 75.

6.2 Reduce sample to test sizes in accordance with Practice C 702.

7. Number of Tests

7.1 *Tests on Aggregate*—One representative sample is required for each test for organic impurities, staining, clay lumps, loss on ignition, grading, and bulk density.

7.2 *Tests on Concrete Masonry Units*— Three specimens are required for the test for popout materials.

8. Test Methods

8.1 *Test for Popout Materials*—Obtain test specimens by one of the following methods: (*1*) Whole concrete masonry units, free of visible cracks or other structural defects; (*2*) Portions of concrete masonry units cut from whole units and having a surface area of at least 580 cm^2(90 in. ^{2}); (*3*) Specimens prepared as described in 8.6. Autoclave test specimens in accordance with Test Method C 151. Visually inspect the autoclaved specimens for the number of popouts that have developed on the surface and report the average number of popouts per specimen.

8.2 *Test for Resistance to Freezing and Thawing*—Make tests for resistance to freezing and thawing of manufactured concrete masonry units and related concrete units in accordance with Test Method C 1262.

8.3 *Grading*—Follow the procedures of Test Method C 136 except that the mass of the test sample for fine aggregate shall be in accordance with Table 2. The test sample for coarse aggregate shall consist of 2830 cm^3 (0.1 ft^3) or more of the material used for determination of bulk density. Mechanical sieving of aggregate shall be for 5 min.

8.4 *Bulk Density (Loose)* (Test Method C 29/C 29M)—The aggregate shall be tested in an oven-dry condition utilizing the shoveling procedure.

8.5 *Clay Lumps and Friable Particles in Aggregates*, shall be in accordance with Test Method C 142.

8.6 *Shrinkage of Concrete*, shall be in accordance with Test Method C 157/C 157M, with the following exceptions:

TABLE 2 Mass of Sieve Test Sample for Fine Lightweight Aggregates

Nominal Bulk Density (Loose) of Aggregate		Mass of Test Sample, g
kg/m^3	lb/ft^3	
80–240	5–15	50
240–400	15–25	100
400–560	25–35	150
560–720	35–45	200
720–880	45–55	250
880–1040	55–65	300
1040–1120	65–70	350

www.technobetar.ir

8.6.1 Prepare a concrete mix in the proportions of one part portland cement to six parts combined aggregates, measured by dry loose volume. Adjust the water content so as to produce a slump of 50 to 75 mm (2 to 3 in.) and thoroughly consolidate the concrete in steel molds 50 by 50 by 285 mm (2 by 2 by 11¼ in.). The surface of the concrete shall be steel-troweled.

8.6.2 Cure the test specimens in a moist condition for 7 days at a temperature of 23 ± 2 °C (73.5 ± 3.5 °F) and a relative humidity of not less than 95 %. Make the initial length measurements immediately after removal of specimens from moist storage. Store the specimens in an atmosphere of 23 ± 2 °C (73.5 ± 3.5 °F) and a relative humidity of 50 ± 5 % for the duration of the test. Make subsequent measurements at 28 and 100 days.

8.6.3 Calculate the difference in length of the specimens, when removed from moist storage at an age of 7 days and at the final measurement at the age of 100 days, to the nearest 0.01 % of the effective gage length, and report as the drying shrinkage of the specimen. Report the average drying shrinkage of the specimens tested as the drying shrinkage of the concrete.

9. Rejection

9.1 Material that fails to conform to the requirements of this specification shall be subject to rejection. The reason for rejection shall be reported to the producer or supplier promptly and in writing.

10. Certification

10.1 When specified in the purchase order or contract, a producer's or supplier's certification shall be furnished to the purchaser that the material was sampled and tested in accordance with this specification and has been found to meet the requirements. When specified in the purchase order or contract, a report of the test results shall be furnished.

APPENDIX

(Nonmandatory Information)

X1. AGGREGATE GRADING GUIDE FOR CONCRETE MASONRY UNITS WITH LOWER DENSITIES

X1.1 Concrete masonry units with lower densities are manufactured with lightweight aggregate, with a blend of lightweight aggregates, or a blend of lightweight and normal-weight aggregates. Because the aggregates being blended may come from several different sources, the proper combined aggregate grading (see Fig. X1.1 and Table X1.1) is important, and is one of the essential ingredients in producing quality concrete masonry units. The combined aggregate grading range shown optimizes the particle size distribution which, in turn, optimizes the quality of the CMU in the following ways:

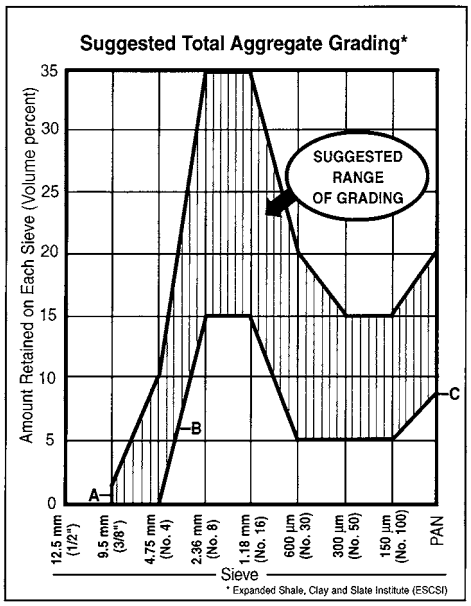

FIG. X1.1 Suggested Total Aggregate Grading

TABLE X1.1 Suggested Total Aggregate Grading

Sieve Size	Amount Retained On Each Sieve (Volume %) (see Fig. X1.1 and [A])
9.5 mm (⅜ in.)	0-2
4.75 mm (No. 4)	0-10
2.36 mm (No. 8)	15-35
1.18 mm (No. 16)	15-35
600 µm (No. 30)	5-20
300 µm (No. 50)	5-15
150 µm (No. 100)	5-15
Pan	8-20

[A] Volume % and mass % retained on each sieve are essentially equal when the particle density of the retained fractions are approximately the same. Volumetric analysis of particle sizes of blended aggregates composed of aggregates of different densities is accomplished by considering the proportions of each aggregate.

X1.1.1 Compactibility and high strengths are obtained without excessive amounts of cementitious materials.

X1.1.2 Shrinkage is reduced by maximizing aggregate packing.

X1.1.3 Water absorption and penetration are reduced because of improved compaction.

X1.1.4 Resistance to freezing and thawing is improved because better compaction results in fewer interconnected voids.

X1.2 Comments

X1.2.1 Keep particles retained on the 9.5 mm (⅜ in.) sieve to a minimum. ("0" is optimum.) (Refer to Letter "A" in Fig. X1.1.)

X1.2.2 A uniform, fine textured surface is controlled by limiting the material on 4.75 mm (No. 4) and 2.36 mm (No. 8) sieves. (Refer to Letter "B" in Fig. X1.1.)

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:11:52 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X1.2.3 A minimum of 8 % passing the 150 μm (No. 100) sieve is desirable for green strength, moldability and compaction. Less than 8 % is acceptable when using mixtures with high cementitious material content. (Refer to Letter "C" in Fig. X1.1.)

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 331–04, which may impact the use of this specification. (Approved December 15, 2005)

(*1*) Revised 5.1.4.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 331–03a, which may impact the use of this specification. (Approved January 1, 2004)

(*1*) Revised X1.1.
(*2*) Changed "Mass %" to "Volume %" in Fig. X1.1 and Table X1.1.
(*3*) Added footnote to Table X1.1.

Designation: C332 – 09

Standard Specification for Lightweight Aggregates for Insulating Concrete[1]

This standard is issued under the fixed designation C332; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers lightweight aggregates intended for use in concrete not exposed to the weather, in which the prime consideration is the thermal insulating property of the resulting concrete.

1.2 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.3 With regard to sieve size and the size of aggregate as determined by the use of testing sieves, the values in inch-pound units are shown for the convenience of the user; however, the standard sieve designation shown in parentheses is the standard value as stated in Specification E11.

1.3.1 With regard to other units of measure, the values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.4 The following precautionary caveat pertains only to the test method portion, Section 6, of the specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

E11 Specification for Woven Wire Test Sieve Cloth and Test Sieves

3. Classification

3.1 Two general types of lightweight aggregate are covered by this specification as follows:

3.1.1 *Group I*—Aggregates prepared by expanding products such as perlite or vermiculite.

NOTE 1—These aggregates generally produce concrete having a density from 15 to 50 lb/ft^3 (240 to 800 kg/m^3), the thermal conductivity of which may be expected to range from 0.45 to 1.50 Btu·in/h·ft^2·°F (0.065 to 0.22 W/m·K).

3.1.2 *Group II*—Aggregates prepared by expanding, calcining, or sintering products such as blast-furnace slag, clay, diatomite, fly ash, shale, or slate; and aggregates prepared by processing natural materials, such as pumice, scoria, or tuff.

NOTE 2—These aggregates generally produce concrete having a density from 45 to 90 lb/ft^3 (720 to 1440 kg/m^3), the thermal conductivity of which may be expected to range from 1.05 to 3.00 BTU·in/h·ft^2· °F (0.15 to 0.43 W/m·K).

3.2 The aggregate shall be composed predominantly of lightweight cellular and granular inorganic material.

4. Physical Properties

4.1 *Insulating Properties*—The thermal insulating properties of concrete made from the lightweight aggregate under test shall conform to the following limits:

Maximum Average 28-Day Oven-Dry Bulk Density, lb/ft^3 (kg/m^3)	Maximum Average Thermal Conductivity, Btu·in/h·ft^2·°F (W/m·K)
50 (800)	1.50 (0.22)
90 (1440)	3.00 (0.43)

4.2 *Grading*—The grading shall conform to the requirements shown in Table 1.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.21 on Lightweight Aggregates and Concrete.

Current edition approved Nov. 1, 2009. Published December 2009. Originally approved in 1954. Last previous edition approved in 2007 as C332 – 07. DOI: 10.1520/C0332-09.

TABLE 1 Grading Requirements for Lightweight Aggregates for Insulating Concrete

Nominal Size Designation	Percentages (Mass) Passing Sieves Having Square Openings								
	19.0-mm (¾-in.)	12.5-mm (½-in.)	9.5-mm (⅜-in.)	4.75-mm (No. 4)	2.36-mm (No. 8)	1.18-mm (No. 16)	600-µm (No. 30)	300-µm (No. 50)	150-µm (No. 100)
Group I									
Perlite	...	...	...	100	85 to 100	40 to 85	20 to 60	5 to 25	0 to 10
Vermiculite[A] (Coarse)	...	...	100	98 to 100	60 to 100	30 to 85	2 to 45	1 to 20	0 to 10
Vermiculite (Fine)	...	...	...	...	100	85 to 100	35 to 85	2 to 40	0 to 10
Group II									
Fine aggregate: 4.75-mm (No. 4) to 0	...	...	100	85 to 100	...	40 to 80	...	10 to 35	5 to 25
Coarse Aggregate: 12.5 to 4.75-mm (½-in. to No. 4)	100	90 to 100	40 to 80	0 to 20	0 to 10	...	...	...	...
9.5 to 2.36-mm (⅜-in. to No. 8)	...	100	80 to 100	5 to 40	0 to 20	...	...	...	...
4.75 to 2.36-mm (No. 4 to No. 8)	...	...	100	90 to 100	0 to 20	...	...	...	...
Combined Fine and Coarse Aggregate:									
12.5-mm (½-in.) to 0	100	95 to 100	...	50 to 80	...	...	...	5 to 20	2 to 15
9.5-mm (⅜-in.) to 0	... 100	90 to 100	65 to 90	35 to 65	...	...	10 to 25	5 to 15	

[A] Attention is directed to the need for adjustment in water content and air entrainment to achieve comparable oven-dry unit weights for the two gradings.

4.2.1 *Uniformity of Grading*—To ensure reasonable uniformity in the gradation of successive shipments of lightweight aggregates, fineness modulus determination shall be made periodically. If the fineness modulus of the aggregate differs by more than 7 % from that of the sample submitted for acceptance, the aggregate is subject to rejection, unless the supplier demonstrates that it will produce concrete of the required characteristics.

4.3 *Loose Bulk Density (Test Method C29/C29M)*—The dry loose bulk density of lightweight aggregates shall conform to the requirements shown in Table 2.

4.3.1 *Uniformity of Loose Bulk Density*—The dry loose bulk density of successive shipments of lightweight aggregates shall not differ by more than 10 % from that of the sample submitted for acceptance.

5. Sampling and Testing for Aggregate Properties

5.1 Sample lightweight aggregates and determine the properties enumerated in this specification in accordance with the following methods:

5.1.1 *Sampling*—Practice D75, except sample bagged materials by riffling and then quartering.

TABLE 2 Bulk Density Requirement for Lightweight Aggregates of Insulating Concrete

Size Designation	Dry Loose Bulk Density lb/ft³ (kg/m³)	
	Min	Max
Group I:		
Perlite	7.5 (120)	12 (196)
Vermiculite	5.5 (88)	10 (160)
Group II:		
Fine aggregate	...	70 (1120)
Coarse aggregate	...	55 (880)
Combined fine and coarse aggregate	...	65 (1040)

5.1.2 *Grading*—Method C136, except that when a mechanical sieving device is used, the sieving time shall be 5 min and the following modification shall apply:

5.1.2.1 *Fine aggregate*—The mass of the test sample shall be in accordance with the following table:

Nominal Density lb/ft³ (kg/m³)	Mass of Test Sample, g
5 to 15 (80 to 240)	50
15 to 25 (240 to 400)	100
25 to 35 (400 to 560)	150
35 to 45 (560 to 720)	200
45 to 55 (720 to 880)	250
55 to 65 (880 to 1040)	300
65 to 70 (1040 to 1120)	350

5.1.2.2 *Coarse Aggregate*—The sample shall be not less than 0.1 ft³ (2830 cm³) of the material obtained in making the bulk density determination.

5.1.3 *Loose Bulk Density*—Test Method C29/C29M utilizing the shoveling procedure described in Test Method C29/C29M, except test the aggregate in an oven-dry condition.

5.1.4 *Fineness Modulus*—Calculate as described in Test Method C136.

6. Test Methods for Insulating Concrete Properties

6.1 Determine the density and thermal conductivity of the concrete in accordance with the following methods:

6.1.1 *Specimen Preparation*—Prepare three specimens for each type of test, applying the same composition and fabrication procedure as is proposed for use. Moist-cure the specimens for 7 days and then remove them from the moist room and store at a temperature of 73.4 ± 3 °F (23 ± 1.7 °C) and at a relative humidity of 50 ± 5 % until the time of test. Dry the specimens at the age of 28 days in an oven at 230 ± 18 °F (110 ± 10 °C) and weigh them at 24-h intervals until the loss in mass does not exceed 1 % in a 24-h period.

6.1.2 *Concrete Density*—Determine the density from specimens each of which has a volume of not less than 0.1 ft³ (2 L).

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:11:54 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Determine the mass and dimensions of the oven-dry specimens and compute the volume and the density from the average data obtained.

6.1.3 *Thermal Conductivity*—Determine the thermal conductivity in accordance with Test Method C177, except prepare and cure the specimens in accordance with 6.1.1. The dimensions of the specimens shall be as required for the testing equipment available. Report the details of the composition and fabrication procedure used in preparing the specimens.

7. Rejection and Rehearing

7.1 Material that fails to conform to the requirements of this specification is subject to rejection. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the result of the test, the producer or supplier shall make claim for a rehearing.

7.2 The purchaser of materials covered by this specification shall have the option of evaluating these materials for rejection by either minimum mass or approximate volume as stated.

7.3 Individual packages are subject to rejection when:

7.3.1 The contents, on a mass basis, are 5 % less than that indicated on the package, or

7.3.2 The contents, on a volume basis, are 10 % less than that indicated on the package.

7.4 The entire shipment is subject to rejection.

7.4.1 On a mass basis when the average contents of two packages for each 100, but not less than 6 packages selected at random, in any one shipment, are less than that indicated on the package.

7.4.2 On a volume basis when the average contents of two packages for each 100, but not less than 6 packages selected at random, in any one shipment differ by more than 5 % from that indicated on the package.

7.5 The net mass of the contents shall be determined by weighing the package or packages and deducting the mass of the container.

7.6 The bulk volume of the contents in a package shall be calculated by determining the mass of the contents of the package and dividing by the bulk density of the aggregate. The bulk density of the aggregate shall be determined in accordance with the shoveling procedure given in Test Method C29/C29M using material from one or more of the packages selected in 7.4.2.

8. Certification

8.1 When specified in the purchase order or contract, a producer's or supplier's certification shall be furnished to the purchaser that the material was manufactured, sampled, tested, and inspected in accordance with this specification and has been found to meet the requirements. When specified in the purchase order or contract, a report of the test results shall be furnished.

9. Packaging and Package Marking

9.1 When lightweight aggregates covered by this specification are delivered in packages, the name of the manufacturer, type of aggregate, and minimum mass and approximate volume of the contents shall be plainly indicated thereon.

10. Keywords

10.1 insulating concrete; lightweight aggregate; thermal properties

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C332 – 07, that may impact the use of this specification. (Approved November 1, 2009)

(*1*) Revised 7.6.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 341/C 341M – 06

Standard Practice for Length Change of Cast, Drilled, or Sawed Specimens of Hydraulic-Cement Mortar and Concrete[1]

This standard is issued under the fixed designation C 341/C 341M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers the determination of the length changes of cast, drilled, or sawed specimens of hydraulic-cement mortar and concrete due to causes other than externally applied forces and temperature changes. It can be readily adapted, if desired, to studies of length change involving different schedules or environmental treatment than the standard procedures prescribed by this practice.

1.2 The values stated in either inch-pound units or SI units shall be regarded separately as standard. The units stated in each system may not be exact equivalents; therefore, each system must be used independently of the other, without combining in any way. The inch-pound units are shown in brackets.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

A 276 Specification for Stainless Steel Bars and Shapes

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 157/C 157M Test Method for Length Change of Hardened Hydraulic-Cement Mortar and Concrete

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 666/C 666M Test Method for Resistance of Concrete to Rapid Freezing and Thawing

3. Terminology

3.1 *Definition*

3.1.1 *length change, n*—an increase or decrease in a linear dimension of a test specimen, which has been caused to change by any factor other than externally applied forces and temperature changes.

4. Significance and Use

4.1 Measurements of length change permit assessment of the potential for volumetric expansion or contraction of cast, drilled, or sawed specimens of hydraulic-cement mortar, and concrete due to various causes other than externally applied forces and temperature changes. This practice is particularly useful for comparative evaluation of this potential in different mortar or concrete specimens.

5. Apparatus

5.1 *Length Comparator*—The length comparator shall generally conform to the requirements of Specification C 490, except that it shall be constructed to accommodate the specimens to be tested under this practice, which shall have gauge lengths of 75 mm [3 in.] or more.

5.1.1 *Gauge Studs in Ends of Specimens*—When the comparator is to be used to measure between gauge studs in the ends of specimens, the gauge length for computing percentage length change shall be considered to be the distance between the innermost ends of the gauge studs, and the contact terminals of the comparator shall be plane, polished, heat-treated surfaces as described in Specification C 490. Fig. 3 of Specification C 490 shows one type of comparator that has been found suitable for such specimens. A horizontal comparator is desirable for specimens that are considered too large to be handled by the type of comparator illustrated in Fig. 3 of Specification C 490.

5.1.2 *Gauge Studs on Sides of Specimen*—When the comparator is to be used to measure between gauge studs on the sides of specimens, the contact terminals shall be conical,

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.68 on Volume Change.

Current edition approved June 1, 2006. Published June 2006. Originally approved in 1954. Last previous edition approved in 2005 as C 341/C 341M – 05.

www.technobetar.ir

heat-treated surfaces as shown in Fig. 1, which illustrates a type of comparator that has been found satisfactory for this type of specimen. In this case, the gauge length shall be the distance between the reference points located in the exposed ends of the gauge studs (see 5.2).

5.2 *Gauge Studs*—Gauge studs shall be Type 316 stainless steel, meeting Specification A 276.

5.2.1 *For Ends of Specimens*—Gauge studs that are to be located in the ends of specimens shall have a rounded surface to provide point contact with the terminals of the comparator. The types of studs described in Specification C 490 are suitable for insertion in drilled holes. Spherical studs having a diameter of 6 to 10 mm [¼ to ⅜ in.], or studs that are sections of spheres of similar diameter, are suitable for cementing to the ends of specimens.

5.2.2 *For Sides of Specimens*—The exposed end of gauge studs that are to be located on the sides of specimens shall have a plane surface with a diameter or diagonal of 10 to 13 mm [⅜ to ½ in.]. For dry setting, the length of the stud shall be 13 to 16 mm [½ to ⅝ in.]. Shorter lengths of stud, including plane disks, shall be satisfactory for studs that are to be cemented.

5.3 *Drying Room and Controls*—A drying room and controls as described in Test Method C 157/C 157M shall be used for storing specimens in air.

6. Sampling

6.1 Samples of drilled or sawed hydraulic cement mortar or concrete shall be obtained in accordance with the section on Sampling of Test Method C 42/C 42M.

6.2 Samples of field cast hydraulic cement mortar or concrete shall be cast in accordance with Practice C 31/C 31M.

6.3 Constituent materials for concrete or mortar specimens made in the laboratory for use in this practice shall be sampled using applicable standard methods.

6.3.1 The specimens for use in this practice prepared from the constituent materials in the laboratory shall be cast prisms or cylinders made and cured in accordance with the applicable requirements of Practice C 192/C 192M and Practice C 490.

7. Test Specimens

7.1 Test specimen geometry shall be either cylindrical or rectangular prisms. Specimens shall be either cast from freshly mixed materials or drilled or sawn from existing concrete or mortar structures. Specimens shall be free from reinforcing steel, visible cracks, or other structural defects. They shall be of any size but specimens that are to be compared shall not differ in their cross-sectional dimensions by more than 10 % or in length by more than 20 % (Note 1). The gauge length shall be at least six times the maximum nominal size of the coarse aggregate but not less than 75 mm [3 in.], and that the minimum cross-sectional dimension be at least three times the maximum nominal size of the coarse aggregate but not less than 50 mm [2 in.]. When the gauge studs are to be located on the sides of the specimen, the over-all length of the specimen shall exceed the gauge length by at least 50 mm [2 in.].

NOTE 1—Specimens used for length change measurements during freeze thaw resistance testing as described in Test Method C 666/C 666M should follow the dimensional requirements of that method.

8. Setting Gauge Studs

8.1 Gauge studs shall either be cast in place, dry-set or cemented in drilled holes, or cemented directly to the surface of the specimen.

8.2 *Drilling Holes*—For gauge studs that are to be cemented, holes shall be drilled (Note 2) only slightly larger than the studs. For gauge studs that are to be dry-set, holes shall be drilled about 0.1 mm [0.005 in.] smaller in diameter than the studs. In the case of small specimens, take care that the

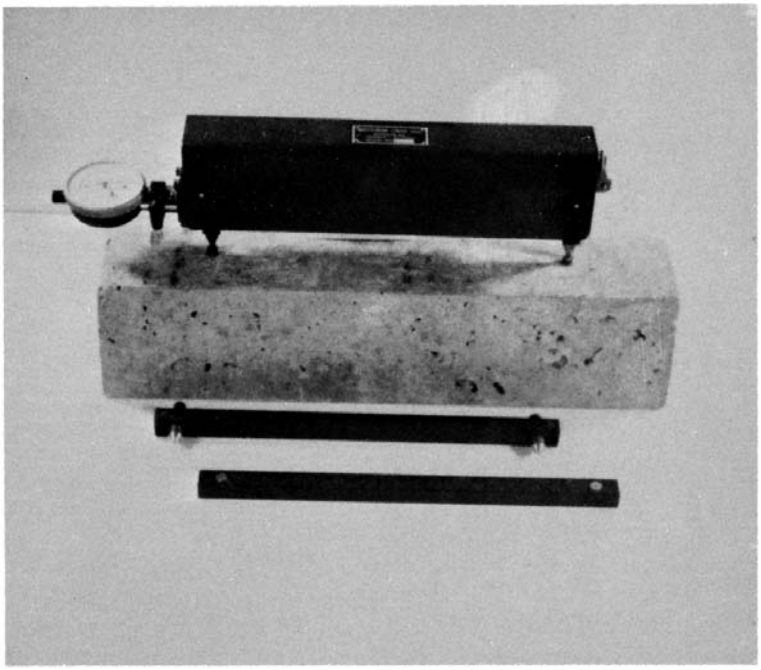

FIG. 1 Type of Suitable Extensometer for Measurement of Length Change of Specimens Having Gauge Studs on Sides

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

specimens are not damaged by the drilling operation. The location and depth of holes shall be as given in 8.2.1 and 8.2.2.

NOTE 2—Carbide-tipped masonry drills have been found most suitable for this purpose.

8.2.1 *For Gauge Studs in Ends of Specimen*—Drill holes in the ends of a specimen so that their longitudinal axes coincide with the longitudinal axis of the specimen. The depth of the holes shall be such that the gauge studs will project from 3 to 5 mm [⅛ in. to 3⁄16 in.] beyond the ends of the specimen.

8.2.2 *For Gauge Studs in Sides of Specimen*—Drill a pair of holes in each of two opposite sides of the specimen to compensate for warping and to provide a better average for length change. Position both pairs of holes in a plane containing the longitudinal axis of the specimen and space to conform to the length of the comparator. The center of each hole shall be at least 25 mm [1 in.] from the end of the specimen. The depth of the holes shall preferably be such that the top surfaces of the gauge studs can be set about 3 mm [0.1 in.] below the surface of the specimen.

8.3 *Cementing Methods*:

8.3.1 *Studs Set in Holes*—Position gauge studs in holes at the depth specified in 8.2.1 or 8.2.2, as appropriate, with the exposed end parallel to the surface of the specimen in the case of studs having plane end surfaces. The cementing material shall be stable and effective in either a wet or dry environment and at temperatures up to 120 °C [250 °F]. The following cementing materials have been found satisfactory:

8.3.1.1 *Epoxy Resin*—Epoxy resins for this purpose shall cure at room temperatures and not soften upon exposure to water immersion. Holes shall be free of loose particles and visually dry to ensure good bond.

8.3.1.2 *Portland-Cement Paste*—Use a thick paste of Type III Portland cement. Moisten each hole with about 5 mL of water, cement the studs in place after the water has been absorbed, and moist-cure the paste for approximately 24 h.

8.3.1.3 *Other Cementing Media*—Sulfur and Rose metal have also proven satisfactory.

8.3.2 *Studs Cemented to Surface*—An epoxy resin system that cures at room temperature and does not soften at a temperature of 120 °C [250 °F] or soften upon exposure to water immersion is the most satisfactory material for cementing studs to the surface of a specimen. To ensure good bond, it is essential that the surface be clean. Acid etching followed by flushing with water and drying is a satisfactory preparation of the surface for bonding. The locations of the studs on the specimen are the same as those prescribed for drilled holes in 8.2.1 and 8.2.2. The exposed end surface of each stud having a plane end surface shall be parallel to the surface of the specimen.

8.4 *Dry-Setting Method*—Drive the gauge studs to the depth specified in 8.2.1 or 8.2.2, as appropriate, into holes that are approximately 0.1 mm [0.005 in.] smaller in diameter than the gauge studs, being careful not to deform the exposed ends of the gauge studs during the driving operation.

8.5 *Reference Points on Gauge Studs*—On each gauge stud located on the side of a specimen, establish a reference point by drilling a hole approximately 1 mm in diameter (see Note 3) in the end of the stud to a depth sufficient to provide clearance between the bottom of the hole and the point of the comparator, as shown in Fig. 1. A template (Fig. 1) will aid in spacing the holes at proper gauge length, which shall be as nearly equal to the mean gauge length of the comparator as practicable. Remove burred edges from the reference point holes.

NOTE 3—A No. 56 American Standard Twist Drill or other bit suitable to drill a hole approximately 1 mm or 0.046 in. in diameter is suitable for this purpose.

9. Determination of Gauge Length of Specimens

9.1 Determine the gauge length of each specimen to an accuracy of 1 %. In the case of specimens having gauge studs on the sides, determine the gauge length by direct measurement between the reference points with a suitable scale. Determine the gauge length of specimens having gauge studs in the ends by first measuring the distance between the ends of the gauge studs with suitable calipers and subtracting the lengths of the two gauge studs.

10. Conditioning of Specimens for Measurement of Base Length

10.1 Prior to the initial measurement for length, condition specimens by immersion in lime-saturated water.

10.2 Maintain the temperature of the conditioning water at 23 ± 2 °C [73.5 ± 3.5 °F], except that during the last 1 h of immersion immediately before making any measurement for length maintain the temperature at 23.0 ± 0.5 °C [73.4 ± 1.0 °F] (Note 4). When measuring for length, remove the specimens from water one at a time, wipe with a damp cloth, and immediately measure for length using the comparator specified in 5.1. Make length measurements at 7-day intervals and continue conditioning until the change in length over a 7-day period is less than 0.001 %. Use the length measurement that determines that this criterion is met as the basis for calculating length change occurring during the air or water storage period.

NOTE 4—Specimens used for length change measurements during freeze thaw resistance testing as described in Test Method C 666/C 666M should follow the conditioning of that method.

11. Storage of Specimens

11.1 After measurement at the end of the conditioning period, store the specimens as described in either 11.2 or 11.3, unless another condition of storage is specified.

11.2 *Water Storage*—Immerse specimens in lime-saturated water at 23 ± 2 °C [73.5 ± 3.5 °F]. Take observations of the length of each specimen after 1, 2, 4, 8, 16, 32, and 64 weeks unless otherwise specified. Make these observations immediately after the specimens have been subjected to storage in water at 23.0 ± 0.5 °C [73.4 ± 1.0 °F] for a period of at least 1 h. When measuring for length, remove the specimens from water one at a time, wipe with a damp cloth, and immediately measure for length using the comparator specified in 5.1.

11.3 *Air Storage*—Store the specimens in circulating air maintained at a temperature of 23 ± 2 °C [73.5 ± 3.5 °F] and a relative humidity of 50 ± 4 % unless some other condition of storage is specified. See 5.3 for reference to a suitable drying room. The air movement past all specimens shall be such that the rate of evaporation is 77 ± 30 mL/24 h from the atmometer referenced in 5.3 or 13 ± 5 mL/24 h from a 400-mL Griffin

www.technobetar.ir

low-form beaker filled initially to 20 mm [¾ in.] from the top. Unless otherwise specified, measure specimens for length at weekly intervals and continue them in air storage until their change in length over a 7-day period is less than 0.001 %. Preferably, make these observations in a room maintained at a relative humidity of 50 ± 4 % while the specimens are at a temperature of 23 ± 2 °C [73.5 ± 3.5 °F].

12. Report

12.1 Report the following information:

12.1.1 Sources of specimen in terms of the structure and particular location in the structure from which the specimen was obtained,

12.1.2 Dimensions of the test specimen,

12.1.3 Maximum size and mineral character of aggregate in concrete,

12.1.4 Description of conditioning, either by indication that the type of conditioning outlined in Section 10 was followed, or by giving details of any procedure not conforming to that condition. In either case, give the total length of the conditioning period,

12.1.5 Description of the storage condition, either by indicating that the type of storage outlined in Section 11 was followed or by giving details of any procedure not conforming to that condition,

12.1.6 Total length of the period of storage, exclusive of the conditioning period, up to each length measurement,

12.1.7 Length change data, measured in accordance with the Procedure for Calculating Length Change in Test Method C 157/C 157M and typically reported to 0.001 %, except the gauge length is defined in terms of Section 9 above, based on the initial measurement made at the end of the conditioning period,

12.1.8 Any condition or characteristic of the concrete of interest to the study, and

12.1.9 Any other pertinent information.

13. Keywords

13.1 comparator; concrete; conditioning; length change; mortar

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 341/C 341M – 05, that may impact the use of this practice. (Approved June 1, 2006)

(*1*) Revised 8.3.2.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 341/C 341M – 03a, that may impact the use of this practice. (Approved May 1, 2005)

(*1*) Revised 8.3.1.1 and 8.3.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 348 – 08

Standard Test Method for Flexural Strength of Hydraulic-Cement Mortars[1]

This standard is issued under the fixed designation C 348; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the flexural strength of hydraulic-cement mortars.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and rounding given in Standard IEEE/ASTM SI 10, of measurements made in other units.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 230/C 230M Specification for Flow Table for Use in Tests of Hydraulic Cement

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 349 Test Method for Compressive Strength of Hydraulic-Cement Mortars (Using Portions of Prisms Broken in Flexure)

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 778 Specification for Standard Sand

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

C 1437 Test Method for Flow of Hydraulic Cement Mortar

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Summary of Test Method

3.1 The test mortar used consists of 1 part cement and 2.75 parts of sand proportion by mass. Portland or air-entraining portland cements are mixed at specified water-cement ratios. Water content of other cements is that sufficient to obtain a flow of 110 ± 5 % with 25 drops of the flow table. Test prisms, 40 by 40 by 160-mm are molded by tamping in two layers. Prisms are cured one day in the molds and stripped until tested by center point loading.

4. Significance and Use

4.1 This test method provides a means for determining the flexural strength of hydraulic cement mortars. Portions of the mortar prisms tested in flexure according to this test method may be used for the determination of compressive strength in accordance with Test Method C 349.

4.2 The values are determined from this test method for research or reference purposes only and are not used for determining compliance with specification requirements.

5. Apparatus

5.1 *Weights, Weighing Devices and Glass Graduates*, shall conform to the requirements of Specification C 1005. The balance shall be evaluated for precision and accuracy at 2000 g.

5.2 *Mixer, Bowl and Paddle*, an electrically driven mechanical mixer of the type equipped with paddle and mixing bowl, as specified in the Apparatus Section of Practice C 305.

5.3 *Flow Table and Flow Mold*, shall conform to Specification C 230/C 230M.

5.4 *Specimen Molds*—Molds for the 40 by 40 by 160-mm prism specimens shall be triple-gang molds and shall be so designed that the specimens will be molded with their longitudinal axes in a horizontal position. The molds shall be made of a hard metal, not attacked by cement mortar, and with a Rockwell hardness of not less than HRB 55. The parts of the

www.technobetar.ir

molds shall be matchmarked and, when assembled, shall be tight-fitting and positively held together. The sides of the molds shall be sufficiently rigid to prevent spreading or warping. The interior faces of the molds shall be plane surfaces with a permissible variation, in any 50-mm line on a surface, of 0.03 mm for new molds and 0.05 mm for molds in use. The distance between opposite sides shall be 40 ± 0.13 mm for new molds and 40 ± 0.3 mm for molds in use. The height of the molds shall be 40 mm with permissible variations of +0.25 and −0.15 mm for new molds, and +0.25 and −0.40 mm for molds in use. The inside length of the molds shall be 160 ± 2.5 mm. The angle between adjacent interior faces and top and bottom planes of the mold shall be 90 ± 0.5°, measured at points slightly removed from the intersections of the faces. The base plate shall be approximately 10 mm in thickness and shall have a plane surface 200 by 180 mm with a permissible variation in any 50-mm line on the surface of 0.03 mm.

5.5 *Tamper*—The tamper (see Fig. 1) shall be made of nonabsorptive, nonabrasive material, such as a rubber compound having a Shore A durometer hardness of 80 ± 10 or seasoned oak wood rendered nonabsorptive by immersion for 15 min in paraffin at approximately 200 °C. The face of the tamper shall be 22 by 85 mm.

5.6 *Tamper Guide*—The tamper guide (see Fig. 2), shall be made of metal (such as brass of Rockwell hardness not less than HRB 55) not attacked by the cement mortar. It shall lie flat on the mold and shall not protrude over any interior edge of the form more than 0.40 mm. The height of the guide shall be 25 mm.

5.7 *Trowel*—The trowel shall have a steel blade 115 by 250 mm in length, with straight edges.

5.8 *Flexure Testing Device*—The centerpoint loading method shall be used in making flexure tests on the prism specimens. The device used shall be designed such that the forces applied to the specimen will be vertical only and applied without eccentricity. A device that accomplishes this purpose, for use in a compression testing machine, is shown in Fig. 3. Apparatus for making flexure tests of mortar specimens shall be designed to incorporate the following principles:

5.8.1 The distance between supports and points of load application shall remain constant.

5.8.2 The load shall be applied normal to the loaded surface of the specimen and in such a manner as to avoid all eccentricity of loading.

5.8.3 The direction of the reactions should be parallel to the direction of the applied load at all times during the test.

5.8.4 The load should be applied at a uniform rate and in a manner to avoid shock.

5.9 *Compression Testing Machine*—The compression testing machine used with the flexure testing device, as shown in Fig. 3, shall be of the hydraulic type and conform to the requirements prescribed in Test Method C 109/C 109M.

NOTE 1—Most hydraulic compression machines designed for breaking 50-mm cubes have a relatively small diameter lower bearing surface directly centered below the upper spherically seated head, on which close-fitting pedestals of appropriate heights are set for breaking 50-mm cubes and 50 by 100-mm or 75 by 150-mm cylinders. The base plate of the flexure testing apparatus shown in Fig. 3 is designed to rest on the low pedestal intended for tests on 75 by 150-mm.

NOTE 2—In the absence of self-centering arrangements on machines with large lower bearing surfaces, the center of this surface directly below the center of the upper spherically seated head shall be accurately located. A circle or concentric circles of appropriate diameters shall be scribed on the lower bearing surface around this point. A cylindrical pedestal of appropriate diameter and height shall be obtained. End faces of the pedestal must be plane and parallel and at 90° to the axis of the cylinder. The upper face shall have a diameter of 77.5 mm.

6. Materials

6.1 *Graded Standard Sand*:

6.1.1 The sand used for making test specimens shall be natural silica sand and conform to Specification C 778.

7. Number of Specimens

7.1 Three or more specimens shall be made for each period of test specified.

8. Preparing Specimen Molds

8.1 Prepare the specimen molds as prescribed in Test Method C 109/C 109M.

9. Procedure

9.1 *Proportioning, Consistency, and Mixing of Mortars*—The proportioning, consistency, and mixing of the standard

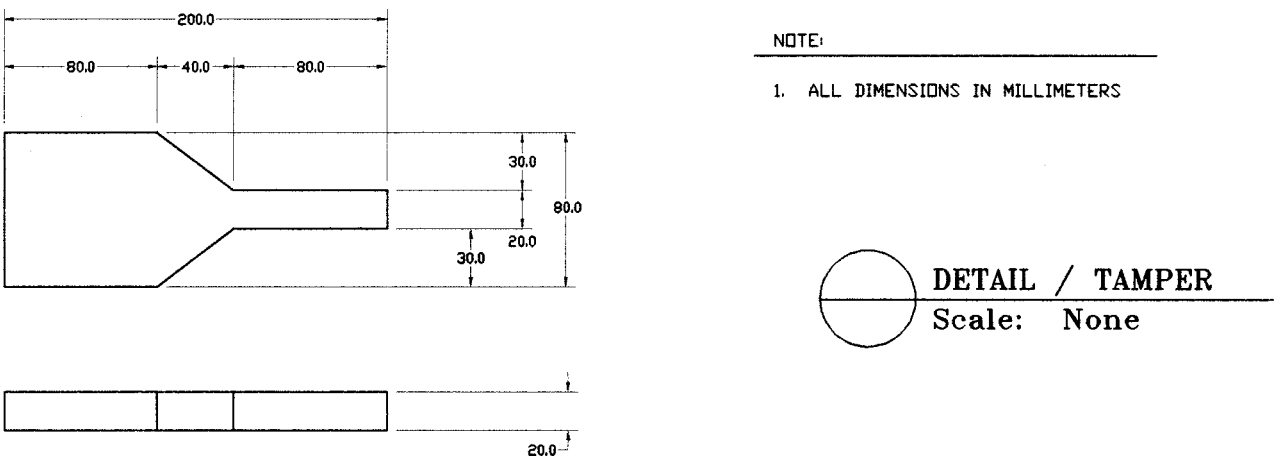

FIG. 1 Tamper

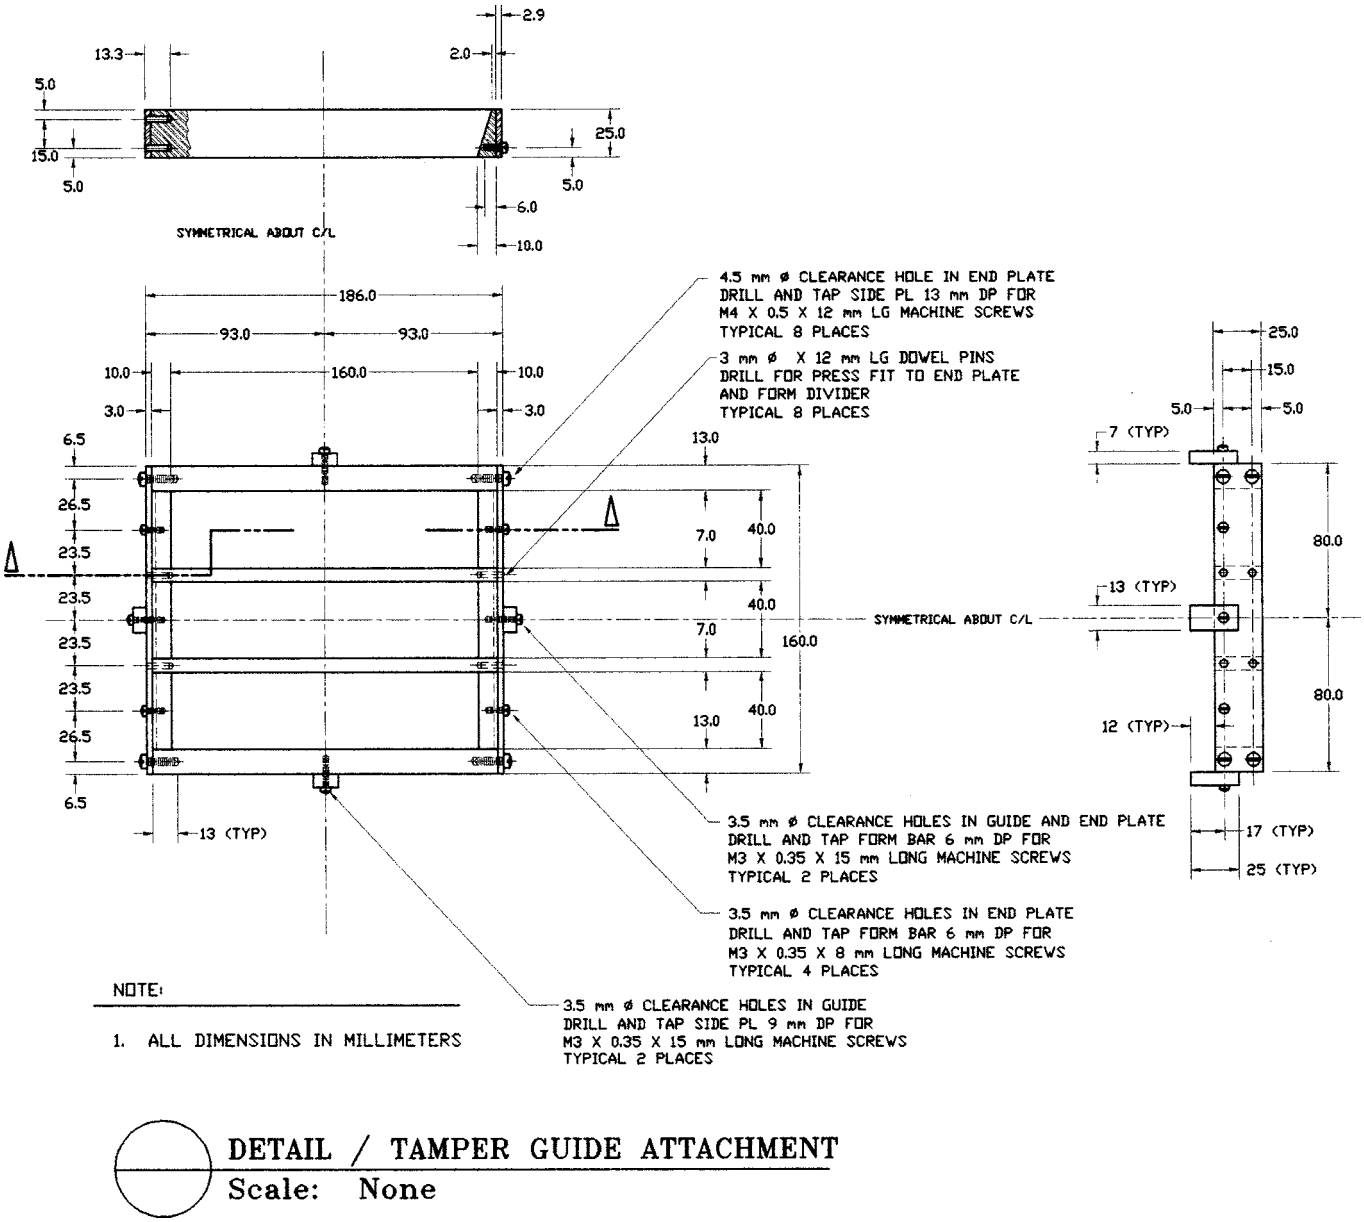

FIG. 2 Tamper Guide Attachment

mortar shall be in accordance with the Procedure Section of Test Method C 109/C 109M.

9.2 *Determination of Flow*—The flow shall be determined in accordance with Test Method C 1437.

9.3 *Molding Test Specimens*:

9.3.1 Immediately following completion of the flow test, return the mortar from the flow table to the mixing bowl. Quickly scrape down into the batch the mortar that may have collected on the side of the bowl and then remix the entire batch 15 s at medium speed. Upon completion of mixing, the mixing paddle shall be shaken to remove excess mortar into the mixing bowl.

9.3.2 When a duplicate batch is to be made immediately for additional specimens, the flow test may be omitted and the mortar allowed to remain in the mixing bowl for 90 s without covering. During the last 15 s of this interval, quickly scrape down into the batch the mortar that may have collected on the side of the bowl. Then remix for 15 s at medium speed.

9.3.3 Start molding the specimens within a total elapsed time of not more than 2 min and 30 s after completion of the original mixing of the mortar batch.

9.3.4 Evenly distribute a layer of mortar about 20 mm in thickness in each of the three molds with the tamper guide in place. Then compact the mortar in each mold by twelve strokes of the tamper, applied in three rounds of four strokes each, as shown in Fig. 4. Complete the twelve strokes in about 15 s. For each stroke hold the tamper face in horizontal position about 25 mm above the mortar level and then thrust directly downward with sufficient force to squeeze out a small amount of mortar from under the tamping surface. Fill the molds with mortar which shall be uniformly distributed and tamped in the same manner as the bottom layer. Then remove the tamper guide and

smooth off the specimens by drawing the flat side of the trowel (with the leading edge slightly raised) once along the length of the molds. Cut the mortar off flush with the top of the molds by the straight edge of the trowel (held nearly perpendicular to the molds) with a sawing motion over the length of the molds. Following the cutting operation repair tears or cracks in the top

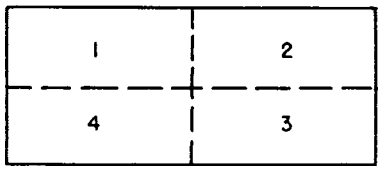

FIG. 4 Order of Tamping in Molding of Specimens (Three Rounds)

surfaces and then make the surfaces of the specimens plane by two or three light longitudinal strokes of the trowel held with the leading edge slightly raised.

9.4 *Storage of Test Specimens*—Store the test specimens in accordance with Test Method C 109/C 109M.

9.5 *Determination of Flexural Strength*:

9.5.1 Test the specimens immediately after their removal from the moist closet in the case of 24-h specimens and from the storage water in the case of all other specimens. All test specimens for a designated test age shall be broken within the permissible tolerance prescribed below:

Test Age	Permissible Tolerance, h
24 h	±½
3 days	±1
7 days	±3
28 days	±12

When the portions of prisms are tested as modified cubes in accordance with Test Method C 349, test the prisms early enough so that the modified cubes are also broken within the above tolerances. If more than one specimen at a time is removed from the moist closet for the 24-h test, cover these specimens with waterproof plastic until the time of test. For older specimens, if more than one specimen at a time is removed from the storage water for testing, place these specimens in water at a temperature of 23 ± 2.0 °C and of sufficient depth to completely immerse each specimen until time of test.

NOTE 3—The flexural strength of prisms is quickly affected by drying which produces skin tension in the specimens and yields low strengths. Specimens for test at 24 h should, therefore, be removed from molds preferably at that age and tested immediately. If there is a delay in testing, specimens shall be wrapped in waterproof plastic and placed in the moist closet until immediately before testing. After breaking, rewrap in plastic until compressive tests are made.

9.5.2 Wipe each prism to a surface-dry condition, and remove any loose sand grains or incrustations from the faces that will be in contact with the bearing surfaces of the points of support and load application. Check these faces by applying a straightedge. If there is appreciable curvature, grind the face or faces to plane surfaces or discard the specimen. Cloths used for wiping 24-h specimens shall be not more than faintly damp.

9.5.3 Center the pedestal on the base plate of the machine directly below the center of the upper spherical head, and place the bearing plate and support edge assembly on the pedestal. Attach the center-loading device to the spherical head. Turn the specimen on its side with respect to its position as molded and place it on the supports of the testing device. The longitudinal center line of the specimen shall be set directly above the midpoint of both supports. Adjust the center-point loading device so that its bearing edge is at exactly right angles to the length of the prism and parallel to its top face as placed, with the center of the bearing edge directly above the center line of the prism and at the center of the span length. Take care to ensure that contact between the specimen and loading edge is continuous when the load is applied. Apply the load at the rate of 2640 ± 110 N which shall be indicated within an accuracy of ±1 % on a dial graduated in increments of not more than 44 N. Estimate the total maximum load to the closest 22 N.

10. Calculation

10.1 Record the total maximum load indicated by the testing machine and calculate the flexural strength (for the particular size of specimen and conditions of test herein described) in MPa as follows:

$$S_f = 0.0028\,P \quad (1)$$

where:

S_f = flexural strength, MPa, and
P = total maximum load, N.

11. Faulty Specimens and Retests

11.1 Test specimens that are manifestly faulty or that result in strengths differing by more than 10 % from the average value of all test specimens made from the same sample and tested at the same period shall not be considered in determining the flexural strength. After discarding specimens or strength values, if less than two strength values are left for determining the flexural strength at any given period a retest shall be made.

12. Precision and Bias

12.1 *Precision*:

12.1.1 The following precision statements are applicable when a test result is the average of flexural strength tests of three prisms molded from a single batch of mortar and tested at the same age. They are applicable to mortars made with Type I, IA, IS, or III cement tested at 3, 7, or 28 days (1, 3, or 7 days for Type III cement).

12.1.1.1 *Multilaboratory Precision*—The multilaboratory coefficient of variation has been found to be 8.4 %. Therefore, results of properly conducted tests of single batches by two different laboratories should not differ by more than 23.8 % of their average.

NOTE 4—These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

12.1.1.2 *Single-Laboratory Precision*—The single-laboratory coefficient of variation has been found to be 5.1 %. Therefore, results of two properly conducted tests of single batches of mortar made with the same materials either on the same day or within the same week should not differ from each other by more than 14.4 % of their average (see Note 4).

12.2 *Bias*—No statement on bias is being made since there is no accepted reference material suitable for determining the bias of this test method.

13. Keywords

13.1 compressive strength; flexural strength; hydraulic-cement mortar; hydraulic-cement strength; mortar strength; strength

Designation: C 349 – 08

Standard Test Method for Compressive Strength of Hydraulic-Cement Mortars (Using Portions of Prisms Broken in Flexure)[1]

This standard is issued under the fixed designation C 349; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the compressive strength of hydraulic-cement mortars, using for the test specimens portions of prisms made and broken in flexure in accordance with Test Method C 348.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and rounding given in Standard IEEE/ASTM SI 10, of measurements made in other units.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. (***Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 348 Test Method for Flexural Strength of Hydraulic-Cement Mortars

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Significance and Use

3.1 This method provides a means of obtaining compressive strength values from the same specimens previously used for flexural strength determinations by Test Method C 348. The compressive strength values are for reference purposes, and not as substitutes for values obtained by Test Method C 109/C 109M for cement acceptance.

4. Apparatus

4.1 *Bearing Plates*—The bearing plates shall be not less than 25 mm in thickness and shall be made of a hard metal. The surfaces of the bearing plates that are placed in contact with the specimens shall be 40.0 ± 0.1-mm by 50.8-mm rectangles, with the 50.8-mm dimension at right angles to the longitudinal axis of the prism. The bearing plate surfaces in contact with the specimen shall have a Rockwell hardness of not less than 60 HRC. These surfaces shall not depart from plane surfaces by more than 0.01 mm when the plates are new and shall be maintained within a permissible variation of 0.03 mm.

4.2 *Device for Aligning Bearing Plates*—A device for aligning the bearing plates to ensure the proper location of the upper plate with reference to the lower plate is shown in Fig. 1. If the upper bearing plate does not have free movement within the aligning plates, these shall be separated from the bottom plate by insertion of 0.05-mm shims on each side of the bottom bearing plate, and the two 6-mm pins in the upper bearing plate filed down just sufficiently to permit free up and down movement in the slots at the top of the aligning plates.

4.3 *Testing Machine*—The testing machine shall conform to the requirements prescribed in Test Method C 109/C 109M, except that the testing machine shall be of the hydraulic type.

5. Test Specimens

5.1 Both portions from each prism broken in flexure shall be used for compression testing, except that the broken portions of prisms selected for the compression test shall have a length of

www.technobetar.ir

not less than 65 mm and shall be free of cracks, chipped surfaces, or other obvious defects.

6. Procedure

6.1 *Determination of Compressive Strength*—During the interval between flexure tests of the prisms and testing the broken portions as modified cubes, cover the specimens for the 24-h test with waterproof plastic and completely immerse all other specimens in water at a temperature of 23 ± 2.0 °C until the time of testing. Wipe the specimen to a surface-dry condition, and remove any sand grains or incrustations from the faces that will be in contact with the bearing plates of the testing apparatus. Check these faces by application of a straightedge. If there is appreciable curvature, grind the face or faces to plane surfaces or discard the specimen (Note 1). Center the pedestal usually provided for breaking 50 by 100-mm cylinders on the base bearing block of the machine, and center the bearing plate assembly on top of this pedestal. If the testing machine has no provisions for automatic accurate centering of a pedestal exactly below the center of its upper spherical bearing head, a hardened steel cylinder of suitable diameter and height and with parallel plane end faces may be used, provided that the bearing plate assembly is centered accurately below the center of the upper bearing head after the specimen has been placed in proper position in the bearing plate assembly. Apply the specimen aligning guide to the outside of one of the aligning plates of the bearing plate assembly, with the lugs at each end resting on or slightly above the edge of the bearing face of the bottom plate. Turn the specimen on its side with respect to its position as molded and place it in the device with the bottom as molded in contact with the aligning lugs, holding the aligning guide against the aligning plate firmly with one hand. Then remove the aligning guide without disturbing the position of the specimen and apply the load in accordance with the Procedure section of Test Method C 109/C 109M. The testing of the broken portions as modified cubes shall follow breaking in flexure within 10 min for 24-h specimens and within 30 min for all other specimens.

NOTE 1—*Modified Cube Faces*—Results much lower than the true strength will be obtained by loading faces of the modified cube that are not truly plane surfaces. It is essential, therefore, that molds be kept scrupulously clean, as otherwise large irregularities in the surfaces will occur. Instruments for cleaning molds should always be softer than the metal in the molds to prevent wear. In case grinding of modified cube faces is necessary, it can be accomplished best by rubbing the specimen on a sheet of fine emery paper or cloth glued to a plane surface, using only moderate pressure. Since such grinding is tedious for more than a few thousandths of an inch or hundredth of a millimetre, it is recommended that where more than this is found necessary, the specimen be discarded.

7. Calculation

7.1 Record the total maximum load indicated by the testing machine and calculate the compressive strength in megapascals to the nearest 0.1 MPa, as follows:

$$S_c = 0.00062\,P \quad (1)$$

where:

S_c = compressive strength, MPa, and
P = total maximum load, N.

8. Faulty Specimens and Retests

8.1 Specimens that are manifestly faulty or that result in strengths differing by more than 10 % from the average value of all test specimens made from the same sample and tested at the same period shall not be considered in determining the compressive strength. After discarding strength values, if less than two strength values are left for determining the compressive strength at any given period a retest shall be made.

NOTE 2—Reliable strength results depend upon careful observance of all of the specified requirements and procedures. Erratic results at a given test period indicate that some of the requirements and procedures have not been carefully observed; for example, those covering the testing of the modified cubes, as prescribed in Sections 5 and 6. Specimens exhibiting oblique fractures on breaking, due to improper centering in the compression machine or to lateral movement of one of the testing machine heads during loading, will often indicate lower strengths than specimens showing a normal pyramidal fracture.

9. Precision and Bias

9.1 *Precision*—The following precision statements are applicable when a test result is the average of compressive strength tests of six modified cubes (using portions of prisms broken in flexure) molded from a single batch of mortar and tested at the same age. They are applicable to mortars made with Type I, IA, IS, or III cement tested at 3, 7, or 28 days (1, 3, or 7 days for Type III cement).

9.1.1 *Multilaboratory Precision*—The multilaboratory coefficient of variation has been found to be 6.3 %. Therefore, results of properly conducted tests of single batches by two different laboratories should not differ by more than 17.8 % of their average (Note 3).

NOTE 3—These numbers represent, respectively, the (1s%) and (d2s%) limits as described in Practice C 670.

9.1.2 *Single-Laboratory Precision*—The single-laboratory coefficient of variation has been found to be 3.5 %. Therefore, results of two properly conducted tests of single batches of mortar made with the same materials either on the same day or within the same week should not differ from each other by more than 9.9 % of their average (Note 3).

9.2 *Bias*—The procedure in this test method has no bias because the value of compressive strength is defined in terms of the test method.

10. Keywords

10.1 compressive strength; hydraulic-cement mortar; hydraulic-cement strength; mortar strength; strength

Designation: C 359 – 08

Standard Test Method for Early Stiffening of Hydraulic Cement (Mortar Method)[1]

This standard is issued under the fixed designation C 359; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of early stiffening in hydraulic-cement mortar.

1.2 The values stated in SI units are to be regarded as standard. The values given in parentheses are mathematical conversions to inch-pound units that are provided for information only and are not considered standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 min. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.[2])

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

3. Terminology

3.1 *Definitions:*

3.1.1 *early stiffening*, *n*—the early development of stiffness in the working characteristics of a hydraulic-cement paste, mortar, or concrete; varieties include false set and flash set.

3.1.2 *false set*, *n*—the early development of stiffness in the working characteristics of a hydraulic-cement paste, mortar, or concrete without the evolution of much heat, which stiffness can be dispelled and plasticity regained by further mixing without addition of water; also known as "grab set," " premature stiffening," "hesitation set," and "rubber set."

3.1.3 *flash set*, *n*—the early development of stiffness in the working characteristics of a hydraulic-cement paste, mortar, or concrete, usually with the evolution of considerable heat, which stiffness cannot be dispelled nor can the plasticity be regained by further mixing without addition of water; also known as "quick set."

4. Summary of Test Method

4.1 A mortar is prepared with the cement to be tested, using specified quantities of cement, standard sand, and an amount of water that will produce a mortar with an initial penetration of 46 ± 3 mm, using the modified Vicat apparatus. Measurements of penetration are made at stipulated intervals after the beginning of the mixing procedure. Upon completion of the first series of penetration measurements, the mortar is returned to the mixer to be remixed. Following the remix procedure, an

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.30 on Time of Set.

Current edition approved June 1, 2008. Published June 2008. Originally approved in 1955. Last previous edition approved in 2007 as C 359 – 07.

www.technobetar.ir

additional penetration, termed the remix penetration, is determined. The report is a tabulation of the penetration measurements and the amount of mixing water used.

5. Significance and Use

5.1 The purpose of this test method is to determine the degree to which a cement mortar develops early stiffening. It is intended for use by those interested in methods for determining the potential early stiffening of hydraulic cement.

5.2 When used for estimating the relative tendency of a cement to manifest early stiffening, a judgment may be made by comparing the behavior in the penetration series (see 10.4.1 and 10.4.2) and the remix procedure (see 10.4.3) to differentiate a relatively less serious and less persistent tendency to early stiffening (false set) from one that is more persistent and, consequently, more serious (flash set).

5.3 Severe false setting in a cement may cause difficulty from a placing and handling standpoint, but it is not likely to cause difficulties where concrete is mixed for a longer time than usual, as usually occurs in transit mixing, or where it is remixed prior to placing or transporting, in concrete pumping operations. It is most likely noticed where concrete is mixed for a short period of time in stationary mixers and transported to the forms in non-agitating equipment, as on some paving jobs, and when concrete is made in an on-site batch plant.

5.4 Cements with severe false setting usually require slightly more mixing water to produce the same consistency, which may result in slightly lower strengths and increased drying shrinkage.

5.5 Early stiffening resulting from false set is not likely to cause a cement to fail the applicable time of setting requirement.

5.6 Early stiffening resulting from flash set, depending on severity, can cause a cement to fail the applicable time of setting requirement.

6. Apparatus

6.1 *Vicat Apparatus*, conforming to the requirements of Fig. 1 in Test Method C 187, with the following modifications:

6.1.1 The 1-mm needle shall be replaced by a mass, such that the total mass of the 10-mm plunger, indicator, and added mass shall be 400 ± 0.5 g.

6.2 *Spoon*, conforming to the requirements of Test Method C 185.

6.3 *Mixer, Bowl, Paddle, and Scraper*, conforming to the requirements of Practice C 305.

6.4 *Glass Graduates*, 200 or 250 mL capacity, conforming to the requirements of Specification C 1005.

6.5 *Masses and Mass Determining Devices*, conforming to the requirements of Specification C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

6.6 *Thermometer*, ASTM No. S12C or S12F, conforming to the requirements of Specification E 2251.

6.7 *Flat Trowel*, having a sharpened straight-edged steel blade 100 to 150 mm in length. The edges when placed on a plane surface shall not depart from straightness by more than 1 mm.

6.8 *Clock Timer*, having a readability to the nearest second.

6.9 *Containers*, approximately 50 by 50 by 150 mm (2 by 2 by 6 in.) inside dimensions (Fig. 1). These containers, which may be made of any suitable materials such as sheet metal or plastic, shall be rigid, watertight, and at least 50 mm (2 in.) deep.

7. Reagents and Materials

7.1 *Standard Sand, 20-30 and Graded*, conforming to the requirements of Specification C 778.

7.2 *Mixing Water*—Potable water is satisfactory for routine tests. For all referee and cooperative tests, reagent water conforming to the requirements of Specification D 1193 for Type III or Type IV grades of reagent water shall be used.

8. Sampling

8.1 When the test is part of acceptance testing, sample the cement in accordance with Practice C 183.

9. Conditioning

9.1 Maintain the temperature of the room, dry materials, paddle, bowl, and containers at 23.0 ± 3.0 °C.

9.2 The relative humidity of the mixing room shall not be less than 50 %.

10. Procedure

10.1 *Batch*—Mix at one time 600 g of cement, 300 g of graded standard sand, 300 g of 20-30 standard sand, and an amount of water that produces a mortar with an initial penetration of 46 ± 3 mm.

10.2 *Mixing of Mortar*—Mix in the mechanical mixer as follows:

10.2.1 Place the sand and cement in the dry bowl, and mix the dry materials for a few seconds with the spoon.

10.2.2 Place the bowl in the mixer, set the paddle in place, and mix the dry materials for 10 s at a slow speed (140 ± 5 r/min).

10.2.3 With the mixer operating at a slow speed (140 ± 5 r/min), add the entire quantity of mixing water within 5 s. Stop the mixer, quickly change to a medium speed (285 ± 10 r/min), and continue the mixing for 1 min, timing from the first addition of water.

10.2.4 Stop the mixer, scrape the sides of the mixing bowl with the rubber scraper, and quickly place the thermometer in the mortar. Allow it to stand undisturbed for the remainder of a 45-s interval from the time of stopping the mixer.

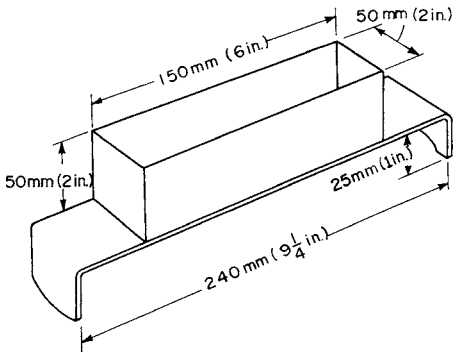

FIG. 1 Container for Early Stiffening Tests

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:12:02 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.2.5 Read the temperature, remove the thermometer, start the mixer, and mix for 15 s at a medium speed (285 ± 10 r/min). If the mortar temperature is not in the range from 23 ± 2.0 °C, discard the batch and adjust the temperature of the water or sand, or both, to give the required temperature.

10.3 *Filling Container*:

10.3.1 Immediately after completion of the mixing, remove the bowl from the mixer and with a spoon, uniformly distribute a portion of the mortar into the container until the container is heaping full. Quickly and gently place each spoonful of mortar in the container. When removing the mortar from the bowl, do not remove the material pushed up on the side of the bowl by the paddle. After the container has been filled, reassemble the mixer, cover the bowl with a lid, and retain the remaining mortar for a remix test to be performed later. To compact the mortar in the container, lift the container approximately 80 mm (3 in.) from the table with both hands and rap it twice against the surface of the table.

10.3.2 With the leading edge slightly raised, strike off the mortar with one stroke of the trowel along the length of the container. Then remove the excess mortar by means of a sawing motion with the straightedge of the trowel along the length of the container in a direction opposite to that used in striking off. Then, smooth the surface of the mortar with a single stroke of the trowel.

10.4 *Penetration Tests*:

10.4.1 After filling the container, immediately place the 10-mm plunger of the modified Vicat apparatus in contact with the surface of the mortar at the midpoint of the container on the longitudinal center line. Set the movable indicator at zero. Release the plunger 3 min after the beginning of the wet mixing and record, as the initial penetration, the depth in millimetres to which the plunger has settled below the surface 10 s after being released. If the plunger does not settle to a depth of 46 ± 3 mm, discard the batch and adjust the quantity of water to produce the required consistency.

10.4.2 Immediately withdraw and clean the plunger. In a similar manner, determine, after moving the Vicat apparatus to the desired location, the penetrations at intervals of 5, 8, and 11 min after the beginning of mixing. Do not move the filled container until these measurements are completed. Make all penetrations along the longitudinal center line of the container. Obtain 5 and 8-min penetrations at a distance of approximately 40 mm (1½ in.) from each end of the container, respectively, and determine the 11-min penetration at a point approximately midway between the points at which the initial and 5-min penetrations were determined.

10.4.3 At the completion of the measurement of the 11-min penetration, immediately return the mortar in the container to the bowl. Start the mixer, raise the bowl into mixing position, and remix the contents of the bowl at medium speed (285 ± 10 r/min) for 1 min. Fill a clean container as outlined in 10.3.1 and 10.3.2, and determine the penetration 45 s after completion of mixing.

11. Calculation

11.1 *Early Stiffening Amount*—The change in penetration from the initial penetration to the 11 min penetration.

11.1.1 Calculate as follows: A – D, where:

A = Initial Penetration
B = Penetration at 5 min
C = Penetration at 8 min
D = Penetration at 11 min
E = Penetration after REMIX

11.1.2 Report to the nearest mm.

11.2 *Average Early Stiffening Rate*—An average of the rate of penetration change between each set of measurements.

11.2.1 Calculate as follows:

$$\frac{\frac{A-B}{2}+\frac{B-C}{3}+\frac{C-D}{3}}{3}$$

where A,B,C,D are as defined in 11.1.1.

11.2.2 Report to the nearest 0.1 mm/min.

11.3 *Early Stiffening Recovery*—The percent penetration recovery accomplished with the REMIX procedure.

11.3.1 Calculate as follows:

$$100 * \frac{E}{A}$$

where E and A are as defined in 11.1.1. (See Note 2)

11.3.2 Report to the nearest percent.

12. Report

12.1 Report the measured and calculated values as shown below:

Mixing Water	___mL
Initial penetration	___mm
5-min penetration	___mm
8-min penetration	___mm
11-min penetration	___mm
Remix penetration	___mm
Early Stiffening Amount	___mm
Average Early Stiffening Rate	___mm/min
Early Stiffening Recovery	___%

13. Precision and Bias [4]

13.1 Early Stiffening Amount

13.1.1 The single-operator standard deviation has been found to be 1.8 mm over a range from 35 to 49 mm. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 5 mm. (See Note 3)

13.1.2 The multilaboratory standard deviation has been found to be 2.5 mm over a range from 35 to 49 mm. Therefore, results of two properly conducted tests from two different laboratories on samples of the same cement are not expected to differ by more than 7 mm. (See Note 3)

13.2 Average Early Stiffening Rate

13.2.1 The single-operator standard deviation has been found to be 0.50 mm/min over a range from 4.0 to 8.0 mm/min. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 1.4 mm/min. (See Note 3)

13.2.2 The multilaboratory standard deviation has been found to be 0.86 mm/min over a range from 4.0 to 8.0 mm/min. Therefore, results of two properly conducted tests from two

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C01-1008.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

different laboratories on samples of the same cement are not expected to differ by more than 2.4 mm/min. (See Note 3)

13.3 Early Stiffening Recovery

13.3.1 The single-operator standard deviation has been found to be 6.6 % over a range from 40 to 100+ %. (See Note 2) Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 19 %. (See Note 3)

13.3.2 The multilaboratory standard deviation has been found to be 16.8 % over a range from 40 to 100+ %. (See Note 2) Therefore, results of two properly conducted tests from two different laboratories on samples of the same cement are not expected to differ by more than 48 %. (See Note 3)

13.4 Bias

13.4.1 Since an acceptable reference material suitable for determining any bias of the method does not exist, no statement on bias is being made.

NOTE 1—For additional useful information on details of cement test methods, reference may be made to the "Manual of Cement Testing," which appears in the *Annual Book of ASTM Standards*, Vol 04.01.

NOTE 2—Since it is possible for the remix penetration to exceed the initial penetration, this number may exceed 100 %.

NOTE 3—These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670.

14. Keywords

14.1 early stiffening; false set; flash set; hydraulic-cement mortar

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 359 – 07, that may impact the use of this test method. (Approved June 1, 2008)

(*1*) Revised 6.5, 6.7, and 9.2.

Committee C01 has identified the location of selected changes to this test method since the last issue, C 359 – 06, that may impact the use of this test method. (Approved June 1, 2007)

(*1*) Revised 6.6.

Designation: C 387/C 387M – 09

Standard Specification for Packaged, Dry, Combined Materials for Mortar and Concrete[1]

This standard is issued under the fixed designation C 387/C 387M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the production, properties, packaging, and testing of packaged, dry, combined materials for concrete and mortars. The classifications of concrete and mortar covered are defined in Section 3.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 The following safety hazards caveat pertains only to the test method portion of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

E 96/E 96M Test Methods for Water Vapor Transmission of Materials

3. Terminology

3.1 *Definitions*—For definitions of terms used in this specification, refer to Terminology C 125.

3.2 Definitions of Terms Specific to This Standard:

3.2.1 *concrete, high-early strength*, *n*—in packaged, dry, combined materials, a product for building and repair requiring a more rapid than normal strength development such as required for the earlier removal of forms.

3.2.2 *concrete, normal strength* , *n*—in packaged, dry, combined materials, a product for general building and repair where thickness exceeds 50 mm [2 in.].

3.2.2.1 *Discussion*—Typical uses include building or repairing sidewalks, patios, steps, footings, and for setting posts.

3.2.3 *concrete, normal strength, lightweight*, *n*—in packaged, dry, combined materials, a concrete product for building and repair where the lightest concrete density is desirable.

3.2.3.1 *Discussion*—These mixtures will produce concrete that is about 25 to 35 % lower in density than normal weight concrete.

3.2.4 *concrete, normal strength, lightweight using normal weight sand*, *n*—in packaged, dry, combined materials, a concrete product for building and repair where a lower density is desirable.

3.2.4.1 *Discussion*—These mixtures will produce concrete that is about 15 to 25 % lower in density than normal weight concrete.

3.2.5 *mortar for unit masonry*, *n*—in packaged, dry, combined materials, a packaged mortar for laying brick, block, and stone, and for masonry repairs.

3.2.5.1 *Discussion*—These products are packaged versions of the masonry mortars that are specified in Specification C 270.

3.2.6 *mortar, high-strength* , *n*—in packaged, dry, combined materials, a product for building or repair requiring a thickness of less than 50 mm [2 in.], or where a high strength mortar mixture is required.

3.2.6.1 *Discussion*—Typical uses include topping and patching existing concrete structures. Often referred to as "sand mix."

4. Ordering Information

4.1 The purchaser shall specify the material desired as concrete, high strength mortar, or mortar for use with unit masonry, and the respective physical requirements as specified in Table 1 shall govern.

5. Materials

5.1 Materials used as ingredients in packaged, dry, combined materials for mortar and concrete shall conform to at least one of the following requirements:

5.1.1 *Aggregates*, shall conform to Specification C 33, Specification C 144, or Specification C 330.

5.1.2 *Air-Entraining Admixtures*, shall conform to Specification C 260.

5.1.3 *Blended Cement*, shall conform to Specification C 595 or Performance Specification C 1157.

5.1.4 *Chemical Admixtures*, shall conform to Specification C 494/C 494M.

5.1.5 *Flyash*, shall conform to Specification C 618.

5.1.6 *Ground Granulated Blast-Furnace Slag*, shall conform to Specification C 989.

5.1.7 *Hydrated Lime*, shall conform to Type S or Type SA of Specification C 207.

5.1.8 *Latex and Powder Polymer Modifiers*, shall conform to Specification C 1438.

NOTE 1—Type II latex polymers should not be used in applications that may be more than superficially wet in service.

5.1.9 *Masonry Cement*, shall conform to Specification C 91.

5.1.10 *Mortar Cement*, shall conform to Specification C 1329.

5.1.11 *Portland Cement*, shall conform to Type I, IA, II, IIA, III or IIIA of Specification C 150.

5.1.12 *Silica Fume*, shall conform to Specification C 1240.

6. Preparation of Aggregate

6.1 All aggregates prepared in the laboratory for the purpose of establishing the correct proportions for the product shall be dried, without disintegration, to a moisture content of less than 0.1 % by mass. Verify moisture content using a ventilated oven in accordance with Test Method C 566.

TABLE 1 Physical Requirements

Kind of Material	Compressive Strength, MPa [psi] min		
	3 days	7 days	28 days
Concrete:			
High-early strength	17.0 [2500]	24.0 [3500]	. . .
Normal strength:			
Normal weight	. . .	17.0 [2500]	24.0 [3500]
Lightweight using normal weight sand[A]	. . .	17.0 [2500]	24.0 [3500]
Lightweight	. . .	17.0 [2500]	24.0 [3500]
Mortar:			
High-strength mortar		20.0 [3000]	35.0 [5000]
Mortar for unit masonry:			
Type M		Shall comply with property requirements of Specification C 270[B]	
Type S			
Type N			

[A] Lightweight concrete using normal weight sand may contain some portion of lightweight fines.

[B] The performance requirements for 28-day compressive strength, water retention, and air content are those for mortars made from masonry cement unless otherwise specified. Manufacturers wishing to comply with the air content requirements for mortar-cement mortar or cement-lime mortar must specify the ingredients used and comply with the applicable portions of Specification C 270.

www.technobetar.ir

7. Proportioning

7.1 The proportions of cementitious material and aggregate shall be such that the strength requirements will be met when an amount of mixing water is used that produces for concrete the slump specified in 13.3 and for mortar the flow specified in 15.2.

8. Physical Properties

8.1 Packaged, dry, combined materials for concrete, high strength mortar, and mortar for use with unit masonry shall conform to the respective physical requirements as given in Table 1 for the material specified when the prescribed amount of water is added.

9. Packaging and Package Marking

9.1 All packages shall be identified as conforming to Specification C 387, and as to kind and type of material listed in Table 1 and the net mass in each bag printed thereon.

9.2 The yield in liters (or cubic feet), and the amount of water recommended for mixing shall be marked on the package.

NOTE 2—The amount of water recommended should be the amount required to produce a slump of 50 to 75 mm [2 to 3 in.].

9.3 *Container Construction*—The material from which the containers are made shall have water vapor transmission not greater than 100 g/m^2 in 24 h as determined in accordance with Procedure B of Test Methods E 96. The strength of the container shall be adequate for the mass of concrete or mortar it is intended to contain.

10. Rejection

10.1 The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the Producer or supplier promptly and in writing.

SAMPLING AND TESTING

11. Accuracy of Measurement

11.1 Use scales conforming to the applicable sections of *Handbook 44*.[3] New and reconditioned scales shall be accurate to ±0.1 % of the total capacity of the scale. When scales have been in use, they shall be accurate to ±0.4 % of the total capacity of the scale.

11.2 Record the mass of concrete in kilograms (pounds) to a minimum accuracy of 0.05 kg [0.1 lb.]. Record the mass of mortar in grams to an accuracy of within 1 g or 0.1 %, whichever is greater.

12. Sampling Concrete

12.1 Use a sufficient quantity of whole packages to conduct all testing from a single batch.

13. Mixing and Testing Concrete

13.1 Determine the net mass of concrete in the package (or packages), then empty into a clean, watertight container.

13.2 Mix the concrete, determine the properties of the fresh concrete, and mold and cure the specimens in accordance with the applicable provisions of Practice C 192/C 192M, or modifications of them as outlined herein. Test the strength of the concrete in accordance with Test Method C 39/C 39M.

13.3 Mix the entire sample of the combined, dry material for concrete either by hand or by machine, except that hand mixing is not applicable to air-entrained concrete. Add mixing water in sufficient amount to produce a slump of 50 to 75 mm [2 to 3 in.].

13.4 Use a watertight, clean metal container for hand mixing, using either a blunted bricklayer's trowel, hands protected by rubber gloves, or a shovel, whichever is more convenient. Mix the dry batch until the materials appear to be uniformly distributed. Add water while mixing until the concrete is homogeneous in appearance and has the desired slump. If prolonged mixing is required because of the addition of mixing water in increments while adjusting the slump, the batch must be discarded and a new batch made without interrupting the mixing to make trial slump tests.

13.5 Place all materials in the mixer to be used for machine mixing. A mixing period of 3 min followed by a 3-min rest, followed by 2-min final mixing is suggested, unless a different procedure is better adapted to the mixer being used. Cover the open end of the mixer during the rest period to reduce evaporation. Test the slump in accordance with Test Method C 143/C 143M upon completion of the mixing. If the slump test of the mixed batch shows that additional water is required, return the sample used for the slump test promptly to the mixer, add additional water, and remix the batch for 2 min. Retest the slump. If the slump is not from 50 to 75 mm [2 to 3 in.], discard the batch.

13.6 Discharge the mixed batch into a clean, watertight container that has been predampened, then remix the batch by hand, using a scoop or trowel, until the batch appears to be uniform. Promptly determine the density in kilograms per cubic meter (or pound per cubic foot) in accordance with Test Method C 138/C 138M. Return samples used for the slump and unit weight test to the container, then remix the batch by hand and mold the specimens.

13.7 Mold six cylinders from each batch, using three cylinders for test at 7 days and three at 28 days, except that in the case of high early strength concrete, three cylinders shall be tested at 3 days and three at 7 days. Compression test specimens shall be cylindrical with a length equal to twice the diameter. The minimum specimen diameter shall be 75 mm [3 in.], but the maximum diameter is not limited, provided the number of specimens for a test as required in this section are molded from a single batch and the sample taken in accordance with 12.1. For acceptance, the average of the strengths of the three specimens tested at each age shall not be less than the

[3] *Specifications, Tolerances, and Other Technical Requirements of Weighing and Measuring Devices, Handbook 44,* National Bureau of Standards.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

compressive strength required in Table 1 for the type of concrete under test and no individual specimen shall have a strength less than 90 % of the required strength.

13.8 The report of the tests of the concrete shall include the following:

13.8.1 Net mass of dry, combined material in the bag or bags determined by subtracting the mass of the empty bag or bags from the gross mass of the package.

13.8.2 Amount of mixing water (*W*) calculated in terms of kilograms (or pounds) per bag, based on mass of the bag.

$$W=(W_b/A)B$$

W_b = mass of water added to batch,
A = mass of dry material in batch, and
B = printed mass of bag contents.

13.8.3 Slump in millimetres (or inches) in accordance with Test Method C 143/C 143M.

13.8.4 Density (*D*) in kilograms per cubic meter (or pounds per cubic foot) in accordance with Test Method C 138/C 138M.

13.8.5 Yield (*Y*) of concrete as determined by Test Method C 138/C 138M in terms of liters (or cubic feet) per bag, based on printed mass of bag contents.

13.8.6 Air content, if required, shall be determined by one of the following Test Methods: C 138/C 138M, C 173/C 173M, (suggested for lightweight concrete); or C 231. The method used to determine the air content shall be reported.

13.8.7 Compressive strength at the ages specified in Table 1; report the method of mixing the concrete. State the size of the cylinder used in the report.

14. Sampling Mortar

14.1 The contents of an entire package of dry, combined material for mortar for unit masonry or for concrete mortar shall be used as a sample. Determine the gross mass of the package and contents to the nearest 0.05 kg [0.1 lb.]. Empty the entire contents of the package into a clean, watertight container. Determine the mass of the empty package and calculate the net mass of the package from the gross mass of the package and contents. Reduce the sample to the proper size for testing in accordance with Practice C 702.

15. Mixing and Testing Mortar

15.1 Mortar mixing equipment shall be as specified in Practice C 305, except that the mixer must be provided with a bowl positioning adapter (Note 3) to ensure clearance for the largest size aggregate in the mix being tested. The mixing procedure shall be modified as given in 15.2.

NOTE 3—Description of such an adapter may be obtained from the Cement and Concrete Reference Laboratory of the National Institute of Standards Technology.

15.2 Mix 3000 ± 3 g [6.61 ± 0.01 lbs.] of mortar in accordance with Practice C 305 with the exception that the combined material is added at the time of cement addition in Practice C 305. Additional water may be added in the final mix period to adjust the flow. Determine the flow in accordance with Test Method C 1437. Use sufficient water to produce a flow of 110 ± 5 %.

15.3 *Compressive Strength*—Specimens shall be 50-mm [2-in.] cubes molded, cured, and tested in accordance with procedures in Specification C 270 for mortars for unit masonry and in accordance with Test Method C 109/C 109M for high-strength mortars.

15.4 *Density and Yield*—Determination of density of the mixed mortar and yield per package of mortar.

15.4.1 Vigorously remix the remaining mortar by hand for 10 s using a spoon. Consolidate the mortar into a 400-mL measure in accordance with Test Method C 185.

15.4.2 Determine the net mass (M) of the mortar in the 400-mL measure to the nearest 1 g.

15.4.3 Calculate the density of the mortar in kilograms per cubic metre (or pounds per cubic foot) using the equations:

$$D_k = 2.5M \text{ or } (D_p = 0.156M) \quad (1)$$

where:
D_k = density in kilograms per cubic metre
D_p = density in pounds per cubic foot

15.4.4 Calculate the yield (Y) per package in litres (cubic feet) as follows:

$$Y = (1 + R)PC/D \quad (2)$$

where:
R = ratio of mass (or weight) of mixing water to mass (or weight) of dry combined material in the batch of mortar.
P = the net mass (or weight) printed on the package.
C = Conversion factor. To determine the yield in litres, P must be in kilograms per cubic metre. The conversion factor is 1000. To determine the yield in pounds per cubic foot; P must be in pounds and D must be in pounds per cubic foot. The conversion factor is 1.

15.5 *Water Retention*—For mortars for unit masonry, determine the water retention in accordance with Test Method C 1506.

15.6 *Air Content* (required for mortars for unit masonry and optional for high-strength mortars)—If the mixture proportions are known, calculate the air content in accordance with Specification C 270. If the proportions are not known, use Test Method C 138/C 138M, or Test Method C 173/C 173M, or Test Method C 231 to determine air content.

15.7 The report of the tests shall include:

15.7.1 Net mass (or weight) of dry, combined material in the bag determined to 0.05 kg [0.1 lb],

15.7.2 Amount of mixing water (*W*) calculated in accordance with the formula specified in 13.8.2,

15.7.3 Flow, in accordance with Test Method C 1437,

15.7.4 Density (D) in kilograms per cubic metre (or pounds per cubic foot) as determined in 15.4 in accordance with Test Method C 138/C 138M,

15.7.5 Yield (*Y*) of mortar in liters (or cubic feet) as determined in 15.4,

15.7.6 Air content, if measured, and test method used to determine air content,

15.7.7 Water retention in percent, if measured, and

15.7.8 Compressive strength at ages specified in Table 1.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 387/C 387M – 08, that may impact the use of this specification. (Approved February 1, 2009)

(*1*) Revised Section 1.

(*2*) Added new Section 3 Terminology and renumbered subsequent sections.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 387/C 387M – 06a, that may impact the use of this specification. (Approved December 1, 2008)

(*1*) Revised 6.1.

Designation: C 400 – 98 (Reapproved 2006)

Standard Test Methods for Quicklime and Hydrated Lime for Neutralization of Waste Acid[1]

This standard is issued under the fixed designation C 400; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the testing of quicklime and hydrated lime for use in the treatment of waste acid solutions and includes the characterization of the liming material and of the acid waste.

NOTE 1—When agreed upon by the manufacturer and the purchaser, this method may be used directly to evaluate the lime requirement for a plant waste acid and in the preparation of the lime slurry; the pH, the time, temperature, and other conditions of treatment may be adjusted to conform to plant practice. Otherwise the test shall be performed as described in this method.

NOTE 2—Under some conditions of test the lime requirement may vary substantially from that indicated by ultimate chemical analysis or by the use of a determination of available alkalinity by titration to a stoichiometric end point.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

E 70 Test Method for pH of Aqueous Solutions With the Glass Electrode

3. Terminology

3.1 *Definitions:*

3.1.1 *neutralization coefficient*—the number of parts of lime required to neutralize one million parts by weight of sulfuric acid solution (1.5 %) to a pH of 4.4 in 30 min (see Note 1).

3.1.2 *pH*—a measure of the hydrogen ion concentration of a sample and representing the logarithm of the reciprocal (negative logarithm) of the activity of hydrogen ions, calculated as follows:

$$pH = \log \frac{1}{(H)^{+}} = -\log(H^{+})$$

where:

H^{+} = activity of hydrogen ions.

4. Significance and Use

4.1 Since all limes and waste acid solutions are different, this test method evaluates the relative quantity of a given lime needed for the neutralization of a specific quantity of acid.

4.2 Liming materials have a specific basicity factor or measure of alkalinity which can be used for comparing their relative neutralizing power. It avoids dependence on chemical analysis and is determined as grams of calcium oxide equivalents per kilogram of liming material.

4.3 Likewise, specific waste acids have an acid value that can be expressed as grams of hydrochloric acid equivalent per litre of acid waste. This value is related on a stoichiometric basis to lime neutralization requirements of a liquid acid waste.

5. Apparatus

5.1 *pH Measuring Apparatus,* conforming to the requirements of Section 5, Apparatus, and Section 6, Reagents and Materials, of Test Method E 70. A time-pH recording device or attachment is desirable but not required.

5.2 *Analytical Balance,* capable of reproducing results within 0.005 g.

5.3 *Stirrer*, motorized, capable of rotating at speeds from 120 to 600 r/min.

5.4 *Miscellaneous Equipment*—Chemically resistant glassware,[3] metal stands for support of the equipment, etc.

6. Purity of Reagents

6.1 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall

[1] These test methods are under the jurisdiction of ASTM Committee C07 on Lime and are the direct responsibility of Subcommittee C07.05 on Chemical Tests.

Current edition approved June 1, 2006. Published July 2006. Originally approved in 1957. Last previous edition approved in 1998 as C 400 – 98.

www.technobetar.ir

conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.[4] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

6.2 Unless otherwise indicated, references to water shall be understood to mean distilled water.

7. Test Method A—for Determining Lime Requirement for the neutralization of a standard sulfuric acid or waste acid solution within a time limit of thirty minutes.

7.1 *Reagents*:

7.1.1 *Sulfuric Acid, Standard Solution* (1.5 ± 0.05 %)—Thoroughly mix 15.8 g of concentrated sulfuric acid (95 % H_2SO_4) with water, dilute to 1 L, analyze to within 0.005 % H_2SO_4, and store in a suitable stoppered bottle.

7.2 *Preparation of Sample*:

7.2.1 Take samples of quicklime and hydrated lime in accordance with Methods C 50.

7.2.2 *Quicklime*—Weigh a sample of quicklime (2.50 ± 0.01 g) ground to pass a No. 50 mesh sieve. Add to a 500-mL tall-form beaker containing 50 mL of boiling water and continue to boil for 2 min. Remove from hot plate and continue stirring with a magnetic stirrer until the slurry reaches room temperature (at least 10 min).

7.2.3 *Hydrated Lime*—Mix a sample of hydrated lime (2.50 ± 0.01 g) with 50 mL of water in a 500-mL tall-form beaker for at least 10 min.

7.3 *Procedure*:

7.3.1 Place the pH electrodes within the beaker about ½ in. (13 mm) above the surface of the lime slurry sample. Set the motor stirrer to the highest speed at which splattering or immersion of the electrodes does not occur. Measure 250 g of H_2SO_4 (1.5 ± 0.05 %) into a separate 500-mL beaker. Add this acid to the sample in a single motion and record the pH as a function of time for a period of 30 min (see Note 1).

7.3.2 Test a second slurry sample using more or less than 250 g of H_2SO_4 (1.5 ± 0.05 %), as indicated by the pH value observed after 30 min reaction in the first test. Repeat the procedure at least four times or until sufficient data are available to give a family of curves that indicate pH at 30 min as a function of grams of lime per 1000 g of H_2SO_4 (1.5 %), with particular emphasis in the region of pH equals 4.4.

7.4 *Results*:

7.4.1 *Neutralization Rate Curves*:

7.4.1.1 Plot pH versus time in minutes for each of the lime-acid ratios used in the initial series of tests. This family of curves serves as the basis for calculation of the lime requirements.

7.4.2 *Lime Requirement Curve*:

7.4.2.1 Plot the pH in 30 min, as determined from the neutralization rate curves described in Section 10, against grams of lime used per 1000 g of H_2SO_4 (1.5 %).

7.4.3 *Neutralization Coefficient*:

7.4.3.1 Interpolate the quantity of lime required to achieve a pH of 4.4 in 30 min from the lime requirement curve (Section 11), correct for the actual acid concentration, and calculate as parts of lime required per million parts of H_2SO_4 (1.5 %) as follows:

$$N=(1.5/Z)\times X\times 1000$$

where:

N = neutralization coefficient (see 3.1.1),
X = grams of lime per 1000 g of H_2SO_4(1.5 %), and
Z = concentration of the H_2SO_4 to the nearest 0.005 %, as determined by analysis.

7.5 *Precision and Bias*:

7.5.1 The precision and bias of this test method has not been determined at this time. Replicate samples are recommended.

8. Test Method B—For Determining Acid Value-Basicity Factor Relationship

8.1 *Procedure*:

8.1.1 *Basicity Factor*—Weigh 2.804 g ± 1 mg of the sample that has been prepared to pass a No. 100 (150-µm) sieve and transfer to a 500-mL Erlenmeyer flask containing approximately 20 mL of cold water. (For quicklime samples, heat to boiling to ensure complete slaking). Add from a buret 100 mL of 1.0 *N* hydrochloric acid and stopper with a two-hole rubber stopper (Note 3). The quantity of acid may be increased or decreased depending on the equivalent strength of the material being tested. Place the flask on a hot plate and boil for 15 min. (Glass beads may be added to prevent bumping.) Remove the flask from the hot plate and cool in water. Add several drops of phenolphthalein indicator solution and titrate the excess acid with 0.5 *N* sodium hydroxide solution. Calculate the basicity factor as follows:

$$\text{Basicity factor} = [(V_1N_1 - V_2N_2)/W] \times 0.02804$$

where:

V_1 = HCl (mL) required for titration of the sample,
N_1 = normality of HCl,
V_2 = NaOH solution (mL) required for titration of the excess acid,
N_2 = normality of NaOH solution, and
W = sample (g).

NOTE 3—A water-cooled condenser with a tapered, ground-glass joint and a magnetic stir plate may be used during the boiling step.

8.1.2 *Acid Value*—Pipet 10 mL of the sample of acidic waste into a 250-mL Erlenmeyer flask. This quantity may be increased or decreased depending on the strength of the acidic waste. Add an excess of 25 to 30 mL of 0.5 *N* sodium hydroxide solution and boil for 3 min. Filter through a small Büchner funnel with the aid of vacuum. Wash the residue on the funnel with water. Add several drops of phenolphthalein indicator solution to the filtrate and titrate the excess sodium hydroxide with 1.0 *N* hydrochloric acid solution. Calculate acid value as follows:

[4] "Reagent Chemicals, American Chemical Society Specifications," Am. Chemical Soc., Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see "Reagent Chemicals and Standards," by Joseph Rosin, D. Van Nostrand Co., Inc., New York, NY, and the "United States Pharmacopeia."

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$$\text{Acid value} = [(V_1N_1 - V_2N_2)/V] \times 0.03646$$

where:

V_1 = NaOH solution (mL) required for titration of the sample,
N_1 = normality of NaOH solution,
V_2 = HCl (mL) required for titration of the excess NaOH solution,
N_2 = normality of HCl, and
V = sample (mL).

8.1.3 *Relationship of Acid Value to Basicity Factor*—Calculate the acid value-basicity factor relationship as follows:

$$\frac{\text{Acid value}}{\text{Basicity factor}} \times 0.7691 = \text{lime or limestone product (kg) per litre of Acidic Waste.}$$

NOTE 4—When agreed upon between the manufacturer and the purchaser, Test Method A may also be used.

8.2 *Precision and Bias*:

8.2.1 The precision and bias of this test method has not been determined at this time. Replicate samples are recommended.

9. Keywords

9.1 acid value; alkalinity; basicity; lime requirement; liming material; neutralization; neutralization coefficient; pH; waste acid

Designation: C 403/C 403M – 08

Standard Test Method for Time of Setting of Concrete Mixtures by Penetration Resistance[1]

This standard is issued under the fixed designation C 403/C 403M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the time of setting of concrete, with slump greater than zero, by means of penetration resistance measurements on mortar sieved from the concrete mixture.

1.2 This test method is suitable for use only when tests of the mortar fraction will provide the information required.

1.3 This test method may also be applied to prepared mortars and grouts.

1.4 This test method is applicable under controlled laboratory conditions, as well as under field conditions.

1.5 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—Definitions are given in Terminology C 125.

4. Summary of Test Method

4.1 A mortar sample is obtained by sieving a representative sample of fresh concrete. The mortar is placed in a container and stored at a specified ambient temperature. At regular time intervals, the resistance of the mortar to penetration by standard needles is measured. From a plot of penetration resistance versus elapsed time, the times of initial and final setting are determined.

5. Significance and Use

5.1 Since the setting of concrete is a gradual process, any definition of time of setting must necessarily be arbitrary. In this test method, the times required for the mortar to reach specified values of resistance to penetration are used to define times of setting.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

Current edition approved April 1, 2008. Published May 2008. Originally approved in 1957. Last previous edition approved in 2006 as C 403/C 403M–06.

5.2 This test method can be used to determine the effects of variables, such as water content; brand, type and amount of cementitious material; or admixtures, upon the time of setting of concrete. This test method may also be used to determine compliance with specified time-of-setting requirements.

5.3 This test method may also be applied to prepared mortars and grouts. However, when the setting time of concrete is desired, the test shall be performed on mortar sieved from the concrete mixture and not on a prepared mortar intended to simulate the mortar fraction of the concrete; it has been shown that the initial and final setting times may be increased when using the prepared mortar.

6. Apparatus

6.1 *Containers for Mortar Specimens*—The containers shall be rigid, watertight, nonabsorptive, free of oil or grease, and either cylindrical or rectangular in cross section. Mortar surface area shall be provided for ten undisturbed readings of penetration resistance in accordance with clear distance requirements specified in Procedure. The lateral dimension shall be at least 6 in. [150 mm] and the height at least 6 in. [150 mm].

6.2 *Penetration Needles*—Needles shall be provided which can be attached to the loading apparatus and which have the following bearing areas: 1, ½ , ¼ , 1/10 , 1/20 , and 1/40 in.^{2} [645, 323, 161, 65, 32, and 16 mm^2]. Each needle shank shall be scribed circumferentially at a distance 1 in. [25 mm] from the bearing area. The length of the 1/40 in.^{2}[16-mm^2] needle shall be not more than 3½ in. [90 mm].

6.3 *Loading Apparatus*—A device shall be provided to measure the force required to cause penetration of the needles. The device shall be capable of measuring the penetration force with an accuracy of ±2 lbf [10 N] and shall have a capacity of at least 130 lbf [600 N].

NOTE 1—Suitable loading apparatus can be of the spring-reaction type as described in Test Method D 1558, or of other types with a calibrated force measuring device, such as an electronic load cell or a hydraulic pressure gage.

6.4 *Tamping Rod*—The tamping rod shall be a round, straight, steel rod 5/8 in. [16 mm] in diameter and approximately 24 in. [600 mm] in length, having the tamping end or both ends rounded to a hemispherical tip, the diameter of which is 5/8 in. [16 mm].

6.5 *Pipet*—A pipet or other suitable instrument shall be used for drawing off bleed water from the surface of the test specimen.

6.6 *Thermometer*—The thermometer shall be capable of measuring the temperature of the fresh mortar to ±1 °F [±0.5 °C]. ASTM liquid-in-glass thermometers having a temperature range from 0 to 120 °F [–20 to 50 °C], and conforming to the requirements of Thermometer 97F (or 97C) as prescribed in Specification E 2251 are satisfactory. Other thermometers of the required accuracy, including the metal immersion type, are acceptable.

7. Sampling, Test Specimens, and Test Units

7.1 For tests under field conditions, prepare three specimens from each sample of concrete.

7.2 For tests under laboratory conditions, the requirements depend upon the purpose of the tests.

7.2.1 For testing to prove compliance of a material with performance requirements, make at least three separate concrete batches for each variable under investigation. Perform one time of setting test on each batch. Make an equal number of batches for each variable on any one day. When it is impossible to perform at least one test for each variable on any one day, mix the entire series of batches in as few days as possible, and repeat one of the mixtures each day as a standard for comparison.

7.2.2 For other tests, prepare three test specimens from one batch of concrete for each test variable.

7.3 Record the time at which initial contact was made between cement and mixing water.

7.4 For tests under field conditions, obtain a representative sample of the fresh concrete in accordance with Practice C 172. For tests under laboratory conditions, make the concrete in accordance with Practice C 192/C 192M. Determine and record the slump (Test Method C 143/C 143M) and air content (Test Method C 173/C 173M or C 231) of the fresh concrete.

7.5 From the concrete not used in the slump and air content tests, select a representative portion of sufficient volume to provide enough mortar to fill the test container, or containers, to a depth of at least 5½ in. [140 mm].

7.6 Using the procedure in Practice C 172, obtain a mortar sample by wet-sieving the selected portion of concrete through a 4.75-mm sieve[3] and onto a nonabsorptive surface.

7.7 Thoroughly remix the mortar by hand methods on the nonabsorptive surface. Measure and record the temperature of the mortar. Place the mortar in the container, or containers, using a single layer. Consolidate the mortar to eliminate air pockets in the specimen and level the top surface. This may be accomplished by rocking the container back and forth on a solid surface, by tapping the sides of the container with the tamping rod, by rodding the mortar, or by placing the container on a vibrating table (see Note 2). If rodding is used, rod the mortar with the hemispherical end of the tamping rod. Rod the mortar once for each 1 in.^{2} [645 mm^2] of top surface area of the specimen and distribute the strokes uniformly over the cross section of the specimen. After completion of the rodding, tap the sides of the containers lightly with the tamping rod to close voids left by the tamping rod and to further level the surface of the specimen. Upon completion of specimen preparation, the mortar surface shall be at least ½ in. [10 mm] below the top edge of the container to provide space for the collection and removal of bleed water and to avoid contact between the mortar surface and the protective covering specified in Section 8.

NOTE 2—Sieved mortar is generally of fluid consistency and air pockets are readily removed by the listed consolidation methods. The user should exercise judgment in the selection of the consolidation method. Rocking the container or tapping of the sides should be sufficient for fluid mortars. Rodding or using a vibrating table may be desirable for stiffer mortars. When using a vibrating table, use low-amplitude vibration so that portions of the sample are not ejected from the container.

[3] Detailed requirements for this sieve are given in Specification E 11.

8. Conditioning

8.1 For tests under laboratory conditions, the storage temperature for specimens shall be within the range 68 to 77 °F [20 to 25 °C], or as specified by the user.

8.2 For tests under field conditions, store the specimens under ambient conditions, or as specified by the user. Shield the specimens from direct sunlight.

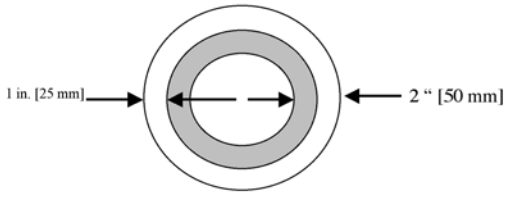
8.3 Measure and record the ambient air temperature at the start and finish of the test. To prevent excessive evaporation of moisture, keep the specimens covered with a suitable material such as damp burlap or a tight-fitting, water-impermeable cover for the duration of the test, except when bleed water is being removed or penetration tests are being made.

9. Procedure

9.1 Just prior to making a penetration test, remove bleed water from the surface of the mortar specimens by means of a pipet or suitable instrument. To facilitate collection of bleed water, tilt the specimen carefully to an angle of about 10° from the horizontal by placing a block under one side 2 min prior to removal of the water.

9.2 Insert a needle of appropriate size, depending upon the degree of setting of the mortar, in the penetration resistance apparatus and bring the bearing surface of the needle into contact with the mortar surface. Gradually and uniformly apply a vertical force downward on the apparatus until the needle penetrates the mortar to a depth of 1 ± 1⁄16 in. [25 ± 2 mm], as indicated by the scribe mark (Note 4). The time required to penetrate to the 1-in. [25-mm] depth shall be 10 ± 2 s. Record the force required to produce the 1-in. [25-mm] penetration and the time of application, measured as elapsed time after initial contact of cement and water. Calculate the penetration resistance by dividing the recorded force by the bearing area of the needle, and record the penetration resistance. In subsequent penetration tests take care to avoid areas where the mortar has been disturbed by previous tests. The clear distance between needle impressions shall be at least two diameters of the needle being used, but not less than ½ in. [15 mm]. The clear distance between any needle impression and the side of the container shall be at least 1 in. [25 mm], but not more than 2 in. [50 mm], as depicted in Fig. 1.

NOTE 3—For a cylindrical container with the smallest allowable outer diameter of 6 in., the operator can reasonably expect to achieve approximately eight penetrations before impinging upon previous penetrations. This is based on using needles of the following surface areas: 1 @ ½ [13], 2 @ ¼ [6], 2 @ 1⁄10 [2.5], 2 @ 1⁄20 [1.3], and 1 @ 1⁄40 [0.6] in.^{2}[mm^2].



NOTE 1—Dark-colored areas define where needle penetrations are permitted.

FIG. 1 Top View of Mortar Test Specimen

NOTE 4—To facilitate determination of when the required penetration has been attained, a sliding marker may be attached to the needle shaft. For example, a paper clip or masking tape may be placed on the shaft so that it coincides with the scribe mark. The marker should not interfere with the penetration of the needle into the mortar. The position of the marker should be checked prior to making a penetration.

9.3 For conventional concrete mixtures at laboratory temperatures of 68 to 77 °F [20 to 25 °C], make the initial test after an elapsed time of 3 to 4 h after initial contact between cement and water. Subsequent tests should be made at ½- to 1-h intervals. For concrete mixtures containing accelerators, or at temperatures higher than laboratory, it is advisable to make the initial test after an elapsed time of 1 to 2 h and subsequent tests at ½-h intervals. For concrete mixtures containing retarders, or at temperatures lower than laboratory, the initial test may be deferred until an elapsed time of 4 to 6 h. In all cases, time intervals between subsequent tests may be adjusted as necessary, depending upon the rate of setting, to obtain the required number of penetrations.

9.4 Make at least six penetrations for each time-of-setting test, with time intervals of such duration as to provide a satisfactory curve of penetration resistance versus elapsed time (Note 5). Continue testing until one at least penetration resistance reading equals or exceeds 4000 psi [27.6 MPa].

NOTE 5—A satisfactory curve is one which represents the overall development of penetration resistance and includes points before and after the times of initial and final setting to improve the accuracy of the required interpolation. For normal setting mixtures, test points are usually at equally spaced time intervals. Premature penetration testing will result in too many data points earlier than the initial setting time. This may decrease the accuracy of the estimated setting time by biasing the best fit line when regression analysis is used to analyze the penetration resistance data.

9.5 *Plotting Test Results*—One of the following alternative procedures may be used to plot the test results and obtain times of setting (Note 6). Appendix X1 illustrates the application of these procedures.

NOTE 6—The plot of penetration resistance versus elapsed time provides information on the rate of setting. The plot may be used to select the time for subsequent penetration tests and it can assist in identifying spurious test results. Therefore, it is recommended that the data be plotted as they are being accumulated.

9.5.1 Use the following plotting procedure to determine the times of setting by hand-fitting a smooth curve through the data. Prepare a graph of penetration resistance, as the ordinate, versus elapsed time, as the abscissa, using a scale such that 500 psi [3.5 MPa] and 1 h are each represented by a distance of at least ½ in. [15 mm]. Plot the values of penetration resistance as a function of elapsed time.

9.5.2 Use the following plotting procedure to determine the times of setting by linear regression analysis of the logarithms of the data by using a suitable calculator. Using log-log graph paper, prepare a graph of penetration resistance, as the ordinate, versus elapsed time in minutes, as the abscissa. The limits of penetration resistance on the ordinate should extend from 10 psi [0.1 MPa] to 10 000 psi [100 MPa], and the limits of elapsed time on the abscissa should extend from 10 to 1000 min. If slow setting mixtures are used, the time limits may have

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:12:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

to be 100 to 10 000 min. Plot the values of penetration resistance as a function of elapsed time (Note 5).

9.5.3 Use the following procedure if a computer is used to plot test results and obtain the times of setting by regression analysis of the data. As the test results are obtained, enter the time and penetration resistance into the computer and plot the penetration resistance as the ordinate and the elapsed time as the abscissa. For software that permits only linear regression analysis, convert the data by taking their logarithms. The converted data will be fitted by a straight line[4] (see Eq 1):

$$\text{Log}\,(PR) = a + b\,\text{Log}\,(t) \quad (1)$$

where:

PR = penetration resistance
t = elapsed time
a and b = regression constants

The data do not have to be converted if the software permits direct fitting of a power function:

$$PR = ct^d \quad (2)$$

where:

c and d = regression constants

9.5.4 The procedures in 9.5.2 and 9.5.3 assume that the data obey (Eq 1) or (Eq 2). Verify that the data obey one of these relationships. If the correlation coefficient for the regression analysis, after removal of outliers (see Note 7), is less than 0.98, use the procedure in 9.5.1.

10. Calculation

10.1 For each variable under investigation, separately plot the results of three or more time-of-setting tests. For each plot prepared according to 9.5.1, hand fit a smooth curve to the data points. For each plot prepared according to 9.5.2 or 9.5.3, use the method of least squares to obtain the constants of the best-fit relationship given by (Eq 1) or (Eq 2), whichever is applicable. Disregard data points that are obvious outliers from the trend defined by the rest of the points (Note 7).

NOTE 7—Outliers may occur because of factors such as: interferences due to the larger particles in the mortar; presence of large voids within the penetration zone; interferences from the impressions created by adjacent penetrations; failure to maintain the instrument perpendicular to the test surface during penetration; errors in reading the load; variations in the penetration depths; or variations in rate of loading. Judgement of the operator is required to identify those points that should not be included in the data analysis.

10.2 For each plot, determine the times of initial and final setting as the times when the penetration resistance equals 500 psi [3.5 MPa] and 4000 psi [27.6 MPa], respectively. For plots made according to 9.5.1, determine times of setting by visual inspection of the drawn curves. For plots made according to 9.5.2 or 9.5.3, determine the times of setting by interpolation using the best-fit regression equation. Record the times of setting in hours and minutes to the nearest 5 min.

10.3 For each variable under investigation, calculate the times of initial and final setting as the average values of the individual test results. Record the average times in hours and minutes to the nearest 5 min.

11. Report

11.1 *Data on Concrete Mixture*—Report the following information on the concrete mixture:

11.1.1 Brand and type of cementitious materials, amounts (mass) of cementitious materials, fine aggregate and coarse aggregate per cubic yard [per cubic metre] of concrete, nominal maximum aggregate size, and water-cement or water-cementitious material ratio,

11.1.2 The name, type, and amount of admixture(s) used,

11.1.3 Air content of fresh concrete and method of determination,

11.1.4 Slump of concrete,

11.1.5 Temperature of mortar after sieving,

11.1.6 Record of ambient temperature during the test period, and

11.1.7 Date of test.

11.2 *Time of Setting Results*—Report the following information on the time of setting tests:

11.2.1 A plot of penetration resistance versus elapsed time for each time of setting test,

11.2.2 The times of initial and final setting for each test, reported in hours and minutes to the nearest minute, and

11.2.3 The average times of initial and final setting for each test condition, reported in hours and minutes to the nearest 5 min.

12. Precision and Bias

12.1 The data used to develop the precision statement were obtained using the inch-pound version of this test method. Estimates of time of setting were determined by both graphical methods and regression analysis. The temperature of the laboratory, where the concrete mixtures were sieved and the resulting mortar fraction measured for penetration resistance, was maintained at 73 ± 2 °F [23 ± 1 °C] for the duration of the round robin test.

12.2 The following precision values were obtained from an interlaboratory study[5] involving five operators and three concrete mixtures. The average time of initial setting varied between 169 and 252 min., and the average time of final setting varied between 240 and 341 min. Three replicate determinations were made by each operator on specimens made from a single batch of each mixture.

12.3 *Single-Operator Precision*—The single-operator standard deviations of a single test result are shown in Table 1.[A] The results of two properly conducted tests by the same operator are not expected to differ by more than the values shown in the third column of Table 1.[A] The test method calls for reporting three test results. The range (difference between highest and lowest) of the three test results obtained by the same operator on specimens from the same batch of concrete are not expected to exceed the values shown in the fourth column of Table 1.[B]

[4] Popovics, S., 1971, "Physical Aspects of the Setting of Portland Cement Concrete," *Journal of Materials*, JMLSA, Vol. 6, No. 1, March, pp. 150–162.

[5] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1032.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:12:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

12.4 *Multi-Operator Precision*—The multi-operator standard deviations of a single test result are shown in Table 2.[A] The results of two properly-conducted tests by different operators on the same material are not expected to differ by more than the values shown in the third Column of Table 2.[A] The averages of three test results by two different operators obtained on specimens from a single batch of the same concrete are not expected to differ by more than the values in the fourth column of Table 2.[B]

TABLE 1 Single-Operator Precision

Time of Setting	Single-Operator Standard Deviation, min[A]	Acceptable Difference Between Two Results, min[A]	Acceptable Range of Three Results, min[B]
Initial	3.5	9.8	11.4
Final	4.4	12.5	14.6

[A]These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.
[B]Calculated as described in the section "*acceptable range of more than two results*" of Practice C 670.

TABLE 2 Multi-Operator Precision

Time of Setting	Multi-Operator Standard Deviation, min[A]	Acceptable Difference Between Two Results, min[A]	Acceptable Difference Between Average of Three Results, min[B]
Initial	6.9	19.4	11.1
Final	10.1	28.7	16.4

[A]These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.
[B]Calculated as described in the section "*multilaboratory precision expressed as a maximum allowable differences between two averages*" of Practice C 670.

12.5 The bias of this test method cannot be determined because times of setting can be defined only in terms of the test method.

13. Keywords

13.1 concrete; mortar; penetration resistance; time of final setting; time of initial setting

APPENDIX

(Nonmandatory Information)

X1. ILLUSTRATIVE EXAMPLES

X1.1 The penetration resistance (*PR*) and the elapsed time (*t*) data in Table X1.1 will be used to illustrate the procedures for determining times of setting.

X1.2 *Hand Fit*—Fig. X1.1 is a plot of the penetration resistance versus elapsed time values in Table X1.1. The smooth curve was drawn by-hand using a flexible drawing curve. The curve was drawn so as to achieve the visual best-fit to the data. Note that the penetration resistance at an elapsed time of 335 min is an obvious outlier, and this point was disregarded in drawing the best-fit curve. Horizontal lines are drawn at penetration resistance values of 500 and 4000 psi. The intersections of the horizontal lines with the curve define the times of initial and final setting, which in this case are 289 min and 389 min, respectively.

X1.3 *Regression Analysis:*

TABLE X1.1 Penetration Resistance

Penetration Resistance (*PR*) (psi)[A]	Elapsed Time (*t*) (min)	Log(*PR*)	Log(*t*)
44	200	1.643	2.301
110	230	2.041	2.362
216	260	2.334	2.415
540	290	2.732	2.462
1000	320	3.000	2.505
1000	335	3.000	2.525
2000	350	3.301	2.544
2560	365	3.408	2.562
3520	380	3.547	2.580
4440	395	3.647	2.597

[A]MPa = psi × 0.00689.

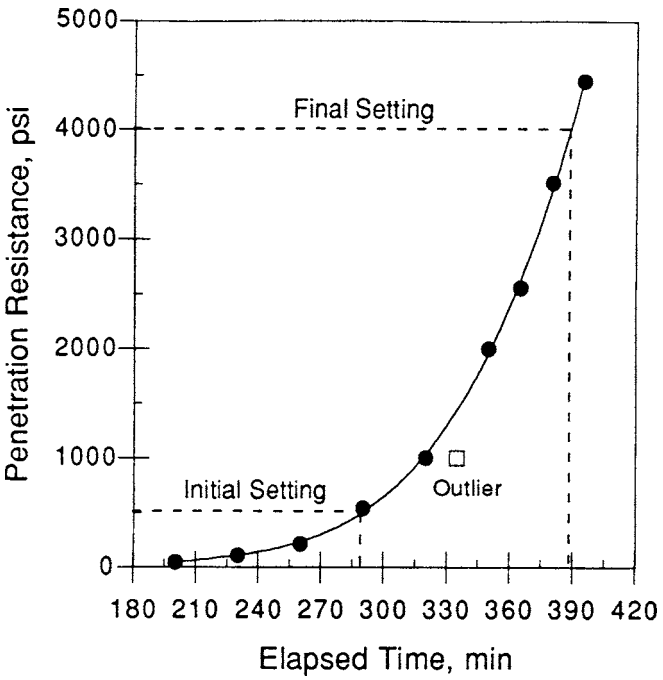


FIG. X1.1 Plot of Penetration Resistance Values Versus Elapsed Time and Hand Fit Curve Used to Determine Time of Setting (Note: Not drawn to actual scale)

X1.3.1 Fig. X1.2 is a log-log plot of the penetration resistance versus elapsed time values. The plot shows that, with the exception of the outlier, there is approximately a straight line relationship between the logarithms of penetration resistance

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

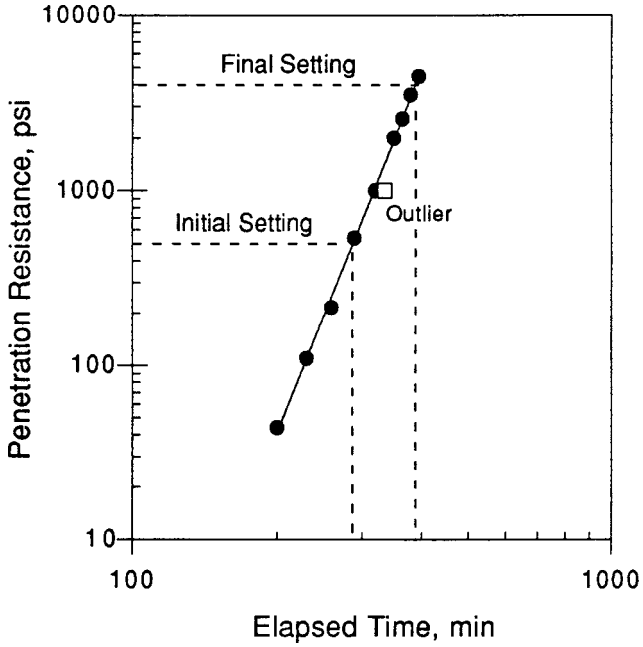

FIG. X1.2 Log-Log Plot Showing Straight Line to Determine Times of Setting by Using Regression Analysis

and elapsed time. The straight line is obtained by linear regression analysis using the logarithms shown in the third and fourth columns of Table X1.1. The equation for this line is:

$$\text{Log}\,(PR) = -14.196 + 6.871\,\text{Log}\,(t) \quad \text{(X1.1)}$$

where:
PR = penetration resistance, and
t = elapsed time.

The correlation coefficient is 0.999, and it is, therefore, acceptable to use linear regression analysis.

X1.3.2 To obtain the times of setting, the equation is rewritten as:

$$\text{Log}\,(t) = \frac{\text{Log}(PR) + 14.196}{6.871} \quad \text{(X1.2)}$$

X1.3.3 For time of initial setting, substitute the value 500 for PR:

$$\text{Log}\,(t) = \frac{\text{Log}(500) + 14.196}{6.871} = \frac{2.699 + 14.196}{6.871} = 2.458 \quad \text{(X1.3)}$$

therefore:
$t = (10)^{2.458} = 287$ min.

X1.3.4 For time of final setting, substitute the value 4000 for PR:

$$\text{Log}\,(t) = \frac{\text{Log}(4000) + 14.196}{6.871} = \frac{3.602 + 14.196}{6.871} = 2.590 \quad \text{(X1.4)}$$

therefore:
$t = (10)^{2.590} = 389$ min.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 403/C 403M – 06, that may impact the use of this test method. (Approved April 1, 2008)

(*1*) Replaced Specification E 1 with Specification E 2251 in Referenced Documents and 6.6.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 403/C 403M – 05, that may impact the use of this test method. (Approved December 15, 2006)

(*1*) Revised Section 12 and added new Table 1 and Table 2.

Designation: C 418 – 05

Standard Test Method for Abrasion Resistance of Concrete by Sandblasting[1]

This standard is issued under the fixed designation C 418; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers determination of the abrasion resistance characteristics of concrete by subjecting it to the impingement of air-driven silica sand. It is intended for use as a basis for the development of informed judgment.

1.2 The values stated in SI units are to be regarded as the standard. Inch-pound units are shown for information purposes in parentheses.

1.3 *This standard does not purport to address the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

NOTE 1—Users of this test method are advised that there are known safety hazards associated with the use of silica as a blasting media. Consult the silica manufactures MSDS to insure that the latest recommended health and safety practices are being followed.

NOTE 2—Other procedures are available for measuring abrasion resistance of concrete surfaces in addition to subjecting it to air driven silica sand. Consideration should be given to other methods of testing as outlined in ASTM C 779/C 779M, ASTM C 944, and ASTM C 1138. The test method most closely representing service conditions should be used.

1.4 The text of this standard references notes and footnotes which are provided as explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 127 Test Method for Density, Relative Density (Specific Gravity), and Absorption of Coarse Aggregate

C 778 Specification for Standard Sand

C 779/C 779M Test Method for Abrasion Resistance of Horizontal Concrete Surfaces

C 944 Test Method for Abrasion Resistance of Concrete or Mortar Surfaces by the Rotating-Cutter Method

C 1138 Test Method for Abrasion Resistance of Concrete (Underwater Method)

3. Significance and Use

3.1 This test method covers the laboratory evaluation of the relative resistance of concrete surfaces to abrasion. This procedure simulates the action of waterborne abrasives and abrasives under traffic on concrete surfaces. It performs a cutting action that tends to abrade more severely the less resistant components of the concrete.

4. Apparatus

4.1 *Scales*—The scale shall have a capacity of 5000 g or more. The permissible variation at a load of 5000 g (11 lb) shall be ± 0.5 g (0.2 oz).

4.2 *Weights*—The permissible variations on weights used in weighing shall be as prescribed in Table 1. The permissible variations on new weights shall be one half of the values given in Table 1.

4.3 *Sand Blast Apparatus*—The sand blast apparatus shall consist of an injector-type gun. The gun shall have a high-velocity air jet fed by a suitably controlled rate of flow for the abrasive material. The nozzle shown in Fig. 1 shall consist of cold-rolled bar stock, 40 mm (1.5 in.) long, or hardened tool steel HRC 48 ± 2 as determined by Test Methods E 18, drilled to 6.40 ± 0.02 mm (0.250 ± 0.001 in.) approximately 700 kPa (100 psi) through the center. The walls of the nozzle shall have a 45° bevel on the inside at the upper end. A compressed air supply of approximately 100 psi (690 kPa) shall be available and equipped with a pressure-control device. Provision shall be made to collect the spent abrasive and dust. Suitable jigs and clamps shall be provided to hold the test specimen in a fixed position with relation to the discharge end of the nozzle. For laboratory wear testing of concrete specimens a commercial sand blast cabinet may be selected similar to that shown in Fig. 2.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.62 on Abrasion Testing of Concrete.

Current edition approved Feb. 1, 2005. Published February 2005. Originally approved in 1958. Last previous edition approved in 1998 as C 418 – 98.

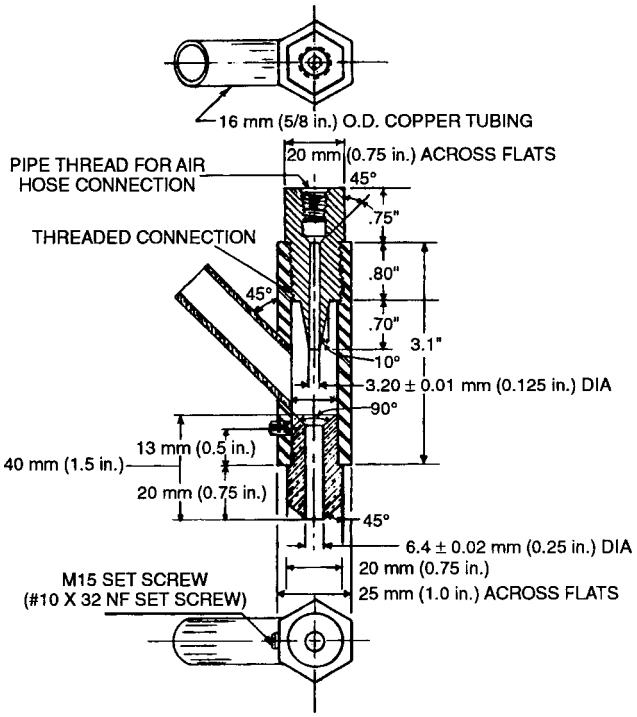
TABLE 1 Permissible Variations on Weights

Weight, g	Permissible Variations on Weights in Use, g
1000	±0.50
500	±0.35
300	±0.30
250	±0.25
200	±0.20



NOTE—All dimensions are approximate except where tolerances are shown. Inch-pound dimensions shown here for clarity purposes only.

FIG. 1 Gun Nozzle Assembly

4.4 *Shield*—The shield shall be square or circular, 150 mm (6 in.) on a side or diameter, made from zinc-coated steel sheet or equivalent, having a thickness in the range of 0.90 to 1.90 mm (0.035 to 0.075 in.). The shield shall have an opening 28.70 ± 0.25 mm (1.13 ± 0.01 in.) in diameter in the center (See Note 3).

NOTE 3—An opening of 28.7 mm (1.13 in.) is equivalent to 6.45 cm^2 (1 $in.^2$). The purpose of the opening in the shield is to limit the abraded area to approximately 1 $in.^2$

4.5 *Abrasive*—The abrasive shall conform to Specification C 778 for 20–30 sand (predominantly graded to pass an 850-µm (No. 20) sieve and be retained on a 600-µm (No. 30) sieve).

5. Preparation of Specimens

5.1 Immerse the specimens in water for 24 h and then surface dry with a damp cloth to obtain a saturated, surface-dry condition at the time of test.

6. Calibration of Apparatus

6.1 Adjust the air pressure to 410 ± 1 kPa (59.5 ± 1 psi) and collect the abrasive for a period of 1 min. Adjust the rate of flow of abrasive to 600 ± 25 g/min (See Note 4).

NOTE 4—A ball valve between the abrasive supply and the gun inlet has been found satisfactory for adjusting the flow of abrasive.

6.2 The abrasive shall be regraded or replaced after every 60 min of operating time in order to maintain a uniform grading.

6.3 A cold-rolled steel nozzle shall be replaced every 60 min of operating time. A hardened tool steel nozzle shall be changed as required to maintain the original uniform flow and original blast pattern.

7. Procedure

7.1 Place the specimen with the surface to be tested normal to the nozzle axis and at a distance of 75 ± 2.5 mm (3.0 ± 0.1 in.) from the end. Clamp the specimen, with shield attached, firmly in place. Expose the surface to the blast for a period of 1 min. Repeat this on at least eight different spots on the surface. Determine the abraded volume by filling the abrasion cavities with an oil base modeling clay. Press the clay into the cavities manually with a moderate amount of finger pressure and level flush with a straight edge. Determine the mass of the clay supply before and after the cavities are filled to the tolerance listed in Table 1 instead of removing the clay from the filled cavities. Repeat filling with clay at least once on each specimen to ensure reproducible results.

8. Calculation

8.1 Calculate the mass of clay, W_c, as follows:

$$W_c = W_i - W_f$$

where:
W_i = mass, initial supply, and
W_f = mass, final supply.

8.2 Calculate the specific gravity of clay, D, as follows:

$$D = B / (B - C)$$

where:
B = mass of clay in air, g, and
C = mass of clay in water, g.

NOTE 5—Appendix X1 of Test Method C 127 provides guidance on the development of the equations used in the calculation of specific gravity (relative density to water) using the mass of clay in air and the mass of clay when suspended in water.

8.3 Calculate the volume of clay, V, per cavity in cubic centimetres, as follows:

$$V = W / D$$

where:
W = mass of clay in cavity, and
D = specific gravity of clay.

8.4 Calculate the abrasion coefficient loss on a volumetric basis, expressed in cubic centimetres per square centimetre, in order to compensate for variable densities of specimens, as follows:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:07 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

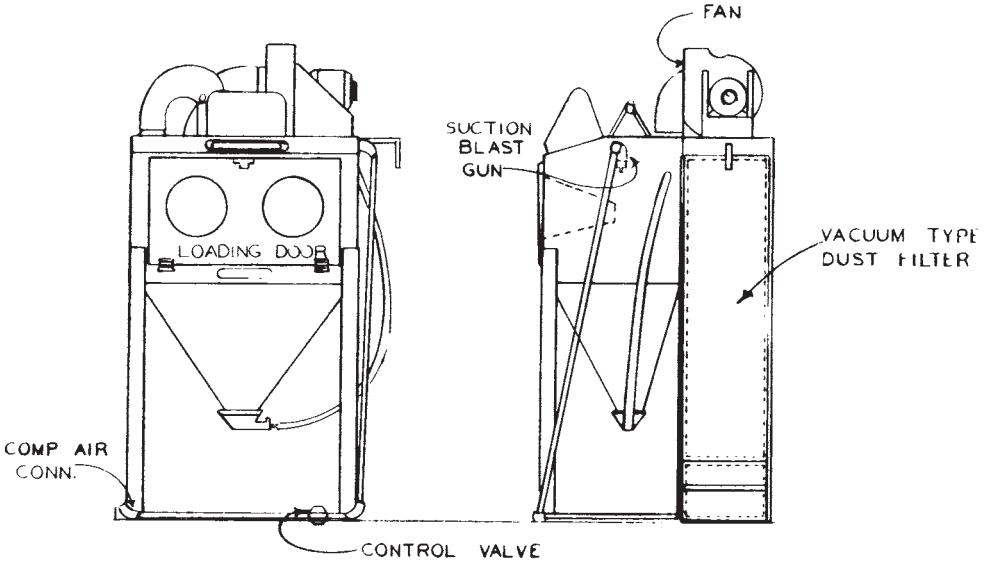


FIG. 2 Sand Blast Cabinet

$$A_c = V / A$$

where:

A_c = abrasion coefficient, cubic centimetres per square centimetre, and

A = area of surface abraded, square centimetres.

9. Report

9.1 Report the following information:

9.2 Report the abrasion coefficient loss to the nearest 0.01 cm^3/cm^2.

9.3 Report the location of the concrete where the specimen was obtained and other characteristics of the concrete, if known.

10. Precision and Bias

10.1 On a limited sampling (Note 6), the single-operator coefficient of variation has been found to be 9.1 %.[3] Therefore, results of two properly conducted tests by the same operator on the same material using the same equipment should not differ by more than 25.8 %[3] of their average.

10.2 On a limited sampling (Note 6), the multi-operator coefficient of variation has been found to be 10.3 %.[3] Therefore, results of two properly conducted tests by two operators on the same material using the same equipment should not differ from each other by more than 29.1 %[3] of their average.

NOTE 6—The data, on file at ASTM Headquarters, involve two operators performing the tests on samples made from the same batch and repeated on another day. Two concrete mixtures having different expected abrasion resistance were also used. The tests were conducted in one laboratory using the same equipment. As more laboratories become more equipped and capable of performing the test, a more detailed interlaboratory test program will be conducted.

10.3 Since there is no acceptable reference material suitable for determining bias for the procedure in this test method, no statement of bias is being made.

[3] These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670 for Preparing Precision and Bias Statements for Test Methods for Construction Materials.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 430 – 08

Standard Test Method for Fineness of Hydraulic Cement by the 45-μm (No. 325) Sieve[1]

This standard is issued under the fixed designation C 430; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the fineness of hydraulic cement by means of the 45-μm (No. 325) sieve.

1.2 The values stated in SI units are to be regarded as the standard. The inch-pound equivalents of SI units may be approximate.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

E 161 Specification for Precision Electroformed Sieves

E 177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods

3. Apparatus

3.1 *Sieve*:

3.1.1 *Sieve Frame*—The sieve frame shall be of metal not subject to corrosion by water and shall be circular, either 51 ± 6 mm (2.0 ± 0.25 in.) when woven-wire cloth is mounted in the frame or 76 ± 6 mm (3.0 ± 0.25 in.) in diameter when an electroformed sheet is mounted in the frame. The depth of the sieve from the top of the frame to the cloth or sheet shall be 76 ± 6 mm (3.0 ± 0.25 in.). The frame shall have either side walls of 89 ± 6 mm (3.5 ± 0.25 in.) in total height, or legs at least 12 mm (0.5 in.) in length, sufficient to allow air circulation beneath the sieve cloth or electroformed sheet.

3.1.2 *Sieve Cloth or Electroformed Sheet*—The sieve frame shall be fitted with either a 45-μm (No. 325) stainless steel AISI Type 304 woven-wire sieve cloth, conforming to the requirements of Specification E 11 or a 45-μm electroformed reinforced nickel sieve sheet conforming to the requirements of Specification E 161 with the exception that the number of openings shall be 71 ± 2 per linear centimetre (180 ± 5 per linear inch).

3.1.3 *Cloth or Sheet Mounting*:

3.1.3.1 *Woven-Wire Cloth Mounting*—Type 304 stainless steel woven-type cloth shall be mounted in the frame without distortion, looseness, or wrinkling. For a sieve fabricated by soldering the cloth to the frame, the joint shall be made smooth to prevent the cement from catching in the joints between the sieve cloth and the frame. Two-piece sieves shall clamp tightly on the cloth to prevent the cement from catching in the joints between the sieve cloth and the frame.

3.1.3.2 *Electroformed Sieve Sheet Mounting*—Electroformed reinforced nickel sieve sheet shall be mounted in the frame without distortion, looseness, or wrinkling. The joint between the sieve cloth and the frame shall be made smooth with a material impervious to water.

3.2 *Spray Nozzle*—The spray nozzle (Fig. 1) shall be constructed of metal not subject to corrosion by water and shall be 17.5 mm (0.69 in.) in inside diameter with a central hole drilled in line with the longitudinal axis, an intermediate row of eight holes drilled 6 mm (0.23 in.) center-to-center at an angle of 5° from the longitudinal axis, and an outer row of eight holes drilled 11 mm (0.44 in.) center-to-center at an angle of 10° from the longitudinal axis. All holes shall be 0.5 mm (0.02 in.) in diameter. The spray nozzle shall have been checked within six months prior to testing a cement sample to ensure that the flow rate is between 1500 and 3000 g/min at 69 ± 3 kPa (10 ± 0.4 psi).

3.3 *Pressure Gage*—The pressure gage shall be 76 mm (3.0 in.) minimum diameter, and shall be graduated in 7-kPa (1-psi) increments, and shall have a maximum capacity of 207 kPa (30 psi). The accuracy at 69 kPa (10 psi) shall be ±2 kPa (±0.25 psi).

4. Calibration of 45-μm (No. 325) Sieve

4.1 Place 1.000 g of the current lot of National Institute of Standards and Technology standard sample No. 114 or No. 46h on the clean, dry, 45-μm (No. 325) sieve and proceed as in Section 5. The sieve correction factor is the difference between

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.25 on Fineness.

Current edition approved Dec. 1, 2008. Published January 2009. Originally approved in 1959. Last previous edition approved in 2003 as C 430 – 96(2003).

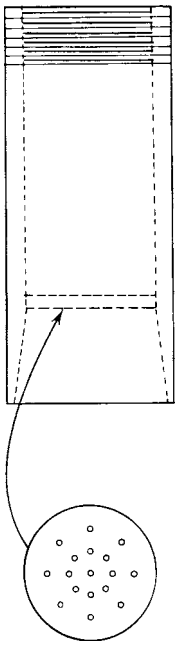

FIG. 1 Spray Nozzle with Seventeen 0.02-in. (0.51-mm) Holes

the test residue obtained and the assigned residue value indicated by the electroformed sheet sieve fineness specified for the standard sample, expressed as a percentage of the test residue.

NOTE 1—It should be observed that the sieve correction as specified is a factor to be multiplied by the residue obtained and that the amount to be added to or subtracted from the residue in any given test is therefore proportional to the amount of residue.

Example of Determination of Sieve Correction Factor:

Residue on 45-μm (No. 325) Sieve, sample No. 114 or No. 46h		12.2 %
Residue for a 1-g sample		0.122 g
Residue on sieve being calibrated		0.093 g
Difference	=	+ 0.029 g
Correction factor = + 0.029/0.093 × 100 = + 31.18	=	+ 31.2 %

5. Procedure

5.1 Place a 1.000 g sample of the cement on the clean, dry 45-μm (No. 325) sieve. Wet the sample thoroughly with a gentle stream of water. Remove the sieve from under the nozzle and adjust the pressure on the spray nozzle to 69 ± 4 kPa (10 ± 0.5 psi). Return the sieve to its position under the nozzle and wash for 1 min, moving the sieve with a circular motion in a horizontal plane at the rate of one motion per second in the spray. The bottom of the spray nozzle should extend below the top of the sieve frame about 12 mm (0.5 in.). Immediately upon removing the sieve from the spray, rinse once with about 50 cm^3 of distilled or deionized water, using caution not to lose any of the residue, and then blot the lower surface gently upon a damp cloth. Dry the sieve and residue in an oven or over a hot plate (see Note 2), supporting the sieve in such a manner that air may pass freely beneath it. Cool the sieve; then brush the residue from the sieve and weigh on an analytical balance capable of reproducing results within 0.0005 g.

NOTE 2—Care should be taken not to heat the sieve hot enough to soften the solder.

6. Cleaning of 45-μm (No. 325) Sieves

6.1 *Frequency of Cleaning and Calibration*—Sieves fitted with woven wire sieve cloth shall be cleaned after no more than five determinations. Sieves fitted with an electroformed reinforced sieve sheet having 71 openings per linear centimetre shall be cleaned after no more than three determinations. Both types of sieves shall be recalibrated after no more than 100 determinations.

6.2 *Acceptable Cleaning Procedures*—One option for cleaning is to place the sieve in a low-power (150 W maximum power input) ultrasonic bath containing an appropriate laboratory cleaning solution. The bath is to be operated for sufficient time (approximately 10 to 15 min at room temperature) to remove particles lodged in the openings. Be apprised that electroformed sieve sheets containing more than 71 openings per linear centimetre may well be damaged by ultrasonic cleaning. An option for cleaning which does not require an ultrasonic bath can also be employed. Immerse the sieve in a bath of appropriate laboratory cleaning solution heated to just below boiling point. Cover with a watch glass to reduce evaporation. Continue this soaking for a time sufficient to loosen lodged particles with a rinse following the bath. Overnight soaking in similar but unheated cleaning solutions is also acceptable, provided a rinse following the bath is able to wash away lodged particles. Cleaning or rinsing with dilute hydrochloric or acetic acid solutions is to be avoided. Appropriate cleaning solutions are restricted to soap or detergent-type solutions.

7. Calculation

7.1 Calculate the fineness of the cement to the nearest 0.1 % as follows:

$$R_c = R_s \times (100 + C) \quad (1)$$

$$F = 100 - R_c \quad (2)$$

where:

F = fineness of the cement expressed as the corrected percentage passing the 45-μm (No. 325) sieve,
R_c = corrected residue, %,
R_s = residue from the sample retained on the 45-μm (No. 325) sieve, g, and
C = sieve correction factor (determined as prescribed in Section 4) which may be either plus or minus.

Example:

Sieve correction factor, C	=	+31.2 %
Residue from sample being tested, R_s	=	0.088 g
Corrected residue, R_c	=	0.088 × (100 + 31.2)
	=	11.5 %
Corrected amount passing, F	=	100 – 11.5 % = 88.5 %

8. Precision and Bias

8.1 *Normal Fineness Product*—The multilaboratory precision has been found to be ±0.75 % (IS) as defined in Practice E 177, therefore, results of properly conducted tests from two different laboratories on identical samples of cement should agree 95 % of the time within ±2.1 %.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:10 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.2 *High Fineness Product*—The multilaboratory precision has been found to be ±0.50 % (IS) as defined in Practice E 177; therefore, results of properly conducted tests from two different laboratories on identical samples of cement should agree 95 % of the time within ±1.4 %.

NOTE 3—The use of outside threads instead of inside threads as shown in this figure is permissible.

8.3 Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

9. Keywords

9.1 fineness of hydraulic cement

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 430 – 96(2003), that may impact the use of this test method. (Approved December 1, 2008)

(*1*) Revised 4.1.

Designation: C 441 – 05

Standard Test Method for Effectiveness of Pozzolans or Ground Blast-Furnace Slag in Preventing Excessive Expansion of Concrete Due to the Alkali-Silica Reaction[1]

This standard is issued under the fixed designation C 441; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the effectiveness of pozzolans or slag in preventing the excessive expansion caused by reaction between aggregates and alkalies in portland cement mixtures. The evaluation is based on the expansion developed in mortar bars by a combination of portland cement and a pozzolan or slag, made with reactive aggregates (borosilicate glass), during storage under prescribed conditions of test.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 150 Specification for Portland Cement

C 227 Test Method for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar-Bar Method)

C 618 Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

C 989 Specification for Ground Granulated Blast-Furnace Slag for Use in Concrete and Mortars

C 1240 Specification for Use of Silica Fume Used in Cementitious Mixtures

C 1437 Test Method for Flow of Hydraulic Cement Mortar

3. Terminology

3.1 *Definitions*—For definitions of terms used in this test method, refer to Terminology C 125.

4. Significance and Use

4.1 This test method may be used as a preliminary or screening test to evaluate the relative effectiveness of a number of different materials being considered for use to prevent excessive expansion due to alkali-silica reaction.

4.2 This test method may also be used to evaluate materials proposed for use on a particular job to prevent excessive expansion due to alkali-silica reaction, by testing in the quantity and in combination with the cement or cements to be used on the job.

4.3 This test method does not assess the suitability of pozzolans or slag for use in concrete. These materials should comply with Specification C 618, Specification C 989 or Specification C 1240.

5. Apparatus

5.1 The apparatus shall be as described in Test Method C 227.

6. Materials

6.1 *Borosilicate Glass* [3] —Borosilicate glass granules graded according to Table 1 or crushed Pyrex Glass No. 7740 cullet or solid glass rod crushed and graded according to Table 1. After the glass cullet or rod has been crushed and separated into the various sieve sizes, wash with a water spray over the sieve to remove adhering dust and fine particles from the aggregate. Dry the portions retained on the various sieves and, unless used immediately, store each such portion individually in a clean container provided with a tight-fitting cover.

6.2 *High-Alkali Cement*—For the preparation of mortar bars for the preliminary or screening tests, use a blend of cement or cements that conform to Specification C 150 and contain between 0.95 and 1.05 % total alkalies as sodium oxide (Na_2O)

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.26 on Chemical Reactions .

Current edition approved May 1, 2005. Published May 2005. Originally approved in 1959. Last previous edition approved in 2002 as C 441–02a.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

[3] The sole source of supply of borosilicate glass granules in the specific sizes called for in this test method known to the committee at this time is Enviroglass International, Caldwell, ID, http://www.enviroglass.net/. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

TABLE 1 Grading Requirements

Sieve Size		Mass, %
Passing	Retained on	
4.75-mm (No. 4)	2.36-mm (No. 8)	10
2.36-mm (No. 8)	1.18-mm (No. 16)	25
1.18-mm (No. 16)	600-µm (No. 30)	25
600-µm (No. 30)	300-µm (No. 50)	25
300-µm (No. 50)	150-µm (No. 100)	15

calculated as % Na_2O + 0.658 × % potassium oxide (K_2O). If blending is needed, introduce the individual cements into the batch separately.

7. Proportioning and Consistency of Mortar

7.1 *Control Mixture*—The quantities of dry materials for the control mixture shall be 400 g of high-alkali cement and 900 g of glass aggregate made by recombining the portions retained on the various sieves in the prescribed grading (Table 1). Test specimens made from the control mixture shall have a 14-day increase in length of at least 0.250 %.

7.2 *Test Mixture Using Pozzolans*—The quantities of dry materials for the test mixture shall be 300 g of high-alkali cement, a mass of pozzolan having an absolute volume equal to the absolute volume of 100 g of portland cement (100 × density of pozzolan/3.15) and 900 g of glass aggregate made as described for the control mixture.

7.3 *Test Mixture Using Slag*—The quantities of dry materials for this test mixture shall be 200 g of high-alkali cement, a mass of slag having an absolute volume of 200 g of portland cement (200 × density of slag/3.15) and 900 g of glass made in accordance with 7.1.

7.4 A smaller quantity of the pozzolan or slag and a proportionately large quantity of cement may be used if there is evidence that it is unusually effective in reducing expansion due to the alkali-silica reaction and that the use of a smaller quantity is likely to produce a large reduction of expansion of the test mixture as compared to that of the control mixture.

7.5 *Job Mixture*—The quantities of dry materials used for the job mixture shall be in accordance with the requirements given above, except that the cement or cements to be used on the job shall be used instead of the high-alkali cement. Also, the quantity of pozzolan or slag, by mass, used with the portland cement shall be equivalent to that proposed for use on the job.

7.6 *Flow*—The amount of mixing water, measured in millilitres, shall be such as to produce a flow of between 100 and 115 as determined in accordance with Test Method C 1437.

8. Temperature and Humidity

8.1 The temperature of the dry materials, water, molding room, and moist cabinet and the humidity of the laboratory and moist cabinet shall conform to the requirements of Test Method C 227.

9. Test Specimen

9.1 *Preparation of Molds*—Prepare the molds as specified in Test Method C 227.

9.2 *Mixing of Mortar*—Mix the mortar as specified in Test Method C 227, except add the admixture or slag with the cement to the water.

9.3 *Molding Test Specimens*—Mold the specimens as specified in Test Method C 227.

9.4 *Dimensions and Number of Test Specimens*—Make three 1 by 1 by 11¼-in. or 25 by 25 by 285-mm test specimens having an effective gage length of 10 ± 0.1 in. or 254 ± 2.5 mm from each batch of each mortar mixture. One set of three specimens shall represent each test mixture or each job mixture. On the same day that the test specimens are made, make one set of three specimens representing the control mixture and store in the same container with the corresponding test specimens. Make all specimens stored in a given container on the same day. If more specimens from test or job mixtures, or both, are made on a given day than can be stored in a single container with the specimens from the control mixture made on that day, make additional control mixture specimens for each additional storage container used.

10. Procedure

10.1 Store and measure the test specimens in accordance with the applicable requirements of Test Method C 227.

11. Calculation

11.1 For tests of mixtures proportioned as prescribed, calculate the reduction of mortar expansion resulting from the use of a pozzolan or slag and report the result to the nearest 0.1 % as follows.

$$R_e = (E_r - E_t) \times 100/E_r$$

where:

R_e = reduction of mortar expansion, %,
E_t = average increase in length of mortar bars from the test mixture, and
E_r = average increase in length of mortar bars from the control mixture.

11.2 For test mixtures proportioned in accordance with the job mixture procedure, report the average length increase of the mortar bars as the length increase of the combination proposed for use in the work. Indicate contraction (length decrease) by prefixing a minus sign to the value of the length change reported.

12. Interpretation

12.1 Information pertaining to this procedure and to the significance of the results obtained has been published[4,5,6,7]

[4] Moran, W. T., and Gilliland, J. L., "Summary of Methods for Determining Pozzolanic Activity," *Symposium on Use of Pozzolanic Materials in Mortars and Concretes, ASTM STP 99,* ASTM International, 1950, p. 109.

www.technobetar.ir

and should be reviewed before results of the test are used as a basis for conclusions and recommendations concerning the properties and use of pozzolans, or slag combinations for concrete.

12.2 Minimum values for the reduction of mortar expansion (R_e) have been selected for use in specifications as a basis for acceptance of pozzolan or slag proposed for use in combination with high-alkali cement and an aggregate known to be potentially deleteriously alkali reactive.

13. Report

13.1 Report the following information:

13.1.1 Type and source of glass used.

13.1.2 The type of portland cement used and its total alkali content as Na_2O in percent. If the test is applied to a cement-pozzolan or cement-slag combination to be used in specific work, the type, brand, and manufacturing plant of the cement.

13.1.3 The type and proportion of pozzolan or slag used. If the test is applied to a cement-pozzolan or cement-slag combination to be used in specific work, the type, brand, source, proportion, and the nature of the pozzolan or slag.

13.1.4 If the control mixture and the test mixture are prepared as specified, the average increase in length of the mortar bars prepared from the control mixture and the average increase in length of the mortar bars from the test mixture, in percent. Also, the reduction in mortar length change resulting from the use of the pozzolan or slag (R_e), in percent.

13.1.5 The average increase in length of the mortar bars prepared from the job mixtures, in percent.

14. Precision and Bias

14.1 *Precision*—Repeatability shall be considered satisfactory if the percentage length increase of each specimen made from the same cement-aggregate combination is within 0.003 of the average, except that, if the average length increase exceeds 0.02 %, the repeatability shall be considered satisfactory if the percentage length increase of each specimen molded from the same cement-aggregate combination is within 15 % of the average.

14.2 *Bias*—This procedure has no bias because the effectiveness is defined in terms of this test method.

15. Keywords

15.1 alkali-silica reaction; concrete; expansion; fly ash; ground blast-furnace slag; mortar; pozzolan; silica fume

Designation: C 451 – 08

Standard Test Method for Early Stiffening of Hydraulic Cement (Paste Method)[1]

This standard is issued under the fixed designation C 451; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of early stiffening in hydraulic-cement paste.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic-cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 min. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 187 Test Method for Normal Consistency of Hydraulic Cement

C 219 Terminology Relating to Hydraulic Cement

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

D 1193 Specification for Reagent Water

3. Terminology

3.1 *Definitions:*

3.1.1 *early stiffening*, *n*—the early development of stiffness in the working characteristics of a hydraulic-cement paste, mortar, or concrete; varieties include false set and flash set.

3.1.2 *false set*, *n*—the early development of stiffness in the working characteristics of a hydraulic-cement paste, mortar, or concrete without the evolution of much heat, which stiffness can be dispelled and plasticity regained by further mixing without addition of water; also known as "grab set," "premature stiffening," " hesitation set," and "rubber set."

3.1.3 *flash set*, *n*—the early development of stiffness in the working characteristics of a hydraulic-cement paste, mortar, or concrete, usually with the evolution of considerable heat, which stiffness cannot be dispelled nor can the plasticity be regained by further mixing without addition of water; also known as "quick set."

3.1.4 Refer to Terminology C 219 for definitions of other terms.

4. Summary of Test Method

4.1 A paste is prepared with the cement to be tested, using sufficient water to give a required initial penetration as measured by the Vicat apparatus at a stipulated time after completion of mixing. A second penetration, termed the final penetration, is measured at a later stipulated time. The ratio of final penetration to initial penetration is calculated as a percentage.

5. Significance and Use

5.1 The purpose of this test method is to determine the degree to which a cement paste develops early stiffening or to establish whether or not a cement complies with a specification limit on early stiffening.

5.2 When used for establishing compliance with a specification limit, the specification requirement is customarily stated in terms of the minimum allowable final penetration, in

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.30 on Time of Set.

Current edition approved June 1, 2008. Published June 2008. Originally approved in 1960. Last previous edition approved in 2007 as C 451 – 07.

www.technobetar.ir

percent, calculated in accordance with the Calculation Section. When used for estimating the relative tendency of a cement to manifest early stiffening, additional information of value may be obtained if the remix procedure described in the Procedure Section is employed. Under some conditions, a judgment may be made by comparing the behavior in the initial test and in the remix procedure to differentiate a relatively less serious and less persistent tendency to early stiffening (false set) from one that is more persistent and, consequently, more serious (flash set).

5.3 Severe false setting in a cement may cause difficulty from a placing and handling standpoint, but it is not likely to cause difficulties where concrete is mixed for a longer time than usual, as usually occurs in transit mixing, or where it is remixed prior to placing or transporting, as occurs in concrete pumping operations. It is most likely to be noticeable where concrete is mixed for a short period of time in stationary mixers and transported to the forms in non-agitating equipment, such as on some paving jobs, and when concrete is made in an on-site batch plant.

5.4 Cements with severe false setting usually require slightly more water to produce the same consistency, which may be expected to result in slightly lower strengths and increased drying shrinkage.

5.5 Early stiffening resulting from false set is not likely to cause a cement to fail the applicable time of setting requirement.

5.6 Early stiffening resulting from flash set, depending on severity, can cause a cement to fail the applicable time of setting requirement.

6. Apparatus

6.1 *Vicat Apparatus*, conforming to the requirements of Test Method C 187.

6.2 *Flat Trowel*, having a sharpened straight-edged steel blade 100 to 150 mm in length. The edges when placed on a plane surface shall not depart from straightness by more than 1 mm.

6.3 *Mixer, Bowl, Paddle, and Scraper*, conforming to the requirements of Practice C 305.

6.4 *Glass Graduates*, 200 or 250 ml capacity, conforming to the requirements of Specification C 1005.

6.5 *Masses and Mass Determining Devices*, conforming to the requirements of Specification C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

6.6 *Conical Ring*, made of a rigid, non-corroding, non-absorbernt material, having a height of 40 ± 1 mm, an inside diameter at the bottom of 70 ± 3 mm, and an inside diameter at the top of 60 ± 3 mm (see Test Method C 187, Fig. 1 item G).

6.7 *Plane Non-Absorptive Plate*, 100 ± 5 mm square, of similar planeness, corrosivity, and absorptivity to that of glass (see Test Method C 187, Fig. 1 item H).

6.8 Inspect and document Section 6 apparatus conformance to the requirements of this test method at least every 2 ½ years.

7. Reagent

7.1 *Mixing Water*—Potable water is satisfactory for routine tests. For all referee and cooperative tests, use reagent water conforming to the requirements of Specification D 1193 for Type III or Type IV grades of reagent water.

8. Sampling

8.1 When the test is part of acceptance testing, sample the cement in accordance with Practice C 183.

9. Conditioning

9.1 Maintain the temperature of the room, dry materials, paddle, bowl, conical ring, and base plate at 23.0 ± 3.0 °C. Maintain the temperature of the mixing water at 23.0 ± 2.0 °C.

9.2 Maintain the relative humidity of the mixing room at not less than 50 %.

10. Procedure

10.1 *Preparation of Cement Paste*—Mix 500 g of cement with sufficient water to produce a paste with an initial penetration of 32 ± 4 mm using the following procedure.

10.1.1 Place the dry paddle and the dry bowl in the mixing position in the mixer.

10.1.2 Introduce the materials for a batch into the bowl and mix in the following manner:

10.1.2.1 Place all the mixing water in the bowl.

10.1.2.2 Add the cement to the water and allow 30 s for the water to absorb.

10.1.2.3 Start the mixer and mix at a slow speed (140± 5 r/min) for 30 s.

10.1.2.4 Stop the mixer for 15 s, and during this time scrape down into the batch any paste that may have collected on the sides of the bowl.

10.1.2.5 Start the mixer at a medium speed (285 ±10 r/min) and mix for 2½ min.

10.2 *Molding Test Specimens*—Quickly form the cement paste into a ball with gloved hands. Press the ball, resting in the palm of one hand, into the larger end of the conical ring held in the other hand, completely filling the ring with paste. Remove the excess at the larger end by a single movement of the palm of the hand. Place the ring on its larger end on the non-absorptive plate and slice off the excess paste at the smaller end at the top of the ring by a single oblique stroke of a sharp-edged trowel held at a slight angle with the top of the ring. Smooth the top of the specimen, if necessary, with one or two light touches of the pointed end of the trowel. During the operation of cutting and smoothing, take care not to compress the paste.

10.3 *Determination of Initial Penetration*—Set the paste confined in the ring resting on the plate, H, under the rod, B, Fig. 1 of Test Method C 187, about one third of the diameter from the edge, and bring the plunger end, C, in contact with the surface of the paste and the tightened setscrew, E. Then set the movable indicator, F, to the upper zero mark of the scale, and release the rod exactly 20 s after completion of the mixing. Keep the apparatus free of all vibrations during the penetration test. Consider the paste to have proper consistency when the rod settles to a point 32 ± 4 mm below the original surface in

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:14 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

30 s after being released. Make trial pastes with varying percentages of water until this consistency is obtained. This consistency is the initial penetration. During the 30-s interval for the initial penetration, return the excess paste to the bowl and cover the bowl and mixing paddle with a lid.

10.4 *Determination of Final Penetration*—After completion of the initial reading, remove the plunger from the paste, clean it, and reset the ring and plate in a new position. Perform this operation with as little disturbance as possible to the paste confined in the Vicat ring. Then bring the plunger again in contact with the surface of the paste, tighten the setscrew, and set the movable indicator to the upper zero mark of the scale. Release the plunger a second time 5 min ± 10 s after completion of the mixing period, and determine the final penetration 30 s after the plunger is released.

10.5 *Determination of Remix Penetration*—If the penetrations determined by the foregoing procedure show the cement to be stiffening rapidly, at the option of the tester, obtain information as to the nature of the stiffening by testing as follows:

10.5.1 After completing the measurement of the 5-min penetration, immediately return the paste in the ring to the bowl.

10.5.2 Start the mixer, raise the bowl into mixing position, and remix the contents of the bowl at a medium speed (285 ±10 r/min) for 1 min.

10.5.3 Fill the ring and determine the penetration following the procedures specified in 10.2 and 10.3.

11. Calculation

11.1 Calculate the percent final penetration, based on the ratio of final penetration to initial penetration, as follows:

$$P, \% = \frac{B}{A} \times 100 \quad (1)$$

where:
P = percent final penetration,
A = initial penetration, mm, and
B = final penetration, mm.

12. Report

12.1 Report the results of the test as follows:

Initial penetration	___ mm
Final penetration	___ mm
Percent final penetration	___ %
Remix penetration	___ mm

13. Precision and Bias

13.1 Precision

13.1.1 On samples testing between 8 % and 89 % Paste False Set, the single-operator (within laboratory) standard deviation has been found to be 10 % (1s), therefore, results of two properly conducted tests by the same operator on samples of the same cement should not differ from each other by more than 28 % (1s and d2s are defined in Practice C 670).

13.1.2 On samples testing between 8 % and 89 % Paste False Set, the multi-laboratory standard deviation has been found to be 12 % (1s), therefore, results of two properly conducted tests from two different laboratories on samples of the same cement should not differ by more than 34 % (1s and d2s are defined in Practice C 670). (See Note 1.)

13.2 Bias

13.2.1 Since an acceptable reference material suitable for determining any bias of this method does not exist, no statement on bias is being made.

NOTE 1—This data is based upon CCRL Portland Cement round robin test samples 47 to 138. The data indicates that precision decreases as the false set values fall below approximately 60 %. These decreases are not clearly statistically significant, however they do indicate the duplication difficulties on cements which exhibit false set tendencies severe enough to fail or possibly fail Specification C 150 optional limits.

14. Keywords

14.1 early stiffening; false set; flash set; hydraulic-cement paste; Vicat.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 451 – 07, that may impact the use of this test method. (Approved June 1, 2008)

(*1*) Revised 6.2, 6.5, and 9.2.

Committee C01 has identified the location of selected changes to this test method since the last issue, C 451 – 05, that may impact the use of this test method. (Approved July 15, 2007)

(*1*) Added new 6.8.

Designation: C 452 – 06

Standard Test Method for Potential Expansion of Portland-Cement Mortars Exposed to Sulfate[1]

This standard is issued under the fixed designation C 452; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method, which is applicable only to portland cements, covers the determination of the expansion of mortar bars made from a mixture of portland cement and gypsum in such proportions that the mixture has a sulfur trioxide (SO_3) content of 7.0 mass %.

1.2 The values stated in SI units (IEEE/ASTM SI-10) are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2]

2. Referenced Documents

D 1193 Specification for Reagent Water

IEEE/ASTM SI-10 Practice for Use of the International System of Units (SI): The Modern Metric System

3. Significance and Use

3.1 This test method is used primarily by those interested in research on methods for determining the potential sulfate resistance of portland cement. This test method is also used to establish that a sulfate-resisting portland cement meets the performance requirements of Specification C 150.

4. Apparatus

4.1 *Weights and Weighing Devices*, conforming to the requirements of Specification C 1005.

4.2 *Flow Table*, conforming to the requirements of Specification C 230/C 230M.

4.3 *Mixer, Bowl, and Paddle*, conforming to the requirements of Practice C 305.

4.4 *Trowel and Tamper*, conforming to the requirements of Test Method C 109/C 109M.

4.5 *Glass Graduates, Molds, and Length Comparator*, conforming to the requirements of Practice C 490.

5. Temperature and Humidity

5.1 *Molding Room, Dry Materials, and Mixing Water*—Maintain the temperature of the molding room, dry materials, and mixing water at 23.0 ± 4.0 °C (73.5 ± 7 °F) and the relative humidity of the molding room at not less than 50 %.

5.2 *Moist Cabinet or Room*, conforming to the requirements of Specification C 511.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.29 on Sulfate Resistance.

Current edition approved May 15, 2006. Published June 2006. Originally approved in 1960. Last previous edition approved in 2002 as C 452 – 02.

6. Materials

6.1 Use graded sand that conforms to Specification C 778 Table 1 Standard Sand Requirements for making the test mortar.

6.2 For the gypsum addition to portland cement, use high grade natural gypsum[4] with 100 % passing the 150-µm (No. 100) sieve, at least 94 % passing the 75-µm (No. 200) sieve, and at least 90 % passing the 45-µm (No. 325) sieve. Calculate the percentage of cement and gypsum required to provide a mixture containing 7.0 mass % SO_3 as follows:

$$\text{Cement, \%} = [(g - 7.0)/(g - c)] \times 100 \quad (1)$$

$$\text{Gypsum, \%} = [(7.0 - c)/(g - c)] \times 100 \quad (2)$$

where:

c = SO_3 content of the portland cement, %,
g = SO_3 content of the gypsum, %, and
7.0 = SO_3 content of the cement-gypsum mixture, %.

6.3 If the SO_3 content of the gypsum is unknown, analyze the gypsum for SO_3 content using Test Methods C 471M. Determine the SO_3 content to the nearest 0.1 %.

6.4 *Purity of Water*—Unless otherwise indicated, references to water mean reagent water conforming to Type IV of Specification D 1193.

7. Number and Dimensions of Test Specimens

7.1 Make six 25 by 25 by 285-mm (or 1 by 1 by 11¼-in.) test specimens, three from each of two batches, for each cement.

7.2 In routine tests, 25 by 25 by 160-mm (or 1 by 1 by 6¼-in.) specimens may be used, but in case of dispute, results obtained with 25 by 25 by 285-mm (or 1 by 1 by 11¼-in.) specimens govern.

8. Preparing Specimen Molds

8.1 Prepare the molds in accordance with Practice C 490.

9. Proportioning, Consistency, and Mixing of Mortar

9.1 Use 400 g (cement plus gypsum) and 1100 g of sand for each batch. Use 194 mL of mixing water for all non-air-entraining portland cements, and 184 mL of mixing water for all air-entraining portland cements.

9.2 Mix the mortar according to the procedure for mixing mortars of Practice C 305, except after placing the mixing water in the bowl, add the gypsum and mix at the slow speed for 15 s, then stop the mixer, add the cement, and continue as prescribed in Practice C 305.

10. Procedure

10.1 *Molding Test Specimens:*

10.1.1 Immediately upon completion of the flow test, return the mortar to the bowl, scrape down into the batch any mortar on the side of the bowl, and remix at the medium speed (285 ± 10 r/min) for 15 s. Remove the paddle and the bowl from the mixer and shake the excess mortar from the paddle into the bowl. Fill the mold in two layers, each layer being compacted with the tamper. Work the mortar into the corners, around the gage studs, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, cut the mortar off flush with the top of the mold and smooth the surface with a few strokes of the trowel.

10.2 *Storage of Test Specimens:*

10.2.1 *Initial Storage*—Cure the specimens in the molds in the moist closet at 23 ± 2 °C (73.5 ± 3.5 °F) for 22 to 23 h. Then remove them from the molds, properly identify, and place in water at 23 ± 2 °C (73.5 ± 3.5 °F) for at least 30 min prior to making the initial length measurement.

10.2.2 *Subsequent Storage*—After the bars have been removed from the molds and measured, store them horizontally in water at 23 ± 2 °C (73.5 ± 3.5 °F). Store the specimens with at least 6-mm (¼-in.) clearance on all sides except for the necessary supports. Cover the specimens with at least 13 mm (½ in.) of water. Use a volume of water that does not exceed 5 times the volume of the bars to prevent excessive leaching. Replenish the water with fresh water every 7 days for the first 28 days and every 28 days thereafter.

11. Length Measurement

11.1 Measure the specimens for length by means of the length comparator. Remove them from the water storage, one at a time, and wipe with a damp cloth before measuring.

11.2 Make the first reading at the age of 24 h ± 15 min from the time the cement and water are mixed together. Measure the specimen again at the age of 14 days.

NOTE 1—Additional information of value may be obtained by returning the specimen to water storage after the 14-day test and making additional measurements at later ages.

12. Calculation

12.1 Calculate the difference in length of the specimen at 24 h and at 14 days to the nearest 0.001 % of the effective gage length and report as the expansion of the specimen at that period. All specimens remaining after 14 days must comprise a set having at least three specimens with a permissible range depending on the number of the remaining specimens, as follows:

No. of Specimens	Maximum Permissible Range, %
3	0.010
4	0.011
5	0.012
6	0.012

13. Report

13.1 Report the average of the specimens comprising the set to the nearest 0.001 %.

14. Precision and Bias

14.1 *Precision*:

14.1.1 The single-operator standard deviation has been found to be: 0.003 % for expansions between 0.01 and 0.04 %. Therefore, results of two properly conducted tests by the same operator on the same material should not differ from each other by more than 0.009 %.

[4] The sole source of supply of the apparatus known to the committee at this time is Terra Alba No. 1, available from the U.S. Gypsum Co., Southard, OK plant. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

14.1.2 The multilaboratory standard deviation has been found to be 0.005 % for expansions between 0.01 and 0.04 %. Therefore, results of two properly conducted tests on the same material in two different laboratories should not differ from each other by more than 0.014 %.

14.1.3 The precision of this test method has been evaluated by cooperative testing.[5]

14.2 *Bias*—Since there is no accepted reference material suitable for determining the bias for this test method, no statement on bias is being made.

15. Keywords

15.1 calcium sulfate; expansion; gypsum; portland cement; sulfate resistance

[5] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: 001–1004.

For additional useful information on details of cement test methods, reference may be made to the "Manual of Cement Testing," which appears in the *Annual Book of ASTM Standards*, Vol 04.01.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 452 – 06, that may impact the use of this test method. (Approved May 15, 2006)

(*1*) Revised 6.1.

(*2*) Added keywords.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 457 – 09

Standard Test Method for Microscopical Determination of Parameters of the Air-Void System in Hardened Concrete[1]

This standard is issued under the fixed designation C 457; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method describes procedures for microscopical determinations of the air content of hardened concrete and of the specific surface, void frequency, spacing factor, and paste-air ratio of the air-void system in hardened concrete (**1**).[2] Two procedures are described:

1.1.1 *Procedure A,* the linear-traverse method (**2, 3**).

1.1.2 *Procedure B,* the modified point-count method (**3, 4, 5, 6**).

1.2 This test method is based on prescribed procedures that are applied to sawed and lapped sections of specimens of concrete from the field or laboratory.

1.3 It is intended to outline the principles of this test method and to establish standards for its adequate performance but not to describe in detail all the possible variations that might be used to accomplish the objectives of this test method.

1.4 The values stated in SI units are to be regarded as standard. The values given in parentheses are mathematical conversions to inch-pound units that are provided for information only and are not considered standard.

1.5 *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific hazard statements see 8.3 and 10.1.

3. Terminology

3.1 For definitions of terms used in this test method, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *average chord length ($\bar{l}$), n*—the average length of the chords formed by the transection of the voids by the line of traverse; the unit is a length.

3.2.2 *paste-air ratio (p/A), n*—the ratio of the volume of hardened cement paste to the volume of the air voids in the concrete.

3.2.3 *paste content (p), n*—the proportion of the total volume of the concrete that is hardened cement paste expressed as percentage by volume.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.65 on Petrography.

Current edition approved July 1, 2009. Published August 2009. Originally approved in 1960. Last previous edition approved in 2008 as C 457 – 08d.

[2] The boldface numbers in parentheses refer to the list of references at the end of this test method.

www.technobetar.ir

3.2.3.1 *Discussion*—When this parameter is calculated, it is the sum of the proportional volumes of the cement, the net mixing water (including the liquid portions of any chemical admixtures), and any supplementary cementitious materials present (**7, 8**).

3.2.4 *spacing factor ($\bar{L}$), n*—a parameter related to the maximum distance in the cement paste from the periphery of an air void, the unit is a length.

3.2.5 *specific surface (α), n*—the surface area of the air voids divided by their volume, expressed in compatible units so that the unit of specific surface is a reciprocal length.

3.2.6 *void frequency (n), n*—voids per unit length of traverse; the number of air voids intercepted by a traverse line divided by the length of that line; the unit is a reciprocal length.

3.2.6.1 *Discussion*—The value for void frequency *(n)* cannot be directly determined by the paste-air ratio method as this value refers to the voids per unit measure of traverse in the total concrete (including aggregate).

3.2.7 *water void, n*—a space enclosed by the cement paste that was occupied by water at the time of setting and frequently found under an aggregate particle or reinforcing bar. A water-void is usually identified by its irregular shape or evidence that a channel or cavity has been created by bleed water trapped in the concrete at the time it hardened.

4. Summary of Test Method

4.1 *Procedure A, Linear-Traverse Method*—This procedure consists of the determination of the volumetric composition of the concrete by summing the distances traversed across a given component along a series of regularly spaced lines in one or more planes intersecting the sample. The data gathered are the total length traversed *(T_t)*, the length traversed through air voids *(T_a)*, the length traversed through paste *(T_p)*, and the number of air voids intersected by the traverse line *(N)*. These data are used to calculate the air content and various parameters of the air-void system. If only the air content is desired, only T_a and T_t need be determined.

4.2 *Procedure B, Modified Point-Count Method*—This procedure consists of the determination of the volumetric composition of the concrete by observation of the frequency with which areas of a given component coincide with a regular grid system of points at which stops are made to enable the determinations of composition. These points may be in one or more planes intersecting the sample. The data gathered are the linear distance between stops along the traverse *(I),* the total number of stops *(S_t)*, the number of stops in air voids *(S_a)*, the number of stops in paste *(S_p)*, and the number of air voids *(N)* intersected by the line of traverse over which the component data is gathered. From these data the air content and various parameters of the air-void system are calculated. If only the air content is desired, only S_a and S_t need be determined.

4.3 *Paste-Air Ratio Modification*—In some instances the sample is not representative of the concrete as a whole, so T_t and S_t lose their significance and cannot be used as a basis for calculations. The most common examples are concrete with large coarse aggregate and samples from the finished surface region, for both of which the examined sample consists of a disproportionately large amount of the mortar fraction. In such instances the usual procedure must be changed, and the paste-air ratio modification must be used (see 5.5).

5. Significance and Use

5.1 The parameters of the air-void system of hardened concrete determined by the procedures described in this test method are related to the susceptibility of the cement paste portion of the concrete to damage by freezing and thawing. Hence, this test method can be used to develop data to estimate the likelihood of damage due to cyclic freezing and thawing or to explain why it has occurred. The test method can also be used as an adjunct to the development of products or procedures intended to enhance the resistance of concrete to cyclic freezing and thawing (**1**).

5.2 Values for parameters of the air-void system can be obtained by either of the procedures described in this test method.

5.3 No provision is made for distinguishing among entrapped air voids, entrained air voids, and water voids. Any such distinction is arbitrary, because the various types of voids intergrade in size, shape, and other characteristics. Reports that do make such a distinction typically define entrapped air voids as being larger than 1 mm in at least one dimension being irregular in shape, or both. The honey-combing that is a consequence of the failure to compact the concrete properly is one type of entrapped air void (**9, 10**).

5.4 Water voids are cavities that were filled with water at the time of setting of the concrete. They are significant only in mixtures that contained excessive mixing water or in which pronounced bleeding and settlement occurred. They are most common beneath horizontal reinforcing bars, pieces of coarse aggregate and as channelways along their sides. They occur also immediately below surfaces that were compacted by finishing operations before the completion of bleeding.

5.5 Application of the paste-air ratio procedure is necessary when the concrete includes large nominal maximum size aggregate, such as 50 mm (2 in.) or more. Prepared sections of such concrete should include a maximum of the mortar fraction, so as to increase the number of counts on air voids or traverse across them. The ratio of the volume of aggregate to the volume of paste in the original mix must be accurately known or estimated to permit the calculation of the air-void systems parameters from the microscopically determined paste-air ratio.

NOTE 1—The air-void content determined in accordance with this test method usually agrees closely with the value determined on the fresh concrete in accordance with Test Methods C 138/C 138M, C 173/C 173M, or C 231 (**11**). However, significant differences may be observed if the sample of fresh concrete is consolidated to a different degree than the sample later examined microscopically. For concrete with a relatively high air content (usually over 7.5 %), the value determined microscopically may be higher by one or more percentage points than that determined by Test Method C 231.

SAMPLING AND SECTION PREPARATION

6. Apparatus and Materials for Sample Preparation (for either procedure)

6.1 Apparatus and materials for the preparation of surfaces of concrete samples for microscopical observation are described in Practice C 856; other apparatus may be equally suitable.

NOTE 2—Apparatus for measurement of prepared samples is described in the two following procedures.

7. Sampling (for either procedure)

7.1 Samples of concrete can be obtained from specimens cast in the field or laboratory, or by coring, sawing, or otherwise removing concrete from structures or products. The procedure followed and the location from which the samples are obtained will depend on the objectives of the program. In general, secure samples of hardened concrete in accordance with Test Method C 42 or Practice C 823 or both. Provide at least the minimum area of finished surface given in Table 1 in each sample. A sample may be composed of any number of specimens.

7.2 For referee purposes or to determine the compliance of hardened concrete with requirements of specifications for the air-void system, obtain samples for analysis by this test method from at least three randomly selected locations over the area or throughout the body of concrete to be tested, depending upon the objectives of the investigation.

8. Preparation of Sections (for either procedure)

8.1 Unless the objectives of the program dictate otherwise, saw the section for observation approximately perpendicular to the layers in which the concrete was placed or perpendicular to the finished surface. Individual sections should be as large as can be ground and examined with the available equipment. The required area may consist of more than one prepared section. Spread the selected traverse length uniformly over the available surface so as to compensate for the heterogeneity of the concrete.

TABLE 1 Minimum Area of Finished Surface for Microscopical Measurement

Nominal or Observed Maximum Size of Aggregate in the Concrete, mm (in).	Total Area to be Traversed for Determination of α or $\bar{L}$ [A], min, cm^2(in.^{2}) Based on Direct Measurement of:	
	Total Air-Void Content,[A,B]	Paste-Air Ratio, *p/A*
150 (6)	1613 (250)	645 (100)
75 (3)	419 (65)	194 (30)
37.5 (1½)	24 (155)	97 (15)
25.0 (1)	77 (12)	77 (12)
19.0 (¾)	71 (11)	71 (11)
12.5 (½)	65 (10)	65 (10)
9.5 (⅜)	58 (9)	58 (9)
4.75 (No. 4)	45 (7)	45 (7)

[A] See Section 3 for the interpretation of symbols employed.

[B] The indicated values refer to reasonably homogeneous, well-compacted concrete. The microscopical measurement should be made on proportionately larger area of sections if the concrete is markedly heterogeneous in distribution of aggregate or large air voids. If more than one finished surface is taken from a single portion of the concrete, the finished surfaces shall be separated by a distance greater than one half of the nominal or observed maximum size of aggregate.

8.2 If gross irregularities are present, begin the surface preparation by lapping (grinding on a flat surface) with nominal 150 µm (No. 100) silicon carbide abrasive. Lap the surface with successively finer abrasives until it is suitable for microscopical observation. An appropriate series of abrasives would include nominal 75, 35, 17.5 and 12.5 µm grit sizes (No. 220, 320, 600, and 800, respectively), and perhaps 5-µm aluminum oxide (Note 3). From time to time during lapping, and when changing to a finer abrasive and when lapping is complete, clean all surfaces of the specimen gently and thoroughly to remove the grinding compound. Use of ultrasonic cleaners may be harmful to the surface. Such treatment should not be used without care and experimentation. Cleaning with a soft cosmetic brush under running water, or by a pressurized dental spray has been successful. A surface that is satisfactory for microscopical examination will show an excellent reflection of a distant light source when viewed at a low incident angle and there shall be no noticeable relief between the paste and the aggregate surfaces. Areas that are scratched or imperfect indicate the need for additional preparation; use special techniques if required (see 8.3). The edges of the sections of the air voids will be sharp and not eroded or crumbled, and air-void sections including those as small as 10 µm ($3.94\ 10^{-5}$ in.) in diameter will be clearly distinguishable. (See Fig. 1.) Do not include scratched or broken portions of the surface in the analyzed area. If needed to meet the requirements of Table 1, prepare additional surfaces.

NOTE 3—Grit numbers of abrasives can denote slightly different particle sizes, depending on the manufacturer. The suggested sizes will usually be appropriate, but others may be selected according to the experience of the user.

8.3 Sometimes difficulty will be encountered in preparing the lapped surfaces. The usual cause is a weak cement-paste matrix. The problem is manifested by the plucking of sand grains from the surface during the lapping, with consequent scratching of the surface, and by undercutting of the paste around the harder aggregate particles. Friable particles of aggregate can also cause difficulty. In such instances the following procedure is helpful. Heat the partially prepared specimen of concrete to about 150 °C (300 °F) in an oven. (**Warning**—If the specimen was sawn with a lubricant other than water, heating must be done so as to avoid inhaling the fumes and to preclude fire or explosion. Some lubricants have a flash point as low as 140 °C (285 °F). (The flash point of the lubricant may be found by use of Test Method D 92.) Unless other precautions are taken, the temperature must not be allowed to approach the flash point. If this cannot be avoided, heating must be done in the open air on a hot plate or in an explosion-proof hood.)

Remove the specimen from the oven and immediately brush melted carnauba wax that was heated to the same temperature onto the surface. Repeat the application as the wax is absorbed by the concrete, so that when the temperature of the concrete falls below the melting point of the wax, a perceptible film remains on the surface. After the specimen has cooled, scrape off any excess wax and repeat the lapping. After completion of lapping, remove the residue of wax from the surface air voids by reheating the concrete to about 150 °C (300 °F) to allow

www.technobetar.ir

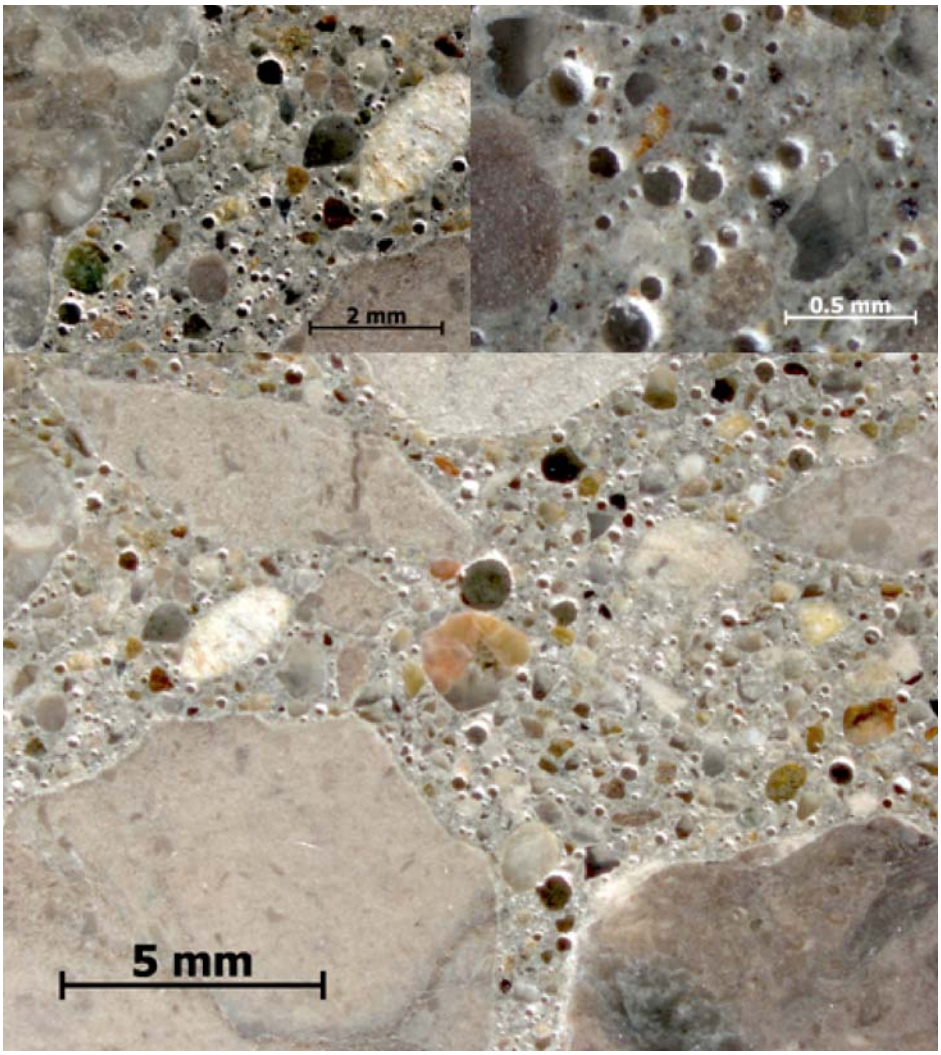

FIG. 1 Photographs of a Satisfactory Surface

absorption of the molten wax into the specimen. Again take care to avoid approaching the flash point of the wax or of any cutting oil present. Protect the surface from dust during heating. The time to remove the wax from the surface air voids varies with the properties and thickness of the specimen, but heating for about an hour is usually sufficient. Exceptionally fragile concrete may require repetition of this process. Substances other than carnauba wax have been used successfully to impregnate and strengthen the surfaces of concrete specimens before grinding.

NOTE 4—If performing a microscopic examination of the cement paste, using Practice C 856, on the same test sample that will be coated with wax or other paste strengthening media, perform the microscopic examination prior to heating the sample and application of the strengthening materials. The application of such materials and exposure to oven temperatures of 150 °C will alter the physical characteristics and appearance of the cement paste.

8.4 If the parameters of the air-void system near a finished or formed surface are desired, then prepare the section examined in such a manner as to allow for the fact that the parameters of the air-void system may vary greatly with the distance from such a surface. Therefore, measure the distance between the section to be examined and the original surface accurately, to at least the nearest 1.2 mm (0.05 in.). Use the following procedure: (*1*) Prepare a specimen that includes a portion of the finished or formed surface to be investigated, and of convenient thickness, but not less than 12 mm (½ in.) or one-half of the nominal maximum size of the aggregate, whichever is greater. (*2*) Lap the surface with a coarse abrasive until the last portion of the original surface is just removed, then complete the lapping operation as described above. Use this surface as the reference plane, to which later measurements are referenced. (*3*) Lap the back surface of the specimen so as to produce a plane section. (*4*) Measure the thickness of the specimen to the nearest 1.2 mm (0.05 in.) at four or more points uniformly spaced around the periphery. Average the results, and record the average to the nearest 1.2 mm. (*5*) Determine the parameters of the air-void system on any plane desired or specified. If nearest surface values are desired, make the determination on the reference plane; if values for the bulk concrete are desired, make the determination on the back plane. If values for some other plane are desired, repeat the grinding process to the desired depth. Redetermine the thickness of the

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

sample as specified above so that the parameters of the air-void system can be correlated with the distance of the examined surface from the reference plane.

8.5 The composition of the near-surface zone differs from that of the concrete as a whole. Therefore, whenever the design of the mixture is known, use the paste-air ratio method for the determination of the air-void system parameters in this region.

PROCEDURE A—LINEAR TRAVERSE METHOD

9. Apparatus for Measurement of Specimens

9.1 The apparatus listed in 9.1.1 to 9.1.5 comprises a recommended minimum selection. Apparatus other than that described has been used and may be equally satisfactory. Apparatus that uses electronic switches and totalizers has been constructed. Computerized apparatus is commercially available. Image analyzers have frequently been used.

9.1.1 *Linear-Traverse Device*—Provide a platform, on which the specimen is carried mounted on lead screws by means of which it can be smoothly translated in two perpendicular directions. Provide one lead screw for movement in the N-S direction and at least two for movement in the E-W direction (Note 5). One of these latter is called the "main" lead screw and the other(s) the "upper" lead screw(s). Ensure that the capacity of the main (E-W) lead screw is at least 100 mm (4 in.), that of each (E-W) lead screw at least 65 mm (2.5 in.), and that of the N-S lead screw at least 75 mm (3.0 in.). Ensure that the pitch of the upper lead screw does not exceed 0.265 mm (0.0105 in.) per revolution. Determine the pitch of all E-W lead screws to the nearest 0.03 mm (0.001 in.). Attach rotation counters readable to the nearest 0.01 of revolution to all E-W lead screws. Provide a manually operated tally counter. For the determination of the paste content, provide a third E-W lead screw complete with rotation counter, unless each traverse is to be repeated, that is, performed once for the air content and again for the paste content. Photographs of satisfactory linear-traverse devices are shown in Figs. 2 and 3.

NOTE 5—In the descriptions of the linear-traverse and point-count devices the term "E-W direction" refers to the direction from the operator's right to his left, and "N-S" means the direction perpendicular to E-W, that is, the directions are analogous to those on a map.

9.1.2 *Stereoscopic Microscope and Support,* with objectives and eyepieces to give final magnification in the range from about 50× to about 125×. While it is possible to use a microscope with a single, fixed magnification, it is more convenient to be able to vary the magnification within the above range by replacing eyepieces or objectives or, better, by means of a zoom attachment. Arrange the microscope so as to permit continuous observations of the surface of the specimen mounted on the platform of the linear-traverse device. Include cross hairs, scale, or some other reticle device to provide an index point in one eyepiece. Since an index point is dimensionless it shall be a point such as the intersection of one pair of edges of the cross hairs or one corner of the end of a line of a scale. Use the same index point throughout any examination.

9.1.3 *Microscope Lamp*, spotlight-type, arranged to provide sufficient illumination at a low and variable incident angle to the surface. The spot of evenly lit area on the specimen surface should be slightly larger than the field of view of the microscope.

9.1.4 *Spirit Level*, the small circular type is convenient.

9.1.5 *Leveling Device*—Provide a means to level the examined surface. This can be done by the insertion of small pieces of modeling clay. A better way is by means of a platform that is mounted on three adjustable leveling screws and that supports the sample on the stage of the traverse device.

10. Procedure

10.1 Place the prepared specimen of concrete on the stage of the linear-traverse device. Level the prepared surface with the leveling device and the spirit level so that the surface may be traversed and microscopically examined with a minimum of refocusing. Adjust the lamp so that the beam evenly illuminates the field of view of the microscope and is incident on the surface at a low angle, so the air voids are demarked by a shadow. Superimpose the index point on the surface to be examined. Do not use a magnification of less than 50× and do not change it during the course of the analysis. For a rectangular section, place the index near an upper corner; for a circular section, place it near the top and at one end of the initial traverse. Engage and adjust all drives so as to remove all play from the gear systems. Set all counters to zero. By operation of the main lead screw move the assembly and specimen in the E-W direction while scrutinizing the prepared surface as it moves beneath the microscope. When the index point is exactly superimposed on the periphery of a section of an air void (Notes 6 and 7) in the prepared surface of the specimen, stop the movement of the carriage, actuate the tally counter once, and by means of the upper lead screw, move the concrete under the microscope until the index point is exactly superimposed upon the opposite periphery of the same air-void section. Stop the rotation of the upper lead screw, and resume the movement by means of the main lead screw. Take extreme care to determine whether or not a section of an air void is intersected by the index point when the line of traverse is nearly tangent to the void section. The results can be affected significantly by consistent error in this respect. If the periphery of an air void is crumbled or rounded, estimate the position of the true periphery in the plane of the surface by extrapolation of the surface contour of the air void. If the paste content is being determined, as will usually be the case, carry out the above procedure for traverses across paste regions, except use the second upper lead screw and do not use the tally counter. Proceed in this way along the E-W traverse line, traversing all chords across air voids with the upper lead screw, all sections of paste with the second upper lead screw (if paste content is being determined), and all other sections with the main lead screw. Stop the traverse at the end of the line, which should be just within the examined area, not at its edge. By means of the N-S lead screw shift the sample an appropriate distance to the next traverse line. Space the segments of the traverse so as to cover the entire prepared surface with at least the minimum required traverse length. If the rotation counters operate in both directions, the next line of traverse can begin just below the

A = Base plate.
B = Front and back rails supporting the middle plate *C*
C = Middle plate.
D = Upper front and back rails carrying the stage *E*
E = Stage.
F = Concrete specimen
G = Rectangular front groove in the base plate.
H = V-shaped back groove in the base plate.
I = Main lead screw.
J = Two bearing blocks for the main lead screw.
K = Revolution counter on main lead screw.
L = Manually operated knurled wheel.
M = Electric motor for driving the main lead screw.
N = Upper lead screw.
O = Revolution counter for upper lead screw.
P = Hand-driven wheel for moving the stage.
Q = Ratchet counter to tally the number of air voids encountered.
R = Stereoscopic microscope.
S = Microscope lamp.

NOTE 1—Not shown are a third lead screw and a disengaging clutch; the former is necessary if a determination of the air-paste ratio is required, and the latter may be required (see 9.1.1).

FIG. 2 Photograph of a Linear-Traverse Device Meeting the Requirements of This Test Method

end of the previous one; if not, return the stage so the new line will begin just below the beginning of the previous one. Start each segment of the traverse just within the prepared area and on the satisfactory plane surface of the specimen rather than at the edge of the surface itself. The length of the segments of the traverse may vary. Superimpose the index point at the beginning of the new line, and perform the traverse as before. Repeat this process for all segments of the total traverse. Accumulate the total rotation on each counter, or read and record each at the end of each traverse line, so that the total will be the summation of such records. If more than one specimen has been prepared from the sample of concrete, repeat the procedure on each such specimen as to comply with the requirements of Table 1. Electronic or computerized equipment will require that the procedures specified by the fabricator be followed but the principles will remain as detailed above. The minimum length of traverse shall be as specified in Table 2.

NOTE 6—Surfaces examined may exhibit features that resemble air voids, but are not: *(a)* Occasionally a transparent section of a grain of quartz sand will look like an air void. *(b)* The socket left when a section of a nearly spherical and smooth sand grain is lost from the surface during grinding looks much like an air void, but can be distinguished by differences in the luster and sheen of the film lining the hole. *(c)* Cenospheres, hollow particles of fly ash, or hollow plastic spheres will

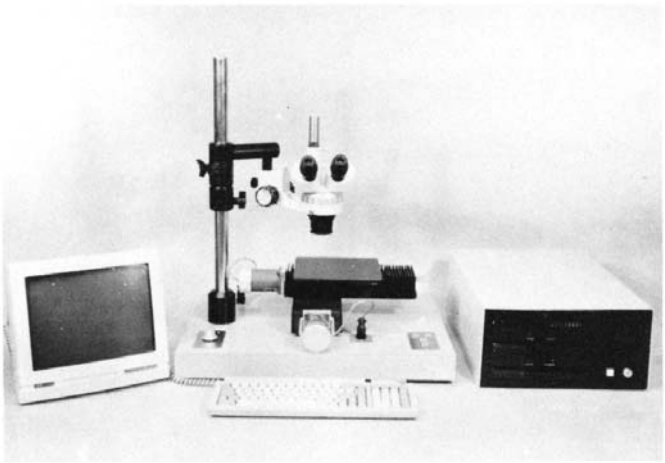

FIG. 3 Photograph of a Computerized Linear-Traverse/Point-Count Device Meeting the Requirements of This Test Method

TABLE 2 Minimum Length of Traverse for the Linear Traverse Method

Nominal or Observed Maximum Size of Aggregate in the Concrete, (mm) in.	Length of Traverse for Determination of[A], α, or $\bar{L}$, min, mm (in.)[A]
6 (150)	4064 (160)
3 (75)	3048 (120)
1½ (37.5)	2540 (100)
1 (25.0)	2413 (95)
¾ (19.0)	2286 (90)
½ (12.5)	2032 (80)
⅜ (9.5)	1905 (75)
4.75 (No. 4)	1397 (55)

[A] The limits of uncertainty of results obtained for air-void content depend upon the length of traverse and the air-void content of the concrete. Based on experience, the recommended minimum length of traverse shown in this table should produce limits of uncertainty such that up to 3 % air-void content the standard deviation is not greater than 0.5 %, which at 3 % air-void content corresponds to a coefficient of variation of 17 %. For traverse lengths greater than 1375 mm (55 in.) and air-void contents greater than 3 % the coefficient of variation is correspondingly reduced. The data obtained can be analyzed by statistical methods to determine the limits of uncertainty to be applied.

also have a different sheen, and are unaffected when the surrounding paste is etched with dilute (10 %) hydrochloric acid.

Warning—Do not acid-etch the sample under the microscope, as the effervescent spatter may damage the lens.

NOTE 7—Occasionally, air voids may become filled, during the service exposure of the concrete, with secondary products. Whether such voids are counted as belonging to the air-void system or not depends on the purposes of the investigation.

11. Calculation

11.1 When based on the air content of the total concrete:

11.1.1 The data will consist of:

where:

N = total number of air voids intersected,
R_i = number of rotations of the respective lead screws, and
P_i = pitch of the corresponding lead screws.

11.1.2 Calculate:

$$T_t = \text{total length of traverse} = \text{sum of } P_i \times R_i \quad (1)$$

$$T_a = \text{traverse length through air} = P_a \times R_a \quad (2)$$

$$T_p = \text{traverse length through paste} = P_p \times R_p \quad (3)$$

11.1.3 *Air Content (A),* in %:

$$A = \frac{T_a \cdot 100}{T_t} \quad (4)$$

11.1.4 *Void Frequency (n)*:

$$n = \frac{N}{T_t} \quad (5)$$

11.1.5 *Average Chord Length* ($\bar{l}$):

$$\bar{l} = \frac{T_a}{N} \quad (6)$$

or

$$\bar{l} = \frac{A}{100n} \quad (7)$$

11.1.6 *Specific Surface* (α):

$$\alpha = \frac{4}{\bar{l}} \quad (8)$$

or

$$\alpha = \frac{4N}{T_a} \quad (9)$$

11.1.7 *Paste Content (p),* in %:

$$p = \frac{T_p \cdot 100}{T_t} \quad (10)$$

11.1.8 *Paste-Air Ratio (p/A)*:

$$\frac{p}{A} = \frac{T_p}{T_a} \quad (11)$$

11.1.9 *Spacing Factor* ($\bar{L}$):

11.1.9.1 When *p/A* is less than or equal to 4.342

$$\bar{L} = \frac{T_p}{4N} \quad (12)$$

11.1.9.2 When *p/A* is greater than 4.342

$$\bar{L} = \frac{3}{\alpha}\left[1.4\left(1 + \frac{p}{A}\right)^{1/3} - 1\right] \quad (13)$$

11.2 If the calculations are based on the paste-air ratio method, the design of the mixture must be known. The microscopically determined data will consist of T_p, T_a, and N. Proceed as follows:

11.2.1 Calculate the *paste-air ratio (r):*

$$r = \frac{T_p}{T_a} \quad (14)$$

11.2.2 From the mixture design calculate the ratio of *aggregate volume* to *paste volume (M):*

$$M = \frac{G_c}{p_c} \quad (15)$$

where:

G_c = sum of the masses of the aggregates; each divided by its specific gravity (Note 8), and
p_c = sum of mass of cement divided by specific gravity of cement + mass of mineral admixture divided by the specific gravity of the mineral admixture + mass of water (including the fluid portion of any admixture) divided by the specific gravity of the fluids (Note 8):

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:17 EDT 2010

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 8—The values used for the calculated G_c and p_c must accurately reflect the differing densities of the constituents and the proportions of the masses of each.

11.2.3 The *percent air (A):*

$$A=\frac{100}{r(1+M)+1} \tag{16}$$

11.2.4 *Paste* expressed as percent *(p):*

$$p=A\cdot r \tag{17}$$

11.2.5 *Average chord length* ($\bar{l}$):

$$\bar{l}=\frac{T_a}{N} \tag{18}$$

11.2.6 *Specific Surface* (α): Use Eqs 8 or 9.

11.2.7 *Spacing Factor* ($\bar{L}$):

11.2.7.1 When *r* is equal to or less than 4.342 use Eq 12.

11.2.7.2 When *r* is greater than 4.342 use Eq 13 with the substitution of *r* for the *p/A* ratio.

11.3 If desired, the spacing factor ($\bar{L}$) may be estimated graphically by use of Fig. 4 rather than calculated directly.

PROCEDURE B—MODIFIED POINT-COUNT METHOD

12. Apparatus for Measurement of Specimens

12.1 The apparatus listed in 12.1.1 to 12.1.5 comprises a recommended minimum selection. Apparatus other than that described has been used and may be equally satisfactory. Apparatus that uses electronic switches and totalizers has been constructed. Computerized apparatus is commercially available. Image analyzers have frequently been used.

12.1.1 *Point-Count Device*, comprising a stage or platform connected to E-W and N-S (Note 5) lead screws and designed in such a way that a specimen of concrete placed on the stage can be moved smoothly and uniformly through equal distances by turning of the screws. Ensure that the total possible translation of the stage is at least 100 mm (4.0 in.) in each direction. Fit lead screws with notched wheels and stopping devices, such that with each rotation of the screws a click can be detected by the operator when a stop position is reached. Ensure that the intervals between the stops correspond to a translation of the stage a distance of 0.025 to 0.64 to 5.0 mm (0.025 to 0.200 in.). Determine the magnitude of the average translation of the stage between stops to the nearest 0.03 mm (0.001 in.). Provide at least four digital counters; more may be better. It may be convenient to attach one counter to the stopping device of the E-W lead screw, so as to register automatically the total number of stops in that direction. A photograph of a satisfactory device for the modified point-count method is given in Fig. 5.

12.1.2 *Stereoscopic Microscope and Support*, as described in 9.1.2.

12.1.3 *Microscope Lamp*, as described in 9.1.3.

12.1.4 *Spirit Level*, as described in 9.1.4.

12.1.5 *Leveling Device*, as described in 9.1.5.

13. Procedure

13.1 Place the prepared surface of concrete on the stage of the point-count device. Using the spirit level, level the prepared surface with the leveling device so that the surface may be traversed and microscopically examined with a minimum of refocusing. Adjust the lamp so the beam evenly illuminates the field of view of the microscope and is incident upon the surface at a low angle, so the air voids are demarked by a shadow. Superimpose the index point of the cross hairs (or other reticle device) on the surface to be examined. Use a magnification not less than 50× and do not change it during the course of the analysis. For a rectangular section, place the index near an upper corner; for a circular section, place it near the top and at one end of the initial traverse. Position the stopping device at a stop or click position at the beginning of the traverse. Do not include the initial stops for each traverse line in the total number of stops or in the number of stops for any component. Zero all counters. By operation of the E-W lead screw, cause movement of the stage and specimen while simultaneously scrutinizing the surface. At each click stop, except not at the beginning of any traverse line, pause and examine the field of view, and record on the appropriate counter the material or phase on which the index point is superimposed (Notes 5, 6 and 7). Normally use one counter for air voids, one for paste, and one for all other phases (or a totaling counter). Other components (fine and coarse aggregate, for example—if they are lithologically distinguishable) of the concrete can be determined with the use of additional counters. Continue in this way along the line until a last stop is reached just within the prepared area, but close to its edge. When the end of the line is reached, turn off the totaling counter. Reverse the E-W lead screw and proceed back along the same line, recording on another counter each air void intersected, whether or not a stop occurred within the air void. Terminate the void counting just before the initial stop. Take extreme care to determine whether a section of an air void is intersected by the movement of the index when the line of traverse is nearly tangent to the void section. The results can be affected significantly by consistent error in this respect. If the periphery of an air void is crumbled or rounded, estimate the position of the true periphery in the plane of the surface by extrapolation of the surface contour of the air void. If the examination is being made to determine only the air content of the concrete, the number of air voids intersected by the line of traverse need not be determined. By means of the N-S lead screw, shift the concrete specimen at right angles to the direction of traverse an appropriate distance. Space the segments of the traverse so as to cover the whole prepared surface and achieve at least the minimum length of traverse and the minimum number of points specified in Table 3. Proceed along the new line of traverse as before, and so on, for all segments of the total traverse and for all sections prepared from a sample of concrete so as to comply with the requirements of this test method. Electronic or computerized equipment will require that the procedures specified by the fabricator be followed but the principles will remain as detailed above. When calculations are based on the paste-air ratio, the minimum length of traverse shall be as shown in Table 3, and the minimum number of points shall comply with the following equation:

$$S_a=\frac{10\,000}{V^2} \tag{19}$$

TABLE 3 Minimum Length of Traverse and Minimum Number of Points for the Modified Point-Count Method[A]

Nominal or Observed Maximum Size of Aggregate in the Concrete, mm (in.)	Length of Traverse for Determination of[A], α, or $\bar{L}$, min, mm (in.)	Number of Points for Determination of[A], α, or $\bar{L}$, min
150 (6)	4064 (160)	2400
75 (3)	3048 (120)	1800
37.5 (1½)	2540 (100)	1500
25.0 (1)	2413 (95)	1425
19.0 (¾)	2286 (90)	1350
12.5 (½)	2032 (80)	1200
9.5 (⅜)	1905 (75)	1125
4.25 (No. 4)	1397 (55)	1000

[A] The limits of uncertainty of results obtained for air-void content depend upon the number of points and the air-void content of the concrete. The recommended minimum number of points shown in this table should produce limits of uncertainty such that up to 3 % air-void content the standard deviation is not greater than 0.5 % which at 3 % air-void content corresponds to a coefficient of variation of 17 %. For number of points greater than 1000 and air-void contents greater than 3 % the coefficient of variation is correspondingly reduced. The data obtained can be analyzed by statistical methods to determine the limits of uncertainty to be applied.

$$\frac{p}{A}=\frac{S_p}{S_a} \tag{24}$$

14.1.6 *Average chord length* ($\bar{l}$):

$$\bar{l}=\frac{S_a \cdot I}{N} \tag{25}$$

or

$$\bar{l}=\frac{A}{100n} \tag{26}$$

14.1.7 *Specific Surface* (α):

$$\alpha=\frac{4}{\bar{l}} \tag{27}$$

or

$$\alpha=\frac{400n}{A} \tag{28}$$

14.1.8 *Spacing Factor* ($\bar{L}$):

14.1.8.1 If *p/A* is less than or equal to 4.342

$$\bar{L}=\frac{p}{400n} \tag{29}$$

14.1.8.2 If *p/A* is greater than 4.342

$$\bar{L}=\frac{3}{\alpha}\left[1.4\left(1+\frac{p}{A}\right)^{1/3}-1\right] \tag{30}$$

14.2 If the calculations are based on the paste-air ratio method, the data will consist of S_a, S_p, N, and I (the distance between stops). Calculate the following:

14.2.1 The *paste-air ratio (r):*

$$r=\frac{S_p}{S_a} \tag{31}$$

14.2.2 From the mixture design, calculate the ratio of *aggregate volume to paste volume (M):*

$$M=\frac{G_c}{p_c} \tag{32}$$

where:

G_c = sum of the masses of the aggregates; each divided by its specific gravity (Note 8), and,

p_c = sum of mass of cement divided by specific gravity of cement + mass of mineral admixture divided by the specific gravity of the mineral admixture + mass of water (including the fluid portion of any admixture) divided by the specific gravity of the fluids (Note 8).

14.2.3 The *percent air (A):*

$$A=\frac{100}{r(1+M)+1} \tag{33}$$

14.2.4 *Paste* expressed as percent *(p):*

$$p=A \cdot r \tag{34}$$

14.2.5 *Specific Surface* (α):

$$\alpha=\frac{4N}{S_a \cdot I} \tag{35}$$

14.2.6 *Average chord length* ($\bar{l}$):

$$\bar{l}=\frac{S_a \cdot I}{N} \tag{36}$$

14.2.7 *Spacing Factor* ($\bar{L}$):

14.2.7.1 When r is equal to or less than 4.342

$$\bar{L}=\frac{S_p \cdot I}{4N} \tag{37}$$

14.2.7.2 When r is greater than 4.342, use Eq 12 with the substitution of r for the *p/A* ratio.

14.3 If desired, the spacing factor *(L)* may be estimated graphically by use of Fig. 4 rather than calculated directly.

15. Report

15.1 Report the following information from the results of the linear-traverse or modified point-count method:

15.1.1 Method used, Procedure A or Procedure B,

15.1.2 Identification of the source of the samples,

15.1.3 Location from which the samples were taken and their orientation with respect to the sources,

15.1.4 Orientation and position of the surfaces cut from the samples for traversing,

15.1.5 The length of traverse, the area traversed, and, if the modified point-count method is employed, the number of stops,

15.1.6 The determined values of air content and, if measured, void frequency, specific surface, spacing factor, and paste-air ratio, and

15.1.7 Method by which the paste content was determined.

15.2 If the parameters of the air-void system have been determined on near-surface sections, the relationship of such parameters to the depth from the reference surface.

16. Precision and Bias

16.1 *Precision*:

16.1.1 The estimates of precision for this test method are given in Table 4 for determinations made on a series of four lapped specimens prepared in one laboratory and then circulated to nine laboratories where a number of determinations were made in each laboratory, usually involving at least two operators per laboratory and two or three determinations per operator. The range of properties covered by the four prepared surfaces used in this study was: for air content, 2 to 9 %; for voids intersected, 79 to 512 voids/m (2 to 13 voids/in.); and for paste content average, in the range of 20 to 22 %. The

www.technobetar.ir

TABLE 4 Average Precision Data Based on a Set of Four Prepared Specimens Circulated to Nine Laboratories[A]

Item	Standard Deviation (1s)[B]	Range of Two Test Results (D2s)[B]	Percent of Average	
			Coefficient of Variation (1s %)[C]	Range of Two Test Results (D2s %)[C]
Air Content, %:				
Within Lab	0.29	0.82	. . .	. . .
Between Lab	0.41	1.16	. . .	. . .
Voids/in.:				
Within Lab	. . .	. . .	3.7	10.3
Between Lab	. . .	. . .	12.4	35.0
Paste Content, %:				
Between Operator (Each in Their Own Laboratory)	3.1	8.8	. . .	. . .

[A] Includes determinations using both point count and linear traverse. In all, 19 operators participated with a total of 41 determinations on each specimen. For point count: 6 labs; 12 operators; and 26 determinations. For linear traverse: 3 labs; 7 operators; and 15 determinations. Paste content determinations were made by 13 operators representing 8 different laboratories. Eleven were by point count and 2 by linear traverse procedures.

[B] These numbers represent, respectively, the (1s) and (D2s) limits as described in Practice C 670.

[C] These numbers represent, respectively, the (1s %) and (D2s %) limits as described in Practice C 670.

variability of the test method would be higher in actual practice for specimens sampled and prepared from in-place concrete since additional variation due to sample selection and surface preparation in different laboratories would increase the coefficient of variation. Additional data are still being gathered on these four prepared specimens and additional statistical analyses will be done on the data to arrive at precision estimates for spacing factor calculated from the results of each determination. Table 5 compares the actual variation from this study with theoretical estimates.

TABLE 5 Comparison of Actual Variation with Theoretical Estimates Based on Binomial and Poisson's Distribution

Specimen Number	Average Value	Standard Deviation		Coefficient of Variation %	
		Actual[A]	Theoretical[B]	Actual	Theoretical
Air Content, % Based on Counts of 1500 Points					
1	2.98	0.45	0.44	15.1	14.8
2	3.65	0.49	0.48	13.4	13.2
3	5.55	0.40	0.59	7.2	10.6
4	8.02	0.64	0.70	8.0	8.7
Voids Per Inch Based on 100 in. Traverses					
1	2.31	0.27	0.15	11.7	6.5
2	5.77	0.78	0.24	13.5	4.2
3	7.69	0.86	0.28	11.2	3.6
4	12.69	1.63	0.36	12.8	2.8

[A] Includes all data—all labs and all operators. Includes both point count and linear traverse data.

[B] Theoretical Standard Deviation:—For air content: Binomial Distribution; Standard deviation in points on air = $\sqrt{npq}$ using an assumed 1500 point count, where n is number of points, p is decimal fraction of air, and q is decimal fraction not-on-air. To convert to units of percent air content, divide by n and multiply by 100 to get percent. For voids per in.: Poisson's Distribution; S.D. = $\sqrt{np}$ where np is the mean number of occurrences (counts per 100 in. of traverse based on results of 100-in. traverses).

16.1.2 Table 6 provides an estimate of precision for air content and spacing factor from a European study **(12)** using predominantly the same procedures as contained in this test method. The great majority of these determinations were made by linear traverse with a magnification of 50×. Two hardened concrete beam specimens with nominal air contents of about 3 and 6.5 % were sampled by one laboratory. A pair of surfaces were sawn from the beams for each participating laboratory; one surface was lapped in the originating laboratory, and the adjacent surface was lapped in the participating laboratory.

16.2 *Bias*:

16.2.1 There is no accepted reference material suitable for determining bias from the true air-void parameters of concrete.

16.2.2 From the results of the interlaboratory study referenced in 16.1.1 and Table 4 there was very little bias between Procedure A and Procedure B for the average results for air content and voids intersected measured on each of the four specimens. The overall averages are given in Table 7. Two few determinations of paste content were made by Procedure A to make any comparison for that property.

17. Keywords

17.1 air content; air void parameters of hardened concrete; area-prepared surface required; average chord-length of voids; determination of air-void parameters; entrained void; entrapped void; grits for lapping hardened concrete; index point; lapping; length of traverse required; linear-traverse method; microscopical; number of points required; paste-air ratio; paste-air ratio modification; paste content; point-count method (modified); sample preparation for microscopical analysis; spacing factor; specific surface; void frequency; water void

TABLE 6 Estimate of Average Precision from a European Study Where Both Prepared Specimens and Companion Unprepared Specimens Were Sent to Participating Laboratories to Determine Air Content and Spacing Factor

Item	Standard Deviation (1s)[A]	Range of Two Test Results (D2s)[A]	Percent of Average	
			Coefficient of Variation (1s %)[B]	Range of Two Test Results (D2s %)[C]
Slabs Prepared in Originating Lab and Measured in Originating Lab				
Air Content, %	0.57	1.61	. . .	. . .
Spacing Factor	. . .	. . .	8.0	22.6
Slabs Prepared in Originating Lab But Measured in Participating Labs				
Air Content, %	0.71	2.01	. . .	. . .
Spacing Factor	. . .	. . .	20.1	56.9
Slabs Lapped and Measured in Participating Labs				
Air Content, %	0.73	2.07	. . .	. . .
Spacing Factor	. . .	. . .	17.5	49.5

[A] These numbers represent, respectively, the (1s) and (D2s) limits as described in Practice C 670.

[B] These numbers represent, respectively, the (1s %) and (D2s %) limits as described in Practice C 670.

No. 4	8.20	7.97	12.42	12.17

[A] Modified Point Count: 6 labs; 12 operators; and 26 determinations.
[B] Linear Traverse: 3 labs; 7 operators; and 15 determinations.

APPENDIX

(Nonmandatory Information)

X1. Interpretation of Results

X1.1 The question of whether or not the determined air-void system parameters are acceptable to provide protection in water-saturated cyclic freezing and thaw conditions shall be made by the specifier, or be determined from actual freeze-thaw testing of the concrete (that is, Test Method C 666/C 666M, Test Method C 672/C 672M, field results). The following text provides useful information on air-void system parameters of known freeze-thaw durable concrete and explains guidelines and specifications from other respected specifying agencies.

X1.2 For air-entrained concrete designed in accordance with ACI 201.2R and ACI 211.1, the paste-air ratio *(p/A)* is usually in the range 4 to 10, the specific surface (α) is usually in the range 24 to 43 mm^{-1} (600 to 1100 $in.^{-1}$), and the spacing factor ($\bar{L}$) is usually in the range 0.1 to 0.2 mm (0.004 to 0.008 in.).

X1.3 Of the parameters determined with this test method, the spacing factor ($\bar{L}$) is generally regarded as the most significant indicator of the durability of the cement paste matrix to freezing and thawing exposure of the concrete. The maximum value of the spacing factor for moderate exposure of the concrete is usually taken to be 0.20 mm (0.008 in.). Somewhat larger values may be adequate for mild exposure, and smaller ones may be required for severe exposure, especially if the concrete is in contact with deicing chemicals. Care should be exercised in using spacing factor values in specifications since the standard deviation of that property has been found to approach one-fifth of the average when determinations are made in different laboratories. Hence, substantial differences in spacing factor may be caused solely by sampling and between laboratory variation. The factors affecting the variability of the test method are discussed in the section on Precision and Bias.

X1.4 The air content and the parameters of the air-void system in hardened concrete depend primarily on the kind and dosage of the air entraining agent used, the degree of consolidation of the concrete, and its water-cement ratio. The values of the specific surface (α) and the void frequency *(n)* decrease rapidly with an increase of the water-cement ratio or the paste content if other conditions are not altered. Satisfactory values of specific surface (α) and spacing factor ($\bar{L}$) require that the void frequency be larger than about 315/m (8/in.). An increase in the water-cement ratio or the paste content must be accompanied by an increase in the air content, if the spacing factor ($\bar{L}$) is not to increase. The air content can be reduced substantially by extended vibration of the concrete, without a significant increase of the spacing factor ($\bar{L}$), provided the concrete was adequately air entrained originally. Extended vibration is not, however, recommended as a field practice because of the dangers of excessive bleeding and segregation.

X1.5 The void frequency *(n)* is a critical parameter in determining the magnitude of the specific surface (α) and the spacing factor ($\bar{L}$). Consequently, utmost care must be taken in conducting either microscopical method to observe and record all air-void sections intersected by the line of traverse. Recognition of air-void sections of small size, for example, 10 μm (3.94 by 10^{-5} in.) is essential to securing a correct evaluation of these parameters. For this reason, care must be taken to prepare extremely smooth and plane sections, the magnification employed should be not less than 50×, and the index point in the cross hairs (or other reticle device) must be observed precisely in relation to the area and periphery of the air-void section.

X1.6 Provided the value of the specific surface (α) or the void frequency *(n)* is sufficiently high, a suitable spacing factor ($\bar{L}$) will be obtained even when the air content is low. However, in order to obtain an air-void system that has both the volume capacity and the geometric parameters necessary to protect saturated mature cement paste during exposure to freezing, it is important to obtain concrete with an acceptably high air content *(A)* and a low enough spacing factor ($\bar{L}$) to provide protection **(12)**.

www.technobetar.ir

X1.7 For concrete exposed to freezing and thawing while critically saturated, a minimum-compressive strength must be developed prior to the freezing exposure, in addition to the securing of adequate air entrainment if the concrete is to be protected properly. Such compressive strength must be at least 28 MPa (4000 psi).

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 457 – 08d, that may impact the use of this test method. (Approved July 1, 2009)

(*1*) Revised Section 3 Terminology according to ASTM Form and Style.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 457 – 08c, that may impact the use of this test method. (Approved December 15, 2008)

(*1*) Revised Fig. 5.

(*2*) Added new 15.1.7.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 457 – 08b, that may impact the use of this test method. (Approved October 1, 2008)

(*1*) Revised Section 5 and moved some subsections into new Appendix X1.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 457 – 08a, that may impact the use of this test method. (Approved July 1, 2008)

(*1*) Revised Fig. 1.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 457 – 08, that may impact the use of this test method. (Approved May 1, 2008)

(*1*) Revised 3.1.5.1.

Designation: C465 – 10

Standard Specification for Processing Additions for Use in the Manufacture of Hydraulic Cements[1]

This standard is issued under the fixed designation C465; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification pertains to the criteria and tests to be used for determining whether a(n) organic or inorganic processing addition, when used in the recommended amount at the option of the cement producer in the manufacture of hydraulic cements, meets the requirements as prescribed by definition in Specifications C150, C1157, C845, and C595. The materials listed in the following former ASTM Specifications shall be considered as meeting the organic processing additions requirements of this specification:

C150 – 62, for Portland Cement
C205 – 58 T, for Portland Blast-Furnace Slag Cement
C340 – 58 T, for Portland Pozzolan Cement
C358 – 58, for Slag Cement

1.2 The following safety hazards caveat pertains only to the test methods described in this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C33 Specification for Concrete Aggregates
C39/C39M Test Method for Compressive Strength of Cylindrical Concrete Specimens
C78 Test Method for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)
C109/C109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)
C114 Test Methods for Chemical Analysis of Hydraulic Cement
C115 Test Method for Fineness of Portland Cement by the Turbidimeter
C138/C138M Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
C143/C143M Test Method for Slump of Hydraulic-Cement Concrete
C150 Specification for Portland Cement
C151 Test Method for Autoclave Expansion of Hydraulic Cement
C173/C173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method
C185 Test Method for Air Content of Hydraulic Cement Mortar
C187 Test Method for Normal Consistency of Hydraulic Cement
C191 Test Methods for Time of Setting of Hydraulic Cement by Vicat Needle
C192/C192M Practice for Making and Curing Concrete Test Specimens in the Laboratory
C204 Test Methods for Fineness of Hydraulic Cement by Air-Permeability Apparatus
C205 Specification for Portland Blast- Furnace Cement[3]
C226 Specification for Air-Entraining Additions for Use in the Manufacture of Air-Entraining Hydraulic Cement
C231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method
C293 Test Method for Flexural Strength of Concrete (Using Simple Beam With Center-Point Loading)
C340 Specification for Corkboard Thermal Insulation[3]
C358 Specification for Slag Cement[3]
C595 Specification for Blended Hydraulic Cements
C596 Test Method for Drying Shrinkage of Mortar Containing Hydraulic Cement
C617 Practice for Capping Cylindrical Concrete Specimens

[1] This specification is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.20 on Additions.

Current edition approved Feb. 1, 2010. Published March 2010. Originally approved in 1961. Last previous edition approved in 2009 as C465–09. DOI: 10.1520/C0465-10.

C845 Specification for Expansive Hydraulic Cement
C1157 Performance Specification for Hydraulic Cement
D891 Test Methods for Specific Gravity, Apparent, of Liquid Industrial Chemicals
E203 Test Method for Water Using Volumetric Karl Fischer Titration

3. Materials

3.1 *Cements*:

3.1.1 In cases where it is desired that the proposed organic processing addition be accepted for general use in portland cement, tests shall be made on cements prepared from at least five different clinkers. As a minimum, these clinkers shall represent two Type I cements containing not less than 9.0 % C_3A, one Type II cement, and two Type III cements, all conforming to Specification C150.

3.1.2 In cases where it is also desired that the proposed organic processing addition be used in blended cements, the test and test procedures shall be as specified with a control and an addition for cement conforming to the appropriate Specification C595 or C1157.

3.1.3 Organic processing additions which have been shown to meet the requirements of this specification may also be used in cements conforming to Specification C845. Testing of the addition with these special cements, where desired, shall be done using the tests and test procedures as specified with a control cement and a cement containing the addition, both conforming to Specification C845.

3.1.4 In cases where it is desired that the proposed organic processing addition be limited in use to specific types of cement less in number than required in 3.1.1, the tests and test procedures shall be as specified, and at least two pairs of cements shall be prepared from two clinkers from different plants for each type under specific consideration.

3.1.5 For inorganic processing additions, or in cases where it is desired that the proposed organic processing addition be limited in use to a single plant, the tests and test procedures shall be as specified and at least two pairs of cements shall be prepared from clinker representing each type under specific consideration.

3.1.6 The two companion cements to be made from any one clinker shall be ground to the same fineness within 7 m^2/kg when tested in accordance with Test Method C115 or within 13 m^2/kg when tested in accordance with Test Method C204, and the SO_3 content, expressed as a percentage of the cement mass and reported to the nearest 0.01 %, shall differ by not more than 0.3, so as to afford comparable samples for indicating the effect of the addition on the cement. Each control cement shall comply with all requirements in the specification applicable to that type of cement, and shall not contain the proposed addition when tested by the method furnished by the producer or seller of the addition.

3.1.7 The percentage of each of the following shall be determined for each lot of cement tested: silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), ferric oxide (Fe_2O_3), calcium oxide (CaO), magnesium oxide (MgO), sulfur trioxide (SO_3), ignition loss, insoluble residue, sodium oxide (Na_2O), and potassium oxide (K_2O). There shall also be calculated the potential percentages of the following compounds: tricalcium silicate, dicalcium silicate, tricalcium aluminate, and tetracalcium aluminoferrite. Determinations for the percentage of the addition shall be made, both on the control cements and on those with which the addition was interground, using the method proposed therefore by the sponsor.

3.2 *Aggregates*—The fine and coarse aggregates shall comply with Specification C33; the coarse aggregate shall comply with the grading requirements for Size No. 57 or Size No. 67. A sufficient quantity from a single lot of coarse aggregate and from a single lot of fine aggregate shall be provided to complete all tests. To prevent the segregation of particle sizes in the fine aggregate, a single lot of sand sufficient for all tests shall either (*1*) be separated on the 4.75-mm (No. 4), 1.18-mm (No. 16), 300 µm (No. 50), and 150 µm (No. 100) sieves and then be recombined in the required quantity for each batch; or (*2*) be blended while in a damp condition, and maintained in that condition for the duration of the tests. Under option (*2*), lots of appropriate size for single mortar and concrete batches shall be carefully split or quartered from the entire batch.

4. General Requirements

4.1 Processing additions shall conform to the respective requirements in this specification.

4.2 The trade name, source, character of the material, and means for the quantitative determination of the addition in the finished cement shall be furnished by the sponsor, manufacturer, or supplier of the addition, and the information shall form a part of the record of tests of the addition. If the processing addition is a liquid, the specific gravity and percent water content shall also be part of the record. If the processing addition is an inorganic solid, the allowable ranges of chemical analysis of the addition shall also be part of the record.

4.2.1 The specific gravity, run in accordance with 7.1.1 shall be within ±0.05 units of the value reported in 4.2.

4.2.2 The chemical analysis in 7.2.1 shall be within the ranges given in 4.2.

4.3 Processing additions shall be evaluated by comparing cements containing the addition to otherwise identical cements from the same source without the addition, or containing a processing addition which has been shown to comply with this specification using control cements without any additions, hereinafter designated the “control” cement.

4.4 The amount of the processing addition to be interground with the cement for evaluation purposes shall be determined by the sponsor of the addition.

4.4.1 The amount of the addition in the cement containing the addition and showing compliance with the requirements of this specification shall be determined quantitatively by means of the quantitative determination required by 4.2.

4.4.2 The amount of addition, so determined, shall be used to state the amount of addition that shows compliance with this specification.

4.4.3 When tests on cements containing the addition show compliance with the requirements of this specification, the addition in cement may be used in any amount up to the maximum amount showing compliance.

4.5 The cement produced for evaluation purposes with the processing addition shall comply with the appropriate Specifications C150, C845, C1157, or C595, except that it contains

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:19 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the addition under test. The effect of the addition on the properties of the cement shall also be within the following limits:

4.5.1 The percentage of water by mass of cement required for normal consistency of cement containing the addition shall not exceed that required by the corresponding control cement by more than 1.0. For those cements not limited to a fixed water requirement, the percentage of water by mass of cement required for standard consistency of the mortar used for strength determinations as described in 4.5.4 shall not be increased by more than 2.0 by the addition over that required for the control cement.

4.5.2 The time of setting of cement containing the addition shall not vary from the time of setting of the corresponding control cement by more than 1 h or 50 %, whichever is the lesser.

4.5.3 The autoclave expansion of cement containing the addition, expressed as a percentage change in length, shall be not more than 0.10 greater than that of the corresponding control cement.

4.5.4 The compressive strength of mortar cubes made with cement containing the addition, in accordance with Test Method C109/C109M, and tested at 1, 3, 7, and 28 days for all types, shall be compared with strengths obtained with the control cement at similar ages. The grand average of these individual strength percentages shall be not less than 95 % of the control cement values. It is required that cubes for companion cements be made and tested on the same days, with storage of specimens side by side in the same section of the moist cabinet during the 24-h curing period. Retesting of companion cements on the same, or a following, day is required in order to provide six, rather than three, test specimens for each cement and age of test.

4.5.5 The ultimate drying shrinkage (percent) of mortar made with cement containing the addition shall not be more than 0.025 greater than that of similar mortar made with the corresponding control cement when tested in accordance with Test Method C596.

4.5.6 The compressive strength of the concrete made with cement containing the addition shall be compared with strengths obtained with the control cement at similar ages. The grand average of these individual strength percentages shall be not less than 90 % of the values for the control cement.

4.5.7 The flexural strength of concrete made with cement containing the addition shall be compared with strengths obtained with the control cement at similar ages. The grand average of these individual strength percentages shall be not less than 90 % of the values for the control cement.

4.5.8 The amount of air-entraining addition required to produce 19 ± 3 % air in the mortar test made in accordance with Test Method C185, with the cement containing the addition under test, shall be not greater than 120 % of the amount required to produce, within ±1 %, the air content obtained with the control cement. The air-entraining addition used shall meet the requirements of Specification C226.

4.6 Processing additions which provide maximum effects as grinding aids or pack set inhibitors may increase cement flowability to a point where mill retention time is reduced sufficiently to affect significantly the particle size distribution of the resulting cement and its physical-chemical properties. Mill retention times are controllable by mechanical means in full-scale grinding mills. Hence, the true physical-chemical effects of the test additive may be determined for acceptance purposes by making supplementary laboratory or pilot-mill grinds, in instances where full-scale tests have shown mill retention time reductions to have significant effects on the properties of the resulting cement.

4.7 In the event that the effect of the addition on the properties of cement are determined on the basis of laboratory or pilot mill grinds, this fact shall be entered in the report specified in Section 13, and the specific tests shall be indicated.

5. Sampling Cement

5.1 Samples of the plant-ground cement shall be taken from the product stream during grinding. Prior to the start of sampling a given lot of cement, the mill shall have run for 4 h or long enough to have reached equilibrium under the general conditions that are to govern during the sampling period.

NOTE 1—Records should be kept as to the rate and continuity of feed of the addition, the form in which the addition is used, strength of solution (if applicable), magnitude of circulating loads, mill discharge temperature, and feed rate of clinker and gypsum. Product fineness should be determined during the grinding immediately subsequent to sampling.

5.2 As the cement samples are taken, they shall be placed in sealable containers which shall be sealed immediately at the end of the sampling period. Prior to use, the samples of a given lot of cement shall be thoroughly blended to form a uniform, representative composite.

6. Test Methods

6.1 Determine the properties enumerated in this specification in accordance with the test methods prescribed in Sections 7-12.

7. Tests on Processing Additions

7.1 Test the liquid, organic processing addition, in the form normally marketed, in accordance with the following test methods:

7.1.1 *Specific Gravity*—Use Test Methods D891, Test Method A or B.

7.1.2 *Water Content*—Use Test Method E203.

7.2 Conduct the following tests on solid, inorganic processing addition in accordance with the following test methods:

7.2.1 *Chemical Analysis*—Use Test Methods C114, and determine silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), ferric oxide (Fe_2O_3), calcium oxide (CaO), magnesium oxide (MgO), sulfur trioxide (SO_3), ignition loss, insoluble residue, sodium oxide (Na_2O), and potassium oxide (K_2O).

8. Tests on Cement

8.1 Test cement in accordance with the following standards:

8.1.1 *Chemical Analysis of Cement*—Test Methods C114.

8.1.2 *Compound Composition*—Specification C150.

8.1.3 *Fineness of Cement*—Test Method C115 or C204.

8.1.4 *Normal Consistency*—Test Method C187.

8.1.5 *Time of Setting (Vicat)*—Test Method C191.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:19 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.1.6 *Autoclave Expansion*—Test Method C151.

8.1.7 *Air Content of Mortar*—Test Method C185.

8.1.8 *Compressive Strength of Mortar*— Test Method C109/C109M.

8.1.9 *Drying Shrinkage of Mortar*—Test Method C596.

9. Concrete Mixtures

9.1 *Preparation and Weighing*—Prepare all materials used in making the concrete mixtures and make all weighings as prescribed in Practice C192/C192M. Report the amount of mixing water used in each batch on the basis of saturated, surface-dry aggregates.

9.2 *Proportions*—Design one basic concrete mixture having an actual cement content of 307 ± 3 kg/m^3 (517± 5 lb/yd^3), and use in all concrete tests herein specified. Adjust the water content of mixtures to provide concrete having a consistency equal to a 64 ± 13-mm (2½ ± ½-in.) slump in each case. Adjust the ratio of fine to coarse aggregate to the optimum for concrete to be consolidated by hand rodding. Recommended trial values for the percentage of fine aggregate in the total aggregate, by absolute volume, are as follows:

Coarse Aggregate, Maximum 25.0 mm (1 in.)	Concrete Without Entrained Air
Angular	45
Rounded	40

9.3 *Mixing of Concrete*—Mix the concrete in accordance with Practice C192/C192M except as follows: Hand mixing will not be permitted. The rated capacity of the machine mixer shall not be more than twice the size of the batch used.

10. Tests on Freshly Mixed Concrete

10.1 Test samples of the freshly mixed concrete for slump in accordance with Test Method C143/C143M; unit weight in accordance with Test Method C138/C138M; and air content in accordance with Test Method C138/C138M, C231, or C173/C173M.

11. Test Specimens of Hardened Concrete

11.1 *Number of Specimens*—At least three specimens shall be made for each test condition. For each cement containing an addition and its companion control cement, make three rounds of concrete mixed on different days. One round of mixes on a given day shall include both the cement containing the addition and its companion control cement. From each round, make at least one test specimen for each test condition. If necessary, to obtain enough concrete for all test specimens to be made in any one round, it may be necessary to make more than one concrete batch for each round.

11.2 *Types of Specimens*:

11.2.1 *Compressive Strength*—Compressive strength test specimens shall be cylinders made and cured as prescribed in Practice C192/C192M. Cylinders shall be capped as prescribed in Practice C617.

11.2.2 *Flexural Strength*—Flexural strength test specimens shall be beams made and cured as prescribed in Practice C192/C192M.

12. Test on Hardened Concrete

12.1 Test the specimens on hardened concrete, as specified in Section 11, in accordance with the following methods and at the specified ages:

12.1.1 *Compressive Strength*—Test specimens in accordance with Test Method C39/C39M at ages 3, 7, and 28 days, except also test Type III cement at 24 h.

12.1.2 *Flexural Strength*—Test specimens in accordance with Test Method C293, or Test Method C78, ages at 3, 7, and 28 days, except also test Type III cement at 24 h. By either method of test, turn the specimen on its side with respect to its position as molded and center it on the bearing blocks.

13. Report

13.1 The report covering the results of the evaluation of a material proposed for use as a processing addition in the manufacture of portland cement under this specification shall include the following information:

13.1.1 Trade name, source and character of the material, and the amount recommended for use, together with means for determination of the proposed addition in the finished cement, all as furnished by the sponsor, manufacturer, or seller of the addition,

13.1.2 If the proposed processing addition is an organic liquid, the specific gravity and percent water content by mass,

13.1.3 If the proposed processing addition is an inorganic solid, report chemical analysis,

13.1.4 Detailed results of all analyses and tests prescribed by this specification, and the amount of the addition used, as well as other pertinent information required,

13.1.5 Comparison of test results to determine compliance with the requirements prescribed in 4.4,

13.1.6 Name and location of the laboratory or laboratories that made the tests covered by the report,

13.1.7 Include as an appendix to the report, letters of certification from the various cement manufacturers stating the name of the addition, the amount used, and the type of cement in which used, and

13.1.8 The highest amount of addition that has demonstrated compliance with the specification in a particular type of cement (see 4.4.3).

14. Manufacturer's Certification Processing Additions

14.1 *Organic Processing Additions*—Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at the time of shipment stating the water content and specific gravity of the samples of the material taken during production or transfer and certifying that the specific gravity value is within the specified limits of the originally qualified product and that the product meets the requirements of this Specification.

14.2 *Inorganic Processing Additions*—Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at time of shipment stating the chemical analysis of the samples of the material taken during production or transfer and certifying that they are within the specified limits of the originally qualified product and that the product meets the requirements of this specification.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C465–09, that may impact the use of this specification. (Approved February 1, 2010)

(*1*) Revised 4.2, 4.2.2, 13.1.3, and 14.2. Deleted 7.2.2.

Committee C01 has identified the location of selected changes to this specification since the last issue, C465–99(2005), that may impact the use of this specification. (Approved May 15, 2009)

(*1*) Revised the Scope to include inorganic processing additions.
(*2*) Revised Section 3 to differentiate requirements for organic and inorganic processing additions.
(*3*) Revised Section 4 to include requirements for chemical analysis and specific gravity of the inorganic processing addition being tested and to clarify that a maximum of two processing additions can be used (an inorganic and an organic for example).
(*4*) Revised Section 7 to include requirements for chemical analysis and specific gravity of the inorganic processing addition being tested.
(*5*) Revised Section 12 to require hardened concrete testing through 28 days instead of 3 months, per the NCHRP 18-11 report.
(*6*) Revised Section 13 to include requirements for reporting of results of chemical analyses and specific gravity determination of the inorganic processing addition being tested.
(*7*) Renamed Section 14 and added new 14.2 for manufacturer's certification for inorganic processing additions.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 469 – 02$^{\epsilon 1}$

Standard Test Method for Static Modulus of Elasticity and Poisson's Ratio of Concrete in Compression[1]

This standard is issued under the fixed designation C 469; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—Adjunct references were corrected editorially in April 2006.

1. Scope

1.1 This test method covers determination of (*1*) chord modulus of elasticity (Young's) and (*2*) Poisson's ratio of molded concrete cylinders and diamond-drilled concrete cores when under longitudinal compressive stress. Chord modulus of elasticity and Poisson's ratio are defined in Terminology E 6.

1.2 The values stated in inch-pound units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2 *ASTM Adjuncts:*

Compressometers (two drawings) and Extensometers (two drawings)[3]

3. Significance and Use

3.1 This test method provides a stress to strain ratio value and a ratio of lateral to longitudinal strain for hardened concrete at whatever age and curing conditions may be designated.

3.2 The modulus of elasticity and Poisson's ratio values, applicable within the customary working stress range (0 to 40 % of ultimate concrete strength), are used in sizing of reinforced and nonreinforced structural members, establishing the quantity of reinforcement, and computing stress for observed strains.

3.3 The modulus of elasticity values obtained will usually be less than moduli derived under rapid load application (dynamic or seismic rates, for example), and will usually be greater than values under slow load application or extended load duration, given other test conditions being the same.

4. Apparatus

4.1 *Testing Machine*—Use a testing machine capable of imposing a load at the rate and of the magnitude prescribed in 6.4. The machine shall conform to the requirements of Practices E 4 (Constant-Rate of-Traverse CRT-Type Testing Machines section). The spherical head and bearing blocks shall conform to the Apparatus Section of Test Method C 39/C 39M.

4.2 *Compressometer*[3]—For determining the modulus of elasticity use a bonded (Note 1) or unbonded sensing device that measures to the nearest 5 millionths the average deformation of two diametrically opposite gage lines, each parallel to the axis, and each centered about midheight of the specimen.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved Aug. 10, 2002. Published October 2002. Originally approved in 1961. Last previous edition approved in 1994 as C469 – 94$^{\epsilon 1}$.

www.technobetar.ir

The effective length of each gage line shall be not less than three times the maximum size of the aggregate in the concrete nor more than two thirds the height of the specimen; the preferred length of the gage line is one half the height of the specimen. Either use gage points embedded in or cemented to the specimen, and read deformation of the two lines independently; or use a compressometer (such as is shown in Fig. 1) consisting of two yokes, one of which (see *B*, Fig. 1) is rigidly attached to the specimen and the other (see *C*, Fig. 1) attached at two diametrically opposite points so that it is free to rotate. At one point on the circumference of the rotating yoke, midway between the two support points, use a pivot rod (see *A*, Fig. 1) to maintain a constant distance between the two yokes. At the opposite point on the circumference of the rotating yoke, the change in distance between the yokes (that is, the gage reading) is equal to the sum of the displacement due to specimen deformation and the displacement due to rotation of the yoke about the pivot rod (see Fig. 2).

4.2.1 Measure deformation by a dial gage used directly or with a lever multiplying system, by a wire strain gage, or by a linear variable differential transformer. If the distances of the pivot rod and the gage from the vertical plane passing through the support points of the rotating yoke are equal, the deformation of the specimen is equal to one-half the gage reading. If these distances are not equal, calculate the deformation as follows:

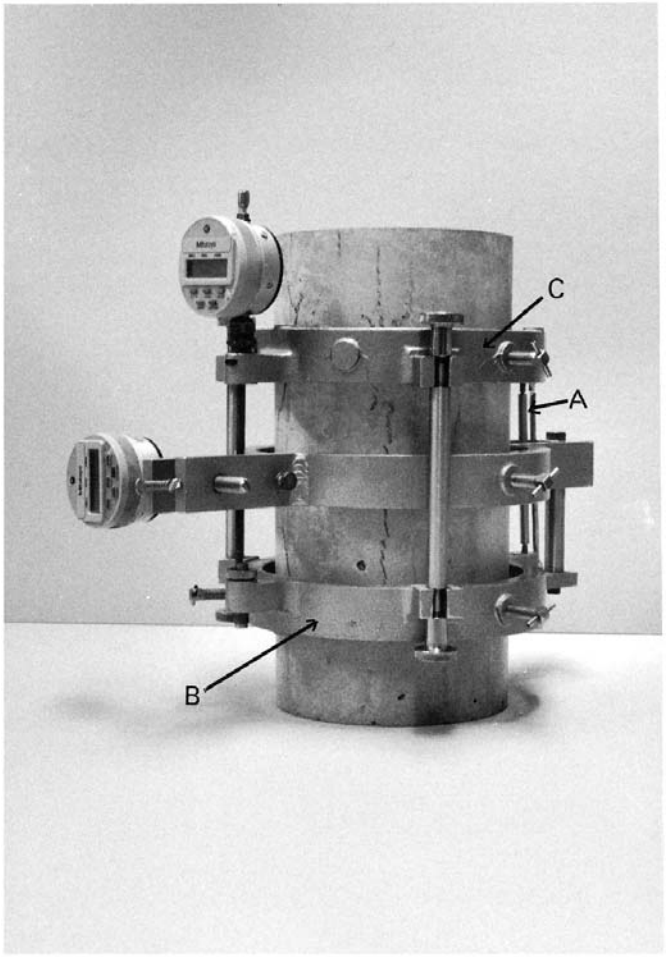

FIG. 1 Suitable Compressometer

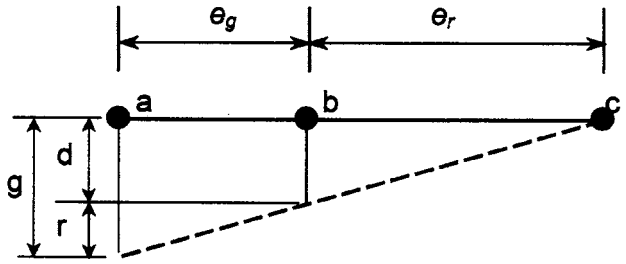

d = displacement due to specimen deformation
r = displacement due to rotation of the yoke about the pivot rod
a = location of gage
b = support point of the rotating yoke
c = location of pivot rod
g = gage reading

FIG. 2 Diagram of Displacements

$$d = g e_r / (e_r + e_g) \quad (1)$$

where:

d = total deformation of the specimen throughout the effective gage length, μin. (μm),
g = gage reading, μin. (μm),
e_r = the perpendicular distance, measured in inches (millimetres) to the nearest 0.01 in. (0.254 mm) from the pivot rod to the vertical plane passing through the two support points of the rotating yoke, and
e_g = the perpendicular distance, measured in inches (millimetres) to the nearest 0.01 in. (0.254 mm) from the gage to the vertical plane passing through the two support points of the rotating yoke.

Procedures for calibrating strain-measuring devices are given in Practice E 83.

NOTE 1—Although bonded strain gages are satisfactory on dry specimens, they may be difficult, if not impossible, to mount on specimens continually moist-cured until tested.

4.3 *Extensometer*[3]—If Poisson's ratio is desired, the transverse strain shall be determined (*1*) by an unbonded extensometer capable of measuring to the nearest 25 μin. (0.635 μm) the change in diameter at the midheight of the specimen, or (*2*) by two bonded strain gages (Note 1) mounted circumferentially at diametrically opposite points at the midheight of the specimen and capable of measuring circumferential strain to the nearest 5 millionths. A combined compressometer and extensometer (Fig. 3) is a convenient unbonded device. This apparatus shall contain a third yoke (consisting of two equal segments) located halfway between the two compressometer yokes and attached to the specimen at two diametrically opposite points. Midway between these points use a short pivot rod (*A′*, see Fig. 3), adjacent to the long pivot rod, to maintain a constant distance between the bottom and middle yokes. Hinge the middle yoke at the pivot point to permit rotation of the two segments of the yoke in the horizontal plane. At the opposite point on the

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

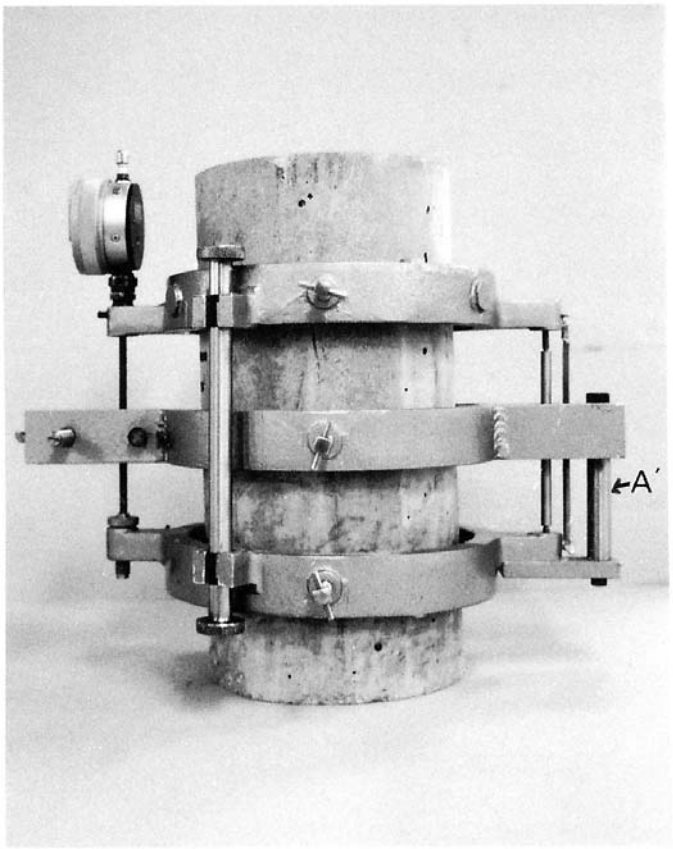

FIG. 3 Suitable Combined Compressometer-Extensometer

circumference, connect the two segments through a dial gage or other sensing device capable of measuring transverse deformation to the nearest 50 µin. (1.27 µm). If the distances of the hinge and the gage from the vertical plane passing through the support points of the middle yoke are equal, the transverse deformation of the specimen diameter is equal to one-half the gage reading. If these distances are not equal, calculate the transverse deformation of the specimen diameter in accordance with Eq 2.

$$d' = g'e'_h/(e'_h + e'_g) \quad (2)$$

where:

d' = transverse deformation of the specimen diameter, µin. (µm),
g' = transverse gage reading, µin. (µm),
e'_h = the perpendicular distance, measured in inches (millimeters) to the nearest 0.01 in. (0.254 mm) from the hinge to the vertical plane passing through the support points of the middle yoke, and
e'_g = the perpendicular distance, measured in inches (millimeters) to the nearest 0.01 in. (0.254 mm) from the gage to the vertical plane passing through the support points of the middle yoke.

4.4 *Balance or Scale*, accurate to 0.1 lb (0.045 kg) shall be used if necessary.

5. Test Specimens

5.1 *Molded Cylindrical Specimens*—Mold test cylinders in accordance with the requirements for compression test specimens in Practice C 192/C 192M, or in Practice C 31/C 31M. Subject specimens to the specified curing conditions and test at the age for which the elasticity information is desired. Test specimens within 1 h after removal from the curing or storage room. Specimens removed from a moist room for test shall be kept moist by a wet cloth covering during the interval between removal and test.

5.2 *Drilled Core Specimens*—Cores shall comply with the requirements for drilling, and moisture conditioning applicable to compressive strength specimens in Test Method C 42/C 42M, except that only diamond-drilled cores having a length-to-diameter ratio greater than 1.50 shall be used. Requirements relative to storage and to ambient conditions immediately prior to test shall be the same as for molded cylindrical specimens.

5.3 The ends of the test specimens shall be made perpendicular to the axis (± 0.5°) and plane (within 0.002 in.). If the specimen as cast does not meet the planeness requirements, planeness shall be accomplished by capping in accordance with Practice C 617, or by lapping, or by grinding. It is not prohibited to repair aggregate popouts that occur at the ends of specimens, provided the total area of popouts does not exceed 10 % of the specimen area and the repairs are made before capping or grinding is completed (Note 2). Planeness will be considered within tolerance when a 0.002 in. (0.05 mm) feeler gage will not pass between the specimen surface and a straight edge held against the surface.

NOTE 2—Repairs may be made by epoxying the dislodged aggregate back in place or by filling the void with capping material and allowing adequate time for it to harden.

5.4 Measure the diameter of the test specimen by caliper to the nearest 0.01 in. (0.25 mm) by averaging two diameters measured at right angles to each other near the center of the length of the specimen. Use this average diameter to calculate the cross-sectional area. Measure and report the length of a molded specimen, including caps, to the nearest 0.1 in. (2.54 mm). Measure the length of a drilled specimen in accordance with Test Method C 174/C 174M; report the length, including caps, to the nearest 0.1 in. (2.54 mm).

6. Procedure

6.1 Maintain the ambient temperature and humidity as constant as possible throughout the test. Record any unusual fluctuation in temperature or humidity in the report.

6.2 Use companion specimens to determine the compressive strength in accordance with Test Method C 39/C 39M prior to the test for modulus of elasticity.

6.3 Place the specimen, with the strain-measuring equipment attached, on the lower platen or bearing block of the testing machine. Carefully align the axis of the specimen with the center of thrust of the spherically-seated upper bearing block. Note the reading on the strain indicators. As the spherically-seated block is brought slowly to bear upon the specimen, rotate the movable portion of the block gently by hand so that uniform seating is obtained.

6.4 Load the specimen at least twice. Do not record any data during the first loading. Base calculations on the average of the results of the subsequent loadings (Note 3).

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 3—At least two subsequent loadings are recommended so that the repeatability of the test may be noted.

During the first loading, which is primarily for the seating of the gages, observe the performance of the gages (Note 4) and correct any unusual behavior prior to the second loading. Obtain each set of readings as follows: Apply the load continuously and without shock. Set testing machines of the screw type so that the moving head travels at a rate of about 0.05 in. (1.25 mm)/min when the machine is running idle. In hydraulically operated machines, apply the load at a constant rate within the range 35 ± 5 psi (241 ± 34 kPa)/s. Record, without interruption of loading, the applied load and longitudinal strain at the point (*1*) when the longitudinal strain is 50 millionths and (*2*) when the applied load is equal to 40 % of the ultimate load (see 6.5). Longitudinal strain is defined as the total longitudinal deformation divided by the effective gage length. If Poisson's ratio is to be determined, record the transverse strain at the same points. If a stress-strain curve is to be determined, take readings at two or more intermediate points without interruption of loading; or use an instrument that makes a continuous record. Immediately upon reaching the maximum load, except on the final loading, reduce the load to zero at the same rate at which it was applied. If the observer fails to obtain a reading, complete the loading cycle and then repeat it. Record the extra cycle in the report.

NOTE 4—Where a dial gage is used to measure longitudinal deformation, it is convenient to set the gage before each loading so that the indicator will pass the zero point at a longitudinal strain of 50 millionths.

6.5 It is not prohibited to obtain the modulus of elasticity and strength on the same loading provided that the gages are expendable, removable, or adequately protected so that it is possible to comply with the requirement for continuous loading given in Test Method C 39/C 39M. In this case record several readings and determine the strain value at 40 % of the ultimate by interpolation.

6.6 If intermediate readings are taken, plot the results of each of the three tests with the longitudinal strain as the abscissa and the compressive stress as the ordinate. Calculate the compressive stress by dividing the quotient of the testing machine load by the cross-sectional area of the specimen determined in accordance with 5.4.

7. Calculation

7.1 Calculate the modulus of elasticity, to the nearest 50 000 psi (344.74 MPa) as follows:

$$E = (S_2 - S_1)/(\epsilon_2 - 0.000050) \quad (3)$$

where:

E = chord modulus of elasticity, psi,
S_2 = stress corresponding to 40 % of ultimate load,
S_1 = stress corresponding to a longitudinal strain, ϵ_1, of 50 millionths, psi, and
ϵ_2 = longitudinal strain produced by stress S_2.

7.2 Calculate Poisson's ratio, to the nearest 0.01, as follows:

$$\mu = (\epsilon_{t2} - \epsilon_{t1})/(\epsilon_2 - 0.000050) \quad (4)$$

where:

μ = Poisson's ratio,
ϵ_{t2} = transverse strain at midheight of the specimen produced by stress S_2, and
ϵ_{t1} = transverse strain at midheight of the specimen produced by stress S_1.

8. Report

8.1 Report the following information:
8.1.1 Specimen identification number,
8.1.2 Dimensions of specimen, in inches (or millimetres),
8.1.3 Curing and environmental histories of the specimen,
8.1.4 Age of the specimen,
8.1.5 Strength of the concrete, if determined,
8.1.6 Unit weight of the concrete, if determined,
8.1.7 Stress-strain curves, if plotted,
8.1.8 Chord modulus of elasticity, and
8.1.9 Poisson's ratio, if determined.

9. Precision and Bias

9.1 *Precision*—The single-operator-machine multibatch precision is ± 4.25 % (R1S %) max, as defined in Practice E 177, over the range from 2.5 to 4×10^6 psi (17.3 to 27.6×10^9 Pa); therefore, the results of tests of duplicate cylinders from different batches should not depart more than 5 % from the average of the two.

9.2 *Bias*—This test method has no bias because the values determined can only be defined in terms of the test method.

10. Keywords

Designation: C470/C470M – 09

Standard Specification for Molds for Forming Concrete Test Cylinders Vertically[1]

This standard is issued under the fixed designation C470/C470M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers molds for use in forming cylindrical concrete specimens. The provisions of this specification include the requirements for both reusable and single-use molds.

NOTE 1—Sizes included are molds having diameters from 50 mm [2 in.] to 900 mm [36 in.].

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. The inch-pound units are shown in brackets.

1.3 The following safety hazards caveat pertains only to the test method described in this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C31/C31M Practice for Making and Curing Concrete Test Specimens in the Field

C33 Specification for Concrete Aggregates

C192/C192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C1077 Practice for Laboratories Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation

D256 Test Methods for Determining the Izod Pendulum Impact Resistance of Plastics

D570 Test Method for Water Absorption of Plastics

3. General Requirements

3.1 The following provisions apply to both reusable and single-use molds:

3.1.1 Molds shall be constructed in the form of right circular cylinders which stand with the cylindrical axis vertical and the top open to receive the concrete. They shall be made of materials that do not react with concrete containing portland or other hydraulic cements. They shall be watertight and sufficiently strong and tough to permit their use without tearing, crushing, or deforming.

NOTE 2—Reusable lids may be used on molds to reduce moisture loss.

3.1.2 Molds shall have a nominal inside height equal to twice the nominal inside diameter. The diameter of a mold, consisting of the average of two measurements taken at right angles to each other at the top of the mold, shall not differ from the nominal diameter by more than 1 %. The height, determined by averaging two measurements taken 180° apart, shall not differ from the nominal height by more than 2 %. The planes of the top rim of the mold and the bottom shall be perpendicular to the axis of the mold within 0.5 degrees—approximately equivalent to 3 mm in 300 mm [⅛ in. in 12 in.]. No diameter of a mold shall differ from any other diameter of the same mold by more than 2 % except that molds that fail to meet this requirement may be used when the user is able to demonstrate that no diameter of hardened concrete specimen produced in a similar mold differs from any other diameter on the same specimen by more than 2 % (see Note 3).

NOTE 3—Certain single-use molds may require the use of a special device such as a tube of heavy-gage metal around the mold during molding to maintain the dimensional tolerances specified in 3.1.2.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved Oct. 1, 2009. Published November 2009. Originally approved in 1961. Last previous edition approved in 2008 as C470/C470M-08. DOI: 10.1520/C0470_C0470M-09.

www.technobetar.ir

3.1.3 The bottom inside surface of the mold shall not depart from a plane by more than 2 mm in 150 mm [1/16 in. in 6 in.] (1 % of the diameter of the mold).

4. Reusable Molds

4.1 Reusable molds are those which are designed to be used more than a single time. Reusable molds shall be made of nonabsorptive materials, and constructed as either one piece or several pieces (see Note 4).

4.2 Reusable molds shall be provided with a closure or base on the lower end at right angles to the axis of the cylinder. Molds may be single piece molds or made from castings with a separate detachable base plate or a base that is an integral part of the sidewall. The mold shall be either coated or made of a material that will prevent adherence to the concrete. At the time of use, molds shall not leak water. An inside fillet, if any, at the bottom of the side wall shall have an indentation around the circumference no more than 3 mm [1/8 in.] in the vertical direction or no more than 5 mm [3/16 in.] in the horizontal direction.

4.3 Reusable molds shall be tested for water leakage as described in 6.4, for resistance to damage as described in 6.3.1, and for dimensional stability in accordance with 3.1.2 and 3.1.3 initially and after every 50 uses or every six months, whichever comes first.

NOTE 4—Satisfactory molds can be made from lengths of steel tubing or pipe that is slit on one side parallel to the axis and fitted with a means of closing the vertical slit as well as a means of attaching a base plate. The required dimensional tolerances must be maintained after slitting, clamping, and attaching the base plate. Other nonabsorptive materials which have been used include iron, brass, steel, and various plastics. Although aluminum and magnesium alloys have been used, some of these alloys may be reactive with cement constituents and are therefore unacceptable.

5. Single-Use Molds

5.1 Single-use molds are molds designed to be used once and discarded. They are permitted to be made of sheet metal, plastic, suitably treated paper products, or other materials and shall conform to the requirements of this specification.

5.2 *Physical Requirements*—The molds as prepared for use shall comply with the following:

5.2.1 *Water Leakage*—When tested as described in Section 6, there shall be no visible leakage.

5.2.2 *Absorptivity*—When tested as described in Section 6, the absorption shall not exceed the values given in Table 1. Intermediate values are proportional to the square of the height.

5.2.3 *Elongation*—When tested as described in Section 6, the elongation after test shall not exceed 0.2 % of height.

TABLE 1 Limits for Absorption and Elongation

Nominal Mold Height, mm [in.]	Absorption, max g	Elongation, max mm [in.]
100 [4]	2.7	0.2 [0.008]
150 [6]	6.0	0.3 [0.012]
200 [8]	11	0.4 [0.016]
300 [12]	24	0.6 [0.024]
450 [18]	54	0.9 [0.036]
600 [24]	96	1.2 [0.048]
900 [36]	216	1.8 [0.072]

5.3 *Single-use Plastic Molds*—Molds shall conform to the following additional requirements when plastic is the predominant material used in construction:

5.3.1 *Wall Thickness*—The side walls shall be of sufficient stiffness to meet the requirements of 3.1 (See Note 5).

NOTE 5—This can be achieved through sufficient side wall thickness alone, or in combination with a stiffened top.

5.3.2 *Bottom Design*—The bottom shall be designed so that it will be flush with the bottom of the sidewall within a tolerance of 2 mm [1/16 in.]. An inside fillet, if any, at the bottom of the sidewall shall have an indentation around the circumference no more than 4 mm [1/8 in.] in the vertical direction or no more than 5 mm [3/16 in.] in the radial direction. The bottom shall be of adequate rigidity to prevent permanent deformation when specimens are molded in accordance with the applicable provisions of Practice C31/C31M or C192/C192M.

5.3.3 *Material*—The mold manufacturer shall certify that: (*1*) the plastic material used in molds has a maximum water absorption of less than 0.5 % in 24 h when tested in accordance with Test Method D570; (*2*) the plastic has an Izod impact toughness of at least 117 J/m [2.2 ft lb/in.] of notch for a 4 mm [1/8 in.] thick specimen tested in accordance with Test Methods D256; and (*3*) after being held at 12 °C [10 °F] for 24 h, the plastic shall not fracture when subject to tapping and jarring that is judged to be typical of what occurs when specimens are molded in accordance with the applicable provisions of Practice C31/C31M or C192/C192M.

5.4 *Paper Molds*—When paper or other potentially absorptive fiber material is used as the primary structural material in the construction of the side walls or bottom of the mold, the mold shall conform to the following additional requirements:

5.4.1 *Side Walls*—The side walls of paper molds shall be made with a minimum of three plies having a combined thickness of not less than 2 mm [0.070 in.]. Seams on the inside of the mold shall not be open by more than 2 mm [1/16 in.].

NOTE 6—The minimum thickness of material used in side walls and bottoms is considered adequate for cylinders up to 150 mm [6 in.] in diameter. For larger cylinders thicker material may be required to meet requirements of 3.1.

5.4.2 *Bottom Caps*—The bottom cap of the mold shall be made of either metal or paper. If metal, it shall not be less than 0.23 mm [0.009 in.] in thickness and coated to prevent corrosion (Note 6). It shall be designed so that it will be flush with the bottom edge of the side wall within a tolerance of 2 mm [1/16 in.] and the inside crimp, if any, shall produce an indentation around the circumference of the cylinder no more than 5 mm [3/16 in.] in the radial, and no more than 4 mm [1/8 in.] in the vertical direction. If made of paper, the bottom cap of the mold shall be of parchment-lined cap stock not less than 0.7 mm [0.028 in.] thick (Note 6). It shall be glued to the outside of the walls by means of a flange not less than 19 mm [3/4 in.] high. The glue shall be water-insoluble adhesive of the resin type that will not react with fresh concrete. Only the practicable minimum amount of adhesive shall be exposed on the inner side of the bottom of the mold.

5.4.3 *Waterproofing*—The mold made from paper or fiber shall be completely coated on inside and outside, side walls,

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

and bottom with a suitable waterproofing medium (Note 7). The top edge shall be waterproofed, or coated, to limit absorption. The surfaces of metal bottoms, which must comply with 5.4.2, need not be coated. Any waterproofing coating used in this application shall have a melting point not less than 49 °C [120 °F] (Note 8). The coating shall provide a film over the inside that will minimize adherence of the concrete to the side walls and the bottom.

NOTE 7—Paraffin coating for this use may be of the grade known to the trade as crude scale wax or of any superior grade. In general, a film of paraffin of sufficient thickness to accomplish the intended purposes will permit one to raise a curl of paraffin with the thumbnail.

NOTE 8—Such coatings may be unsuitable for molds that are subjected to temperatures above 49 °C [120 °F], either before or after filling with concrete.

5.5 *Single-Use Sheet Metal Molds*—Molds shall conform to the following additional requirements when light-gage sheet metal is the predominant material used in their construction:

5.5.1 *Metal Thickness*—The side wall of steel sheet metal molds shall be manufactured from sheet metal not thinner than can-making quality blackplate and shall have a minimum metal thickness corresponding to that of 48.5-kg [107-lb] blackplate, which is approximately 0.300 mm [0.0118 in.] thick or 30½ gage. The metal for the bottom of the mold shall have a minimum thickness of 0.23 mm [0.009 in.] (Note 6).

5.5.2 *Bottom Design*—The bottom shall be so designed that it will be flush with the bottom of the side wall within a tolerance of 2 mm [1⁄16 in.]. An inside crimp, if used, shall produce an indentation around the circumference of the cylinder no more than 4 mm [⅛ in.] in the vertical or 5 mm [3⁄16 in.] in the radial direction.

5.5.3 *Top Edge*—The top edge of the side wall shall be curled or beaded to strengthen the mold and protect the user from sharp edges. If such bead protrudes to the inside of the mold, the indentation produced in the concrete cylinder shall not exceed 4 mm [⅛ in.] in either a radial or vertical direction.

5.5.4 *Coating*—If the mold is made of material which will rust, corrode, react, or adhere to the freshly mixed or hardened concrete, it must be coated with a protective coating of lacquer or other suitable material.

6. Test Methods for Elongation, Absorption, and Water Leakage

6.1 *Apparatus*—The assembly used for the absorption-elongation test shall follow the principles illustrated in Fig. 1.

6.2 *Specimens*—Molds shall be selected as described in Section 2. Single-use molds shall not be reused nor the same mold retested.

6.3 *Test Procedure for Molds:*

6.3.1 Samples of all types of single-use molds and reusable plastic molds shall be subjected to the dry rodded coarse aggregate test as described in 6.3.2 to evaluate their resistance to damage under use and to the water leakage test described in 6.3.3 and 6.3.4. Paper or other potentially absorptive molds shall additionally be tested for absorptivity and elongation described in 6.3.5. Plastic and sheet metal molds need not be tested for elongation and absorption, but should be tested for water leakage. Dimensional requirements for all molds shall be verified.

6.3.2 Prepare the mold for test by filling with dry crushed stone coarse aggregate meeting the grading requirements of Specification C33 size No. 57, 25.0 to 4.75 mm [1 in. to No. 4] or No. 67, 19.0 to 4.75 mm [¾ in. to No. 4]. Fill and compact the mold by the rodding procedure specified in Practice C192/C192M for compression test specimens using the tamping rod, number of layers and number of strokes per layer specified. It will generally not be possible to obtain the penetration of the tamping rod specified in Practice C192/

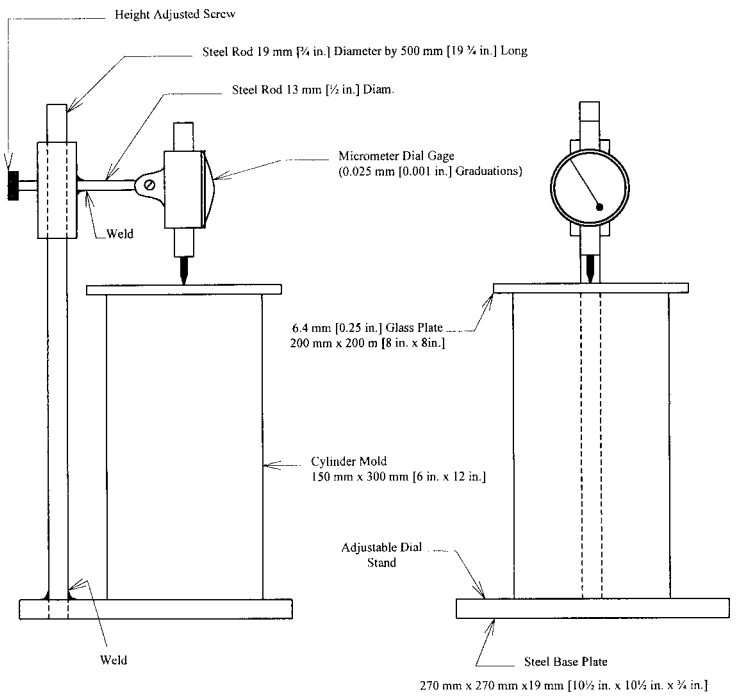

FIG. 1 Apparatus for Absorption-Elongation Test of Paper Molds

www.technobetar.ir

C192M. After rodding the final layer, empty the coarse aggregate, wipe lightly with a dry cloth and examine the mold for physical damage.

6.3.3 After completion of 6.3.2, determine the mass of the mold and record to the nearest 0.004 g/mm [0.1 g/in.] of mold height. Place the mold on a firm, flat surface and fill with water at room temperature to a depth of 90 to 95 % of the mold height. Then place the mold on the dial stand, cover with the glass or metal plate and record the initial length by dial micrometer to the nearest 0.025 mm [0.001 in.].

6.3.4 Allow the mold to stand for 3 h and take a final reading of the micrometer. Examine and record any visible leakage. Empty water from the mold, dry lightly with a towel and record the final mass to the nearest 0.04 g/cm [0.1 g/in.] of mold height.

6.3.5 Calculate the elongation as the difference between the final length and initial length. Calculate the absorption as the difference between the final mass and initial mass of the mold.

6.3.6 Verify all dimensional requirements.

6.4 *Water Leakage Test for Reusable Molds:*

6.4.1 Prepare reusable molds with the sealant to be used, if required. Fill molds with water to a depth of 90 to 95 % of the nominal height. Subject the mold to tapping and jarring which is judged to be typical of what occurs when specimens are molded in accordance with the applicable provisions of Practice C31/C31M or C192/C192M.

6.4.2 One hour after tapping, examine for visible leakage.

7. Sampling and Rejection

7.1 At least three single-use and reusable molds shall be selected at random from each shipment by the purchaser to ensure that the molds are in compliance with this specification.

7.2 Failure of any one of the three molds to comply with this specification shall be basis for rejection of the shipment.

8. Record to be Prepared by the Purchaser

8.1 Where applicable for the type of mold tested, record and retain in accordance with Practice C1077 the following information for each mold tested:

8.1.1 Brand or source of molds,

8.1.2 Shipment or lot from which the mold was taken,

8.1.3 Date sampled and date tested,

8.1.4 Brief general description of the mold including nominal dimensions, type of mold, and materials of which it is made,

8.1.5 Total absorption, g, if specified,

8.1.6 Total expansion, mm [in.], if specified, and

8.1.7 Water leakage reported in terms of compliance, or failure by leakage.

8.2 Where applicable for the type of mold tested, record and retain the following information for samples which do not meet the requirements of the specification:

8.2.1 Average diameter or height, mm [in.],

8.2.2 Maximum and minimum diameters or heights, mm [in.],

8.2.3 Nonconformance with required perpendicularity of rim or base to the axis of the mold,

8.2.4 Apparent reaction between mold materials and concrete or mortar or corrosion of metal in contact with concrete,

8.2.5 Melting point less than 49 °C [120 °F],

8.2.6 Minimum thickness of materials in side walls or bottom, and

8.2.7 Dimension of crimp in bottom, top edge or construction of paper bottom.

9. Keywords

9.1 concrete; molds; test cylinders

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C470/C470M – 08, that may impact the use of this specification. (Approved October 1, 2009)

(*1*) Revised 4.3 to require initial compliance testing of reusable molds before being placed in service.

(*2*) Replaced “report” with “record and retain” in Section 8.

(*3*) Added Practice C1077 to 8.1 and Referenced Documents.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 471M – 01 (Reapproved 2006)$^{\epsilon 1}$

Standard Test Methods for Chemical Analysis of Gypsum and Gypsum Products (Metric)[1]

This standard is issued under the fixed designation C 471M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ϵ^1 NOTE—Note 1 and certain footnotes were removed editorially to conform to ASTM Form and Style requirements for sole source of supply January 2007.

1. Scope

1.1 These test methods cover the chemical analysis of gypsum and gypsum products, including gypsum ready-mixed plaster, gypsum wood-fibered plaster and gypsum concrete.

1.2 The test methods appear in the following order:

	Sections
Alternative Procedure for Analysis for Calcium Sulfate by Ammonium Acetate Method	17-22
Alternative Procedure for Analysis for Sodium Chloride by the Coulometric Method	23-29
Complete Procedure	5-16
Determination of Sand in Set Plaster	30-36
Optional Procedure for Analysis for Sodium by Flame Photometry	47-54
Optional Procedure for Analysis for Sodium by the Atomic Absorption Method	40-46
Preparation of Sample	4
Wood-Fiber Content in Wood-Fiber Gypsum Plaster	37-39

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 The values stated in SI units are to be regarded as the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems
C 22/C 22M Specification for Gypsum
C 28/C 28M Specification for Gypsum Plasters
C 59 Specification for Gypsum Casting Plaster and Gypsum Molding Plaster
C 61 Specification for Gypsum Keene's Cement
C 317/C 317M Specification for Gypsum Concrete
C 842 Specification for Application of Interior Gypsum Plaster
D 1193 Specification for Reagent Water
D 1428 Methods of Test for Sodium and Potassium in Water and Water-Formed Deposits by Flame Photometry[3]
D 2013 Practice for Preparing Coal Samples for Analysis
E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 *Definitions*—Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *sample as received*, *n*—a representative portion of raw gypsum or gypsum product in the state received by the testing laboratory, including aggregates, impurities and water content.

3.2.2 *dried sample*, *n*—a sample devoid of free water.

3.2.3 *riffle*, *n*—a hand feed sample divider device that divides the sample into parts of approximately the same weight. **(D 2013)**

4. Preparation of Sample

4.1 *General Procedures*—Details of sample preparation will vary according to the type of material being tested.

4.1.1 *Sample As Received*—Use a sufficient amount of sample such that, after sieving, not less than 50 g of sample will remain for testing. Weigh the entire sample immediately after opening the container in which the material was received. This will become the weight of the sample as received.

[1] These test methods are under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and are the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Dec. 1, 2006. Published January 2007. Originally approved in 1961. Last previous edition approved in 2001 as C 471 – 01.

www.technobetar.ir

4.1.2 *Drying*—Dry the sample in accordance with Section 7. This will be the weight of the dried sample.

4.1.3 *Crushing and Grinding*—Crush and grind the sample by hand with a mortar and pestle or by mechanical crushing and grinding equipment to pass a 250-µm (No. 60) sieve. Take care, particularly with mechanical equipment, not to expose the sample to temperatures of more than 52 °C. Clean the equipment thoroughly between samples. Thoroughly remix the ground sample and store it in an airtight container to avoid contamination.

4.1.4 *Rehydrating*—Thoroughly blend and rehydrate samples which contain calcium sulfate in forms other than $CaSO_4 \cdot 2H_2O$ and natural anhydrite. Place the sample in distilled water and keep it wet for not less than 48 h. Dry the hydrated sample in an oven at 45 ± 3 °C to constant weight and recrush or grind it in accordance with 4.1.3.

4.1.5 *Sample Reduction*—Thoroughly mix and reduce large samples as required by quartering or by the use of a riffle to obtain a specimen of approximately 50 g.

4.2 *Gypsum (C 22/C 22M)*—Gypsum samples will be received in the form of rocks, powder or both. If necessary crush and reduce the entire dried sample in accordance with 4.1.3 and 4.1.5.

4.3 *Gypsum Plaster*, (C 28).

4.3.1 *Gypsum Ready-Mixed Plaster or Gypsum WoodFibered Plaster*—Screen the dried sample through a 150-µm (No. 100) sieve[4] and discard the residue retained on the sieve. Reweigh the remaining sample and calculate the percentage of the dried sample. Reduce the sample in accordance with 4.1.5. Thoroughly blend and rehydrate the specimen in accordance with 4.1.4.

4.3.2 *Gypsum Neat Plaster or Gypsum Gauging Plaster*—Reduce the dried sample in accordance with 4.1.5. Thoroughly blend and rehydrate the specimen in accordance with 4.1.4.

4.4 *Gypsum Casting and Molding Plaster , (C 59)*—Reduce the dried sample in accordance with 4.1.5. Thoroughly blend and rehydrate the specimen in accordance with 4.1.4.

4.5 *Gypsum Keene's Cement, (C 61)*—Reduce the dried sample in accordance with 4.1.5. Blend in no more than 1 % molding plaster or K_2SO_4 and rehydrate the specimen in accordance with 4.1.4.

4.6 *Gypsum Concrete, (C 317)*—Screen the dried sample through a 150-µm (No. 100) sieve[4] and discard the residue retained on the sieve. Reweigh the remaining sample and calculate the percentage of the dried sample. Reduce the sample in accordance with 4.1.5. Thoroughly blend and rehydrate the specimen in accordance with 4.1.4.

4.7 *Gypsum Board*—Cut or break the dried sample into small pieces. Using a mortar and pestle, strike the pieces of the sample to loosen the paper face. Remove the pieces of paper by hand as they are separated from the core of the gypsum board. Carefully scrape any remaining powder from the paper. When all the paper has been removed from the pieces of the sample, reduce the sample in accordance with 4.1.5. Thoroughly blend and rehydrate the specimen in accordance with 4.1.4.

[4] Detailed requirements for this sieve are given in Specification E 11.

COMPLETE PROCEDURE

5. Apparatus

5.1 *Analytical Balance*—Capable of weighing the weighing bottles, lids and samples.

5.2 *Balance*—Capable of weighing not less than 100 g at a precision of 0.001 g.

5.3 *Drying Oven*—A mechanical convection oven set at 45 ± 3 °C.

5.4 *Desiccator*—Capable of being tightly sealed and containing calcium chloride or equivalent desiccant.

5.5 *Calcining Oven or Furnace*—Capable of achieving and maintaining temperatures to not less than 1000 °C.

5.6 *Weighing Bottles*—Borosilicate glass or ceramic containers with tightly sealable lids.

5.7 *Hot Plate*—A controllable hot plate capable of heating casseroles to approximately 120 °C.

5.8 *Porcelain Casseroles*—With a capacity of 50 to 100 mL.

5.9 *Filtering Funnels*.

5.10 *Filter Paper*.

5.11 *Porcelain Crucibles*.

5.12 *Mortar and Pestle*.

5.13 *Mechanical Jaw Crusher*—Capable of crushing gypsum rocks up to 50 mm diameter.

5.14 *Mechanical Grinder*—Burr mill or equivalent capable of grinding the granular output of the jaw crusher specified in 5.13.

6. Reagents

6.1 *Purity of Reagents*—Use reagent grade chemicals in all tests. Unless otherwise indicated, use reagents that conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.[5] If it is necessary to use other grades first ascertain that the reagent is of sufficiently high purity so that its use will not lessen the accuracy of the determination.

6.1.1 *Ammonium Chloride* (NH_4Cl).

6.1.2 *Ammonium Hydroxide (sp gr 0.90)*—Concentrated ammonium hydroxide (NH_4OH).

6.1.3 *Ammonium Nitrate (25 g/L)*—Dissolve 25 g of ammonium nitrate (NH_4NO_3) in water and dilute to 1 L.

6.1.4 *Ammonium Oxalate* ($(NH_4)_2C_2O_4$).

6.1.5 *Barium Chloride (100 g/L)*—Dissolve 100 g of barium chloride ($BaCl_2 \cdot 2H_2O$) in water and dilute to 1 L.

6.1.6 *Calcium Chloride ($CaCl_2$)*—Anhydrous Calcium Chloride with a combined water of not more than 5 %.

6.1.7 *Hydrochloric Acid (sp gr 1.19)*—Concentrated hydrochloric acid (HCl).

6.1.8 *Hydrochloric Acid (1 + 4)*—Mix 1 volume of HCl (sp gr 1.19) with 4 volumes of water.

6.1.9 *Hydrochloric Acid (1 + 5)*—Mix 1 volume of HCl (sp gr 1.19) with 5 volumes of water.

[5] *Reagent Chemicals, American Chemical Society Specifications* , American Chemical Society, Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see *Analar Standards for Laboratory Chemicals*, BDH Ltd., Poole, Dorset, U.K., and the *United States Pharmacopeia and National Formulary*, U.S. Pharmacopeial Convention, Inc. (USPC), Rockville, MD.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.1.10 *Nitric Acid (sp gr 1.42)*—Concentrated nitric acid (HNO_3).

6.1.11 *Potassium Chromate Solution (100 g/L)*—Dissolve 5 g of potassium chromate (K_2CrO_4) in 50 mL of water, mix, add 10 drops of 0.05 N silver nitrate ($AgNO_3$) solution, allow to stand for 5 min, and filter.

6.1.12 *Potassium Permanganate (5.6339 g/L)*—Dissolve 5.6339 g of potassium permanganate ($KMnO_4$) in water and dilute to 1 L.

6.1.13 *Silver Nitrate, Standard Solution (0.05 N)*—Prepare and standardize a 0.05 N silver nitrate ($AgNO_3$) solution.

6.1.14 *Sodium Ammonium Phosphate*—($NaNH_4HPO_4$).

6.1.15 *Sulfuric Acid (sp gr 1.84)*—Concentrated sulfuric acid (H_2SO_4).

6.1.16 *Sulfuric Acid (1 + 6)*—Carefully mix 1 volume of H_2SO_4(sp gr 1.84) with 6 volumes of water.

6.1.17 *Nitric Acid (0.1 N)*—Mix 1.4 mL of HNO_3(sp gr 1.42) with 200 mL of water.

6.1.18 *Phenolphthalein Indicator Solution*— Dissolve 0.25 g of phenolphthalein in 30 mL of methanol and dilute to 50 mL with water.

6.1.19 *Sodium Hydroxide Solution (0.1 N)*—Dissolve 1 g of sodium hydroxide (NaOH) in 250 mL of water.

6.1.20 *Water*—Reagent water shall be in accordance with Specification D 1193, type II. Specification D 1193 gives the following values for type II grade water.

Electrical conductivity, max, μS/cm at 298 K (25-C)	1.0
Electrical resistivity, min, MΩ·cm at 298 K (25-C)	1.0
Total organic carbon (TOC), max, μg/L	50.0
Sodium, max, μg/L	5.0
Chlorides max, μg/L	5.0
Total silica, max, μg/L	5.0

7. Free Water

7.1 *Significance and Use*—The free water analysis determines the amount of free water contained in the sample as opposed to chemically combined water, and prepares the sample for further analysis.

7.2 *Procedure*:

7.2.1 Weigh a sample of the material as received of not less than 50 g to a precision of 0.001 g and spread it out in a thin layer in a suitable vessel. Place in an oven and dry at 45 ± 3 °C for 2 h, then cool in a desiccator and weigh again. The loss of weight corresponds to the free water.

7.2.2 Retain the sample in a sealed container or in the desiccator for further analysis.

7.3 *Calculation and Report*—Calculate and report loss in weight as a percentage of the sample as received or of the dried sample as required.

7.4 *Precision and Bias*—Neither the precision nor the bias for the free water analysis has been determined.

8. Combined Water

8.1 *Significance and Use*—The combined water analysis determines the percent of chemically combined water and is used to calculate the purity of gypsum or the amount of gypsum or gypsum plaster in gypsum products.

8.2 *Interferences*—Some materials, such as organic and hydrated compounds that decompose within the same temperature range as gypsum, will cause high results. When the maximum temperature is exceeded, some carbonates undergo decomposition, which will result in high results.

8.3 *Procedure*:

8.3.1 For each sample, place three weighing bottles with lids in the preheated calcining oven or furnace and heat for 2 h at 215 to 230 °C. Place in the desiccator and allow to cool to room temperature. Weigh the bottles and lids to the nearest 0.0001 g and record the tare weights.

8.3.2 Weigh out three specimens of approximately 1 g each of the sample as prepared in Section 4 and dried in Section 7 to a precision of 0.0001 g in the previously tared weighing bottles and record the total weight with lids.

8.3.3 Place the specimens in the calcining oven with the lids placed loosely on each bottle or crucible for 2 h or until constant weight has been obtained.

8.3.4 Place the lids tightly on the weighing bottles, remove from the oven, and place in the desiccator to cool to room temperature.

8.3.5 Weigh each specimen to a precision of 0.0001 g and record the weights.

8.3.6 Retain the residues for carbon dioxide analysis.

8.4 *Calculation and Report*—Calculate and report the average loss in weight of the three specimens as a percentage of the sample as received or of the dried sample, as required, to the nearest 0.001 g and record the tare weights.

8.5 *Precision and Bias*—Neither the precision nor the bias for the combined water analysis has been determined.

9. Carbon Dioxide

9.1 *Summary of Test Method*—The sample is decomposed with HCl and the liberated CO_2 is passed through a series of scrubbers to remove water and sulfides. The CO_2 is absorbed with Ascarite, a special sodium hydroxide absorbent, and the gain in weight of the absorption tube is determined and calculated as percent CO_2.

9.2 *Significance and Use*—The carbon dioxide analysis is useful in estimating carbonates and organic carbon for chemical balance.

9.3 *Special Reagents*:

9.3.1 *Magnesium Perchlorate Desiccant*—for drying.

9.3.2 *Sodium Hydroxide Absorbent*—a coarse sodium hydroxide coated silica.

9.4 *Special Apparatus*—The apparatus illustrated in Fig. 1 consists of the following:

9.4.1 *Purifying Jar A*, Fleming, containing sulfuric acid.

9.4.2 *Drying Tube B*, U-shaped with side arms and glass-stoppers. Side arms are shaped to hold rubber tubing. Contains Anhydrone on left side and Ascarite on right side.

9.4.3 *Erlenmeyer Flask C*, 250 mL, 24/20 ground-glass joint.

9.4.4 *Separatory Funnel D*, with ground glass stopper and interchangeable hollow ground-glass joint. A delivery tube bent at the end extends into the sample flask approximately 15 mm from the bottom and is used to introduce acid into flask.

9.4.5 *Condenser E*.

9.4.6 *Gas-Washing Bottle F*, 250 mL, with fitted disk containing distilled water to retain most of the acid volatilized from the alkalimeter.

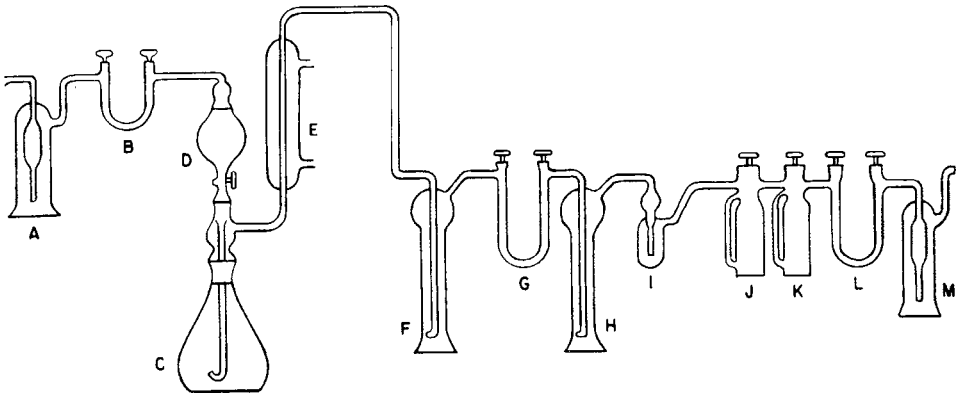

FIG. 1 Apparatus for Carbon Dioxide Analysis

9.4.7 *U-Tube G*, containing mossy zinc to remove the last traces of HCl.

9.4.8 *Gas Washing Bottle H*, 250 mL, with fritted disk, containing concentrated H_2SO_4 and trap *I*, to remove any SO_3 mist that is carried over.

9.4.9 *Absorption Bulb J*, containing Anhydrone to remove last traces of water vapor.

9.4.10 *CO_2 Absorption Bulb*, containing Ascarite filled as follows: On the bottom of the bulb, place a layer of glass wool extending above the bottom outlet and on top of this a layer of Anhydrone approximately 10 mm thick; immediately above this place another layer of glass wool, then add Ascarite to almost fill the bulb. Place a top layer of Anhydrone approximately 10 mm thick on top of the Ascarite and top it off with a covering of glass wool.

9.4.11 *U-Guard Tube L*, filled with Anhydrone in left side and Ascarite in right side.

9.4.12 *Purifying Jar M*, Fleming, containing H_2SO_4.

9.5 *Procedure*:

9.5.1 After drying as described in Section 8 place the residue obtained in the 250 mL Erlenmeyer flask (*C*). Connect the flask to the apparatus as shown in Fig. 1. Purge the system free of carbon dioxide by passing a current of CO_2-free air through the apparatus for 10 to 15 min.

9.5.2 Weigh the absorption bulb to 0.0001 g and attach it to the train. Remove the glass stopper from the separatory funnel, place 50 mL of dilute HCl (1 + 1) in the separatory funnel (*D*) and replace the stopper with the interchangeable hollow ground-glass joint through which passes a tube for admitting purified air. Open the stopcock of the separatory funnel and admit air through the top of the funnel to force the hydrochloric acid into the Erlenmeyer flask (*C*).

9.5.3 Start cold water circulating through the condenser (*E*) and, with CO_2-free air passing at a moderate rate through the absorption train, place a small hot plate or gas burner under the sample flask and boil for approximately 2 min. Remove the hot plate and continue the flow of purified air at approximately three bubbles per second for 10 min to sweep the apparatus free of CO_2. Close the absorption bulb, disconnect it from the train and weigh, opening the stopper momentarily to equalize the pressure. Use a second absorption bulb as counterpoise in all weighings unless a single pan balance is used.

9.6 *Calculation*—Calculate the percent CO_2 to the dried sample as follows:

$$\text{Percent } CO_2 = ((A - B)/C \times 100)(1 - D) \quad (1)$$

where:

A = mass of absorption bulb + CO_2 g,
B = mass of absorption bulb before the run, g,
C = mass of specimen, g, and
D = percent combined water as determined in Section 8 as a decimal.

Calculate the percent CO_2 to the sample as received as follows:

$$\text{Percent } CO_2 = E(1 - F) \quad (2)$$

where:

E = result of Eq 1, and
F = percent free water as determined in Section 7 as a decimal.

9.7 *Precision and Bias*—Neither the precision nor the bias for the carbon dioxide analysis has been determined.

10. Silicon Dioxide and Other Acid Insoluble Matter

10.1 *Summary of Test Method*—The gypsum and other acid soluble components of the sample are dissolved in dilute hydrochloric acid (HCl). The residue is weighed and calculated as silicon dioxide and other acid insoluble matter.

10.2 *Significance and Use*—The silicon dioxide and other acid insoluble matter analysis determines and is used to report the percentage of one of the inert impurities in gypsum and gypsum products.

10.3 *Procedure*—Perform in triplicate.

10.3.1 Weigh approximately 1 g of the specimen prepared in Section 4 to the nearest 0.0001 g.

10.3.2 Place the specimen in a porcelain casserole. Add approximately 50 mL of 1 + 5 hydrochloric acid. Evaporate slowly and carefully to apparent dryness on a hot plate. Take not less than 20 min to do the evaporation. Make a blank determination with one casserole in parallel. Cool to room temperature.

10.3.3 Add enough hydrochloric acid (sp gr 1.19) to wet the solid residue. Add 20 mL of water, boil and filter through filter paper. Wash the filter paper thoroughly using not less than 100 mL of room temperature water to render the precipitate chloride free. The most effective washing technique is to use many small quantities of wash water rather than fill the funnel to the brim two or three times. Test the filtrate for chloride by collecting a small amount and adding a few drops of 0.1

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

normal silver nitrate ($AgNO_3$) solution. A white precipitate indicates more washing is needed. Discard this test solution.

10.3.4 Place all the filtrate back in the same casserole. Evaporate to dryness and heat to 120 °C for 1 h and cool. To the cooled casserole add enough HCl (sp gr 1.19) to wet the solid residue. Add 50 mL of water and boil.

10.3.5 Wash the second contents of the casserole through another filter paper. Thoroughly wash the residue in the filter paper until chloride free as in 10.3.3. Retain the filtrate for the iron and aluminum oxide analysis.

10.3.6 Dry sufficient crucibles by placing in a cold muffle furnace during warm up or by placing in a drying oven for 15 to 20 min, then placing in a 900 °C muffle furnace. Cool crucibles to room temperature in a desiccator.

10.3.7 Transfer both filter papers to a tared crucible and char slowly without flaming. Burn off all the carbon and ignite in a muffle furnace at 900 °C for 15 min.

10.3.8 Cool the crucibles in a desiccator and weigh to the nearest 0.0001 g.

10.4 *Calculation and Report*—Calculate the average weight of the three precipitates and report as silicon dioxide (SiO_2) and other insoluble matter to the percentage of sample as received or to the dried sample as required.

10.5 *Precision and Bias*—Neither the precision nor the bias for the silicon dioxide and other acid insoluble matter has been determined.

11. Iron and Aluminum Oxides

11.1 *Significance and Use*—The iron and aluminum oxides ($Fe_2O_3 + Al_2O_3$) analysis is used to determine the quantity of these metal oxides in gypsum or gypsum products.

11.2 *Procedure*—To the filtrate, obtained as described in Section 10, add a few drops of nitric acid (HNO_3), and boil to ensure oxidation of the iron. Add 2 g of ammonium chloride (NH_4Cl) previously dissolved in water. Make alkaline with ammonium hydroxide (NH_4OH). Digest hot for a few minutes until the precipitate coagulates. Filter, wash, ignite the precipitate at 1000 °C for 30 min or to constant weight in a muffle furnace and weigh as $Fe_2O_3 + Al_2O_3$. Save the filtrate for the CaO analysis.

NOTE 1—The addition of a pinch of ashless filter paper pulp will aid in the filtration of the precipitate.

11.3 *Calculation*—Calculate $Fe_2O_3 + Al_2O_3$ to the percentage of sample as received or the dried sample as required. This precipitate may be further treated to separate the two oxides, but this is generally unnecessary.

11.4 *Precision and Bias*—Neither the precision nor the bias for the iron and aluminum oxides analysis has been determined.

12. Calcium Oxide

12.1 *Significance and Use*—The calcium oxide (CaO) analysis is used to determine the amount of CaO and calculate the amount of calcium carbonate ($CaCO_3$) in gypsum and gypsum products.

12.2 *Procedure*:

12.2.1 To the filtrate obtained as described in Section 11 add 5 g of ammonium oxalate ($(NH_4)_2C_2O_4$) dissolved in water. Digest hot for 30 min, making sure that the solution is always alkaline with NH_4OH. Filter, wash, and ignite the precipitate at 1000 °C for 2 h to constant weight in a platinum crucible in a muffle furnace.

12.2.2 *Alternative Method*—To the filtrate obtained as described in Section 11, add 5 g of $(NH_4)_2C_2O_4$ dissolved in water. Digest hot for 30 min, making sure that the solution is always alkaline with NH_4OH. Filter and wash, transfer the precipitate to a beaker, and wash the filter paper with hot H_2SO_4(1 + 6), catching the washing in the same beaker. Heat gently to complete solution, adding more H_2SO_4 if necessary. While still warm, titrate with potassium permanganate ($KMnO_4$) solution (5.6339 g/L) until the pink color persists.

12.3 *Calculation*—The number of milliliters of $KMnO_4$ solution used gives directly the percentage of lime in the dried sample. Calculate the CaO to the percentage of sample as received or the dried sample as required.

12.4 *Precision and Bias*—Neither the precision nor the bias for the calcium oxide analysis has been determined.

13. Magnesium Oxide

13.1 *Significance and Use*—The magnesium oxide (MgO) analysis is used to determine the amount of MgO and calculate the amount of magnesium carbonate $MgCO_3$ in gypsum and gypsum products.

13.2 *Procedure*—To the filtrate obtained as described in 12.2.1 or 12.2.2, add enough water to give a total volume of approximately 600 mL. Cool, and add 10 mL of NH_4OH and 5 g of sodium ammonium phosphate ($NaNH_4HPO_4$) dissolved in water. Stir vigorously until a precipitate begins to form. Let stand overnight. Filter, using a Gooch crucible, and wash with NH_4NO_3 solution. Ignite at 1000°C for 2 h to constant weight in a muffle furnace.

13.3 *Calculation*—Multiply this weight by 0.36207 to find the weight of magnesium oxide (MgO). Calculate the MgO to the percentage of sample as received or to the dried sample as required.

13.4 *Precision and Bias*—Neither the precision nor the bias for the magnesium oxide analysis has been determined.

14. Sulfur Trioxide

14.1 *Summary of Test Method*—In this test method, sulfate is precipitated from an acid solution of the gypsum with barium chloride ($BaCl_2$). The precipitate is filtered and weighed as barium sulfate ($BaSO_4$) and the sulfur trioxide (SO_3) equivalent is calculated.

14.2 *Significance and Use*—The specification for gypsum and some gypsum products specifies the amount of calcium sulfate ($CaSO_4$) required, either in the dihydrate ($CaSO_4 \cdot 2H_2O$) or hemihydrate ($CaSO_4 \cdot ½ H_2O$) form. This procedure assumes that an insignificant amount of sulfate other than calcium sulfate is present. This test method is used to determine compliance to the gypsum and gypsum product specifications. It is also commonly used in quality control work.

14.3 *Interference*—This test method has been developed for natural gypsum and for impurities generally found associated with natural gypsum. Synthetic gypsum will sometimes have an additional number of interfering elements and compounds, and if so, this procedure will not give accurate results. This test

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

method has a number of interferences that theoretically affect the results. Co-precipitation and occlusion are problems if the solution is either too acidic or too basic. Calculations using SO_3 analysis are most accurate on samples that are known to be completely hydrated or completely dehydrated.

14.4 *Procedure*:

14.4.1 Having properly selected and prepared the samples as specified in Section 4, weigh a representative specimen of approximately 0.5 g, to the nearest 0.0001 g.

14.4.2 Place the weighed sample into a 400-mL beaker. Add 50 mL of HCl (1 + 5). Boil and disperse with the flattened end of a glass rod while stirring until the sample is completely broken down. Add approximately 100 mL boiling water and continue boiling for 15 min, with this step to be extended as required, so the combined boiling time is not less than 1 h.

14.4.3 Using filter paper, filter into a clean 600-mL flask and rinse the 400-mL beaker thoroughly with hot distilled water. Carefully wash the sides of the 400-mL beaker while wiping the insides with a rubber-tipped glass rod making sure all splatters and insoluble are washed into the filter paper. Dry and burn off the filter paper leaving the residue to be dried and weighed for insoluble matter, if this test method is not otherwise conducted.

14.4.4 Dilute the filtrate to 400 to 500 mL. Add 1 to 2 drops of 0.1 % methyl red indicator. Prepare a 400 to 500-mL sample of 0.05 to 0.1 NHCl. Add 1 to 2 drops of 0.1 % methyl red indicator. Compare the color of this solution to the color of the filtrate. Dilute the filtrate or add HCl (1 + 5) solution as necessary to match the pH of the 0.05 to 0.1 NHCl solution.

14.4.5 Boil the filtrate solution and add 20 mL of near-boiling 10 % barium chloride solution, preferably with the help of a pipette, drop by drop while stirring. The barium chloride solution should be prepared not less than one day before use. Continue boiling the solution for 10 to 15 min and digest hot for 3 h or until the precipitate settles.

14.4.6 Filter and wash with approximately 125 to 150 mL of hot water to render the precipitate chloride free. Test the filtrate for chloride by collecting a small amount and adding a few drops of 0.1 N $AgNO_3$ solution. A white precipitate indicates more washing is needed. Alternately, use filtering crucibles for quick filtering if the particular crucibles to be used are tested prior to use by refiltering the filtrate from the crucibles with filter paper, and no more than 2 mg is collected on the filter paper.

14.4.7 Ignite the precipitate and paper in a tared crucible, and slowly char the paper without inflaming. Burn off all the carbon and ignite in a muffle furnace at 800 to 900 °C or using bright red heat over a Bunsen burner for 15 to 20 min. Dry the filtering crucibles by placing in a cold muffle furnace during warm-up or in a drying oven prior to igniting in a muffle furnace at 800 to 900 °C for 15 to 20 min.

NOTE 2—Thoroughly cleans crucibles before each use and heat in a furnace at 800 to 900 °C and cool in a desiccator before taring.

14.4.8 Cool all crucibles in a desiccator and weigh to the nearest 0.0001 g.

14.5 *Calculation*—Multiply the weight of the precipitate by 0.343 to determine the weight of sulfur trioxide (SO_3). Calculate the SO_3 to the percentage of sample as received or to the dried sample as required.

14.6 *Precision and Bias*—Neither the precision nor the bias for the sulfur trioxide analysis has been determined.

15. Chlorides

15.1 *Significance and Use*—Small amounts of chlorides in gypsum or gypsum products often have a detrimental effect on their use. This procedure is used to measure the amount of chlorides present and report it as sodium chloride.

15.2 *Procedure*:

15.2.1 Weigh approximately 20.0 g of sample as prepared in Section 4 to 0.001 g and transfer to a 400-mL beaker. Add 150 mL of water, stir, and heat to just below the boiling point. Cover with a watch glass and maintain at just below boiling (not less than 80 °C) for 1 h with occasional stirring. Filter with suction on a Buchner funnel fitted with a medium filter paper. Wash the residue with four 20-mL portions of hot water.

15.2.2 Add 2 drops of phenolphthalein indicator solution to the filtrate. If the filtrate fails to turn pink, add 0.1 NNaOH solution dropwise with stirring until a faint pink color develops. Add 0.1 $NHNO_3$ dropwise until the pink color just disappears.

15.2.3 If the chloride content is very low, transfer the entire filtrate quantitatively to a 400-mL beaker and proceed as described in 15.2.4. If larger amounts of chloride are expected, transfer the filtrate quantitatively to a 250-mL volumetric flask, cool to room temperature, and dilute to 250 mL. Take a suitable aliquot, transfer to a 400-mL beaker, and dilute to a volume of 100 to 250 mL.

15.2.4 Place the beaker containing the sample on a white surface, add 0.5 mL (10 drops) of K_2CrO_4 solution and titrate with $AgNO_3$ solution using a micro buret having a 10-mL capacity and graduated in divisions of 0.02 mL. Titrate until a faint but definite orange color is visible.

15.2.5 Perform a blank titration using the same volume of water as the sample volume and the same amount of K_2CrO_4 solution. Titrate to the same color as obtained with the sample.

15.3 *Calculation*—Subtract the volume of $AgNO_3$ solution used for the blank titration from the volume used for the sample to give the net titration. A 1-mL net titration is equivalent to 0.002923 g of sodium chloride (NaCl). Calculate the NaCl as a percentage of the sample as received or the dried sample as required.

15.4 *Precision and Bias*—Neither the precision nor the bias for the chloride analysis has been determined.

16. Report

16.1 Report the results obtained in the analysis as follows:

	Percent
Free water	...
Combined water	...
Carbon dioxide (CO_2)	...
Silicon dioxide (SiO_2) and insoluble matter	...
Iron and aluminum oxides (Fe_2O_3 + Al_2O_3)	...
Lime (CaO)	...
Magnesium oxide (MgO)	...
Sulfur trioxide (SO_3)	
Sodium chloride (NaCl)	...
Total	100.00±

NOTE 3—Since it is frequently advisable to recalculate the results

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

obtained in the chemical analysis in order that they may be more enlightening, the following is submitted for consideration:

(*1*) Multiply the percentage of combined water by 4.778 to obtain purity or percentage gypsum. To calculate the percentage of $CaSO_4 \cdot ½ H_2O$ in plasters, multiply the percentage of gypsum by 0.8430.

(*2*) Multiply the percentage of combined water by 2.222 to obtain the amount of SO_3 combined as gypsum.

(*3*) Subtract the result obtained in (*2*) from the total SO_3 found by analysis to obtain the excess SO_3.

(*4*) Multiply the excess SO_3 by 1.700 to obtain the percentage anhydrite, $CaSO_4$.

(*5*) Multiply the percentage of gypsum found in (*1*) by 0.3257 to obtain the percentage of CaO combined as gypsum.

(*6*) Multiply the percentage of anhydrite found in (*4*) by 0.4119 to obtain the percentage of CaO combined as anhydrite.

(*7*) Add (*5*) and (*6*) together. Then subtract this result from the total CaO percentage found by analysis.

(*8*) Multiply the excess CaO percentage by 1.785 to obtain the percentage of calcium carbonate.

(*9*) Multiply the percentage of MgO by 2.091 to obtain the percentage of magnesium carbonate.

NOTE 4—Having made the calculations in Note 3, the results may be reported as follows:

	Percent
Gypsum ($CaSO_4 \cdot 2H_2O$)	...
Anhydrite ($CaSO_4$ natural and manufactured) (Note 3)	...
Silicon dioxide and insoluble (SiO_2 + Ins.)	...
Iron and aluminum oxide (R_2O_3)	...
Calcium carbonate ($CaCO_3$)	...
Magnesium carbonate ($MgCO_3$)	...
Sodium chloride (NaCl)	...
Total	100.00±

NOTE 5—The presence of the different forms of $CaSO_4$ may be determined by a microscopic examination. A paper titled "Gypsum Analysis with the Polarizing Microscope" containing suggested methods can be found in ASTM STP 861.[6]

ALTERNATIVE PROCEDURE FOR ANALYSIS FOR CALCIUM SULFATE BY THE AMMONIUM ACETATE METHOD[7]

17. Significance and Use

17.1 This test method covers the determination of calcium sulfate in gypsum and gypsum products by extraction with ammonium acetate solution.

18. Reagents and Materials

18.1 *Ammonium Acetate Solution*—Dissolve 454 g of ammonium acetate in 2 L of water. Add sufficient NH_4OH to make the solution distinctly ammoniacal, using phenolphthalein as the indicator.

18.2 *Ammonium Hydroxide Wash Solution*— Dilute 100 mL of concentrated ammonium hydroxide (NH_4OH, sp gr 0.90) to 1 L with water.

18.3 *Filter Aid*—Diatomaceous silica, analytical grade.

18.4 *Phenolphthalein Indicator Solution*.

19. Procedure Using Gooch Crucible

19.1 Weigh rapidly approximately 4 g of the well-mixed sample and transfer to a 600-mL beaker. Make all weighings to 0.001 g, except weigh the crucibles and their contents to 0.0001 g.

19.2 Without delay, weigh approximately 1 g of the well-mixed sample in a tared weighing bottle having a ground-glass stopper. Dry the sample and weighing bottle to constant weight at 45 °C. Stopper weighing bottles immediately upon removal from the oven in order to prevent absorption of moisture from the air upon cooling.

19.3 If the percentage by weight of combined water held by the calcium sulfate is required, heat the sample and weighing bottle to constant weight at 220 °C.

19.4 To the contents of the 600-mL beaker (19.1), add 350 mL of the ammonium acetate solution, and stir the mixture thoroughly to loosen all of the solid matter from the bottom of the beaker. Add 0.2000 g of redried diatomaceous silica to the mixture. Heat the beaker and contents to 70 °C on a steam or hot water bath, and maintain at that temperature for 30 min, while stirring frequently. During heating, keep the solvent ammoniacal by additions of NH_4OH and phenolphthalein, if indicated. Meanwhile, heat a supply of the ammonium acetate solution to 70 °C, keeping it also distinctly ammoniacal. Filter the mixture, with suction, through a tared Gooch crucible, stirring frequently during filtration to keep the diatomaceous earth suspended in the liquid. Wash the Gooch crucible containing the residue with five 10-mL portions of the warm acetate solution, draining thoroughly after each washing. Wash in the same manner with eight 10-mL portions of the NH_4OH wash solution. Take care to wash the upper walls of the Gooch crucible. Drain the crucible dry with suction, place in an oven at 70 °C, and dry to constant weight (Note 6). Allow the crucible to cool in a desiccator before weighing.

NOTE 6—Avoid overheating in all oven drying of ammonium acetate residues; that is, place crucibles well away from the heating elements. This is of particular importance for samples high in impurities, as these impurities often have water of hydration that is lost on local overheating.

20. Procedure Using Tared Filter Papers

NOTE 7—This procedure is suggested where several samples are to be analyzed at once. It has been found that gravity filtration on six samples will proceed as rapidly as it is possible to handle the samples.

20.1 Dry a quarter-folded, 110-mm quantitative filter paper overnight at 70 °C in a wideform, glass-stoppered, 30 by 60-mm weighing bottle. After drying, cool the weighing bottle and paper in a desiccator, and weigh.

20.2 Treat the sample exactly as described in 19.1, 19.2, and 19.4 prior to the filtration. Filter the mixture by gravity through a 70-mm glass funnel, stirring frequently during filtration to keep the diatomaceous silica suspended in the liquid. Wash the filter paper and residue with five 10-mL portions of warm acetate solution, draining thoroughly after each washing. Wash in the same manner with eight 10-mL portions of the NH_4OH wash solution. After final draining, replace the paper and residue in the weighing bottle, and dry at 70 °C to constant weight. Cool the weighing bottle, paper, and residue in a

[6] Green, George W., "Gypsum Analysis with the Polarizing Microscope," *The Chemistry and Technology of Gypsum, ASTM STP 861*, ASTM, 1984, pp. 22–47.

[7] This procedure was developed by L. S. Wells and W. F. Clarke, National Bureau of Standards, and modified by B. E. Kester, United States Gypsum Co.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

freshly prepared desiccator before weighing; this is essential, due to the hygroscopic character of paper.

21. Calculation

21.1 Calculate the percentage of loss in weight at 45 °C (free water) as follows:

$$\text{Loss in weight at 45 °C, \%} = [(A - B)/C] \times 100 \quad (3)$$

where:

A = original weight of sample and weighing bottle,
B = weight of sample and weighing bottle dried to constant weight at 45 °C, and
C = original weight of sample.

Calculate the weight of the 4-g sample (19.1), corrected for loss on heating to constant weight at 45 °C.

21.2 Calculate the percentage of combined water as follows:

$$\text{Combined water, \%} = [(B - D)/(B - E)] \times 100 \quad (4)$$

where:

B = weight of sample and weighing bottle dried to constant weight at 45 °C,
D = weight of sample and weighing bottle dried to constant weight at 220 °C, and
E = weight of weighing bottle.

21.3 Calculate the percentage of $CaSO_4 \cdot nH_2O$ on the basis of the sample dried to constant weight at 45 °C as follows:

$$CaSO_4 \cdot nH_2O, \% = [F - (G - H)/F] \times 100 \quad (5)$$

where:

F = weight of sample, corrected for loss on heating to constant weight at 45 °C,
G = weight of dried crucible and contents (19.4) or weight of weighing bottle and contents (20.2), and
H = weight of crucible plus diatomaceous silica used as filter aid (19.4), or weight of weighing bottle, diatomaceous silica used as a filter aid and the weight of filter paper (20.2).

22. Precision and Bias

22.1 Neither the precision nor the bias for the analysis of calcium sulfate by the ammonium acetate method has been determined.

ALTERNATIVE PROCEDURE FOR ANALYSIS FOR SODIUM CHLORIDE BY THE COULOMETRIC METHOD[8]

23. Significance and Use

23.1 This test method covers the determination of sodium chloride in gypsum and gypsum products by the coulometric method.

24. Interferences

24.1 The presence of sulfide, sulfhydryl, or other silver reactive substances will lead to high results. Such interfering substances are removed by alkaline oxidation with hydrogen peroxide.

[8] This procedure was developed by Westroc Industries Limited.

25. Apparatus

25.1 *Chloride Meter*:

25.1.1 The instrument shall be equipped to measure the concentration of dissolved chloride in aqueous solutions by the coulometric method.

25.1.2 The instrument shall be capable of measuring chloride concentrations in the range from 10 to 260 mg/L with a repeatability of ± 1 mg/L.

26. Reagents

26.1 *Acid Buffer Solution*—Dissolve 100 mL of 99.5 % acetic acid ($HC_2H_3O_2$) and 5.5 mL of concentrated nitric acid (sp gr 1.42) in approximately 200 mL of water and dilute to 500 mL.

26.2 *Diluted Standard Solution (100 mg Cl/L)*—Dilute 5.00 mL of stock standard solution to 500 mL.

26.3 *Gelatin Solution*—Add 2.5 g of gelatin and 0.5 g of thymol blue to 250 mL of water and dissolve by stirring continuously while bringing to a boil. With the solution just boiling, continue stirring until all the thymol blue is dissolved. Add 0.5 g of thymol, cool, and dilute the solution to 500 mL.

NOTE 8—The gelatin solution holds the precipitated silver chloride (AgCl) in suspension and also indicates the presence of the acid buffer. The solution will keep for 3 months at room temperature or longer if refrigerated. Warm the refrigerated solution to room temperature before use.

26.4 *Stock Standard Solution (10 g Cl/L)*—Dissolve 8.240 g of dried sodium chloride (NaCl) in water and dilute to 500 mL.

27. Procedure

27.1 Weigh 20.0 g of the well-mixed sample and transfer to a 150-mL beaker.

27.2 Add 50 mL of water, boil, allow the solid material to settle, and filter off the solution. Add an additional 50 mL of water to the solids, boil, and pour the contents of the beaker into the filter. Wash the residue with 100 mL of hot water, adding the washing to the filtrate. Cool and dilute with water to 250 mL.

27.3 Switch on the chloride meter and allow a period of 25 min before use. Set the counter to zero.

27.4 Place a magnetic stirring bar in the test beaker, add 10 mL of diluted standard solution, 3 mL of acid buffer solution, and 5 drops of gelatin solution. Place the test beaker on the platform and lower the electrodes into the solution. Press the "start" button until the pilot light is extinguished. The counter will begin to register after a few seconds. Do not remove the electrodes from the sample until the pilot light comes on. Read the chloride content from the counter. If a reading of 100 ± 1 mg Cl/L is not obtained, refer to the manufacturer's instruction manual. Reset the counter to zero.

27.5 Repeat the procedure used in 27.4, using 10 mL of the sample solution instead of the diluted standard solution. Read the result as milligrams of chlorine per litre. When all tests are completed, lower the electrodes into reagent water.

28. Calculation

28.1 Calculate the amount of NaCl as a percentage of the sample as received or dried sample as follows:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$$\text{NaCl, \%} = 0.00206 \times A \quad (6)$$

where:
A = chloride meter reading, mg Cl/L.

29. Precision and Bias

29.1 Neither the precision nor the bias for the sodium chloride analysis by the coulometric method has been determined.

DETERMINATION OF SAND IN SET PLASTER

30. Summary of Test Method

30.1 This test method for the determination of the sand content of set gypsum plaster requires for accurate results the following determinations:

30.1.1 Determination of the percentage of insoluble matter in the sand used with the plaster,

30.1.2 Determination of the percentage of insoluble matter in the gypsum neat plaster, and

30.1.3 Determination of the percentage of insoluble matter in the sanded calcined plaster.

NOTE 9—If samples of the original gypsum neat plaster and the sand are not available, an approximation of the insoluble matter may be obtained by the use of this method on plaster and sand from the same sources as those from which the plaster to be analyzed was originally prepared.

31. Significance and Use

31.1 This test method is used for determining the sand content of samples of aggregated plaster taken from job sites to determine compliance with Specification C 842.

32. Reagents

32.1 *Ammonium Acetate (250 g/L)*—Dissolve 250 g of ammonium acetate ($NH_4C_2H_3O_2$) in water and dilute to 1 L.

32.2 *Ammonium Hydroxide (1 + 59)*—Mix 1 volume of concentrated ammonium hydroxide (NH_4OH) (sp gr 0.90) with 59 volumes of water.

33. Sampling

33.1 Where plaster to be tested is part of a two-coat or three-coat plastering operation, take the sample for analysis from that portion of the entire plaster sheet that comprises the single coat being tested. Separate succeeding coats of plaster by use of a stiff putty knife or similar implement. Not less than 500 g shall be taken as a sample, the sample preferably being obtained from different sections of the wall or ceiling under examination.

34. Procedure

34.1 In a clean porcelain mortar, grind the set plaster sample to the size of the largest sand particles present, or smaller, so that approximately 100 % of the sample will pass a 2.36-mm (No. 8) sieve. Fine grinding makes solution of the gypsum faster. Place approximately 200 g of the ground sample in a porcelain casserole or evaporating dish, and calcine on a sand bath. Stir the sample continuously with a thermometer during the heating, and adjust the rate of heating so that 20 to 30 min will be required to raise the temperature of the sample to 160 ± 5 °C. Cool the sample to room temperature in a desiccator.

34.2 After cooling, weigh accurately 20 ± 0.05 g of the calcined sample into a 600-mL beaker. Add 300 to 350 mL of $NH_4C_2H_3O_2$ solution. If acidic to litmus paper, add a few millilitres of NH_4OH (1 + 59) to the stock $NH_4C_2H_3O_2$ solution to render it slightly alkaline prior to the addition to the test sample.

34.3 Warm the suspension to a temperature of 70 ± 5 °C and stir continuously for 20 to 30 min. Filter the warm suspension with the aid of suction through a small Büchner funnel or Gooch crucible in which filter paper has previously been placed. Refilter the first 100 mL of the filtrate. Wash the sand remaining in the beaker onto the filter with an additional 100 mL of warm ammonium acetate solution. Wash the beaker and residue with 200 to 300 mL of water, dry the funnel and sand at 100 °C to constant weight. The weight of the residue is the weight of insoluble matter.

34.4 *Insoluble Matter in Sand*—Determine the weight of insoluble matter in sand as described in 34.1-34.3, except that no grinding of the sample is necessary.

34.5 *Insoluble Matter in Gypsum Neat Plaster*—Determine the weight of insoluble matter in the gypsum neat plaster as described in 34.1-34.3, except that only a 5-g sample is required and no grinding of the sample is necessary.

35. Calculation

35.1 *Insoluble Matter in Plaster*—Multiply by 5 the weight of the insoluble matter obtained as described in 34.3 to obtain the percentage of insoluble matter in sanded plaster.

35.2 *Insoluble Matter in Sand*—Multiply by 5 the weight of the insoluble matter in sand obtained as described in 34.4 to obtain the percentage of insoluble matter in sand.

35.3 *Insoluble Matter in Gypsum Neat Plaster*—Multiply by 20 the weight of the insoluble matter in gypsum neat plaster obtained as described in 34.5 to obtain the percentage of insoluble matter in gypsum neat plaster.

35.4 Calculate the percentage of sand in the sanded plaster as follows:

$$X = [(C - B)/(A - B)] \times 100 \quad (7)$$

where:
X = % of sand in sanded plaster,
A = % of insoluble matter in the sand,
B = % of insoluble matter in the gypsum neat plaster, and
C = % of insoluble matter in the sanded plaster.

35.5 To express the results as a ratio of the parts of sand per part of plaster by weight, use the following equation:

$$\text{Ratio of sand to plaster} = X/(100 - X) \quad (8)$$

NOTE 10—The results obtained by the above procedure indicate the amount of sand originally mixed with the gypsum neat plaster before it had been gaged with water or set.

36. Precision and Bias

36.1 Neither the precision nor the bias for the analysis of sand in set plaster has been determined.

WOOD-FIBER CONTENT IN WOOD-FIBER GYPSUM PLASTER

37. Significance and Use

37.1 This test method is used to determine the weight of wood fiber in wood-fibered plaster.

38. Procedure

38.1 Place a 100-g sample of wood-fiber plaster, prepared as described in Section 4 on a 600-µm (No. 30) sieve[4] nested over a 150-µm (No. 100) sieve.[4] Wash the plaster on the 600-µm sieve with a stream of cold water, removing the 600-µm sieve when the fiber on it is practically or entirely free of plaster. Next, wash the material on the 150-µm sieve until the bulk of the plaster has been washed through the sieve and the residue is mainly fiber. Transfer the material retained on the 150-µm sieve to a 300-mL, vitreous enamel, lipped pan, adding the charge on the 600-µm sieve if the fiber contains any adhering particles of plaster. Elutriate the material in the pan (purify by washing and straining, effecting as clean a separation of fiber from plaster as is practical), catching the elutriated fibers on a 150-µm sieve. To avoid loss of the fine particles of fiber, make the transfer from the pan to the 150-µm sieve by several stages of washing, stirring the charge, and quickly pouring upon the sieve the fiber flotations, repeating the elutriation procedure several times. Examine the fiber collected on the 150-µm sieve and repeat the elutriation if necessary.

38.2 Dry the sieves (or sieve) and the residue contained thereon overnight in an oven maintained at a temperature of 45 °C. Carefully invert the sieves, or sieve, over a piece of white paper, and transfer the residual material to the paper by brushing the bottom of the inverted sieve. Examine the transferred material visually, noting whether the separation of fibers from plaster has been complete. Then transfer the material to a weighed platinum crucible and dry to constant weight at a temperature of 45 °C. If the previous visual examination of the charge on the white paper showed that the fiber was practically free of particles of plaster, report as the percentage of fiber the weight of the fiber dried at 45 °C, divided by 100. If, on the other hand, the visual examination revealed the presence of an appreciable quantity of plaster associated with the fiber, carefully ignite the contents of the crucible to constant weight. In this case, report as the percentage of fiber the loss on ignition, divided by 100.

39. Precision and Bias

39.1 Neither the precision nor the bias for the analysis of wood-fiber content in wood-fiber gypsum plaster has been determined.

OPTIONAL PROCEDURE FOR ANALYSIS FOR SODIUM BY THE ATOMIC ABSORPTION METHOD

40. Significance and Use

40.1 This test method covers the determination of sodium in gypsum and gypsum products by the atomic absorption method.

41. Interferences

41.1 Sodium is partially ionized in the air-acetylene flame. The effects of ionization will be significantly overcome by the addition of 1 to 2 g/L of another alkali to blanks, standards, and samples. Alternatively, use the air-hydrogen flame, as it produces less ionization and less visible emission than the air-acetylene flame.

42. Apparatus

42.1 *Atomic Absorption Spectrophotometer*:

42.1.1 The instrument shall be equipped to measure the concentration of dissolved sodium in aqueous solutions using either the air-acetylene or air-hydrogen flame.

42.1.2 The instrument shall be capable of measuring sodium concentrations within the optimum analytical range of 0.1 to 0.5 absorbance units while providing a coefficient of variation of approximately 0.5 to 2 %.

43. Reagents

43.1 *Solvent*—Use deionized water to prepare all solutions. If an alkali is to be included for the purpose of suppressing sodium ionization, it is most convenient to add it to the solvent at the start. In this way a constant concentration of alkali in blank, standards, and sample solution is ensured.

43.2 *Stock Standard Solution (1.000 g Na/L)*—Dissolve 2.5418 g of dried sodium chloride (NaCl) in water and dilute to 1 L with water.

43.3 *Dilute Standard Solutions*—Prepare dilute standard solutions bracketing the absorbance range of the dilute sample solution, using the stock standard solution. (Solutions having a concentration less than approximately 0.500 g/L are unstable for periods of more than one day.)

44. Procedure

44.1 Take 18 g of the well-mixed sample and transfer to a 150-mL beaker.

44.2 Add 50 mL of water, boil, allow the solids to settle, and decant the supernatant liquid into a filter. Add an additional 50 mL of water to the solids, boil, and pour the contents of the beaker into the filter. Wash the residue with 100 mL of hot water, adding the washing to the filtrate. Cool the filtrate to room temperature and dilute to 500 mL in a volumetric flask to make the stock sample solution. Take 10 mL of the solution and make up to 500 mL in a second volumetric flask, to make the dilute sample solution.

44.3 Determine the absorbance readings on the dilute standard solutions and the solvent blank at a wavelength of 589.0 to 589.6 nm, following the manufacturer's instruction manual. Subtract the absorbance value for the blank from the absorbance values for the dilute standard solutions and prepare a curve relating sodium concentration in milligrams per litre to absorbance values.

NOTE 11—If the absorbance of the dilute sample solution is known to lie within the linear range, that is, the sodium concentration is below approximately 1 mg/L only one standard and the solvent blank are needed to prepare the curve.

44.4 Determine absorbance readings on the dilute sample solution using the same technique, followed with the dilute

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

standard solutions. The concentration of sodium in the dilute sample solution in milligrams per litre is then found by consulting the standard curve.

45. Calculation

45.1 Calculate the amount of NaCl as a percentage of the sample received or the dried sample as required as follows:

$$\text{Sodium calculated as \% NaCl} = A \times 6.3553/S \quad (9)$$

where:

A = concentration of dilute sample solution, mg/L, and
S = weight of sample, g.

46. Precision and Bias

46.1 Neither the precision nor the bias for the analysis of sodium by the atomic absorption method has been determined.

OPTIONAL PROCEDURE FOR ANALYSIS FOR SODIUM BY FLAME PHOTOMETRY

47. Significance and Use

47.1 This test method covers the determination of sodium in gypsum and gypsum products by flame photometry. This test method is based on Methods D 1428.

48. Interferences

48.1 Radiation interferences caused by elements other than that being determined are the greatest contributor to error in flame photometry. Some effects are positive and others negative. Of the elements encountered in this analysis, the greatest effect is that of one alkali metal on another. The foreign-element effects cannot be entirely compensated for without employing calibration standards closely duplicating the composition of the sample. However, the effects are minimized by operating at the lowest practical sodium concentration range or by removal of the interfering elements. For example, aluminum has a depressing effect on alkali-metal emission, which is of serious consequence. Remove aluminum from the extraction liquid prior to flame photometry if its concentration has been found, by preliminary tests, to exceed that of the sodium.

48.2 Self-absorption causes the curve of intensity versus concentration to decrease its slope at higher concentrations, tending to reduce accuracy. Bracketing the unknown by known standard solutions tends to minimize this interference.

49. Apparatus and Materials

49.1 *Flame Photometer*—The instrument shall consist of an atomizer and burner; suitable pressure-regulating devices and gages for fuel and air or oxygen; an optical system, consisting of suitable light-dispensing or filtering devices capable of preventing excessive interference from light of wavelengths other than that being measured; and a photosensitive indicating device.

49.2 *Supply of Fuel and Air or Oxygen*— The supplies of fuel and air or oxygen shall be maintained at pressures somewhat higher than the controlled operating pressure of the instrument.

50. Reagents

50.1 Prepare the following stock solutions from reagents that have been dried to constant weight at 105 °C. Store the stock solutions in polyethylene or equally alkali-metal-free containers.

50.2 *Sodium Chloride Solution (2.5418 g/L)*—Dissolve 2.5418 g of sodium chloride (NaCl) in water and dilute to 1 L with water. This stock standard solution contains 1.000 g/L of sodium ion.

50.3 *Dilute Standard Solutions*—Prepare dilute standard solutions from stock standard solution, bracketing the expected sodium concentration range of the diluted sample extraction liquid. For example, if the expected range of the sample extraction liquid is between 0 and 0.010 g/L, prepare eleven equally spaced standards in tenths of the maximum.

51. Calibration of Instrument

51.1 Select the proper photocell; the blue-sensitive phototube having a range from 320 to 620 nm is required for sodium determination. Open the slit width to approximately one fourth of the maximum opening, set the instrument to the maximum sensitivity range, and balance the meter to obtain electrical equilibrium.

51.2 Feed fuel and air or oxygen to the burner and ignite the emitted mixture. Adjust fuel and air or oxygen pressures and follow the procedures for warm-up time prescribed by the instrument manufacturer. Set the scale-reading dial at approximately 95 % of full scale, introduce a solution containing the maximum amount of sodium in the range to be covered, and allow the emitted light to strike the photocell.

51.3 Select the proper filter, if a filter-type instrument is used. For instruments employing spectral dispersing devices, turn the wavelength dial back and forth slowly and carefully in the vicinity of 589 nm until the galvanometer reaches a maximum deflection. This wavelength setting produces maximum sensitivity. Do not disturb the wavelength dial during the test.

51.4 Continue to atomize the maximum standard of the range to be covered, and set the scale-reading of the dial at exactly full scale (100 or 1000) (Note 12). Adjust the gain so as to balance the galvanometer needle.

NOTE 12—For instruments equipped with a variable slit, carry out the procedure described above with the slit width between fully closed and one fourth open for the preliminary test. In determining the proper slit width for optimum instrument performance, consideration must be given to the fact that the intensity of the emission line is approximately proportional to the slit width, whereas continuous background intensity increases as the square of the slit width. A decrease in slit width results in decreased illumination of the phototube for a given concentration and is compensated for by increasing the gain of the instrument. The most favorable operating conditions are obtained with the smallest slit width that does not result in instability of the galvanometer needle when it is set to give full-scale reading with the maximum standard in the range to be covered. When altering the slit width, determine the background by atomizing a zero standard, and check for sensitivity setting and instrument stability with the maximum standard in the range to be covered. Lower ranges require wider slit widths. Determine and record the optimum slit width for each range and element to be covered. Use these values in all subsequent tests.

51.5 Determine the emission intensity of all standards.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:14:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

51.6 Plot emission intensity (scale reading) versus concentration on linear graph paper. For the lower ranges, the curve thus prepared approximates a straight line but sometimes will not intersect zero because of background intensity. At higher ranges, the curves show a decrease in slope with increasing concentration. Record on graphs all data in regard to slit width, fuel pressure, and air or oxygen pressure.

52. Procedure

52.1 Weigh 25 g of the well-mixed sample and transfer to a 150-mL beaker.

52.2 Add 50 mL of water, boil, allow the solid material to settle, and decant the supernatant liquid into a filter. Add an additional 50 mL of water to the solids, boil and pour the contents of the beaker into the filter. Wash the residue with 75 mL of hot water, adding the washing to the filtrate. Cool and dilute with water to 200 mL in a volumetric flask to make the stock sample solution.

52.3 Take 5 mL of the stock sample solution and make up to 100 mL in a volumetric flask to make the dilute sample solution.

NOTE 13—If the concentration of sodium in the sample is found to be greater than the maximum standard, further dilute sample solution with water to bring the concentration within the range. If the concentration of sodium in the sample is less than one tenth of the value of the maximum standard, prepare a new dilute sample solution from the stock sample solution to bring the concentration within the range.

52.4 Turn the instrument on and feed fuel and air or oxygen to the burner. Ignite the gas mixture. For instruments with an adjustment slit, set the width to the value determined as outlined in Note 12.

52.5 Place the scale-reading dial at maximum. Atomize the sample and allow its emitted light to strike the photocell. Set the wavelength to 589 nm as described and adjust the gain to balance the galvanometer. Determine the emission intensity of the sample.

52.6 Refer to the standard curve prepared above and read off the concentration of sodium ion in the dilute sample solution in milligrams per litre.

53. Calculation

53.1 Calculate the amount of NaCl as follows:

$$\text{Sodium, calculated as NaCl, } \% = A \times 0.04067 \quad (10)$$

where:

A = concentration of sodium, mg/L read off the standard curve.

54. Precision and Bias

54.1 Neither the precision nor bias of the analysis for sodium by flame photometry has been determined.

55. Keywords

55.1 ammonium acetate method; atomic absorption; chemical analysis; coulometric method; flame photometry; gypsum; gypsum concrete; gypsum board; gypsum products; plaster; sand in set plaster; wood-fiber plaster

Designation: C 472 – 99 (Reapproved 2009)

Standard Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete[1]

This standard is issued under the fixed designation C 472; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 These test methods cover the physical testing of gypsum, gypsum plasters, and gypsum concrete.

1.2 The test methods appear in the following sections:

	Sections
Precautions for Physical Tests	4
Reagents and Materials	5
Free Water	6
Fineness	7
Normal Consistency of Gypsum Plaster	8
Normal Consistency of Gypsum Concrete	9
Setting Time	10
Setting Time (Temperature Rise Method)	11
Compressive Strength	12
Density	13

1.3 The values regarded as the standard are either in inch-pound units or SI (metric). The values stated first shall be regarded as the standard. Values following in parentheses are approximate and are provided for information purposes only.

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) are not requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. For a specific precautionary statement, see X1.2.1.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 778 Specification for Standard Sand

E 11 Specification for Woven Wire Test Sieve Cloth and Test Sieves

3. Terminology

3.1 *Definitions:*

3.1.1 For useful definitions refer to Terminology C 11.

4. Precautions for Physical Tests

4.1 Gypsum products are greatly affected by small amounts of impurities introduced by careless laboratory manipulation. In order to obtain accurate results, it is absolutely essential to observe the following precautions:

4.1.1 Keep all apparatus thoroughly clean. Remove all traces of set plaster.

NOTE 1—For mixing pastes and mortars, a 500-ml rubber dental bowl is a convenience.

NOTE 2—Use care when drying gypsum, gypsum plasters, or gypsum concrete. Exceeding the specified drying temperatures may calcine the specimens, which will cause inaccurate test results.

5. Reagents and Materials

5.1 *Distilled or Deionized Water*—free of chlorides and sulfates at a temperature of 21 ± 1°C (70 ± 2°F).

5.2 *Standard Sand*— Specification C 778, 20–30 sand.

6. Free Water

6.1 *Significance and Use*—This test method determines the free water contained in gypsum, gypsum plasters, and gypsum concrete samples, and prepares the sample for subsequent testing.

6.2 *Apparatus*:

6.2.1 *Balance*, capable of weighing not less than 500 g at a precision of 0.1 g.

6.2.2 *Drying Oven*, set at 45 ± 3°C.

6.2.3 *Desiccator*, containing calcium chloride or equivalent desiccant.

6.3 *Procedure*:

[1] These test methods are under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and are the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Sept. 1, 2009. Published September 2009. Originally approved in 1961. Last previous edition approved in 2004 as C 472–99(2004).

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.3.1 Weigh a sample of not less than 500 g of the material as received to the nearest 0.1 g and spread it to a thin layer in a suitable-vessel. Place in an oven (6.2.2) and dry for 2 h; then cool in a desiccator (6.2.3) and weigh again.

6.3.2 Retain the dried sample in an airtight container until used for the fineness test (Section 7).

6.4 *Report*—Report the loss in weight as a percentage of the original weight of the sample as received to a precision of 0.1%.

6.5 *Precision and Bias*—The precision and bias of the free water test method have not been determined.

7. Fineness

7.1 *Significance and Use*—This test method covers a procedure for determining the fineness of gypsum and gypsum plasters and is used to determine compliance with gypsum and gypsum plaster specifications. The degree of correlation between the results of this test method and service performance has not been determined.

7.2 *Apparatus*:

7.2.1 *Sieves*, as required by a particular gypsum or gypsum plaster specification, in accordance with Specification E 11.

7.2.2 *Balance*, capable of weighing not less than 1000 g at a precision of 0.1 g.

7.2.3 *Mechanical Sieving Machine*

7.3 *Procedure*:

7.3.1 Determine fineness by sieving a known weight of the dried sample through sieves of the specified sizes (Note 3 and Note 4). The size of the sample to be used in determining fineness depends upon the particle size of the material. If the material will pass a 6.3-mm (¼-in.) sieve, a 100-g sample will be sufficient; if the largest particles are more than 25 mm (1 in.) in diameter, use not less than a 1000-g sample. With these limitations the size of sample to be used is left to the discretion of the operator. Shake the sample through each sieve with as little abrasion as possible (Note 5). Weigh the amount of material retained on each sieve and calculate the fineness, expressed as a percentage of the weight of the original sample.

7.3.2 If a mechanical sieving machine is used, make a series of tests at one minute intervals, with each type of material and sieve size combination to be used. When not more than 0.5 g passes each sieve in a one minute interval, use that time as the standard sieving time for that test procedure on that machine.

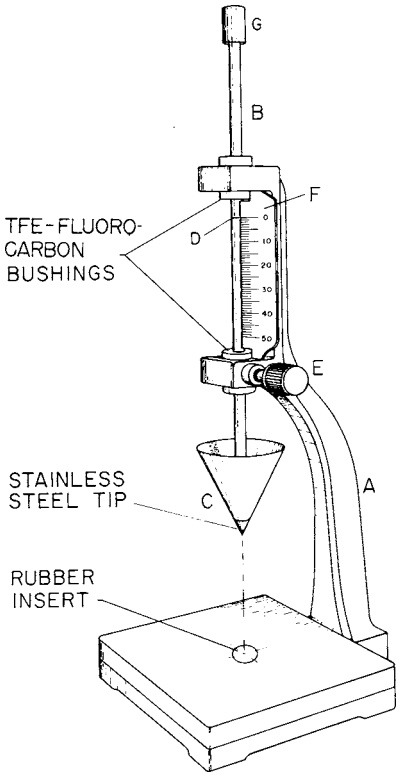
NOTE 3—For suggested method of sieving gypsum through a 45-µm (No. 325) sieve, see Appendix X1.

NOTE 4—The sizes of the sieves to be used are given in the specifications of ASTM covering the particular product in question.

NOTE 5—When sieving by hand through a 150-µm (No. 100) sieve, use a lateral motion, and tap the side of the sieve with the palm of the hand. Continue without brushing until not more than 0.5 g passes through during 1 min of sieving. If the sieve openings become clogged, transfer the retained material temporarily to another vessel, invert the sieve over a sheet of paper on the table and tap it sharply against the table. Then transfer all the retained material back into the sieve and continue sieving.

7.4 *Report*—Report the percent by weight retained on each sieve or passing particular sieves in accordance with the material specification to the nearest full percentage point.

7.5 *Precision and Bias*—The precision and bias of the fineness test method have not been determined.



A—Hinged support bracket
B—Plunger support rod
C—Conical plunger
D—Graduation mark
E—Lock screw
F—Modified scale
G—Weight

FIG. 1 Modified Vicat Apparatus (Conical Plunger Method)

8. Normal Consistency of Gypsum Plaster

8.1 *Significance and Use*—This test method is used to determine the volume of water required for mixing gypsum plaster when performing the setting time and compressive strength tests.

8.2 *Apparatus*:

8.2.1 *Modified Vicat Apparatus*—The modified Vicat apparatus (Fig. 1)[3] shall consist of a bracket, *A*, bearing a movable brass rod, *B*, 6.3 mm in diameter and of suitable length to fit the Vicat Bracket. A conical plunger made of aluminum with an apex angle of 53° 08 min and a height of 45 mm shall be attached to the lower end of the rod. The total weight of the rod and plunger shall be 35 g. A means shall be provided for adding a weight, *G*, to the rod, increasing the total weight to 50 g. The rod shall be capable of being held in any position by a screw, *E*. The rod shall have a mark, *D*, midway between the ends which moves under a scale, *F*, graduated in millimetres, attached to the bracket, *A*.

8.2.2 *Mold*—The conical ring mold shall be made of a noncorroding, nonabsorbent material, and shall have an inside diameter of 60 mm at the base and 70 mm at the top and a height of 40 mm.

[3] This method is described by Kuntze, R. A., "An Improved Method for the Normal Consistency of Gypsum Plasters," *ASTM Bulletin No. 246*, ASTM, May 1960, p. 35.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.2.3 *Base Plate*—The base plate for supporting the ring mold shall be of plate glass and about 100 mm square.

8.2.4 *Balance*, capable of weighing not less than 500 g at a precision of 0.1 g.

8.2.5 *Graduated Cylinder*, shall be made to deliver the indicated volume at 20°C (68°F) and shall be subdivided to not less than 1 mL.

8.3 *Procedure*:

8.3.1 Clean the plunger, mold, and base plate of the modified Vicat apparatus. Apply a thin coat of petroleum jelly or other suitable lubricant to the upper surface of the base plate in order to prevent leaks during the test.

8.3.2 Sift a weighed quantity of the sample (200 to 300 g as required to fill the mold) into a known volume of water (See 5.1). If the plaster is unretarded, add to the mixing water 0.2 g of sodium citrate per 100 g of sample. After allowing the sample to soak for 2 min, stir the mixture for 1 min to an even fluidity. Pour this sample into the ring mold, work slightly to remove air bubbles, and then strike off flush with the top of the mold. Wet the plunger of the modified Vicat apparatus and lower it to the surface of the sample at approximately the center of the mold. Read the scale and release the plunger immediately. After the rod has settled, read the scale again. Make three determinations on each mix, care being taken to have the mold completely filled and the plunger clean and wet.

8.3.3 Test gypsum molding plaster and gypsum gauging plaster with different amounts of water until a penetration of 30 ± 2 mm is obtained. Use the rod and plunger for this determination weighing 35 g.

8.3.4 Test all gypsum mixtures containing aggregates with different amounts of water until a penetration of 20 ± 2 mm is obtained. Add weight to the rod and plunger to bring the total weight to 50 g for these determinations.

8.3.5 Mix gypsum neat plaster with standard sand (see 5.2) in the ratio of 200 g of sand to 100 g of plaster before testing for normal consistency.

8.4 *Report*:

Report the normal consistency as the average number of millilitres of water required to be added to 100 g of the dry mixture to the nearest whole millilitre.

8.5 *Precision and Bias*—The precision and bias of the test method for normal consistency of gypsum plaster have not been determined.

9. Normal Consistency of Gypsum Concrete

9.1 *Significance and Use*—This test method is used to determine the volume of water required for mixing gypsum concrete when performing the setting time and compressive strength tests.

9.2 *Apparatus*:

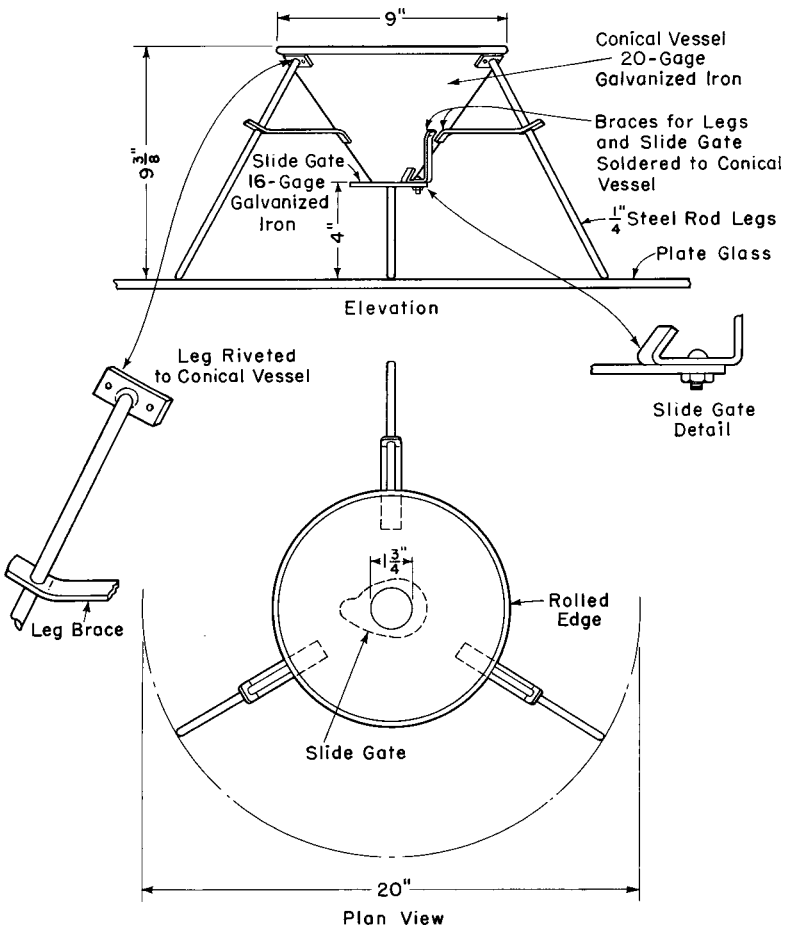


FIG. 2 Consistometer

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.2.1 *Consistometer (*Fig. 2*)*—The consistometer consists of a conical vessel made of noncorroding, nonabsorbent material, and having an inside diameter of 9 in. (229 mm) at the top and 1¾ in. (44.5 mm) at the bottom, and a height of 5½ in. (139.7 mm). It shall be provided with a sliding gate at the bottom and supported so that the bottom is 4 in. (102 mm) above the base plate. The base plate shall be of plate glass, free of scratches and about 18 in. (457 mm) square.

9.2.2 *Balance*, capable of weighing not less than 2000 g at a precision of 1 g.

9.3 *Procedure*:

9.3.1 Clean and dry the consistometer and the base plate and close the sliding gate.

9.3.2 Sift 2000 g of the sample into a known volume of water (see 5.1) to which 1.0 g of sodium citrate has previously been added. After allowing the sample to soak for 1 min, stir the mixture for 3 min to an even fluidity. Pour the mixture into the consistometer until level with the top. Then rapidly and completely open the sliding gate, allowing the mixture to run out onto the base plate. When the sliding gate is opened, take care to avoid jarring the consistometer.

9.3.3 Measure the resulting patty along its major and minor axes and determine the average diameter.

9.3.4 Test gypsum concrete with different amounts of water until a patty diameter of 380 ± 13 mm (15 ± ½ in.) is obtained.

9.4 *Report*—Report the normal consistency as the number of millilitres of water to the nearest whole millilitre required to be added to 100 g of the gypsum concrete.

9.5 *Precision and Bias*—The precision and bias of the test method for normal consistency of gypsum concrete have not been determined.

10. Setting Time

10.1 *Significance and Use*—This test method is used to determine the setting time of gypsum plaster and gypsum concrete, and is used to determine compliance with gypsum plaster and gypsum concrete specifications. Since variable job conditions influence the setting time, the degree of correlation between this test method and service performance has not been determined.

10.1.1 This test method does not determine the time of complete hydration of gypsum plaster or gypsum concrete. To determine the time of complete hydration see Setting Time, (Temperature Rise Method,) Section 11.

10.2 *Apparatus*:

10.2.1 *Vicat Apparatus*—The Vicat apparatus (Fig. 3) shall consist of a frame, *A*, bearing a movable rod, *B*, weighing 300 g, one end, *C*, the plunger end, being 10 mm in diameter for a distance of not less than 50 mm, the other end having a removable needle, *D*, 1 mm in diameter and 50 mm in length. The rod, *B*, shall be reversible, shall be able to be held in any position by a screw, *E*, and shall have an adjustable indicator, *F*, that moves over a scale (graduated in millimetres) attached to the frame, *A*. The paste shall be held in a rigid conical ring, *G*, resting on a glass plate, *H*, about 100 mm square. The ring shall be made of a noncorroding, nonabsorbent material and shall have an inside diameter of 70 mm at the base and 60 mm at the top, and a height of 40 mm.

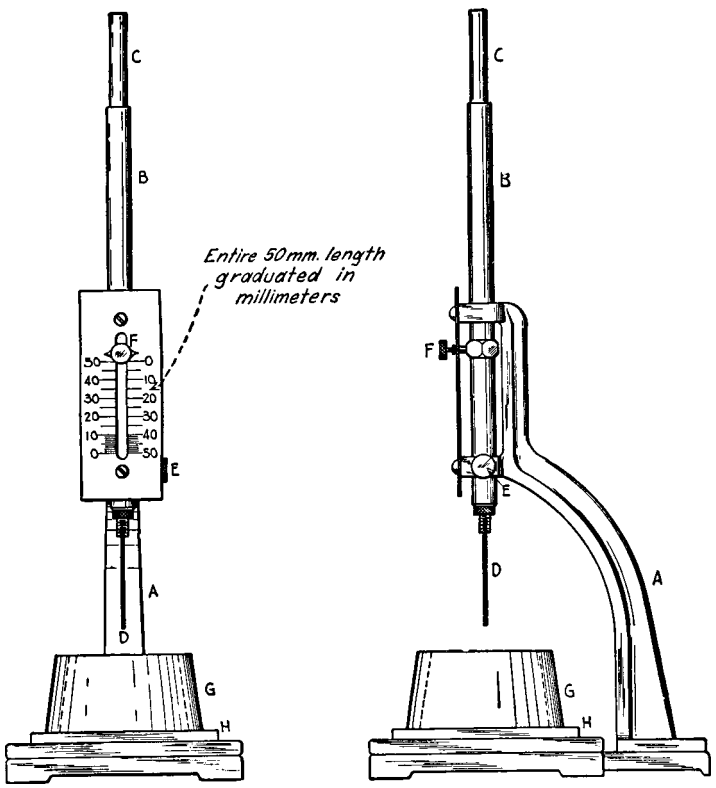

FIG. 3 Vicat Apparatus

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.2.2 In addition, the Vicat apparatus shall conform to the following requirements:

Weight of plunger	300 ± 0.5 g
Diameter of larger end of plunger	10 ± 0.05 mm
Diameter of needle	1 ± 0.05 mm
Inside diameter of ring at bottom	70 ± 3 mm
Inside diameter of ring at top	60 ± 3 mm
Height of ring	40 ± 1 mm
Graduated scale	The graduated scale, when compared with a standard scale accurate to within 0.1 mm at all points, shall not show a deviation at any point greater than 0.25 mm.

NOTE 6—Automatic setting time apparatus are commercially available and may be used provided they can be shown to give the same results as the specified apparatus and procedure.

10.2.3 *Balance*, capable of weighing not less than 500 g at a precision of 0.1 g.

10.2.4 *Stopwatch or Clock*, for determining setting time.

10.2.5 *Temperature and Humidity Controlled Cabinet*, capable of maintaining a temperature of 21 ± 1°C (70 ± 2°F) and a relative humidity of not less than 85 %.

10.3 *Procedure*:

10.3.1 *Gypsum Concrete and All Gypsum Plasters, Except Gypsum Neat Plaster*—Start the timing of the test approximately at the moment of contact of the dry material with the water (see 5.1). Mix enough paste to fill the conical ring. For the quantity of water and directions for mixing, see Section 8, but do not add retarder. Place the conical ring on the base plate and fill the ring with the paste level with the top of the ring. Position the end of the needle so that it just touches the top surface of the paste and tighten the screw. Release the screw so that the needle falls freely into the paste. After each penetration, wipe the needle clean, and move the base plate and ring slightly so that the needle will not strike the same place twice. Test the sample at intervals according to the table in 10.3.3. Setting time is complete when the needle no longer penetrates to the bottom of the paste. When setting times are expected to be longer than ½ h, store the test specimens in the cabinet described in 10.2.5.

10.3.2 *Gypsum Neat Plaster*—Test gypsum neat plaster for setting time as mixed with three parts by weight of standard sand (see 5.2). Mix dry a 100-g sample of the gypsum neat plaster and 300 g of the sand, and then add sufficient water to produce a normal consistency. For the quantity of water (see 5.1) and mixing instructions, see Section 8, but do not use retarder. Stir for 1 min to an even, lump-free consistency. Place the mortar in the conical ring and test for setting time as described in 10.3.1

10.3.3 *Frequency of Testing*—Test the materials according to the following schedule:

Kind of Material	First Test	Frequency of Subsequent Tests
Molding plaster	15 min	5 min
Keene's cement:		
Standard	15 min	1 h
Quick set	15 min	5 min
Gypsum concrete	15 min	5 min
Ready mixed plaster	1½ h	1 h
Neat plaster	2 h	1 h
Wood-fibered plaster	1½ h	1 h
Bond plaster	1½ h	1 h
Gauging plaster:		
Slow set	40 min	2 h
Quick set	15 min	5 min

10.4 *Report*—Report the setting time as the elapsed time in minutes from the time when the sample was first added to the water to the time when set is complete.

10.5 *Precision and Bias*—The precision and bias for the setting time test method have not been determined.

11. Setting Time (Temperature Rise Method)

11.1 *Significance and Use*:

11.1.1 This test method determines the hydration time by measuring the maximum temperature rise of gypsum plaster or gypsum concrete. The temperature rise is caused by the reaction of calcium sulfate hemihydrate with water to form calcium sulfate dihydrate. It is assumed that the maximum temperature rise coincides with the completion of the reaction. This test method is not used to determine compliance with specifications for gypsum plaster or gypsum concrete unless it is specified in the purchase contract.

11.1.2 The setting time determined by this test method is usually longer than the setting time determined in Section 10.

11.1.3 The degree of correlation between this test method and service performance has not been determined.

11.2 *Apparatus*:

11.2.1 *Potentiometer*—A single- or multiple-channel recording potentiometer or thermistor bridge shall be used to record the temperature change of the sample under test. The chart speed shall be not less than 1 in. (25 mm)/h. Imprints recording the temperature shall not be longer than 1 min apart for each sample.

11.2.2 *Temperature Sensors*—Temperature changes shall be indicated by either thermocouples or thermistors which shall be movable or in a fixed position. Temperature sensing elements shall be of such capacity and sensitivity that, when connected to the recording potentiometer, a temperature change of 0.5°C (1°F) in the sample shall be recorded on the chart.

11.2.3 *Sample Cups*—Cups with a capacity of 175 to 275 mL (6 to 9 oz) shall be used. The cup containing the mixture under test shall be placed inside a matching cup held in an insulated block or beaker, as specified in 11.2.4. The temperature sensor, in this case, shall be positioned 25 to 33 % of the distance up from the bottom and between the inner and outer cup. Alternately, the cup containing the test mixture shall be positioned over a spring-loaded sensor to ensure close contact with the bottom of the cup.

11.2.4 *Insulated Block or Beaker*, with walls and bottom having a thermal resistance of not less than R6 (1.1 ($m^2 \cdot K$)/W) (6 ($h \cdot ft^2 \cdot °F$)/Btu), and a centered cavity into which the sample cup fits snugly.

NOTE 7—An insulating block may be constructed from a block of expanded polystyrene. Carve a cavity in the block so that the sample cup fits snugly, leaving walls and bottom not less than 40 mm (1.5 in.) thick. An insulating beaker may be made by stuffing glass fiber or mineral wool insulation not less than 50.8 mm (2 in.) thick around the sample container and within the walls of a beaker. The insulated block or beaker should have an insulated cover of the same insulating material through which the temperature probe can extend into the test material.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11.3 *Test Conditions*— Perform tests in a room or cabinet maintained at a temperature of 21 ± 1.1°C (70 ± 2°F). Maintain materials and mixing water used for the test at a temperature of 21 ± 1.1°C (70 ± 2°F).

NOTE 8—If a constant-temperature cabinet is not available, a constant-temperature water bath may be fitted with a cover which will admit the body of the cup holder but not its rim, so that the cup holder is in contact with the water in the bath.

11.4 *Procedure*:

11.4.1 *Gypsum Concrete and All Gypsum Plasters, Except Gypsum Neat Plaster*—Start the timing of the test at the moment of contact of the dry material with the water. Mix approximately 200 g of the sample to make a paste of normal consistency. Place the paste in a clean dry sample cup to about 20 mm (¾ in.) from the top. Place the filled cup in an empty cup in the insulated block or beaker and adjust the sensing element as required in 11.2.3. Cover the cup with a watch glass or plastic film or cover the surface of the paste with mineral oil to a depth of approximately 5 mm (¼ in.).

11.4.2 *Gypsum Neat Plaster*—Prepare the plaster in accordance with 10.3.2 and test in accordance with 11.4.1.

11.5 *Report*—Report the setting time as the elapsed time in minutes from the time when the sample was first added to the water to the time when maximum temperature rise is attained.

11.6 *Precision and Bias*—The precision and bias for the setting time, temperature rise method, have not been determined.

12. Compressive Strength

12.1 *Significance and Use*—This test method is used to determine the compressive strength of gypsum plaster and gypsum concrete and is used to determine compliance with applicable specifications. The correlation between this test method and service performance has not been determined.

12.2 *Apparatus*:

12.2.1 *Specimen Molds*—Molds for making test specimens shall be 2-in. (50.8 mm) split cube molds made of noncorrodible material and shall be sufficiently rigid to prevent spreading during molding. The molds shall have not more than three cube compartments and shall be separable into not more than two parts. When assembled, the parts of the molds shall be held firmly together, and dimensions shall conform to the following requirements: Interior faces shall be plane surfaces with a maximum variation of 0.001 in. (0.03 mm) for new molds and 0.002 in. (0.05 mm) for old molds; distance between opposite faces, and height of the molds, measured separately for each cube compartment, shall be 2 ± 0.005 in. (50.8 ± 0.13 mm) for new molds or 2 ± 0.020 in. (50.8 ± 0.51 mm) for old molds, angle between adjacent interior faces and between interior faces and top and bottom planes of the mold shall be 90 ± 0.5°, measured at points slightly removed from the intersection of the faces.

12.2.2 *Testing Machine*, either the hydraulic or the screw type, with sufficient opening between the upper bearing surface and the lower bearing surface of the machine for the use of verifying apparatus. The load applied to the test specimen shall be indicated with an accuracy of ±1.0 %. The load indicating device shall have a means of indicating maximum load. The upper bearing shall be a spherically seated, hardened metal block firmly attached at the center of the upper head of the machine. The center of the sphere shall lie at the center of the surface of the block in contact with the specimen. The block shall be free to tilt in any direction. A hardened metal bearing block shall be used beneath the specimen to minimize wear of the lower platen of the machine. The lower bearing block shall have concentric circles at ¼-in. intervals centered on the block to facilitate accurate centering of the test specimen. The bearing block surfaces intended for contact with the specimen shall have a Rockwell hardness number not less than 60 HRC. These surfaces shall not depart from plane surfaces by more than 0.0005 in. (0.013 mm) when the blocks are new and 0.001 in. (0.025 mm) after use.

12.2.3 *Drying Oven*, a mechanical convection oven maintained at a temperature of 45 ± 3°C and a relative humidity not more than 50 %.

12.2.4 *Desiccator*, containing magnesium perchlorate or calcium chloride that is capable of being tightly sealed and of such a size as to hold not less than one set of 6 cubes.

12.3 *Test Specimens*:

12.3.1 Mix sufficient sample at normal consistency to produce not less than 1000 mL (34 fluid oz) of mixed mortar and cast into six specimen molds (see 12.2.1). Premix neat gypsum plaster dry with two parts by weight of standard sand (see 5.2). For the quality and quantity of water, see 5.1 and Section 8, but do not add retarder. Place the required amount of water in a clean 2-L (2-qt) mixing bowl.

12.3.2 For all gypsum plasters except gypsum concrete, add the required amount of dried plaster and allow to soak for 2 min. Mix vigorously (about 150 complete circular strokes per minute) for 1 min with a metal spoon, stiff-bladed spatula or mechanical mixer (see Note 9) to produce a mortar of uniform consistency. For gypsum concrete, soak for 1 min, and stir vigorously (about 150 complete circular strokes per minute) with a large spoon or mechanical mixer for 3 min. Setting time of the mortar, as determined by Sections 10-10.5, shall be within the time limits shown in Table 1.

NOTE 9—The Hobart N-50 mixer has been found satisfactory for this purpose.

12.3.3 If setting times as determined in accordance with Section 10 are more than the maximum limits shown in Table 1, discard the cubes and adjust the setting time by adding

TABLE 1 Setting-Time Limits for Mortar

Kind of Material	Setting Time, min	
	min	max
Molding plaster	20	140
Keene's cement:		
Standard	40	120
Quick set	20	40
Gypsum concrete	20	40
Ready-mixed plaster	90	120
Neat plaster (with 2 parts sand)	120	150
Wood-fibered plaster	90	120
Bond plaster	120	150
Gauging plaster:		
Slow set	40	120
Quick set	20	40
Veneer plaster	30	90

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

freshly ground gypsum accelerator to the plaster, or add molding plaster to Keene's cement. Do not use more gypsum accelerator or molding plaster than 1 % of the dry weight of plaster or Keene's cement.

12.3.4 Coat the molds with a thin film of mineral oil or other mold release agent and place on an oiled glass or metal plate. Place a layer of mortar about 25 mm (1 in.) in depth in each mold and puddle ten times across the mold between each pair of opposite faces with a 25 mm (1 in.) wide spatula to remove air bubbles. Fill the molds to a point slightly above the tops of the molds, by the same filling and puddling procedure used for the first layer. Also fill the conical mold for the Vicat apparatus described in 10.2.1 and 10.2.2 and determine the setting time (see 10.3). As soon as the mortar or paste has set, cut off the excess to a plane surface flush with the top of the mold, using a stiff broad knife or similar implement.

12.3.5 Place the filled molds in moist air (90 to 100 % relative humidity). Remove the cubes from the molds at any time after they are thoroughly hardened, but retain in the moist air for not less than a total of 16 h. Place the cubes in an oven as specified in 12.2.3. Dry until successive weights are identical to 0.1 g (or differ by no more than 0.1 g). Then place the cubes in a desiccator as described in 12.2.4 for a minimum of 16 h before testing. Test the cubes immediately on removal from the desiccator.

12.4 *Procedure*—As soon as the cube specimens have been dried (12.3), determine their compressive strengths. (If density is to be determined, do so at this time. (See Section 13)). Position the cubes in the testing machine so that the load is applied on surfaces formed by faces of the molds, not on top and bottom. Apply the load continuously and without shock, at a constant rate within the range 15 to 40 psi/s. Do not exceed 40 psi/s ((275 kPa)/s) after 50 % of the maximum load has been reached.

12.5 *Report*—Report the average compressive strength as the compressive strength of the material, in psi (Mpa) rounded to the nearest whole psi (0.1 Mpa) except that if the strengths of one or two of the cubes vary more than 15 % from the average of the six, discard them and report the compressive strength as the average of the remaining specimens. In case the compressive strengths of three or more cubes vary more than 15 % from the average, discard the results and repeat the test.

12.6 *Precision and Bias*—The precision and bias for the compressive strength test method have not been determined.

13. Density

13.1 *Significance and Use*—This test method is used to determine the density of cast gypsum concrete and is used to determine compliance with the specification for gypsum concrete. The correlation between this test method and service performance has not been determined.

13.2 *Apparatus*:

13.2.1 *Balance*, capable of weighing not less than 1500 g to the nearest gram.

13.3 *Procedure*—Determine the density of gypsum concrete by weighing the six cubes to the nearest gram after drying and cooling, as described in 12.3.4, and before determining the compressive strength.

13.4 *Calculation*—Calculate the density by multiplying the total weight of the six cubes by 0.0794.

13.5 *Report*—Report the density in pounds per cubic foot to the nearest 1 lb/ft^3 (10 kg/m^3).

13.6 *Precision and Bias*—The precision and bias for the density test method have not been determined.

14. Keywords

14.1 compressive strength; density; free water; fineness; gypsum; gypsum concrete; gypsum plasters; normal consistency; setting time

APPENDIX

(Nonmandatory Information)

X1. ALCOHOL WASH METHOD OF SIEVING GYPSUM AND GYPSUM PRODUCTS

X1.1 Scope

X1.1.1 This appendix covers a sieve test for fine gypsum and gypsum products using an alcohol wash method.

X1.2 Significance and Use

X1.2.1 It is impractical to sieve dry gypsum through a fine sieve, and water cannot be used as a washing agent without introducing errors due to hydration or solution. This method is used when a purchase order specifies fineness through fine sieves.

X1.3 Apparatus

X1.3.1 Sieves, complying with Specification E 11.

X1.3.2 Mechanical Sieving Machine.

X1.3.3 Vessel, with a diameter not less than 50 mm greater than the sieves, and a depth not less than 75 mm greater than the height of the sieves.

X1.3.4 Balance, capable of reading to a precision of 0.01 g.

X1.4 Reagents

X1.4.1 Isoprophyl alcohol, 99%. The alcohol may be reused after decanting or filtering, provided its strength does not fall below 95%

X1.4.1.1 **Caution—**When using isoprophyl alcohol, keep fire away, provide good ventilation, and avoid excessive inhalation of vapor.

X1.5 Calibration and Standardization

X1.5.1 See 7.3.2 for method of calibrating a mechanical sieving machine.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X1.6 Procedure

X1.6.1 Place the alcohol in a vessel (X1.3.3) to a depth of 50 mm more than the height of the sieve. Weigh approximately 50 g of the sample to a precision of 0.01 g and place on a 45-μm or coarser sieve up to and including the 150 μm (No. 100).

X1.6.2 Lower the sieve into the alcohol until the specimen is wetted throughout. Lift the sieve out of the alcohol, with a swirling motion, permitting the alcohol to drain through the specimen back into the vessel. Repeat this operation not less than eight times, until the alcohol passes freely through the sieve and the specimen is essentially free from fines. Wash the residue retained on the sieve with about 100 mL of clear alcohol, and then blot the bottom of the sieve with a soft, dry, lint-free cloth. Dry the sieve containing the residue at 45 ± 3°C.

X1.6.3 Shake the sieve on a mechanical shaker for 2 min ± 2 s. If desired, to permit simultaneous determinations of coarser fractions, transfer the residue after drying and before shaking to a series of coarser sieves up to and including the 150 μm nested in sequential order above the 45-μm sieve. Weigh the material retained on each sieve to the nearest 0.01 g.

X1.7 Calculation

X1.7.1 Calculate the percent of the original specimen retained on or through each sieve as follows:

$$\%\ retained = (B/A) \cdot 100$$

$$\%\ through = \frac{A - B}{A} \cdot 100$$

where:

A = Weight of original specimen, and
B = weight of specimen retained on sieve.

X1.8 Report

X1.8.1 Report the percent retained or through each sieve to the nearest 0.1 percent.

X1.9 Precision and Bias

X1.9.1 The precision and bias of the alcohol wash method of sieving gypsum and gypsum products has not been determined.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Designation: C 473 – 09

Standard Test Methods for Physical Testing of Gypsum Panel Products[1]

This standard is issued under the fixed designation C 473; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 These test methods cover the physical testing of gypsum panel products.

1.2 The test methods appear in the following order:

	Section
Flexural Strength (Method A)	7
Core, End and Edge Hardness (Method A)	8
Nail Pull Resistance (Method A)	9
Flexural Strength (Method B)	11
Core, End and Edge Hardness (Method B)	12
Nail Pull Resistance (Method B)	13
Humidified Deflection	14
End Squareness	15

1.3 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.4 The text of these test methods references notes and footnotes that provide explanatory material. These notes and footnotes, excluding those in tables and figures, shall not be considered as requirements of these test methods.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

D 3285 Test Method for Water Absorptiveness of Nonbibulous Paper and Paperboard (Cobb Test)

E 4 Practices for Force Verification of Testing Machines

E 177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods

E 691 Practice for Conducting an Interlaboratory Study to Determine the Precision of a Test Method

3. Terminology

3.1 Definitions used in these test methods are in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *edge*, *n*—the paper-bound edge, or long edge, as manufactured.

3.2.2 *ends*, *n*—the end perpendicular to the paper-bound edge or long edge.

4. Sampling

4.1 For use in these test methods, a sample shall consist of not less than 0.25 % of the number of gypsum panel products in a shipment, but not less than three gypsum panel products. Test specimens shall be taken from the sample lot as indicated in each method.

5. Conditioning

5.1 Condition specimens to constant weight at a temperature of 85 ± 15 °F (29.5 ± 8.5 °C) and relative humidity of 50 ± 2 % (Note 1). Test specimens individually after constant weight is reached and within 10 min upon removal from the conditioning chamber.

NOTE 1—Laboratory test results indicated that conditioning temperatures may range from 70 to 100 °F (21 to 38 °C) without significantly affecting the results. However, relative humidity is critical. This is the reason for testing specimens within 10 min upon removal from the conditioning chamber.

[1] These test methods are under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and are the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Sept. 1, 2009. Published September 2009. Originally approved in 1961. Last previous edition approved in 2007 as C 473 – 07.

Method A—Constant Rate of Loading

INTRODUCTION

The following procedures are applicable to so-called "shot machines" that utilize lead or steel shot that applies a load to the specimen at a constant stress rate or any other device that applies the load at a constant stress rate.

6. Apparatus—Method A

6.1 *Testing Machine*—Apply the test load at a uniform rate of 1 lbf/s (4.45 N/s) ±10 %. Apply the load with a device independent of manual control of the rate of loading during an individual sample test (see Fig. 1). The deformation of the specimen controls the cross head speed.

7. Flexural Strength (Method A)

7.1 *Summary of Test Method*—Flexural properties of gypsum panel products are evaluated by supporting the specimen near the ends and applying a transverse load midway between the supports.

7.2 *Significance and Use*—This test method covers a procedure for evaluating the ability of gypsum panel products to withstand flexural stresses during handling or use of the material. This test method is used to determine compliance with gypsum panel product specifications. The degree of correlation between this test and service performance has not been fully determined.

7.3 *Apparatus*—See Section 6.1.

7.3.1 *Specimen Supports*—All specimen bearing supports and load surfaces shall be true, shall engage the full width of the test specimen, shall be of such strength they will not deform under the test load, and shall be rounded to a radius of 0.125 in. (3.2 mm). The specimen supports shall be spaced 14 ± 0.016 in. (356 ± 0.41 mm) on centers measured at the points of surface contact with the specimen. The supports shall be attached to a plate that shall be rigidly attached to the test apparatus. The supports shall be parallel to each other and perpendicular to the long dimension of the test specimen. The bearing surface of the end supports shall be on the same plane to ensure contact along the entire bearing surfaces. Supports shall be not less than 12 in. (305 mm) in length. When a load is being applied, the loading bar shall be in contact with the full width of the specimen. The load-bearing surface shall be parallel to the bearing surface of the specimen supports. The specimen and supports shall be located so that the vertical axis through the center of the load-bearing surface passes through the specimen at one half of the specimen width and one half of the distance between the supports.

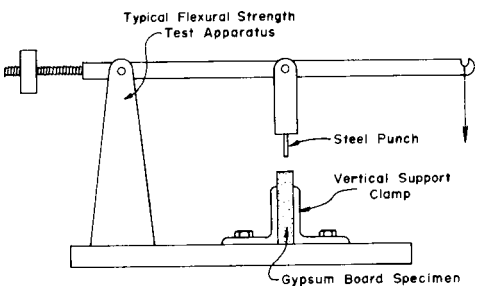

FIG. 1 Apparatus Schematic for Core, End, and Edge Hardness Test

7.4 *Sampling*—Sampling shall be in accordance with Section 4.

7.5 *Test Specimens*:

7.5.1 Cut four specimens, each 12 in. (305 mm) by approximately 16 in. (406 mm) from each gypsum panel product in the sample, two having the 16-in. dimension parallel to the edge and two having the 16-in. dimension perpendicular to the edge. Cut the specimens not less than 4 in. (102 mm) away from the ends and edges of the gypsum panel product except where the product is 24-in. or less in width, where it is impossible to do so.

7.5.2 Condition specimens in accordance with Section 5.

7.6 *Procedure*:

7.6.1 Use the apparatus in 7.3, supporting each specimen centrally on the fixed parallel bearings, 14-in. (356 mm) on centers, and apply the load on a similar bearing midway between the supports. Position perforated gypsum lath so the load is not applied over perforations.

7.6.2 For specimens with the long dimension parallel to the edge, test one specimen from each gypsum panel product face up and the other face down. For specimens with the long dimension perpendicular to the edge, test one specimen from each gypsum panel product face up and the other face down.

7.6.3 For gypsum panel products with surfacing material, the load is determined at the time of transverse failure of the surfacing material and core through the thickness of the specimen. The specimens shall not show a break in the bond between the surfacing and the core before transverse failure of the gypsum panel product. If a single specimen fails, test two additional specimens from the same sample, and, if either one of the two specimen fail, the sample has failed. For gypsum panel products without surfacing material, the load is determined at the time of transverse failure through the thickness of the specimen.

7.7 *Report*—Calculate and report the average breaking load in pound-force or newtons for each test condition, rounded to the nearest 1 lbf (N). The test conditions are: (*1*) parallel, face up; (*2*) parallel, face down; (*3*) perpendicular, face up; and, (*4*) perpendicular, face down.

7.8 *Precision and Bias*—See Section 22 and Tables 1 and 2.

8. Core, End, and Edge Hardness (Method A)

8.1 *Summary of Test Method*—The core, end, and edge hardness of gypsum panel products is evaluated by determining the force required to push a steel punch into the area of test.

8.2 *Significance and Use*—This test method covers a procedure for evaluating the ability of the gypsum panel product core, ends, and edges to resist crushing during handling or use of the material. This test method is used to determine compliance with gypsum panel product specifications. The degree of correlation between these test methods and service performance has not been determined.

8.3 *Apparatus*—See 6.1. Clamp or secure the specimen to the base of the test apparatus shown in Fig. 1 with the face of the specimen perpendicular to the base of the test apparatus and parallel to the movement of the steel punch. Secure the steel punch to the moving head of the test apparatus, positioned so

C	35.6045	4.3757	6.3969	7.2970	17.9112	20.4316

[A]The average of the laboratories' calculated averages.

TABLE 2 Perpendicular Flexural Strength, Method B (lbf) 7 Labs / 117 Data Points

Panel	Average[A]	Standard Deviation of the Sample Averages	Repeatability Standard Deviation	Reproducibility Standard Deviation	Repeatability Limit	Reproducibility Limit
	$\bar{\chi}$	$s_{\bar{\chi}}$	s_r	s_R	r	R
A	138.1732	3.8219	6.2402	6.8598	17.4725	19.2075
B	206.7995	7.4186	8.8020	10.9361	24.6457	30.6212
C	80.0015	1.9580	1.5868	2.4356	4.4431	6.8196

[A]The average of the laboratories' calculated averages.

that its center axis is parallel with the line of travel and so that the punch is inserted into the core equidistant from the surfaces of the specimen. Use a steel punch 0.099 ± 0.003 in. (2.515 ± 0.076 mm) in diameter and more than ½ in. (12.7 mm) long with the bearing surface machined to a 90° angle in reference to the punch center line (see Fig. 1 for test setup schematic).

8.4 *Sampling*—Sampling shall be in accordance with Section 4.

8.5 *Test Specimens*:

8.5.1 *Specimens for Core Hardness*—Using a table or band saw, cut one specimen from the center of each gypsum panel product sample approximately 12 by not less than 3 in. (305 by 76 mm), with the 12-in. dimension perpendicular to the edges of the products. The smaller, not less than 3 in., dimension will vary depending on the specific punch length and opening in the testing machines. Place the sample in the tester, with the loading arm in a horizontal position and with the punch resting on the specimen. Saw cuts along the 12-in. dimension shall be smooth and square with the smaller (not less than 3-in.) dimension, as well as with the specimen.

8.5.2 *Specimens for End Hardness*—Cut specimens the same size and method as described in 8.5.1 from one mill-cut end of the gypsum panel product, with the 12-in. (305-mm) dimension perpendicular to the edges and run tests only on the mill-cut end of the specimens.

8.5.3 *Specimens for Edge Hardness*—Cut specimens the same size and method as described in 8.5.1 from the opposite edges of each gypsum panel product, with the 12 in. (305 mm) dimension of the specimens parallel with the edges. For gypsum panel products with surfacing material, cut a ¼ to ½-in. (6 to 13-mm) strip of surfacing material from the edge of the test specimens exposing the core for test. Remove as little of the core as possible when removing the surfacing material. Prepare the first test area 2 ± ½ in. (51 ± 13 mm) from one edge of the specimen, with the next two test areas approximately 4 in. (102 mm) apart.

8.5.4 Condition specimens in accordance with Section 5.

8.6 *Procedure*—Using the apparatus in 8.3, clamp or secure the specimen in a fixed vertical position on its 12 in. (305 mm) dimension edge (see Fig. 1 for test setup schematic. If necessary, modify the flexural strength test equipment to conduct the core, end, and edge hardness test). Place this test surface not less than 1 in. (25 mm) above the grip of the specimen holder. Conduct three tests spaced approximately 4 in. (102 mm) apart on each specimen, with the first test area 2 ± ½ in. (51 ± 13 mm) from one edge of the specimen. Position the steel punch over the test area and apply the load. Report as the core, end, or edge hardness the load required to push the steel punch a distance of ½ in. (13 mm) into the core of the specimen.

8.6.1 *Procedure for Core Hardness*—Test in 3 locations on either of the 12-in. (305-mm) saw cut edges of each specimen.

8.6.2 *Procedure for End Hardness*—Test in 3 locations on the 12-in. (305-mm) mill-cut end of each specimen.

8.6.3 *Procedure for Edge Hardness*—Test in 3 locations along each of the two 12-in. (305-mm) edges. For products with surfacing material, test where the surfacing material has been removed.

8.7 *Report*—Report the core, end, and edge hardness individually as the average load in pounds-force or newtons rounded to the nearest 1 lbf (N). Discard any single test value that varies from the average by more than 15 % and repeat the test on the same sample to obtain a new value.

8.8 *Precision and Bias*—See Section 22 and Tables 3-5.

9. Nail Pull Resistance (Method A)

9.1 *Summary of Test Method*—The ability of gypsum panel products to resist nail pull-through is evaluated by determining the load required to push a standard nail head through the product.

9.2 *Significance and Use*—This test method covers a procedure for evaluating the ability of gypsum panel products to resist nail pull-through by determining the load required to force a standard nail head through the product. This test

method is used to determine compliance with gypsum panel product specifications. The degree of correlation between these test methods and service performance has not been determined.

9.3 *Apparatus*—See 6.1. This apparatus shall be used with either of the specimen support plates in 9.3.1 or 9.3.2.

9.3.1 Fig. 2 shows a schematic of a nail pull resistance apparatus adaptable to a typical flexural strength apparatus commonly used in the gypsum industry. The specimen support plate shall have a 3-in. (76-mm) diameter hole in the center. The support plate shall be not less than 6 by 6 in. (152 by 152 mm). It shall be attached to the apparatus as necessary to maintain the surface of the plate perpendicular to the travel of the test nail. The support plate must also be located so that the vertical axis through the center of the nail shank passes through the center of the hole in the support plate. The test nail shank shall be 0.099 ± 0.003 in. (2.515 ± 0.076 mm) in diameter and the nail head shall be 0.250± 0.005 in. (6.350 ± 0.127 mm) in diameter. The nail shall be attached at the head to the movable cross head of the test apparatus. This attachment shall not exceed the diameter of the nail head and shall be placed directly over the head. It shall also be attached so that the vertical axis through the nail shank is parallel with the travel.

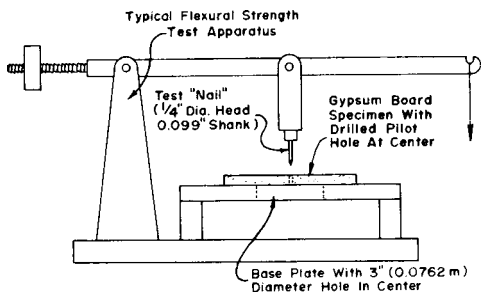

FIG. 2 Apparatus Schematic for Nail-Pull Resistance Test

9.3.2 Fig. 3 shows a schematic of an alternate nail pull resistance apparatus adaptable to a typical flexural strength apparatus commonly used in the gypsum industry. This apparatus mirrors all of the requirements of 9.3.1, except that the nail is not attached at the head to the movable cross head of the test apparatus. The alternate apparatus utilizes a machined plunger with the nail head and shank incorporated as an integral part of the plunger. The plunger fits into a bushing that keeps the nail aligned perpendicular to the test specimen. Manufacture the plunger to slide freely through the bushing without the application of any load.

NOTE 2—Other devices or means of allowing the plunger to move freely (such as collar bearings, etc.) are also acceptable.

9.4 *Sampling*—Sampling shall be in accordance with Section 4.

9.5 *Test Specimens*:

9.5.1 Cut five specimens 6 by 6 in. (152 by 152 mm) from a strip cut across the width of each 48-in. (1220-mm) gypsum panel product starting not less than 4 in. (102 mm) in from the edge. Cut a total of five specimens from more than one full width strip from gypsum panel products less than 38 in. (965 mm) wide. Do not cut the specimen closer than 3 in. (76 mm) from the product edges.

9.5.2 Drill a 7⁄64-in. (2.778-mm) diameter pilot hole through the thickness of the gypsum panel product in the center of each test specimen and perpendicular to the surface.

9.5.3 Condition specimens in accordance with Section 5.

9.6 *Procedure*—Using the apparatus in 9.3, center the specimen face up on the base plate and manually lower the test nail, inserting the nail shank in the pilot hole, until the nail head is flush with the surface of the specimen. Apply the load until the maximum load is achieved. Normally, this will occur as the nail head breaks through the gypsum panel product surface.

9.7 *Report*—Calculate the average maximum load in pounds-force or newtons, rounded to the nearest 1 lbf (N). Discard any single test that varies from the average by more than 15 %. If more than 15 % of the test values are discarded, repeat the test.

9.8 *Precision and Bias*—See Section 22 and Table 6.

Method B—Constant Rate of Cross Head Speed

INTRODUCTION

The following procedures are applicable to so-called universal test machines. These instruments often use electronic load cells and data acquisition equipment to gather information about the specimen being tested. The instruments generally in use move the cross head at a constant speed, as opposed to having the deformation on the specimen control cross head speed, which would be a true constant rate of strain instrument.

10. Apparatus

10.1 *Testing Machine*, of any type that is of sufficient capacity and that is capable of providing a rate of loading at a strain rate of 1.0 in./min ± 5 s (25 mm/min ± 5 s). The load platform of the test equipment shall be of sufficient size to accept the specimen holder and load applying apparatus. The testing machine shall be power operated and shall apply the load continuously and without shock.

10.2 The test apparatus shall be verified according to Practices E 4, the three sections titled "Basis of Verification," "Corrections," and "Time Interval Between Verifications."

10.3 *Load-Indicating Equipment*, capable of reading to 1-lbf (4.45-N) increments, shall be provided for the test apparatus. A means shall be provided to indicate the maximum load attained during the test.

11. Flexural Strength (Method B)

11.1 *Summary of Test Method*—Flexural properties of gypsum panel products are evaluated by supporting the specimen near the ends and applying a transverse load midway between the supports.

11.2 *Significance and Use*—This test method covers a procedure for evaluating the ability of gypsum panel products to withstand flexural stresses during handling or use of the material. This test method is used to determine compliance with gypsum panel product specifications. The degree of correlation between this test and service performance has not been fully determined.

11.3 *Apparatus*—See Section 10.

11.3.1 *Specimen Supports*—All bearing supports and load surfaces shall be true, shall engage the full width of the test specimen, shall be of such strength they will not deform under the test load, and shall be rounded to a radius of 0.125 in. (3.2 mm). The specimen supports shall be spaced 14 ± 0.016 in. (356 ± 0.41 mm) on centers measured at the points of surface contact with the specimen. The supports shall be attached to a plate that shall be rigidly attached to the test apparatus. Test specimen supports shall be parallel to each other and perpendicular to the long dimension of the test specimen. The bearing surface of the end supports shall be on the same plane to ensure contact along the entire bearing surfaces. Supports shall be not less than 12 in. (305 mm) in length. When a load is being applied, the loading bar shall be in contact with the full width of the specimen. The load-bearing surface shall be parallel to the bearing surface of the specimen supports. The specimen and specimen supports shall be located so that the vertical axis through the center of the load-bearing surface passes through the specimen at one half of the specimen width and one half of the distance between the supports (see Fig. 4).

11.4 *Sampling*—Sampling shall be in accordance with Section 4.

11.5 *Test Specimen*:

11.5.1 Cut four specimens, each 12 in. (305 mm) by approximately 16 in. (406 mm) from each gypsum panel product in the sample, two having the 16-in. dimension parallel to the edge and two having the 16-in. dimension perpendicular to the edge. Cut the specimens not less than 4 in. (102 mm) away from the ends and edges of the gypsum panel product except where the product is 24-in. or less in width, where it is impossible to do so.

11.5.2 Condition specimens in accordance with Section 5.

11.6 *Procedure*:

11.6.1 Use the apparatus in 11.3, supporting each specimen centrally on the fixed parallel supports, 14-in. (356-mm) on centers, and apply the load on a similar bearing midway between the supports. Position perforated gypsum lath so the load is not applied over perforations.

11.6.2 For specimens with the long dimension parallel to the edge, test one specimen from each gypsum panel product face

TABLE 6 Nail Pull Resistance, Method B (lbf) 10 Labs / 180 Data Points

www.technobetar.ir

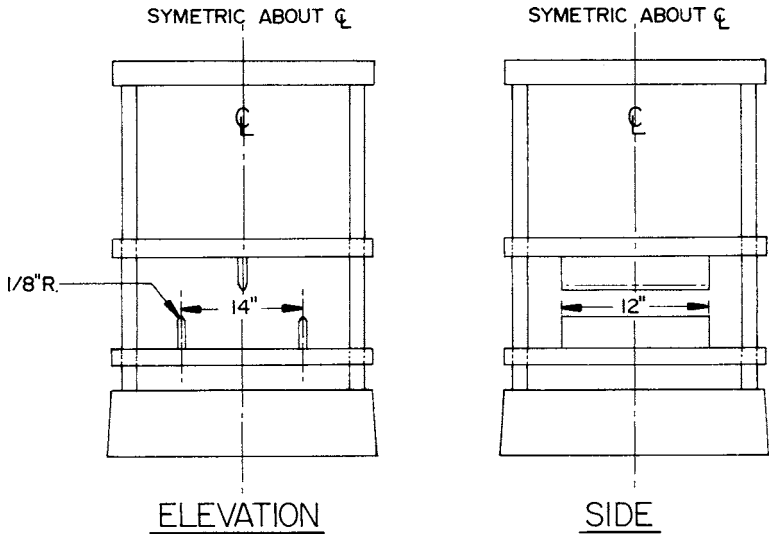

FIG. 4 Testing Machine

up and the other face down. For specimens with the long dimension perpendicular to the edge, test one specimen from each gypsum panel product face up and the other face down.

11.6.3 For gypsum panel products with surfacing material, the load is determined at the time of transverse failure of the surfacing material and core through the thickness of the specimen. The specimens shall not show a break in the bond between the surfacing and the core before transverse failure of the gypsum panel product. If a single specimen fails, test two additional specimens from the same sample, and, if either one of the two specimens fail, the sample has failed. For gypsum panel products without surfacing material, the load is determined at the time of transverse failure through the thickness of the specimen.

11.7 *Report*—Calculate and report the average breaking load in pounds-force or newtons for each test condition, rounded to the nearest 1 lbf (N). The test conditions are: (*1*) parallel, face up; (*2*) parallel, face down; (*3*) perpendicular, face up; and, (*4*) perpendicular, face down.

11.8 *Precision and Bias*:

11.8.1 *Precision*—The 95 % repeatability limit of the Parallel, Face Up (Method B) test is the test result ±4.796 lbf [21.33 N]. The 95 % reproducibility limit of the Parallel, Face Up (Method B) test is the test result ±8.992 lbf [40.00 N].

11.8.2 *Precision*—The 95 % repeatability limit of the Parallel, Face Down (Method B) test is the test result ±5.087 lbf [22.63 N]. The 95 % reproducibility limit of the Parallel, Face Down (Method B) test is the test result ±7.370 lbf [32.78 N].

11.8.3 *Precision*—The 95 % repeatability limit of the Across, Face Up (Method B) test is the test result ±10.290 lbf [45.77 N]. The 95 % reproducibility limit of the Across, Face Up (Method B) test is the test result ±13.368 lbf [59.46 N].

11.8.4 *Precision*—The 95 % repeatability limit of the Across, Face Down (Method B) test is the test result ±11.704 lbf [52.06 N]. The 95 % reproducibility limit of the Across, Face Down (Method B) test is the test result ±19.429 lbf [86.42 N].

11.8.5 *Bias*—No information can be presented on the bias of the procedure in these test methods for measuring the Flexural Strength (Method B) because there is no material having an accepted reference value.

12. Core, End, and Edge Hardness (Method B)

12.1 *Summary of Test Method*—The core, end, and edge hardness of gypsum panel products is evaluated by determining the force required to push a steel punch into the area of test.

12.2 *Significance and Use*—This test method covers a procedure for evaluating the ability of the gypsum panel product core, ends, and edges to resist crushing during handling or use of the material. This test method is used to determine compliance with gypsum panel product specifications. The degree of correlation between this test method and service performance has not been fully determined.

12.3 *Apparatus*—See Section 10.

12.3.1 A means of securing the specimen to the base of the test apparatus shall be provided. The face of the specimen shall be perpendicular to the base of the test apparatus and parallel to the movement of the steel punch. The steel punch shall be secured to the moving head of the test apparatus. It shall be positioned so that its center axis is parallel with the line of travel. It also shall be positioned so that the punch is inserted into the core equidistant from the surfaces of the specimen. The steel punch shall be 0.099 ± 0.003 in. (2.515 ± 0.076 mm) in diameter and more than ½ in. (12.7 mm) long with the bearing surface machined to a 90° angle in reference to the punch center line (see Fig. 5 and Fig. 6).

12.4 *Sampling*—Sampling shall be in accordance with Section 4.

12.5 *Test Specimens*:

12.5.1 *Specimens for Core Hardness*—Using a table or band saw, cut a specimen not less than 12 by 3 in. (305 by 76 mm) from the center of each gypsum panel product. The 12-in. (305-mm) dimension shall be perpendicular to the edges of the gypsum panel product. Cuts along the 12 in. (305 mm) dimension shall be smooth and perpendicular to the face of the specimen.

12.5.2 *Specimens for End Hardness*—Cut a specimen not less than 12 by 3 in. (305 by 76 mm) from one mill-cut end of

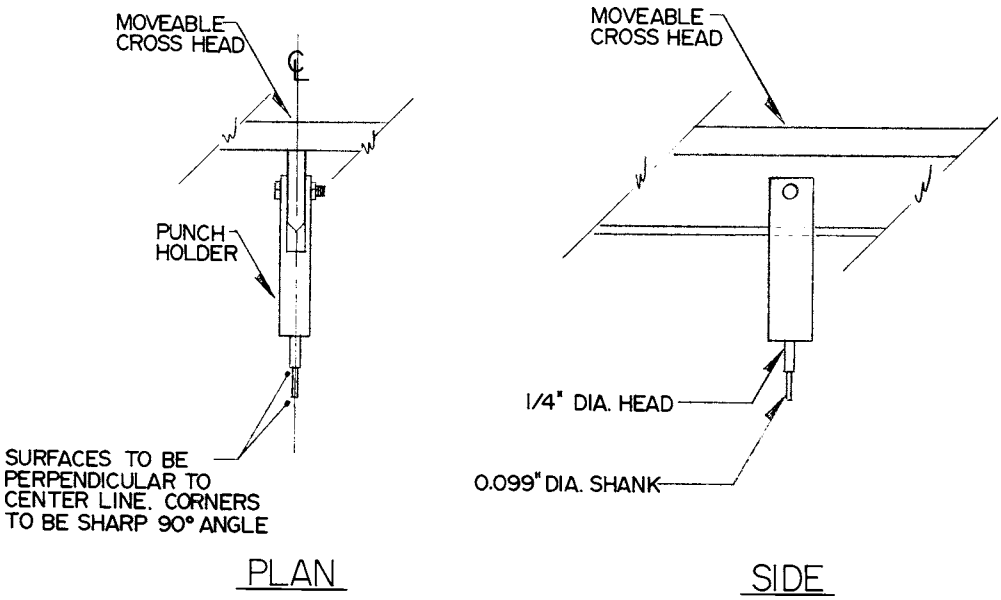

FIG. 5 Test Setup—Punch for Hardness and Nail Pull Resistance

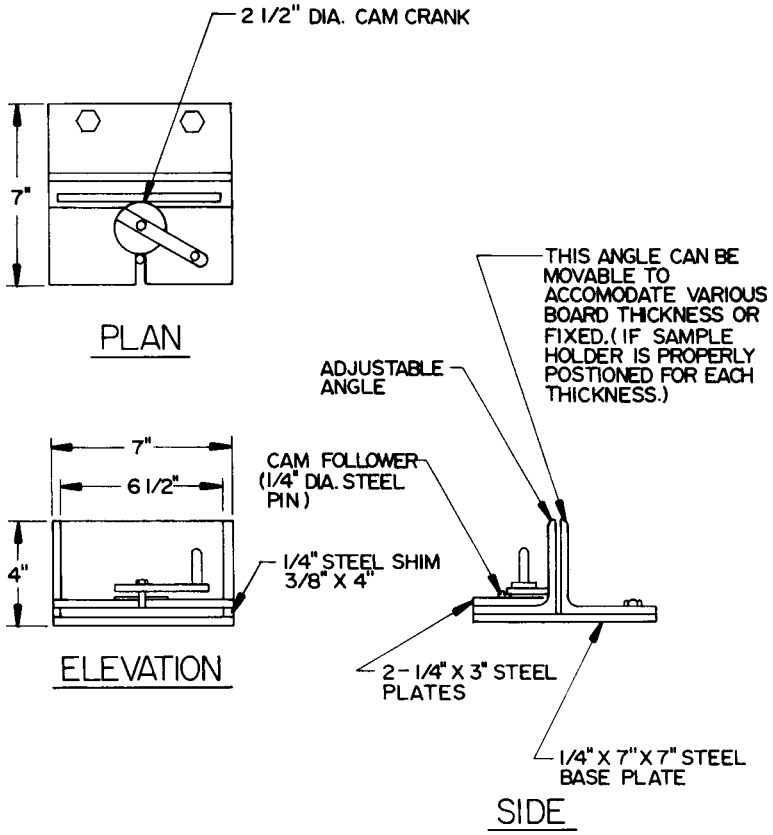

FIG. 6 Test Setup—Sample Holder for Hardness Test

each gypsum panel product. Cut the 12-in. (305-mm) dimension perpendicular to the edges of the gypsum panel product.

12.5.3 *Specimens for Edge Hardness*—Cut a specimen not less than 12 by 3 in. (305 by 76 mm) from each edge of each gypsum panel product. Cut the 12-in. (305-mm) dimension parallel to the edge of the gypsum panel product. For gypsum panel products with surfacing material, cut a ¼ to ½-in. (6 to 13-mm) strip of surfacing material from the edge of the test specimens exposing the core for test. Remove as little of the core as possible when removing the surfacing material. Prepare the first test area 2 ± ½ in. (51 ± 13 mm) from one edge of the specimen, with the next two test areas spaced approximately 4 in. (102 mm) apart.

12.5.4 Condition specimens in accordance with Section 5.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

12.6 *Procedure*—Using the apparatus in 12.3, clamp or secure the specimen in a fixed vertical position on its 12 in. (305 mm) dimension edge. If necessary, modify the flexural strength test equipment to conduct the core, end, and edge hardness test. Place this test surface not less than 1 in. (25 mm) above the grip of the specimen holder. After the specimen is in place, zero the load indicator. Conduct three tests spaced approximately 4 in. (102 mm) apart on each specimen, with the first test area 2 ± ½ in. (51 ± 13 mm) from one edge of the specimen. Position the steel punch over the test area and apply the load. Report as the core, end, or edge hardness the load required to push the steel punch a distance of ½ in. (13 mm) into the core of the specimen.

12.6.1 *Procedure for Core Hardness*—Test in 3 locations on either of the 12-in. (305-mm) saw cut edges of each specimen.

12.6.2 *Procedure for End Hardness*—Test in 3 locations on the 12-in. (305-mm) mill-cut end of each specimen.

12.6.3 *Procedure for Edge Hardness*—Test in 3 locations along each of the two 12-in. (305-mm) edges. For products with surfacing material, test where the surfacing material has been removed.

12.7 *Report*—Report the core, end, and edge hardness individually as the average load in pounds-force or newtons rounded to the nearest 1 lbf (N). Discard any single test value that varies from the average by more than 15 % and repeat the test on the same sample to obtain a new value.

12.8 *Precision and Bias*:

12.8.1 *Precision*—The 95 % repeatability limit of the End Hardness (Method B) test is the test result ±8.103 lbf [36.04 N]. The 95 % reproducibility limit of the End Hardness (Method B) test is the test result ±9.725 lbf [43.56 N].

12.8.2 *Precision*—The 95 % repeatability limit of the Core Hardness (Method B) test is the test result ±4.231 lbf [18.82 N]. The 95 % reproducibility limit of the Core Hardness (Method B) test is the test result ±9.668 lbf [43.01 N].

12.8.3 *Precision*—The 95 % repeatability limit of the Edge Hardness (Method B) test is the test result ±7.730 lbf [34.38 N]. The 95 % reproducibility limit of the Edge Hardness (Method B) test is the test result ±23.031 lbf [102.45 N].

12.8.4 *Bias*—No information can be presented on the bias of the procedure in these test methods for measuring the End, Core, and Edge Hardness because there is no material having an accepted reference value.

13. Nail Pull Resistance (Method B)

13.1 *Summary of Test Method*—The ability of gypsum panel products to resist nail pull-through is evaluated by determining the load required to push a standard nail head through the product.

13.2 *Significance and Use*—This test method covers a procedure for evaluating the ability of gypsum panel products to resist nail pull-through by determining the load required to force a standard nail head through the product. This test method is used to determine compliance with gypsum panel product specifications. The degree of correlation between these test methods and service performance has not been determined.

13.3 *Apparatus*—See Section 10. The apparatus shall be used with either of the specimen support plates in 13.3.1 or 13.3.2.

13.3.1 *Specimen Support Plate*, shall be true and have a 3-in. (76-mm) diameter hole in the center. The support plate shall be not less than 6 by 6 in. (152 by 152 mm). It shall be attached to the apparatus as necessary to maintain the surface of the plate perpendicular to the travel of the test nail. The support plate must also be located so that the vertical axis through the center of the nail shank passes through the center of the hole in the support plate. The test nail shank shall be 0.099 ± 0.003 in. (2.515 ± 0.076 mm) in diameter and the nail head shall be 0.250 ± 0.005 in. (6.350 ± 0.127 mm) in diameter. The nail shall be attached at the head to the movable cross head of the test apparatus. This attachment shall not exceed the diameter of the nail head and shall be placed directly over the head. It shall also be attached so that the vertical axis through the nail shank is parallel with the travel. See Figs. 5 and 7 for examples of the test setup configuration.

13.3.2 Fig. 3 shows a schematic of an alternate nail pull resistance apparatus adaptable to a typical flexural strength apparatus commonly used in the gypsum industry. This apparatus mirrors all of the requirements of 13.3.1, except that the nail is not attached at the head to the movable cross head of the test apparatus. The alternate apparatus utilizes a machined plunger with the nail head and shank incorporated as an integral part of the plunger. The plunger fits into a bushing that keeps the nail aligned perpendicular to the test specimen. Manufacture the plunger to slide freely through the bushing without the application of any load.

NOTE 3—Other devices or means of allowing the plunger to move freely (such as collar bearings, etc.) are also acceptable.

13.4 *Sampling*—Sampling shall be in accordance with Section 4.

13.5 *Test Specimens*:

13.5.1 Cut five specimens 6 by 6 in. (152 by 152 mm) from a strip cut across the width of each 48-in. (1220-mm) gypsum panel product starting not less than 4 in. (102 mm) in from the edge. Cut a total of five specimens from more than one full width strip from gypsum panel products less than 38 in. (965 mm) wide. Do not cut the specimen closer than 3 in. (76 mm) from the product edges.

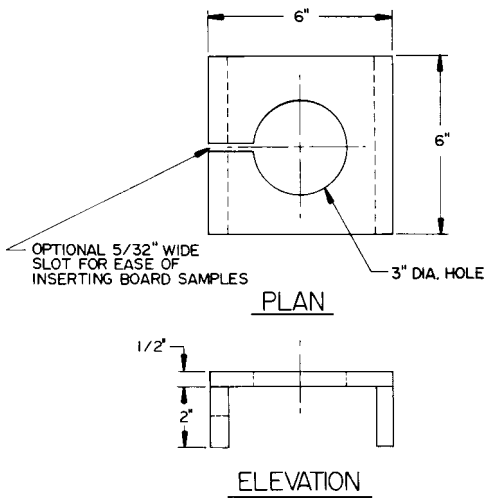

FIG. 7 Test Setup—Sample Holder for Nail Pull Resistance

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

13.5.2 Drill a 7⁄64-in. (2.778-mm) diameter pilot hole through the thickness of the gypsum panel product in the center of each test specimen and perpendicular to the surface.

13.5.3 Condition specimens in accordance with Section 5.

13.6 *Procedure*—Using the apparatus in 13.3, place the specimen on the specimen support plate so that the drilled hole is aligned with the nail shank tip. After the specimen is in place, zero the load indicator. Insert the nail shank into the specimen hole and apply the load until the maximum load is achieved. Normally, this will occur as the nail head breaks through the gypsum panel product surface and is followed by a very significant decrease in load.

13.7 *Report*—Calculate the average maximum load in pounds-force or newtons, rounded to the nearest 1 lbf (N). Discard any single test that varies from the average by more than 15 %. If more than 15 % of the test values are discarded, repeat the test.

13.8 *Precision and Bias*:

13.8.1 *Precision*—The 95 % repeatability limit of the Nail Pull (Method B) test is the test result ±5.610 lbf [24.95 N]. The 95 % reproducibility limit of the Nail Pull (Method B) test is the test result ±8.961 lbf [39.86 N].

13.8.2 *Bias*—No information can be presented on the bias of the procedure in these test methods for measuring Nail Pull because there is no material having an accepted reference value.

14. Humidified Deflection

14.1 *Summary of Test Method*—The humidified deflection of gypsum panel products is evaluated by supporting a specimen that has been cut with the long dimension perpendicular to the machine direction, supported horizontally, and subjected to high humidity for 48 h.

14.2 *Significance and Use*—This test method covers a procedure for evaluating the deflection of gypsum panel products when horizontally suspended and subjected to high humidity. This test method is used to determine compliance with gypsum panel product specifications. Since job factors other than high humidity influence the deflection of gypsum panel products, the degree of correlation between this test method and service performance has not been determined.

14.3 *Apparatus*—A humidity cabinet of sufficient size to accommodate test specimens 12 by 24 in. (305 by 610 mm) capable of maintaining an atmosphere of 90 ± 3 °F (32 ± 1.7 °C) and 90 ± 3 % relative humidity for 48 h.

14.4 *Sampling*—Sampling shall be in accordance with Section 4.

14.5 *Test Specimens*:

14.5.1 Cut two specimens 12 by 24 in. (305 by 610 mm) from each gypsum panel product in the sample so the 12-in. dimension is parallel to the edges. Cut specimens not less than 12-in. away from the ends and edges of gypsum panel products 48 in. (1220 mm) or more in width. Cut specimens from the center of gypsum panel products that are narrower than 48 in. (1220 mm) as noted in Fig. 8.

14.5.2 Condition specimens in accordance with Section 5.

14.6 *Procedure*—Suspend each specimen face down on parallel and level bearing edges, having ⅛-in. (3.2-mm) radii, 12 in. (305 mm) long, and 23 in. (584 mm) apart in the humidity cabinet in an atmosphere of 90 ± 3 °F (32 ± 1.7 °C) and 90 ± 3 % relative humidity for 48 h. Measure the humidified deflection of each specimen, while suspended on the bearing edges, as the distance between a straightedge placed on the top end edges of the gypsum panel product and the upper surface of the product at its center. Take measurements to the nearest 1⁄16 in. (1.6 mm).

14.7 *Report*—Report the humidified deflection as the average of the specimens to the nearest ⅛ in. (3 mm).

14.8 *Precision and Bias*—See Section 22 and Table 7.

15. End Squareness

15.1 *Summary of Test Method*—The end squareness of gypsum panel products is evaluated by drawing a line perpendicular to the edge of a full width specimen to its opposite edge and measuring the length of the side of the triangle formed.

15.2 *Significance and Use*—This test method covers a procedure for determining the end squareness of gypsum panel products. This test method is used to determine compliance with gypsum panel product specifications. The degree of correlation between this test method and service performance has not been determined.

15.3 *Apparatus*—A T-shaped or L-shaped square for drawing or testing right angles. The long edge of the square shall be not less than 48 in.

15.4 *Sampling*—Sampling shall be in accordance with Section 4.

TABLE 7 Humidified Deflection (in.) 10 Labs / 176 Data Points

Panel	Average[A]	Standard Deviation of the Sample Averages	Repeatability Standard Deviation	Reproducibility Standard Deviation	Repeatability Limit	Reproducibility Limit
	$\bar{\chi}$	$s_{\bar{\chi}}$	s_r	s_R	r	R
A	0.1566	0.0826	0.0397	0.0902	0.1112	0.2525
B	0.1143	0.0487	0.0644	0.0763	0.1802	0.2137
C	0.5952	0.3575	0.0829	0.3655	0.2323	1.0233

[A]The average of the laboratories' calculated averages.

15.5 *Test Specimens*—Use full-size gypsum panel products with undamaged ends for test specimens.

15.6 *Procedure*—Place one edge of the square flush against the edge of the gypsum panel product with the apex of the square at one corner of the product. Determine the distance *b*, to the nearest 1⁄16 in. (1.6 mm) at the specified distance *a*. Distance is measured from the apex of the square (see Fig. 9).

15.7 *Report*—Report the average of distance *b* to the nearest 1⁄8 in. (3.2 mm).

15.8 *Precision and Bias*—The precision and bias of this test method has not been determined.

16. Thickness

16.1 *Summary of Test Method*—The thickness of gypsum panel products is evaluated by measuring the thickness of the specimen with a micrometer.

16.2 *Significance and Use*—This test method covers a procedure for determining the average thickness of gypsum panel products, and is used to determine compliance with gypsum panel product specifications. The degree of correlation between this test method and service performance has not been determined.

16.3 *Apparatus*—A micrometer gage for determining the thickness measurement to 0.001 in. (0.025 mm). The micrometer shall be a 1-in. (25.4-mm) hand micrometer with 1⁄4-in. (6.35-mm) diameter anvils graduated to 0.01 in. (0.25 mm).

16.4 *Sampling*—Sampling shall be in accordance with Section 4.

16.5 *Test Specimens*:

16.5.1 Use full-size gypsum panel products for test specimens.

16.5.2 Mark the product to be tested, score on both sides, and break at 12 in. (305 mm) from each end, discarding the two ends prior to testing. Retain the remaining part of each gypsum panel product as a test specimen.

16.6 *Procedure*—Mark measurement points at approximately equal points across the width at each end of the gypsum panel product excluding the tapered, beveled, or recessed edges if applicable. Engage the micrometer firmly, but do not indent the surfacing material of the gypsum panel product. Measure the thickness of the gypsum panel product with the micrometer not less than 1⁄2 in. (13 mm) from cut ends. Take a minimum of not less than seven readings at each end of the 54-in. (1370-mm) wide gypsum panel product, six readings at each end of the 48-in. (1220-mm) wide gypsum panel product, five readings at each end of the 32-in. (813-mm) wide gypsum panel product, four readings at each end of the 24-in. (610-mm) wide gypsum panel product, or three readings at each end of the 16-in. (406-mm) wide gypsum panel product.

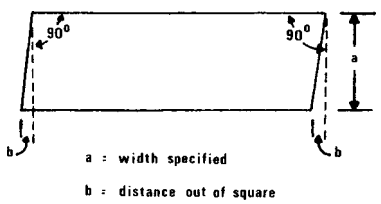

FIG. 9 End Squareness Determination

16.7 *Report*—Calculate the thickness of each specimen as the sum of the individual readings taken on each gypsum panel product specimen then divided by the quantity of individual readings made on each specimen. Calculate and report the sample thickness as the average measured thickness of all the specimens in the sample to the nearest 0.001 in. (0.1 mm).

16.8 *Precision and Bias*—The precision and bias of this test method has not been determined.

17. Recessed- or Tapered-Edge Depth

17.1 *Summary of Test Method*—The recessed- or tapered-edge depth of gypsum panel products is evaluated by comparing the thickness near the edge of the specimen to the thickness in the field of the specimen.

17.2 *Significance and Use*—This test method provides a procedure for determining the depth of the recess or taper on the edge of gypsum panel products board and is used to determine compliance with gypsum panel product specifications. The degree of correlation between this test method and service performance has not been determined.

17.3 *Apparatus*—Use the micrometer gage described in 16.3. Engage the micrometer firmly but do not indent the surfacing material. Take all readings to the nearest 0.001 in. (0.025 mm) of specimen thickness.

17.4 *Sampling*—Sampling shall be in accordance with Section 4.

17.5 *Specimens*:

17.5.1 Use the same specimens prepared in 16.5, or prepare another set of specimens as indicated in 16.5.

17.6 *Procedure*:

17.6.1 At one corner, determine the thickness 6 in. (152 mm) from the cut end and 3⁄8 in. (9.5 mm) from the edge.

17.6.2 Subtract the specimen as determined in 17.6.1 from the average specimen thickness as determined in Section 16.

17.6.3 Repeat the procedure in 17.6.1 and 17.6.2 on the remaining three corners of this specimen and on the remaining two specimens of the sample.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

17.6.4 Determine the average recessed or tapered-edge depth from all the individual recessed or tapered-edge depths, as in 17.5.

17.6.5 Determine the variation of any individual recessed or tapered-edge depth from the average as determined in 17.6.4 using the subtraction method.

17.6.6 Reject or discard any individual recessed- or tapered-edge depth calculation, as in 17.6.2, if the variation from average, as in 17.6.5, exceeds 0.050 in. (1.27 mm). To constitute a valid test do not discard more than three individual calculations.

17.7 *Report*—Report the average recessed- or tapered-edge depth as in 17.6.4 after any adjustments for exclusions of data as in 17.6.5 or 17.6.6 to the nearest 0.001 in. (0.025 mm).

17.8 *Precision and Bias*—The precision and bias of this test method has not been determined.

18. Width

18.1 *Summary of Test Method*—The width of gypsum panel products is evaluated by measuring the edge-to-edge dimension of a full size specimen.

18.2 *Significance and Use*—This test method provides a procedure for determining the width of gypsum panel products and is used to determine compliance with gypsum panel products specifications. The degree of correlation between this test method and service performance has not been determined.

18.3 *Apparatus*—Any accurate measuring device capable of measuring the width of the gypsum panel product to the nearest 1⁄32 in. (1 mm).

18.4 *Sampling*—Sampling shall be in accordance with Section 4.

18.5 *Test Specimens*—Use full-size gypsum panel products for test specimens.

18.6 *Procedure*:

18.6.1 Measure the width of an individual gypsum panel product by placing the measuring device perpendicular to the edges of the gypsum panel product when measurements are taken. The width of the specimen is the distance between extremities of the edges, so in cases where the edge or edges are beveled (slope in or out) with the face or back of the specimen, or are round, determine the overall distance. One exception is tongue and groove edge specimens, the width of which is the distance between the rip of the tongue and the bottom of the groove.

18.6.2 The width of an individual gypsum panel product is the maximum of two readings taken not less than 48 in. (1220 mm) apart and about 6 in. (152 mm) away from both ends of the specimen. Cut off 6 in. (152 mm) from both ends before taking measurements at ends of tongue and groove-edge specimens.

18.7 *Report*—Report the width as the average width of not less than three specimens to the nearest 1⁄32 in. (1 mm).

18.8 *Precision and Bias*—The precision and bias of this test method has not been determined.

19. Length

19.1 *Summary of Test Method*—The length of gypsum panel products is evaluated by measuring the end-to-end dimension of a full size specimen.

19.2 *Significance and Use*—This test method provides a procedure for determining the length gypsum panel products and is used to determine compliance with gypsum panel products specifications. The degree of correlation between this test method and service performance has not been determined.

19.3 *Apparatus*—Any accurate measuring device capable of measuring the length of the gypsum panel product to the nearest 1⁄16 in. (2 mm).

19.4 *Sampling*—Sampling shall be in accordance with Section 4.

19.5 *Test Specimens*—Use full-size gypsum panel products for test specimens.

19.6 *Procedure*:

19.6.1 Measure the length of an individual gypsum panel product by placing the measuring device parallel with the edges when measurements are taken. The length of the specimen is the distance between extremities of the ends, so in cases where the ends are beveled, determine the overall distance.

19.6.2 The length of a specimen is the maximum of two readings taken about 3 in. (76 mm) away from both edges of the specimen.

19.7 *Report*—Report the length as the average length of not less than three specimens to the nearest 1⁄8 in. (3 mm).

19.8 *Precision and Bias*—The precision and bias of this test method has not been determined.

20. Water Resistance of Core-Treated Water-Repellent Gypsum Panel Products

20.1 *Summary of Test Method*—The water resistance of core-treated water-repellent gypsum panel products is evaluated by immersing the specimen in water for the specified period of time.

20.2 *Significance and Use*—This test method provides a procedure for evaluating the ability of core-treated gypsum panel products to resist water penetration. This test method is used to determine compliance with gypsum panel product specifications. The degree of correlation between this test method and service performance has not been determined.

20.3 *Apparatus*:

20.3.1 *Water Bath*, not less than 16 by 16 by 3 in. (406 by 406 by 75 mm) capable of maintaining the water at a constant temperature of 70 ± 1 °F (21 ± 0.5 °C).

20.3.2 *Glass Rods*, 0.25 in. (6 mm) in diameter, or other supports capable of keeping the specimens off the bottom of the water bath.

20.4 *Sampling*—Sampling shall be in accordance with Section 4.

20.5 *Test Specimens*:

20.5.1 Prepare a 12 by 12-in. (305 by 305-mm) test specimen cut from the center of the gypsum panel product being tested by scoring and breaking. Cut specimens approximately centered between both edges and not less than 6 in. (152 mm) from either end. Do not treat the edges of the specimen nor damage any surfacing material.

20.5.2 Condition the specimens in accordance with Section 5, except at a temperature of 70 ± 5 °F (21 ± 2 °C), and then weigh to within 0.5 g.

20.6 *Procedure*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:17 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

20.6.1 Position the specimen so that it rests flatwise on glass rods or other supports in the water bath with a head of 1 in. (25 mm) of water over the top of the specimen. If the specimen floats, place sufficient weight on the specimen to keep it in contact with the supports under the 1-in. (25-mm) head of water.

20.6.2 After 2 h have elapsed, remove the specimen from the bath, wipe excess water from the surfaces and edges of the specimen and weigh immediately to within 0.5 g.

20.7 *Report*—Calculate the gain in weight for each specimen as a percentage of the original weight as determined in 20.5.2 to the nearest 1 % and report the average percentage as the water absorption of the gypsum panel product.

20.8 *Precision and Bias*—See Section 22 and Table 8.

21. Surface Water Resistance of Gypsum Panel Products with Water-Repellent Surfaces

21.1 *Summary of Test Method*—The surface water resistance of gypsum panel products with water-repellent surfaces is evaluated by damming a specified area on the treated surface, filling that area with water, and allowing it to remain undisturbed for the specified time period.

21.2 *Significance and Use*—This test method provides a procedure for evaluating the ability of water-repellent surfacing of gypsum panel products to resist water penetration. This test method is used to determine compliance with gypsum panel product specifications. The degree of correlation between this test method and service performance has not been determined.

21.3 *Apparatus*—A Cobb Tester conditioned to a temperature of 70 ± 1 °F (21 ± 0.5 °C).

NOTE 4—For a description of the test apparatus see Test Method D 3285. The studs that anchor the metal crossbar may need to be lengthened to accommodate gypsum panel products.

21.4 *Sampling*—Sampling shall be in accordance with Section 4.

21.5 *Test Specimens*:

21.5.1 Cut three specimens 5 in. (127 mm) square from the field of each sample piece of gypsum panel product.

21.5.2 Condition the specimens in accordance with Section 5, except at a temperature of 70 ± 5 °F (21 ± 2 °C), to constant weight within 0.1 % and then weigh to within 0.05 g.

21.6 *Procedure*:

21.6.1 Place the conditioned test specimens in the Cobb Tester with the side to be exposed to water facing up. Fill the Cobb ring with tap water adjusted to a temperature of 70 ± 1 °F (21 ± 0.5 °C), resulting in a 1 in. (25.4 mm) head of water above the test area of the specimen.

21.6.2 After 2 h have elapsed, pour the water out of the Cobb ring and remove the specimen from the Cobb Tester. Immediately remove excess water from the specimen by blotting and weigh to the nearest 0.05 g.

21.7 *Report*—Calculate average difference between the dry and wet weights of the test specimens to the nearest 0.1 g and report this as the surface water absorption of the gypsum panel product.

21.8 *Precision and Bias*—See Section 22 and Table 9.

22. Precision and Bias

22.1 The precision of these test methods is based on an interlaboratory study of Test Methods C 473-07 conducted in 2007. Ten laboratories tested five different gypsum panel products. Every "test result" represents an individual determination. Participants were asked to submit six replicate test results for each parameter/material combination (twelve replicates for Edge Hardness). Practice E 691 was followed for the design and analysis of the data.

22.1.1 *Repeatability limit (r)*—Two test results obtained within one laboratory shall be judged not equivalent if they differ by more than the "*r*" value for that material; "*r*" is the interval representing the critical difference between two test results for the same material, obtained by the same operator using the same equipment on the same day in the same laboratory.

22.1.1.1 Repeatability limits are listed in Tables 1-9.

22.1.2 *Reproducibility limit (R)*—Two test results shall be judged not equivalent if they differ by more than the "*R*" value for that material; "*R*" is the interval representing the critical difference between two test results for the same material, obtained by different operators using different equipment in different laboratories.

22.1.2.1 Reproducibility limits are listed in Tables 1-9.

22.1.3 The above terms (repeatability limit and reproducibility limit) are used as specified in Practice E 177.

22.1.4 Any judgment in accordance with statements 22.1.1 and 22.1.2 would normally have an approximate 95 % probability of being correct, however not all of the precision statistics obtained in this ILS may be treated as definitive mathematical quantities, applicable to all circumstances and uses. The limited number of replicates tested and laboratories reporting results for some analyses guarantees that there will be times when differences greater than predicted by these ILS results will arise, sometimes with considerably greater or smaller frequency than the 95 % probability limit would imply. The repeatability limits and the reproducibility limits for those analyses should be considered as general guides, and the

TABLE 9 Water Resistance - Surface (gm) 9 Labs / 107 Data Points

Panel	Average[A]	Standard Deviation of the Sample Averages	Repeatability Standard Deviation	Reproducibility Standard Deviation	Repeatability Limit	Reproducibility Limit
	$\bar{\chi}$	$s_{\bar{\chi}}$	s_r	s_R	r	R
D	1.2929	0.0759	0.1161	0.1303	0.3250	0.3649
E	1.3040	0.0703	0.0660	0.0926	0.1847	0.2592

[A]The average of the laboratories' calculated averages.

associated probability of 95 % as only a rough indicator of what can be expected.

22.2 *Bias*—At the time of the study, there was no accepted reference material suitable for determining the bias for this test method, therefore no statement on bias is being made.

22.3 The precision statement was determined through statistical examination of 1019 test results, from ten laboratories, on five materials. These five materials were described as the following:

Panel A: ½ " regular gypsum wallboard
Panel B: ⅝ " type X gypsum wallboard
Panel C: ¼ " regular gypsum wallboard
Panel D: gypsum sheathing
Panel E: water-resistant gypsum backing board

To judge the equivalency of two test results, it is recommended to choose the material closest in characteristics to the test material.

23. Keywords

23.1 absorption testing; core hardness testing; dimension measurements; edge hardness testing; end hardness testing; flexural strength; gypsum panel products; humidified sag; nail pull testing

APPENDIXES

(Nonmandatory Information)

X1. INTRODUCTION

X1.1 ASTM specifications for gypsum panel products do not contain a specification for weight. The procedure, however, is referenced in other industry standards, and is therefore retained as an appendix item.

X2. WEIGHT

X2.1 *Test Specimens*—A sample shall consist of not less than three full size pieces of the gypsum panel product.

X2.2 *Procedure*—Measure the length and width of each specimen in accordance with Sections 17 and 18. Weight the specimens on a suitable scale and record the weight to the nearest ¼ lb (0.1 kg).

X2.3 *Calculation*—Calculate the weight in accordance with the following equation and table:

$$W = \frac{(K \times P)}{(L \times B)}$$

Where:	Meaning of Symbol	Inch-Pound Units	SI Units
W =	weight of specimen	lb/1000 ft^2	kg/100 m^2
L =	length of specimen	in.	mm
B =	width of specimen	in.	mm
P =	weight of specimen	lb	kg
K =	constant	1.44×10^5 in.^{2}/1000 ft^2	1×10^8 mm^2/ 100 m^2

X2.4 *Report*—Report the weight as the average calculated weight, in lb/1000 ft^2(kg/100 m^2) of the three gypsum specimens.

X3. COMPRESSIVE STRENGTH

X3.1 *Introduction*—The following procedure is intended to evaluate the compressive strength of the core of the gypsum panel products.

X3.2 *Summary of Test Method*—The core strength of gypsum panel products is evaluated by crushing the sample.

X3.3 *Significance and Use*—This test method covers a procedure for evaluating the compressive strength of the gypsum panel product. The degree of correlation between this test and service performance has not been fully determined.

X3.4 *Apparatus*—See Section 10.

Testing Machine, as described for test Method B—Constant Rate of Cross Head Speed with the rate of loading at a strain rate of ⅛ in./min. ± 5 s (4 mm/min. ± 5 s).

X3.4.1 *Specimen Supports*—All bearing supports and load surfaces shall be true, shall engage the full width of the test specimen, shall be of such strength they will not deform under the test load and shall be flat. The minimum diameter of the supporting and load plates shall be 3.0 in. (75 mm). The loading and supporting plates shall be 90° to the direction of loading and parallel to each other.

X3.5 *Sampling*—Sampling shall be in accordance with Section 4.

X3.6 *Test Specimen*

X3.6.1 Cut nine specimens, each approximately 2.4-in. (61-mm) in diameter with a 0.25-in. (6.4-mm) center hole. (A 2.5-in. (63-mm) outside diameter hole saw may be used to cut sample.) Three specimens are taken from each side and the center of the gypsum panel product. Cut the specimens not less than 12 in. (300 mm) away from the ends and edges of the gypsum panel product except where the product is 24 in. (600 mm) or less in width, where it is impossible to do so.

X3.6.2 Measure and record the actual diameter of each specimen to the nearest 0.01 in. (0.1 mm). Calculate and record the area of each specimen using the measured diameter and subtracting the area of the center hole.

X3.6.3 Condition specimens at 113 °F ± 5 °F (45 °C ± 3 °C) in a ventilated oven until constant weight.

X3.7 *Procedure*

X3.7.1 Weigh each specimen and record its mass to 0.1 g.

NOTE X3.1—It is very important to perform the test on dry specimens. Only one specimen should be removed from the drying oven at a time. Testing should immediately follow weighing.

X3.7.2 Use the apparatus in X3.4, supporting each specimen centered on the supporting plate.

X3.7.3 Bring the loading plate in contact with the specimen (a faster rate of loading may be used but do not exceed 2.5 lb (10 N) initial load).

X3.7.4 Begin test at specified load rate.

X3.7.5 Failure load is the maximum load at the end of the elastic portion of the loading. (In Fig. X3.1, this would be at the sharp change in slope as shown by the X in Area 1 for one of the specimens.)

X3.7.6 Test can be terminated at any time after the maximum elastic load is obtained. (In Fig. X3.1, anywhere in Area 2).

X3.7.7 Remove the specimen. Clean the test surfaces.

X3.7.8 Repeat for next specimen.

X3.8 *Report*—Record the weight of each specimen and the compressive strength in psi (MPa) (total load/specimen area) for each specimen. Calculate and report the average weight and average compressive strength for each side and the center and the overall average.

X3.9 *Precision and Bias*—The precision and bias for this test method has not been determined.

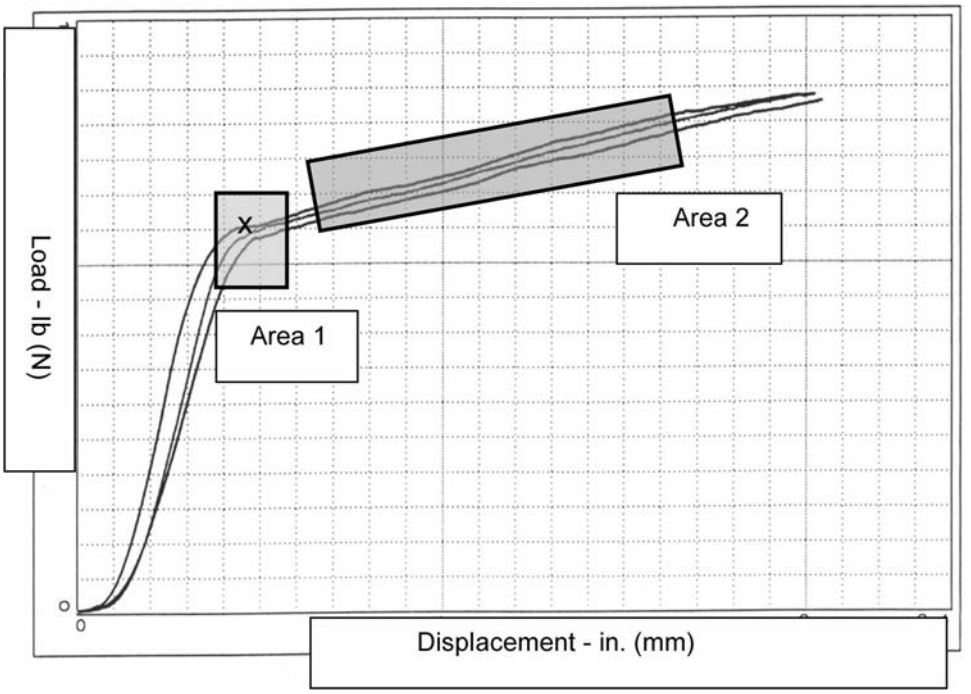

FIG. X3.1 Example Compression Test—Results for 3 Specimens Are Shown

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to these test methods since the last issue, C 473 – 07, that may impact the use of these test methods. (Approved September 1, 2009)

(*1*) Added new Section 22 and Tables 1-9.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 474 – 05

Standard Test Methods for Joint Treatment Materials for Gypsum Board Construction[1]

This standard is issued under the fixed designation C 474; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 These test methods cover the physical testing of joint compound, paper joint tape, glass-mesh joint tape, and an assembly of joint compound and paper joint tape.

1.1.1 Joint treatment materials are specified in Specification C 475/C 475M.

1.1.2 The joint treatment material described in this standard are for use with gypsum board installed in accordance with Specification C 840.

1.2 The test methods appear in the following order:

	Section
Joint Compound Tests:	
Viscosity	5
Shrinkage	6
Check Cracking	7
Putrefaction	8
Joint Tape Tests:	
Tensile Strength	9
Width	10
Thickness	11
Paper Joint Tape Tests	
Dimensional Stability	12
Assemblages of Paper Joint Tape and Joint Compound:	
Bond of Paper Joint Tape to Joint Compound	15
Cracking of Joint Compound at Tape Edges	14
Glass-Mesh Joint Tape Test	
Skewness	13

1.3 The values stated in inch-pound units are to be regarded as the standard. The SI (metric) values given in brackets are approximate and are provided for information purposes only.

1.4 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters, and Gypsum Concrete

C 475/C 475M Specification for Joint Compound and Joint Tape for Finishing Gypsum Board

C 840 Specification for Application and Finishing of Gypsum Board

C 1396/C 1396M Specification for Gypsum Board

D 685 Practice for Conditioning Paper and Paper Products for Testing

D 828 Test Method for Tensile Properties of Paper and Paperboard Using Constant-Rate-of-Elongation Apparatus

D 3882 Test Method for Bow and Skew in Woven and Knitted Fabrics

E 100 Specification for ASTM Hydrometers

2.2 *TAPPI Standard:*

T 411 Thickness (Caliper) of Paper, Paperboard, and Combined Board[3]

3. Terminology

3.1 *Definitions*—For definitions of terms relating to gypsum, see Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *bond*, *n—in joint systems*, the quality of adhesion between the paper joint tape and joint compound.

3.2.1.1 *Discussion*—A 0 % bond means that no paper fiber is adhering to the joint compound. A 100 % bond means that there is cohesive failure of the paper joint tape.

3.2.2 *check cracking*, *n—in joint systems*, short, narrow cracks randomly oriented in the surface of the dried joint compound.

3.2.3 *joint compound, powder*, *n*—A drying-type or setting-type cementitious material to be mixed with water.

[1] These test methods are under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and are the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved Jan. 1, 2005. Published February 2005. Originally approved in 1961. Last previous edition approved in 2002 as C 474 – 02.

www.technobetar.ir

3.2.4 *joint compound, ready-mix*, *n*—A drying-type cementitious material that is factory mixed in ready-to-use form.

4. Specimen Preparation

4.1 *Joint Compound, Powder*:

4.1.1 Mix 300 g of joint compound, powder, with approximately 150 to 160 mL of water.

4.1.2 Allow the specimen to stand for 30 min (Note 1), remix and adjust the temperature to 77 ± 2 °F [25 ± 1 °C] by placing the container holding the specimen in warm or cool water.

NOTE 1—Allow setting type compounds to stand for one half of their setting times, as determined by Test Methods C 472 but not more than 30 min, prior to remixing.

4.1.3 Measure the viscosity in accordance with Section 5.

4.1.4 If the measured viscosity is not between 480 and 520 Brabender units, repeat 4.1.1-4.1.3 through with an increase or decrease in water as necessary.

4.1.5 Record the volume of water used to adjust the viscosity to 500 ± 20 Brabender units (see Note 2).

NOTE 2—Making note of the volumes of water, in millilitres per 100 g of material, used to adjust the viscosity, will facilitate specimen preparation in other tests.

4.2 *Joint Compound, Ready-Mix*:

4.2.1 Remix joint compound, ready-mix, to reincorporate any separated ingredients. Adjust the temperature to 77 ± 2 °F [25 ± 1 °C] by placing the container holding the specimen in warm or cool water.

4.2.2 Measure the viscosity in accordance with Section 5.

4.2.3 If the viscosity is more than 520 Brabender units, add water to achieve a viscosity of 500 ± 20 Brabender units (see Note 2).

4.2.3.1 If the original sample viscosity is less than 480 Brabender units, test as received.

JOINT COMPOUND

5. Joint Compound Viscosity

5.1 *Significance and Use*:

5.1.1 This test method provides a procedure for measuring joint compound viscosity.

5.2 *Sampling*:

5.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

5.3 *Specimen Preparation*:

5.3.1 Prepare specimens in accordance with Section 4.

5.4 *Apparatus*:

5.4.1 *Viscosity Specimen Container*, metal or plastic with an open top having an inside diameter of 2½ to 3 in. [65 to 75 mm] and a height of 2½ to 3 in. [65 to 75 mm].

5.4.2 *Viscometer*[4], adjusted to operate at 78 ± 1 r/min, and with a 250 cm-g sensitivity cartridge.

5.4.3 *Viscometer Pin*, having dimensions as follows:

	in. [mm]
Shaft diameter	0.187 ± 0.015 [4.75 ± 0.38]
Pin diameter	0.094 ± 0.015 [2.39 ± 0.38]
Immersion depth (from bottom of spindle)	1.625 ± 0.015 [41.3 ± 0.38]
Length of pin projecting from shaft	0.750 ± 0.015 [19.1 ± 0.38]
Upper pin from bottom of shaft	0.313 ± 0.015 [7.95 ± 0.38]
Lower pin from bottom of shaft	0.125 ± 0.015 [3.28 ± 0.38]

5.5 *Procedure*:

5.5.1 Fill the viscosity container with the mixed specimen until level with the top of the container.

5.5.1.1 Remove all air bubbles by puddling the sample container with a spatula and sharply rapping the bottom of the container on a hard flat surface.

5.5.2 Lock the filled container in the center of the viscometer spindle platform. Raise the platform until the level of the specimen reaches the mark on the viscometer pin and lock the platform in place.

5.5.3 Start the viscometer. Read the viscosity after the pen starts to trace a straight line (usually within 1 min). If the tracing remains inconsistent, estimate the average viscosity reading.

5.6 *Report*:

5.6.1 Report the viscosity of the joint compound specimen in Brabender units.

5.7 *Precision and Bias*:

5.7.1 Precision and bias of this test method have not been determined.

6. Shrinkage

6.1 *Significance and Use*:

6.1.1 This test is used to measure the amount of shrinkage in joint compound. The degree of correlation between this test and service performance has not been determined.

6.2 *Sampling*:

6.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

6.3 *Specimen Preparation*:

6.3.1 Specimen preparation shall be in accordance with Section 4.

6.4 *Apparatus*:

6.4.1 *Plastic or Rubber Film*, approximately 5 by 5 in. [130 by 130 mm]. Any thin, flexible film that peels clean from a partially dried patty may be used.[5]

6.4.2 *Balance*, having a sensitivity of 10 mg (Fig. 1 and Fig. 2).

6.4.3 *Beaker, Ring Stand, and Wire Cradle* (see Fig. 1).

6.4.4 *Forced Air Drying Oven*, capable of being maintained at 90 to 120 °F [32 to 49 °C].

6.4.5 *Spatula*, having a blade approximately 4 in. by ½ in. [100 by 13 mm].

6.4.6 *Steel-Reinforced Broad Knife*, a 5 to 8 in. [130 by 200 mm] drywall broad knife reinforced by a steel bar, 1 in. [25 mm] wide by ⅛ in. [3 mm] thick, by the knife width, attached to the back of the knife blade ¼ in. [6 mm] from the edge.

6.4.7 *Hydrometer*, having a range of 0.7 to 0.8 sp gr, in accordance with Specification E 100.

[4] The sole source of supply of the apparatus known to the committee at this time is the Brabender "Visco-Corder" Model VC-3, manufactured by C.W. Brabender Instruments Inc., South Hackensack, NJ. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee [1], which you may attend.

[5] Rubber dental dam dusted with talc, polyethylene, or PTFE films have been found satisfactory for this use.

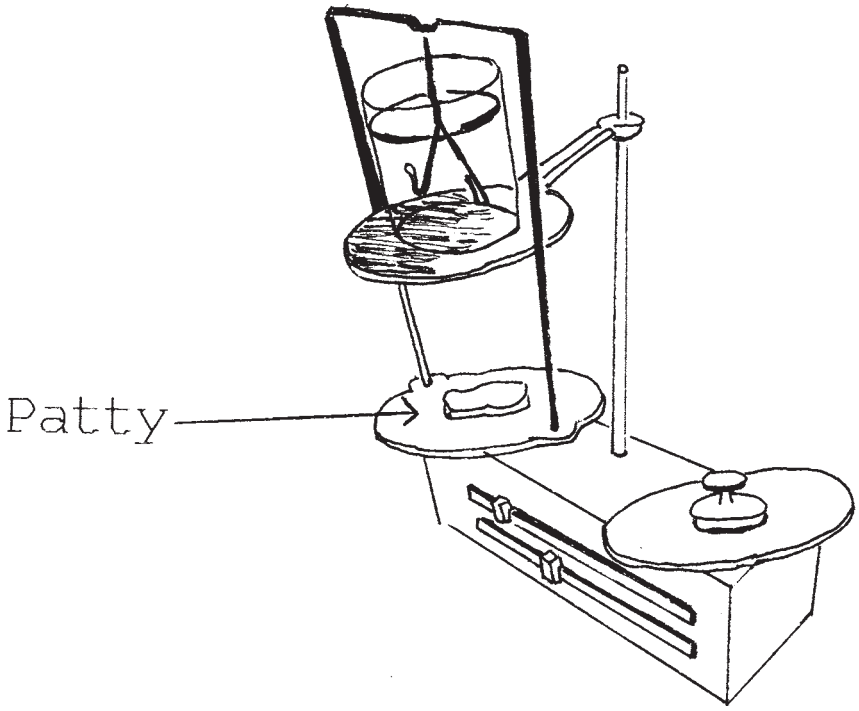

FIG. 1 Wire Cradle in Kerosine

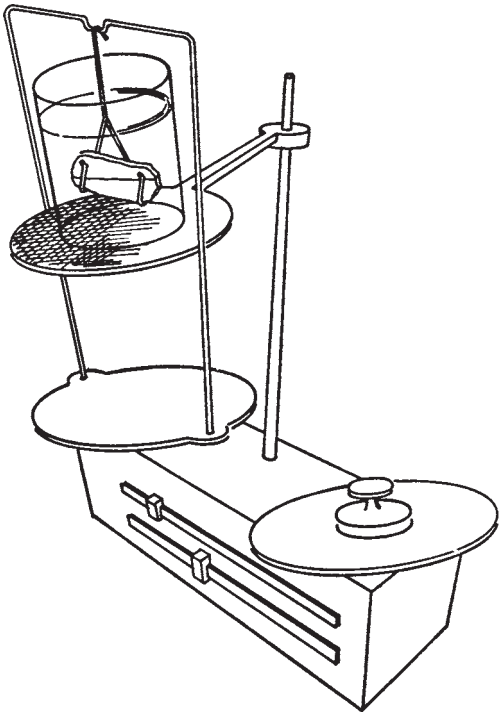

FIG. 2 Patty Immersed in Kerosine

6.4.8 *Volumetric Container*, a container which has a volume between 25 and 300 cm^3.

6.5 *Reagents and Materials*:

6.5.1 *Displacement Fluids*.

6.5.1.1 *Mineral Spirits*, odorless.

6.5.1.2 *Kerosine*.

6.6 *Preparation of Apparatus*:

6.6.1 *Support Plates*—Cover three plastic or glass plates with plastic or rubber film.

6.6.2 Obtain and record the tare weight of each assembly.

6.7 *Calibration*:

6.7.1 *Volumetric Container*—Determine the container volume in cubic centimetres and its tare weight in grams.

6.7.2 *Mineral Spirits, Kerosine*—Using the hydrometer, determine the specific gravity and record the result as *M*.

6.8 *Determination of Wet Volume*:

6.8.1 Prepare a specimen to determine the wet specific gravity by weighing the specimen in the volumetric container.

6.8.1.1 Adjust the temperature to 77 ± 2 °F [25 ± 1 °C] by placing the container holding the specimen in warm or cool water.

6.8.1.2 Puddle the specimen with the spatula to remove entrapped air bubbles.

6.8.1.3 Fill the container completely and strike off the surface flush with the top using the steel-reinforced broad knife.

6.8.1.4 Weigh the filled container to the nearest 0.01 g. Record the weight of the filled container.

6.9 *Preparation of Specimen to Determine Dry Volume*:

6.9.1 Place approximately 30 g of specimen onto each prepared support plate.

6.9.1.1 Spread the specimen into an elongated patty 3⁄16 to ¼ in. [5.0 to 6.5 mm] thick with a spatula.

6.9.1.2 Remove any specimen remaining on the spatula and add to the patty.

NOTE 3—The patty may be scored across its narrowest width to facilitate breaking the patty after it is dry.

6.9.1.3 Weigh and record the total weight of each patty, film and plate.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:20 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.9.1.4 When testing setting type joint compounds, place the patties in the drying oven one h after the setting time has been reached as determined by Test Methods C 472.

6.9.1.5 When testing drying type joint compounds, place the patties in the drying oven immediately after weighing.

6.9.2 Dry patties at a temperature between 100° and 120 °F [32 to 49 °C] for 16 to 24 h.

6.9.3 Strip off the plastic or rubber film, and continue to dry until constant weight is reached.

6.10 *Determination of Dry Volume*:

6.10.1 Immerse each patty in a beaker of the displacement fluid, such that they do not touch the sides of the beaker, until constant weight is reached.

NOTE 4—Each patty may be broken into two or three pieces to fit in the beaker without touching the sides.

6.10.2 Remove each patty from the displacement fluid. Using a cloth moistened in the same fluid, lightly blot off the excess fluid from the surface of the patty.

6.10.3 With the wire cradle suspended in the beaker of displacement fluid, weigh each patty in air on the pan of the balance (Fig. 1), and record as its air weight.

6.10.4 Next, weigh each patty in the wire cradle, making sure that the patty is completely immersed in the liquid and that it does not touch the sides of the beaker (Fig. 2). Record these weights as the immersed weight.

6.11 *Calculation of Shrinkage*:

6.11.1 Determine the net weight of the compound in the volumetric container by subtracting the weight obtained in 6.8.1.4 from the weight obtained in 6.7.1.

6.11.2 Divide the net weight obtained in 6.11.1 by the volume of the container obtained in 6.7.1. Record the result as *G*, grams per millilitre.

$$G = \frac{\text{Total weight} - \text{Container tare weight}}{\text{Volume of Container}} \quad (1)$$

6.11.3 Determine the net weight of each specimen by subtracting the tare weight of its support plate weight and its weight obtained in 6.9.1.3.

6.11.4 Divide the net weight obtained in 6.11.3 by *G*. Record as *V*, volume of patty.

$$V = \frac{\text{Dry weight} - \text{Support plate tare weight}}{G} \quad (2)$$

6.11.5 Subtract the immersed patty weight obtained in 6.10.4 from the air patty weight obtained in 6.10.3. Record as *D*, the weight difference.

6.11.6 Calculate the percent shrinkage as follows:

$$\% \text{ Shrinkage} = D(X/V), \quad (3)$$

where:

D = the difference in air and immersed weight,
X = 100/displacement fluids specific gravity, and
V = weight of wet patty/specific gravity of the compound.

6.12 *Report*:

6.12.1 Take the average of the three patties tested. If there is a difference between the percent shrinkage of the three patties of more than 1.5 %, completely retest an additional three specimens and take the average of the six.

6.13 *Precision and Bias*:

6.13.1 Precision and bias of this test method have not been determined.

7. Check Cracking of Joint Compound

7.1 *Significance and Use*

7.1.1 This test method is used to measure the degree and type of field and edge cracking of joint compound. The degree of correlation between this test and service performance has not been determined.

7.2 *Sampling*:

7.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

7.3 *Specimen Preparation*:

7.3.1 Prepare specimens in accordance with Section 4, except use a quantity of 100 g.

7.4 *Apparatus*:

7.4.1 *Rod*, metal or glass, ⅛ in. [3.2 mm] in diameter by 7 in. [180 mm] in length.

7.4.2 *Steel-Reinforced Broad Knife*, as defined in 6.4.6.

7.4.3 *Gypsum Wallboard*, Specification C 1396/C 1396M.

7.4.3.1 To determine compliance to Specification C 475/C 475M, Specification C 1396/C 1396M gypsum wallboard shall be used.[6]

7.4.4 *Electric Fan*, capable of forcing a continuous current of air at a velocity of 350 to 450 ft/min [1.8 to 2.3 m/s] at a distance of approximately 3 ft [1 m].

7.5 *Procedure*:

7.5.1 Place the rod on a piece of gypsum wallboard and place some of the specimen next to the rod.

7.5.2 Form a 3½ to 4 in. [90 to 100 mm] wide wedge of the specimen with the steel-reinforced broad knife, with the rod on one side and the wallboard on the other side to guide the knife.

7.5.2.1 Hold the broad knife at an angle less than 45° with respect to the plane of the wallboard. Draw the broad knife over the specimen two or more times to leave the surface smooth.

7.5.3 Remove the rod and adjust the wedge to a 5 in. [130 mm] length.

7.5.4 Immediately place the wedge-shaped specimen in front of the fan blowing over the surface of the wedge for 8 to 16 h. The current of air shall be maintained at 70 to 85 °F [21 to 29 °C] and 45 to 55 % relative humidity.

7.6 *Report*:

7.6.1 Report the type and amount of cracking in both the thick half and the thin half of the wedge.

7.7 *Precision and Bias*:

7.7.1 Precision and bias of this test method have not been determined.

8. Putrefaction

8.1 *Significance and Use*:

[6] Other substrates may be used to evaluate the effect that they have on the performance of the joint compound and assemblies of joint compound and joint tape.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:20 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.1.1 This test method is used to evaluate the tendency of the joint compound to putrefy. The degree of correlation between this test and service performance has not been determined.

8.2 *Sampling*:

8.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

8.3 *Apparatus*:

8.3.1 *Humidity Cabinet*, a chamber capable of maintaining 85 to 95 °F [29 to 35 °C] and 85 to 95 % relative humidity.

8.3.2 *Glass Container*, capable of being sterilized in an autoclave, having a minimum volume of 250 mL.[7]

8.3.3 *Cover*, made of glass or aluminum foil large enough to cover the glass container and capable of being sterilized in an autoclave.

8.3.4 *Autoclave*, capable of maintaining 260 °F [130 °C] at 21 psi [145 kPa] steam pressure for not less than 15 min.

8.4 *Preparation of Apparatus*:

8.4.1 Sterilize the glass container and cover in an autoclave at 21 psi [145 kPa] and 260 °F [130 °C] for 15 min or more.

8.5 *Procedure*:

8.5.1 *Joint Compound, Powder*—Mix 50 g of joint compound with water, as determined in 4.1 in the glass container. Allow it to soak 30 min and then remix. Place the cover over the glass container and place in the humidity cabinet.

8.5.2 *Joint Compound, Ready-mix*—Select an unopened container that has not exceeded the producer's specified shelf life.

8.5.2.1 Open the container. If the material in the container has separated, mix thoroughly.

8.5.2.2 Remove 100 g of joint compound, ready-mix, from the container.

8.5.2.3 Put the specimen in the glass container and cap with the cover.

8.5.2.4 Place in the humidity cabinet.

8.6 *Interpretation of Results*:

8.6.1 Observe daily for putrefaction.

8.7 *Report*:

8.7.1 Report the number of days required to produce putrefaction.

8.8 *Precision and Bias*:

8.8.1 Precision and bias of this test method have not been determined.

JOINT TAPE

9. Tensile Strength

9.1 *Significance and Use*:

9.1.1 This test method is used to evaluate the cross-directional strength of joint tape used to reinforce the joints created by gypsum wallboard construction. The degree of correlation between this test and service performance has not been determined.

9.2 *Sampling*:

9.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

9.2.2 A sample for the purpose of testing shall consist of not less than 12 ft [3.6 m] of tape from each roll.

9.2.3 Take ten specimens in the cross direction at not less than 1 ft (300 mm) intervals. Cut each specimen to 1 in. [25 mm] by roll width.

9.3 *Apparatus*:

9.3.1 The apparatus shall be in accordance with Test Method D 828 except that the distance of the jaw spacing shall be reduced to ½ ± 1/64 in. [12.7 ± 0.4 mm]; the rate of elongation shall be 0.66 in./min ± 5 s [17 mm/min ± 5 s].

9.4 *Procedure*:

9.4.1 Condition the specimens for a minimum of 24 h at 72 ± 4 °F [22 ± 2 °C] and 50 ± 2 % relative humidity.

9.4.2 Test in accordance with Test Method D 828 with equipment as set forth in 9.3.

9.5 *Interpretation of Results*:

9.5.1 Accept or reject results of the individual test specimens in accordance with Test Method D 828.

9.5.2 If any results are rejected, test additional specimens so that there are at least ten test results for the evaluation of any unit of tape.

9.6 *Report*:

9.6.1 Report test results as pounds-force per inch (Newtons per millimetre) of width of specimen.

9.7 *Precision and Bias*:

9.7.1 Precision and bias statements as listed in Test Method D 828 are suitable for use with this product.

10. Width

10.1 *Significance and Use*:

10.1.1 This test method is used to determine the average variation in width of the joint tape. The degree of correlation between this test and service performance has not been determined.

10.2 *Sampling*:

10.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

10.3 *Specimen Preparation*:

10.3.1 Cut a specimen of joint tape not less than 12 ft [3.5 m] long from the roll to be tested.

10.4 *Apparatus*:

10.4.1 *Steel Rule, Caliper Rule*, or other measuring device capable of resolving 1/32 in. A metric device must be capable of resolving 1.0 mm.

10.5 *Procedure*:

10.5.1 Measure the width of the specimen in ten places, at least 1 ft [300 mm] apart, to the nearest 1/32 in. [1.0 mm]. Record each measurement.

10.6 *Calculation of Results*:

10.6.1 Determine the maximum and minimum widths. Calculate the average width.

10.6.2 Determine the difference between the maximum and minimum width by subtraction.

10.7 *Report*:

10.7.1 Report the average width, and the difference between the maximum and minimum width.

10.8 *Precision and Bias*:

[7] Deep Petri dishes and 250 mL beakers have been found suitable for this purpose.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.8.1 Precision and bias of this test method have not been determined.

11. Thickness

11.1 *Significance and Use*:

11.1.1 This test method is used to determine the average thickness of joint tape. The degree of correlation between this test and service performance has not been determined.

11.2 *Sampling*:

11.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

11.3 *Specimen Preparation*:

11.3.1 Cut a specimen of tape not less than 12 ft [3.5 m] long from the roll to be tested.

11.3.2 Condition the specimen for a minimum of 24 h as described in Practice D 685.

11.4 *Apparatus*:

11.4.1 *Paper Micrometer* having circular faces of 0.25 to 0.33 in.^{2} [160 to 215 mm^2] in area. Faces shall be under steady pressure of 7 to 9 psi [50 to 60 kPa].

NOTE 5—For details see TAPPI T 411, except waive Section 7.

11.5 *Procedure*:

11.5.1 Measure the thickness of the specimen in 10 places, between the edges, at least 1 ft [300 mm] apart. Skived areas on the tape edges shall not be included in the area measured for thickness.

NOTE 6—Skiving is not present on all tapes.

11.5.2 Record the thickness to the nearest 0.001 in. [0.01 mm].

11.6 *Report*:

11.6.1 Report the average thickness.

11.7 *Precision and Bias*:

11.7.1 Precision as reported in the TAPPI Standard T 411 states that the within-laboratory repeatability is 1.25 % and the laboratory reproducibility is 5.50 %.

PAPER JOINT TAPE

12. Dimensional Stability

12.1 *Significance and Use*:

12.1.1 This test method is used to determine the lengthwise and crosswise expansion characteristics of the paper joint tape used to reinforce the joints created in gypsum wallboard construction. The degree of correlation between this test and service performance has not been determined.

12.2 *Sampling*:

12.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

12.3 *Specimen Preparation*:

12.3.1 Cut not less than three specimens of tape 10 to 16 in. [250 to 400 mm] long from the roll to be tested.

12.3.2 Condition the specimens for a minimum of 16 h at 72 ± 4 °F [22 ± 2 °C] and 50 ± 2 % relative humidity.

12.4 *Apparatus*:

12.4.1 *Steel Rule, Caliper Rule, Cathetometer* or other measuring device capable of resolving 0.005 in. over a minimum span of 10 in. A metric rule must be capable of resolving 0.10 mm over a minimum span of 250 mm.

12.4.2 *Sharp Knife, 4 to 5× Magnifying Glass, Pencil*.

12.4.3 *Glass Container* at least 2½ in. [65 mm] deep and 6 in. [150 mm] in diameter.

12.5 *Reagents and Materials*:

12.5.1 *Water*, distilled or deionized.

12.6 *Procedure*:

12.6.1 Place the conditioned specimens on a flat surface.

12.6.1.1 At about ½ in. [10 mm] from each end of the paper tape, cut two ½ in. [10 mm] long reference marks for the length-wise measurement crosswise of the tape with a sharp knife.

12.6.1.2 Place the rule on the tape so that one edge is centered lengthwise.

12.6.2 Move the rule so that starting mark (A) coincides with the reference mark at one end of the tape. Record the value at A. Take the reading at the other reference mark. Read to the nearest 0.005 in. [0.10 mm]. (See Fig. 3).

NOTE 7—Measuring from the 1 in. [25 mm] mark and subtracting this value may be a useful method to obtain an accurate measurement. Reading the rule with a magnifying glass of 4 to 5× is recommended.

12.6.3 Place the rule across the width of the tape.

12.6.3.1 Align the starting mark (B) of the rule with one edge of the tape. Record the value at B.

12.6.3.2 Take the reading at the opposite edge of the tape. Mark the location of this crosswise measurement by drawing a 1½ in. [40 mm] long pencil mark across the tape without marring the edges of the tape. (See Fig. 4.)

12.6.4 Roll up the tape and submerge it in the container full of water at 72 ± 4 °F [22 ± 2 °C].

12.6.5 After 30 min, remove the tape from the water and roll it out on the flat surface. Repeat the lengthwise and crosswise measurements.

12.7 *Calculation of Results*:

12.7.1 Subtract A from the reading obtained in 12.6.2 and record as the dry length of the tape at this point.

12.7.2 Subtract B from the reading obtained in 12.6.3.2 and record as the dry width of the tape at this point.

12.7.3 Determine the amount of expansion by subtracting the original measurement from the final measurement. Divide the expansion in inches (millimetres) by the original reading and multiply by 100 to obtain the percentage expansion.

$$\% \text{ Expansion} = \frac{(\text{Wet Measurement} - \text{Dry Measurement})}{\text{Dry Measurement}} \times 100 \quad (4)$$

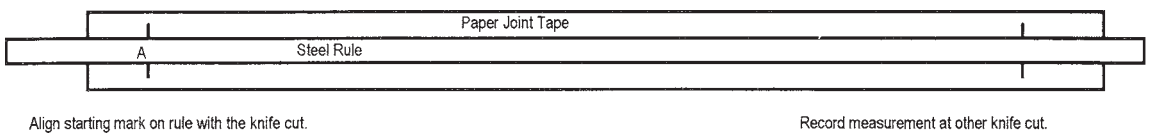

FIG. 3 Arrangement for Length Expansion Measurement

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

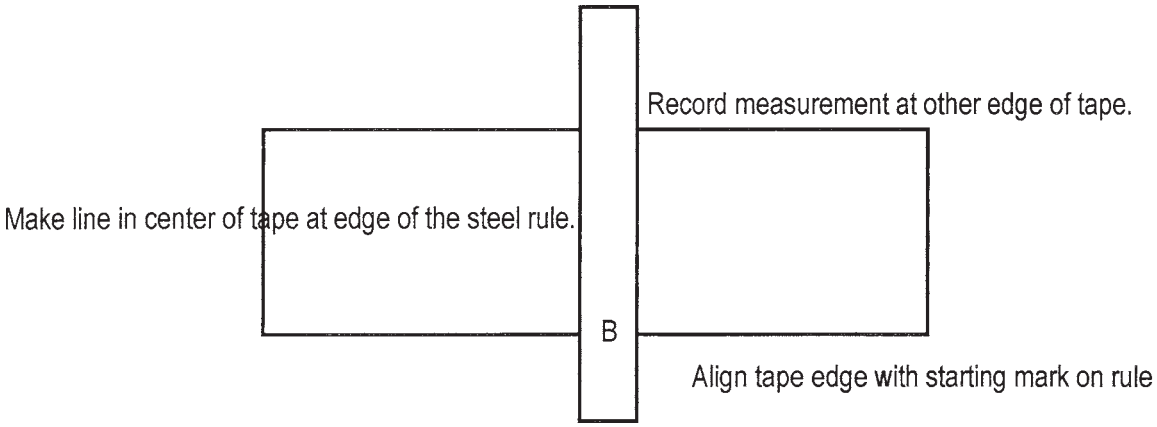

FIG. 4 Arrangement for Width Expansion Measurement

12.8 *Report*:

12.8.1 Report test results as percent expansion in the lengthwise and crosswise directions.

12.9 *Precision and Bias*:

12.9.1 Precision and bias of this test method have not been determined.

GLASS-MESH JOINT TAPE

13. Skewness

13.1 The skewness of the warp and fill yarns shall be tested in accordance with Test Method D 3882.

ASSEMBLAGES OF JOINT TAPE AND JOINT COMPOUND

14. Cracking of Joint Compound at Tape Edges

14.1 *Significance and Use*:

14.1.1 This test method is used to determine the adhesion of the joint compound to the edges of the joint tape. The degree of correlation between this test and service performance has not been determined.

14.2 *Sampling*:

14.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

14.3 *Specimen Preparation*:

14.3.1 Select specimens of joint tape in accordance with 9.2.2.

14.3.2 Cut specimens of joint tape into not less than 12 in. [300 mm] specimens.

14.3.3 Prepare specimens of joint compound in accordance with Section 4, except use a quantity of 200 g.

14.4 *Apparatus*:

14.4.1 *Feeler Gage Strips*, two required for each test, each 12-in. [300 mm] long, ½ in. [13 mm] wide, 0.040 in. [1 mm] thick.

14.4.2 *Steel-Reinforced Broad Knife*, see 15.4.2.

14.4.3 *Gypsum Wallboard*, Specification C 1396/C 1396M (See 7.4.3.1), approximately 6 by 12 in. [150 by 300 mm].

14.4.4 *Electric Fan*, in accordance with 7.4.4.

14.5 *Procedure*:

14.5.1 Place the two feeler gage strips on the face of the wallboard about 4 in. [100 mm] apart.

14.5.2 Fill the space between the feeler gage strips with joint compound specimen and level to the thickness of the feeler gage strips.

14.5.3 After leveling to the correct thickness, center a specimen of joint tape between the feeler gage strips.

14.5.3.1 Using the steel-reinforced broad knife at about a 45° angle, press the tape specimen firmly into contact with the joint compound.

14.5.3.2 Use a final flat stroke of the knife to smooth the joint compound on both sides of the tape. Do not press so hard that the joint compound will be squeezed out from under the tape, but hard enough so that the tape is in full contact with the joint compound.

14.5.4 Remove the feeler gage strips.

14.5.5 Place this assembly in front of the electric fan blowing a current of air over the surface of the assembly. Maintain a current of air at 100 ± 5 °F [38 ± 2 °C] and 25 ± 5 % relative humidity.

14.5.5.1 Alternatively, in very dry air (under 20 % relative humidity) at temperatures between 75 and 90 °F [24 to 32 °C] just allow the electric fan to blow a current of air over the surface.

14.5.6 After 1 h, examine the assembly for cracks along the edges of the tape with a magnifying glass of 4 to 5×.

14.6 *Calculation of Results*:

14.6.1 Measure the total length of any cracking at the edge of the joint tape and joint compound.

14.6.2 Divide the total length of cracked edges by the total length of the edges exposed and multiply 100 to obtain percent of cracked edge.

14.7 *Report*:

14.7.1 Report the percentage of cracking along the edges of the tape.

14.8 *Precision and Bias*:

14.8.1 Precision and bias of this test method have not been determined.

15. Bond of Paper Joint Tape to Joint Compound

15.1 *Significance and Use*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:20 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

15.1.1 This test method is used to determine the bonding properties of the paper joint tape. The degree of correlation between this test and service performance has not been determined.

15.2 *Sampling*:

15.2.1 Sampling shall be in accordance with Specification C 475/C 475M.

15.3 *Specimen Preparation*:

15.3.1 Select specimens of paper joint tape in accordance with 9.2.2.

15.3.2 Cut specimens of paper joint tape into at least 12 in. [300 mm] specimens for use in test.

15.3.3 Prepare specimens of joint compound in accordance with Section 4, except use a quantity of 200 g.

15.4 *Apparatus*:

15.4.1 *Feeler Gage Strips* (two required for each test), each 12 in. [300 mm] long, ½ in. [14 mm] wide, 0.025 in. [0.64 mm] thick with a small hole drilled in one end.

15.4.2 *Steel-Reinforced Broad Knife*, in accordance with 6.4.6.

15.4.3 *Gypsum Wallboard*, Specification C 1396/C 1396M (See 7.4.3.1), two pieces, 6 by 14 in. [150 by 350 mm] with the 14-in. [350-mm] length in the machine direction of the paper.

15.4.4 *Overlay Transparency Grid*—A transparent photo copy of 10 by 10 divisions/in. graph paper. An area 2 by 5 in. [50 by 125 mm] enclosing 1000 square divisions is outlined.

15.5 *Procedure*:

15.5.1 Place two feeler gage strips parallel to each other about 4 in. [100 mm] apart and fasten to the face of the gypsum wallboard with a thumb tack through the hole in the end.

15.5.2 Using the steel reinforced broad knife, apply an amount of joint compound sufficient to cover the area between the feeler gage strips. Spread the specimen evenly between the feeler gage strips leaving the specimen slightly thicker than the strips.

15.5.3 Center a 12-in. [300-mm] length of the paper tape in the specimen. Press one end of the tape into the specimen and hold it in place.

15.5.4 Embed the tape by applying two or three pressure strokes with the steel-reinforced broad knife. Wipe away from the end being held so the excess joint compound is squeezed out.

NOTE 8—The thickness of the joint compound plus the tape is about 0.025 in. [0.64 mm].

15.5.4.1 Carefully remove the feeler gages before drying.

15.5.5 Allow the test assembly to dry to constant weight in an atmosphere of 75 ± 5 °F [24 ± 2 °C] and 50 ± 5 % relative humidity.

15.5.6 When the test assembly is dry, use a sharp knife to make a cut across and perpendicular to the tape 3½ in. [90 mm] from one end. Make a second cut 5 in. [140 mm] from and parallel to the first cut. Make two diagonal cuts across the tape connecting the opposite corners of the 5-in. [140 mm] section. With the tip of the knife, peel back the tabs formed by the "X" cuts and pull up sharply.

15.5.6.1 Make a second test by repeating 15.5.6 below the first test.

15.5.7 Using a sharp pencil, lightly outline the areas where fiber remains attached to the compound. Align the overlay transparency grid so that the grid outline matches the 2 by 5-in. [50 by 125-mm] sides of the tape bond area.

15.6 *Calculation of Results*:

15.6.1 Using the overlay transparency grid, count the number of squares that are more than half bare of fiber separated from the tape and outlined by pencil.

15.6.2 Subtract this number from 1000 and divide by 10 to determine the percent bond. Record the average of the two tests.

15.7 *Report*:

15.7.1 Report the average percent bond failure.

15.8 *Precision and Bias*:

15.8.1 Precision and bias of this test method have not been determined.

16.1 bond of tape; cracking; glass-mesh joint tape; joint compound; joint tape; joint treatment; paper joint tape; putrefaction; shrinkage; tensile strength; topping compound; viscosity

APPENDIX

(Nonmandatory Information)

X1. TEST METHOD FOR EVALUATING TENSILE PROPERTIES OF GYPSUM PANEL JOINTS

X1.1 *Introduction:*

X1.1.1 ASTM standards do not include a method to determine the strength of a joint between pieces of panel products. After significant investigation, the following procedure is proposed to evaluate reinforced gypsum panel product joints. This method is intended for use with any joint compound or tape intended for use as a joint reinforcement in construction of gypsum panel product systems in accordance with Specification C 840. Forward any comments relating to the suitability of this procedure to Technical Committee C11 for review.

X1.2 *Significance and Use:*

X1.2.1 This procedure is used to determine the tensile strength of the joint created by an assemblage of joint

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:20 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

compound and joint tape. The degree of correlation between this test and service performance has not been determined.

X1.3 *Sampling:*

X1.3.1 Sampling shall be in accordance with Specification C 475/C 475M, except the number of specimens prepared shall be as shown.

X1.3.2 *Number of Specimens Required*

The number of specimens required for 5 % accuracy with 95 % confidence on the mean, assuming the set in question is a population, is calculated as follows:

$$n = (tv/A)^2 \quad \text{(X1.1)}$$

where:

n = number of samples required
t = student t distribution for 95 % confidence. t_∞= 1.645 for n>30
σ = population standard deviation
μ = population mean
v = coefficient of variation = % standard deviation = σ/μ*100
A = value of the allowable variation (that is, A = 0.05 for 5 % variation)

Without proper historical data for A, set n at 18 samples until such data is achieved.

X1.4 *Apparatus:*

X1.4.1 *Materials Required To Create the Standard Substrate*:

X1.4.1.1 High-density polyethylene plastic ½ in. [12.7 mm] thick,

X1.4.1.2 Jigsaw or table saw with blade suitable for cutting plastic,

X1.4.1.3 Router table with straight edging bit,

X1.4.1.4 Orbital sander with 60-grit sandpaper,

X1.4.1.5 Drill press with ½ in. [12.7 mm] drill bit,

X1.4.1.6 Six ¼ in. by 16 in. by 20 in. [6 mm by 400 mm by 500 mm] aluminum trays, and

X1.4.1.7 Ruler and fine-tip permanent ink marker.

X1.4.2 *Materials Required for Preparation of the Reinforced Joint*:

X1.4.2.1 Joint tape roll (of required tape or style),

X1.4.2.2 Two 20 in. by 1 in. by 0.030 in. [500 mm by 25 mm by 0.76 mm] thick stainless steel spacers,

X1.4.2.3 Two 20 in. by 1 in. by 0.045 in. [500 mm by 25 mm by 1.14 mm] thick stainless steel spacers,

X1.4.2.4 Two 20 in. by 1 in. by 0.055 in. [500 mm by 25 mm by 1.40 mm] thick stainless steel spacers,

X1.4.2.5 Six in. [150 mm] finishing trowel,

X1.4.2.6 Two 4 in. [100 mm] putty knife,

X1.4.2.7 Ruler,

X1.4.2.8 Fine-tip permanent ink marker,

X1.4.2.9 Joint compound, ready-mix or powder prepared in accordance with Test Methods C 474,

X1.4.2.10 One in. [25 mm] masking tape,

X1.4.2.11 Razor knife,

X1.4.2.12 Sanding block with 320-grit sandpaper,

X1.4.2.13 High-purity air-drying conductive silver paint, and

X1.4.2.14 Test circuit: 9 V battery, light-emitting diode, 27 KΩ resistor, wires, and breadboard.

X1.4.3 *Tensile Test Machine*:

X1.4.3.1 A tensiometer, universal test machine, or other suitable device capable of being operated at test speeds of 0.04 in. per min [1.0 mm per min] and 0.4 in. per min [10.0 mm per min].

X1.4.3.2 *Load Cell*—Installed in the load train of the test machine. It shall have a capacity such that the crack and peak values fall within 20 % to 80 % of its stated capacity.

X1.4.3.3 *Specimen Tensile Jaws/Grips*—Installed in the tensiometer. They shall be as illustrated in Fig. X1.1 and Fig. X1.2, or a similar device capable of isolating the joint face along the center line of the apparatus.

NOTE X1.1—Alternately, if the special "eccentric" grips are not available, conventional grips that open greater than 1 in. [25 mm] can be used, provided that ½ in. [13 mm] spacers are used to isolate the joint face along the center line.

X1.4.3.4 *Data Acquisition*—The load-versus-extension data shall be acquired by mechanical or electronic means. The data may be captured electronically by data acquisition equipment or mechanically with a chart recorder, either X-Y or strip chart styles. If using a mechanical method, ensure that the plotting parameters (that is, load range and proportion) are such that the maximum load falls between 30 % and 90 % of the chart paper range.

X1.4.4 Eighteen 6 in. [150 mm] wide prepared joints.

X1.5 *Preparation of the Substrate:*

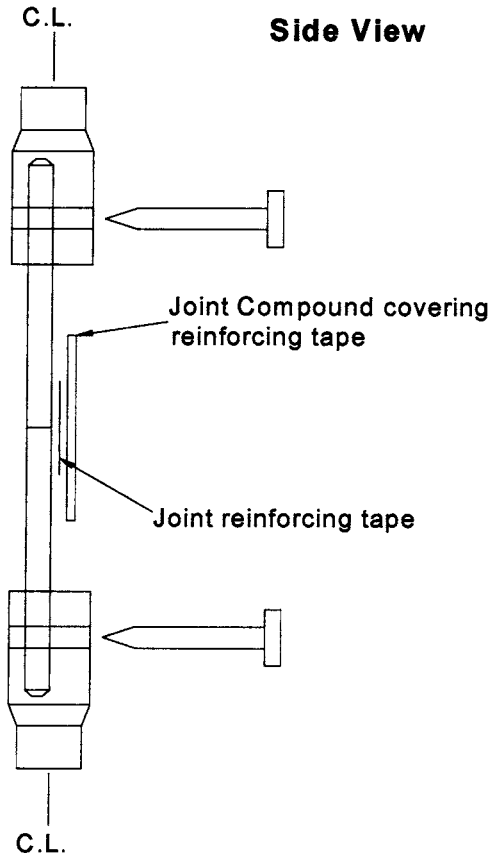

FIG. X1.1 Side View of Test Specimen and Tensile Jaw/Grips

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:20 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

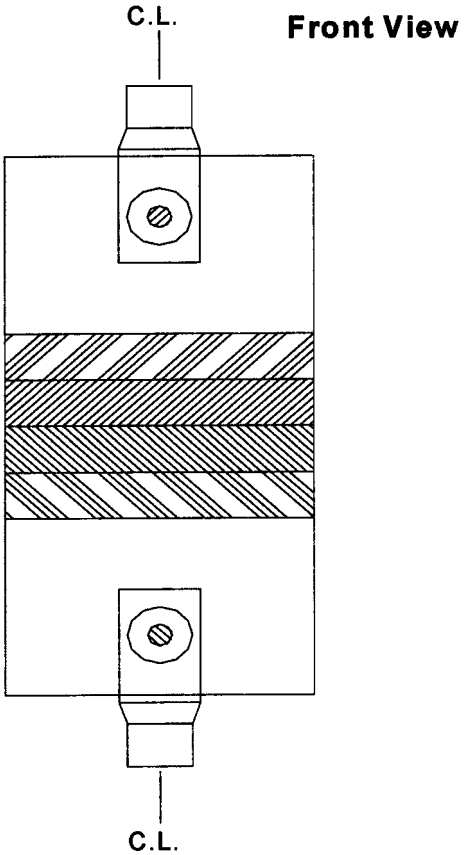

FIG. X1.2 Front View of Test Specimen and Tensile Jaw/Grips

X1.5.1 Sand one surface of high-density polyethylene plastic sheets with the orbital sander loaded with 60-grit sandpaper. Use average pressure and a circular motion to abrade the surface so that the shiny look of the unsanded plastic is completely gone.

X1.5.2 Cut plastic sheets into 6 ¼ in. by 6 ¼ in. [160 mm by 160 mm] pieces. Thirty-six pieces are required for one joint set of 18 samples.

X1.5.3 Set router guide to 6 ⅛ in. [155 mm] and pass each sample through, smoothing one edge of each piece. Send each piece through again, only smoothing the edge perpendicular to the one done previously.

X1.5.4 Set router guide to 6 in. [150 mm] and repeat previous step, but smooth the two remaining unfinished edges.

X1.5.5 Resand the surface of each finished piece to get rid of irregularities caused by cutting and smoothing.

X1.5.6 On each piece, drill a ½ in. [12.7 mm] hole 5 in. [125 mm] from the bottom edge, and 3 in. [75 mm] from either side edge. Also, place an index mark using a fine marker on either side of each piece, 2 in. [50 mm] from the sanded edge. See Fig. X1.3.

X1.6 *Preparation of the Joint Set:*

X1.6.1 Match up the substrate pieces by twos, with sanded faces down. Push one piece to the other and tape the joint tightly using masking tape. Repeat this with remaining 17 pairs.

X1.6.2 Trim excess tape and set three taped pairs on each aluminum tray, with sanded faces up. Maneuver the samples to ensure the joints are aligned. Place a stirp of masking tape across either side of the samples (parallel to the joint), covering the drill holes and securing one sample to another.

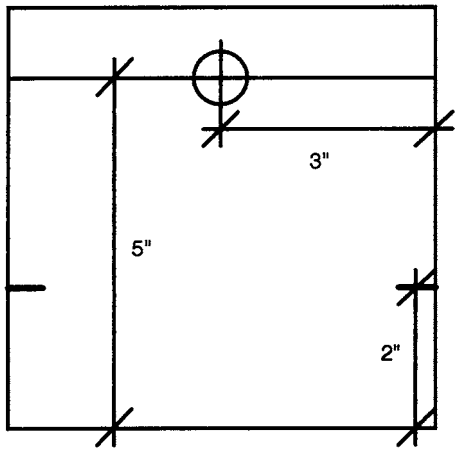

FIG. X1.3 Placement of Drill Hole in Plastic Substrate

X1.6.3 *Applying Glass Mesh Tape and First Coat*:

X1.6.3.1 Apply glass mesh tape centered on joint across the three samples on each tray, and press onto the substrate firmly, ensuring a flat, even adhesion. Trim excess tape.

X1.6.3.2 Set the 0.030 in. [0.76 mm] spacers on the 2 in. [50 mm] marks on either side of the joint. Apply compound to the joint, working it through the tape. Apply more compound, using the guides to estimate when enough compound has been used.

X1.6.3.3 Lightly wet one edge of the trowel. Set the trowel at a 45° angle to the surface of the samples, and smooth along the spacers in two even strokes. Remove any excess compound on the trowel and do one more pass with the trowel set at a 90° angle to the surface of the samples, to finish.

X1.6.3.4 Remove the spacers and any excess compound on the samples. Let samples dry overnight.

X1.6.3.5 Repeat steps for the remaining trays.

X1.6.4 *Applying Paper Tape and First Coat*:

X1.6.4.1 Set the 0.055 in. [1.4 mm] spacers on the 2 in. [100 mm] marks on either side of the joint. Apply general purpose compound to the joint, using the guides to estimate when enough compound has been used.

X1.6.4.2 Lightly wet one edge of the trowel. Set the trowel on a 45° angle to the surface of the samples, and smooth along the spacers in two even strokes. Remove any excess compound on the trowel and make one more pass with the trowel set at a 90° angle to the surface of the samples.

X1.6.4.3 Cut a length of selected paper tape slightly longer than the samples on the tray, and gently place the paper tape centered on the joint.

X1.6.4.4 Change spacers to the 0.030 in. [0.76 mm] spacers. Apply a small amount of compound to the working edge of the trowel and work the tape into the compound with the trowel at 45° as in X1.6.4.2, but use no water. This step ensures that the tape is at a level of 0.030 in. above the substrate.

X1.6.4.5 Repeat steps for the remaining trays.

X1.6.5 *Applying Second Coat*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:20 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X1.6.5.1 Second coat is to be applied on the day following the application of the first coat (that is, allow a 24-h cure for the first coat).

X1.6.5.2 Set the 0.045 in. [1.14 mm] spacers on either side of the joint. Apply compound to the joint, using the guides to estimate when enough compound has been used.

X1.6.5.3 Lightly wet one edge of the trowel. Set the trowel at a 45° angle to the surface of the samples, and smooth along the spacers in two even strokes. Remove any excess compound on the trowel and do one more pass with the trowel set at a 90° angle to the surface of the samples.

X1.6.6 *Applying Conductive Paint*:

X1.6.6.1 Lightly sand the joint surface with a 320-grit sanding block to smooth out any superficial irregularities.

X1.6.6.2 Apply conductive paint no sooner than one day after the application of the second coat (that is, allow a minimum 24-h cure for the second coat) and no later than 24 h before tensile testing.

X1.6.6.3 Using a razor knife, score the compound between the samples to separate them from one another. Also, trim any excess compound from the ends of each sample to ensure a 6 in. [150 mm] joint length.

X1.6.6.4 Shake the bottle of silver conductive paint to ensure uniform consistency. Draw a trace in conductive paint over the test area as shown in Fig. X1.4. Extend the trace at least 0.4 in. [10 mm] from the centerline, and have a spacing of 0.4 in. [10 mm]. The thickness of the trace should not exceed 0.08 in. [2 mm]. At each end of the trace, paint an excess amount as a "pad" for attaching the circuit.

X1.6.7 *Test Circuit*:

X1.6.7.1 Connect the battery, LED, and resistor in series, leaving two long wires to attach to the test trace "pads" (see Fig. X1.5). The resistor is included to save battery life, and the resistance may be reduced if a brighter light is desired.

X1.6.8 *Curing Time*:

X1.6.8.1 Cure prepared samples for six days following the application of the second coat in a room or cabinet at a temperature of 70 ± 3.5 °F [21 ± 2 °C] and relative humidity of 50 ± 2 %. The total time from sample preparation and curing to testing is seven days.

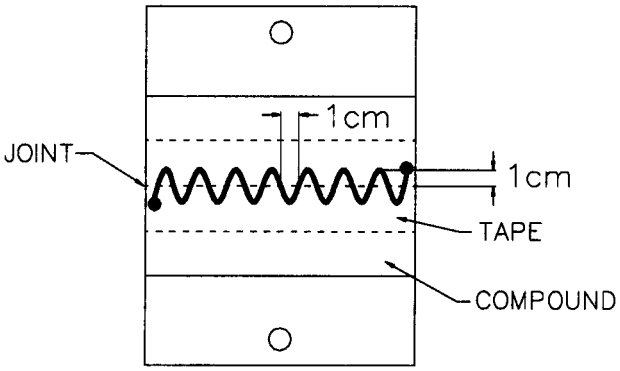

FIG. X1.4 Conductive Paint Trace

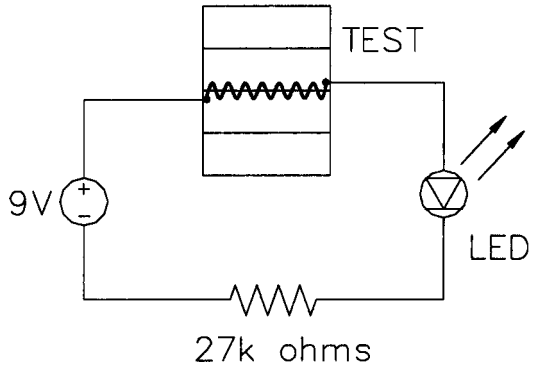

FIG. X1.5 Test Circuit Schematic

X1.7 *Tensile Testing:*

X1.7.1 Use extreme care while handling the samples, as cracking at the joint may occur, rendering the sample invalid.

X1.7.2 Use the tensiometer with a load cell having limits such that the crack and peak values fall within 20 % to 80 % of its capacity. Use plotting parameters (that is, load range and proportion) to ensure that the maximum load falls between 30 % and 90 % of the chart paper range. Set the speed of testing to 0.04 in. per min [1.0 mm per min] until first visible crack, then 0.4 in. per min [10 mm per min] until joint failure occurs.

X1.7.3 Load a sample by placing the pins in the loading apparatus through the drilled holes in the sample. Connect the trace into the circuit by taping the free wires to each end of the conductive paint line. This completes the circuit, illuminating the LED. Place a 10 lbf [50 N] preload on the sample by jogging the crosshead up slightly.

X1.7.4 Start the machine at 0.04 in. per min [1 mm per min] and note first crack at circuit failure when the LED deactivates. Increase the speed to 0.4 in. per min [10 mm per min] until failure of the joint occurs. Repeat these steps until all samples have been tested.

X1.8 *Report:*

X1.8.1 In all reports, a description of the preparation, conditioning, and testing conditions is necessary.

X1.8.2 Set up all data in a tabular format. Include the following information in the table, along with the corresponding standard deviation values:

X1.8.2.1 Force at first cracking (at circuit failure) in pounds-force (Newtons),

X1.8.2.2 Extension at first cracking (at circuit failure) in inches (millimeters),

X1.8.2.3 Force at peak load in pounds-force (Newtons), and

X1.8.2.4 Extension at peak load in inches (millimeters).

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this test method since the last issue, C 474 – 02, that may impact the use of this test method. (Approved January 1, 2005)

(*1*) Section 15, which contained test methods specifically applicable to glass-mesh tape, has been moved and renumbered as Section 13. No content was changed.

(*2*) The title of the sections applicable to assemblages of tape has been renamed to ASSEMBLAGES OF JOINT TAPE AND JOINT COMPOUND to indicate that there are some test methods applicable to paper and glass-mesh joint tapes.

(*3*) Section 14, which contained a test method to evaluate Cracking of Joint Compound at Tape Edges, has been moved so that it immediately follows the heading referenced in item change (*2*). Instructions that contain the word "paper" as a modifier for joint tape were changed to have the word "paper" removed to indicate that the method is applicable to paper and glass-mesh joint tape.

(*4*) The information formerly in Section 13 has been moved to Section 15. The word "paper" in the section title indicates that it is applicable only to paper joint tape.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 475/C 475M – 02 (Reapproved 2007)

Standard Specification for Joint Compound and Joint Tape for Finishing Gypsum Board [1]

This standard is issued under the fixed designation C 475/C 475M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers all-purpose, taping and finishing joint compounds, paper joint tape and glass-mesh joint tape.

1.1.1 The joint materials used in this standard are designed to be used with gypsum board installed in accordance with Specification C 840.

1.2 This specification also covers the minimum requirements for an assembly of taping and all-purpose compound and joint tape.

1.3 The text of this specification references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.4 The values stated in either inch-pound or SI (metric) units are to be regarded separately as standard. Within the text, the SI units are shown in parentheses. The values stated in each system shall be used independent of the other. Values from the two systems shall not be combined.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 474 Test Methods for Joint Treatment Materials for Gypsum Board Construction

C 840 Specification for Application and Finishing of Gypsum Board

D 123 Terminology Relating to Textiles

D 3382 Test Methods for Measurement of Energy and Integrated Charge Transfer Due to Partial Discharges (Corona) Using Bridge Techniques

F 1615 Specification for Cautionary Labeling for Five-Gallon Open-Head Plastic Containers

3. Terminology

3.1 *Definitions*—Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *glass-mesh joint-tape*, *n*—a strip of multidirectional glass yarn material designed to reinforce the joint between two gypsum boards.

3.2.2 *joint tape*, *n*—a strip of material used to conceal and reinforce the joint between two gypsum boards.

3.2.3 *joint tape, self-adhering*, *n*—a joint tape manufactured to adhere directly to the substrate.

3.2.3.1 *Discussion*—Tapes having this quality do not require mechanical or embedment means of attachment to the substrate.

3.2.4 *paper joint tape*, *n*—a strip of paper reinforcing material designed to be embedded in the joint compound and to reinforce the joint between two gypsum boards.

3.2.5 *skewness*, *n*—as defined in Terminology D 123.

4. Physical Properties

4.1 *General*—The physical properties shall be determined in accordance with Test Methods C 474, except as noted.

4.2 *Joint Compounds*.

4.2.1 *Check Cracking*—No cracks in the thinner half of the wedge and no deep fissure cracks in the thicker half of the wedge.

4.2.2 *Putrefaction*—No putrefaction in less than 4 days.

4.2.3 *Shrinkage*—Not more than 35 % by volume.

4.3 *Joint Tape*—The following tests are required of all joint tape:

4.3.1 *Width*—Shall be not less than 1⅞ in. (48 mm) nor more than 2¼ in. (60 mm). The width of an individual roll shall vary not more than ±1⁄32 in. (1 mm).

4.3.2 *Thickness*—Shall be not more than 0.012 in. (0.30 mm).

4.3.3 *Tensile Strength*—Shall be not less than 30 lbf/in. (5.25 N/mm) in the cross direction.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved June 1, 2007. Published October 2007. Originally approved in 1961. Last previous edition approved in 2002 as C 475 – 02.

www.technobetar.ir

4.4 The following tests are required of paper joint tape:

4.4.1 *Dimensional Stability*—Shall expand not more than 0.4 % lengthwise and not more than 2.5 % crosswise.

4.4.2 *Assembly of Taping or All-Purpose Compound and Joint Tape*:

4.4.2.1 *Bond* between the joint tape and the joint compound shall be not less than 90 %.

4.4.2.2 *Edge Cracking* shall be not more than 10 % along the edges of the tape specimen.

4.5 The following test is required of glass-mesh joint tape:

4.5.1 *Skewness*, when tested in accordance with Test Method D 3882, shall be not more than 8.75 %.

5. Sampling

5.1 *Sampling of Joint Compound*—At least 1 %, but not less than one package or container shall be sampled and shall be so selected as to be representative of the shipment. The material so obtained shall be thoroughly blended and divided. Provide not less than one 6-lb (2.75-kg) sample for the test.

5.2 *Sampling of Joint Tape*—At least one roll for every ten cases or a fraction thereof, but not more than ten rolls per shipment shall constitute a sample.

6. Inspection

6.1 Inspection of the joint compound and joint tape shall be agreed upon between the purchaser and the supplier as part of the purchase agreement.

7. Rejection

7.1 Rejection of joint compound and joint tape that fails to conform to requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the joint compound or joint tape has failed to conform to the requirements of this specification.

8. Certification

8.1 When specified in the purchase agreement, a producer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

9. Packaging and Package Marking

9.1 Joint compound and joint tape shall be marked on each item or package with the name, brand or trademark of the manufacturer or seller, size, and volume or net weight of contents.

9.2 Joint compound packaged in 3-½ through 6-½ gal (U.S. liquid) (13 through 25 L) open-head pails shall be labeled in accordance with Specification F 1615.

10. Keywords

10.1 all-purpose compound; bond; check cracking; dimensional stability; edge cracking; finishing compound; glass-mesh joint tape; joint compound; joint tape; paper joint tape; putrefaction; shrinkage; taping compound; tensile strength; topping compound

Designation: C490/C490M – 09

Standard Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete[1]

This standard is issued under the fixed designation C490/C490M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers the requirements for the apparatus and equipment used to prepare specimens for the determination of length change in hardened cement paste, mortar, and concrete, the apparatus and equipment used for the determination of these length changes, and the procedures for its use.

1.2 Methods for the preparation and curing of test specimens, conditions of testing and curing, and detailed procedures for calculating and reporting test results are contained in applicable test methods.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

3. Terminology

3.1 *length change*—an increase or decrease in the linear dimension of a test specimen, measured along the longitudinal axis, due to causes other than applied load.

4. Significance and Use

4.1 This practice is intended to provide standard requirements for apparatus common to many test methods used in connection with cement and concrete and standardized procedures for its use. The detailed requirements as to materials, mixtures, specimens, conditioning of specimens, number of specimens, ages at which measurements are to be made, interpretation of results, and precision and bias are left to be dealt with in specific test methods.

5. Apparatus

5.1 *Reference Masses and Devices for Determining Mass and Volume*, shall conform to the requirements of Specification C1005.

5.2 *Molds*, shall have either one or two compartments and shall be constructed as shown in Fig. 1 or Fig. 2. Molds for test specimens used in determining the length change of cement pastes and mortars shall provide for 25 by 25 by 285-mm prisms having a 250-mm gauge length, or for 1 by 1 by 11¼ –in. prisms having a 10–in. gauge length. Molds for test specimens used in the length change of concretes shall provide for prisms of the desired cross section having a 10-in. or 250-mm gauge length. In some routine tests, 25 by 25 by 160-mm specimens with a gauge length of 125 mm, or 1 by 1 by 6¼ –in. specimens with a gauge length of 5-in. are permitted, but in case of dispute, results obtained with specimens of 250-mm [10-in.] gauge length shall govern.

5.2.1 The gauge length shall be considered as the nominal length between the innermost ends of the gauge studs. The parts of the molds shall be tight fitting and firmly held together when assembled, and their surfaces shall be smooth and free of pits. The molds shall be made of steel or other hard metal not readily attacked by the cement paste, mortar, or concrete. The sides of the molds shall be sufficiently rigid to prevent spreading or warping. For the molds shown in Fig. 1, the tolerance on dimension A is ±0.7 mm. For the molds shown in Fig. 2, the tolerance on dimension A is ±0.03 in.

5.2.2 Each end plate of the mold shall be equipped to hold properly in place, during the setting period, one of the gauge studs shown in Fig. 1 or Fig. 2. The gauge studs shall be of American Iron and Steel Institute (AISI)[3] Type 316 stainless steel or other corrosion-resistant metal of similar hardness.

[1] This practice is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.95 on Coordination of Standards.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 1962. Last previous edition approved in 2008 as C490 – 08. DOI: 10.1520/C0490_C0490M-09.

NOTE—Dimension A to be specified by the purchaser.

FIG. 1 Molds (SI Units)

Gauge studs of Invar or similar metal shall be used when specimens are tested at widely different temperatures. To prevent restraint of the gauge studs before demolding of the specimen, the device for holding the gauge studs in position shall be so arranged that, if necessary, it can be partially or completely released after the compaction of the paste or mortar into place in the mold. The gauge studs shall be set so that their principal axes coincide with the principal axis of the test specimen. For the molds shown in Fig. 1, gauge studs shall extend into the specimen 17.5 ± 0.5 mm and the distance between the inner ends of the gauge studs shall be 250.0 ± 2.5 mm and 250 mm shall be considered the gauge length for calculating length change. For the molds shown in Fig. 2, gauge studs shall extend into the specimen 0.625 ± 0.025 in. and the distance between the inner ends of the gauge studs shall be 10.00 ± 0.10 in. and 10 in. shall be considered the gauge length for calculating length change.

5.3 *Length Comparator*, for determining length change of specimens, shall be designed to accommodate the size of specimen employed and to provide or permit a positive means of contact with the gauge studs and the convenient and rapid obtaining of comparator readings (Note 1).

5.3.1 The comparator for determining length changes of specimens produced in the molds shown in Fig. 1 shall provide a dial micrometer or other measuring device graduated to read in 0.002-mm units or less, accurate within 0.002 mm in any 0.020-mm range, and within 0.004 mm in any 0.200-mm range, and sufficient range (at least 8.0 mm) in the measuring device to allow for small variations in the actual length of various specimens. The terminals of the comparator shall be plane, polished and heat-treated. They shall be fitted with collars held in place with set screws. The collars shall extend 1.5 ± 0.1 mm beyond the plane face of the terminal. The collars shall allow free rotation of the gauge stud tips that fit inside the collars and have an inside diameter no more than 0.5 mm larger than the average diameter of that portion of the gauge stud tips that fit into the collars.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

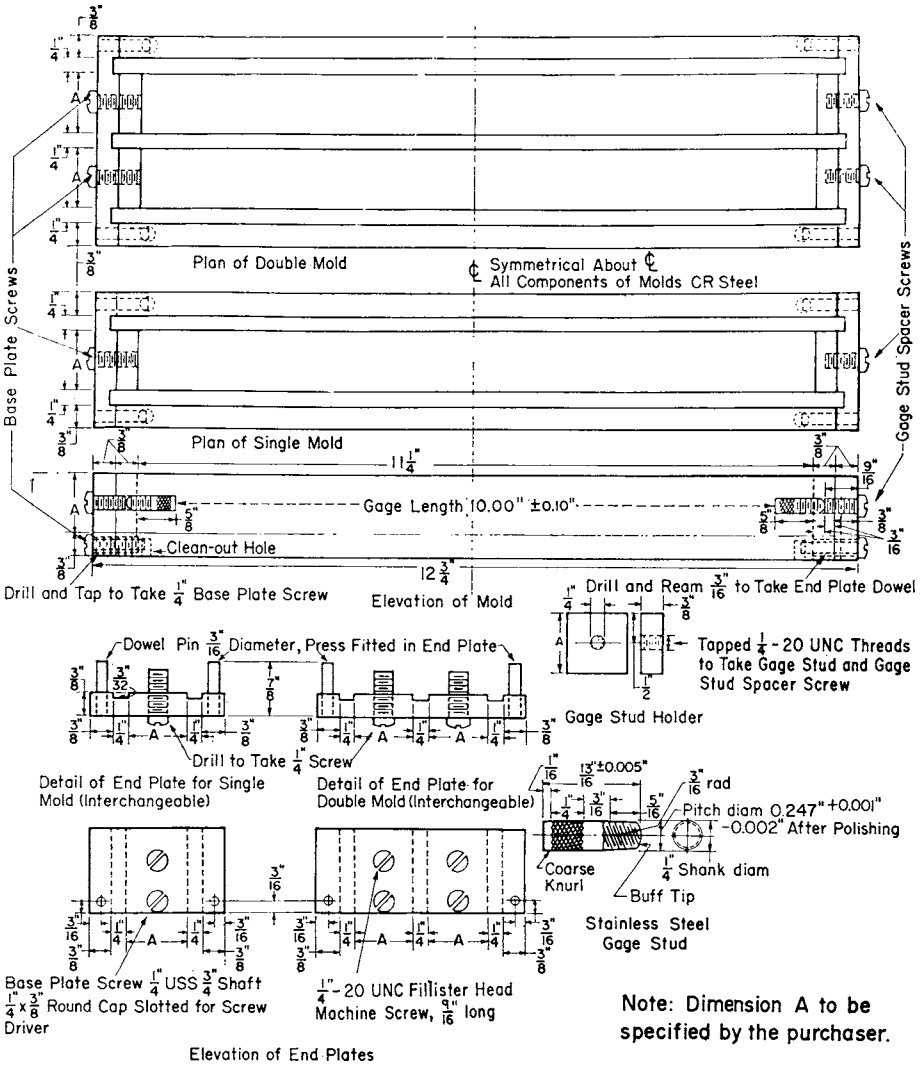

FIG. 2 Molds (Inch-Pound Units)

NOTE 1—One type of instrument that has been found satisfactory for use with small prisms is shown in Fig. 3. A horizontal comparator should be used with prisms with a cross section greater than 9 in.^{2} or 58 cm^2.

5.3.2 The comparator for determining length changes of specimens produced in the molds shown in Fig. 2 shall provide a dial micrometer or other measuring device graduated to read in 0.0001-in. units, accurate within 0.0001 in. in any 0.0010-in. range, and within 0.0002 in. in any 0.0100-in. range, and sufficient range (at least 0.3 in.) in the measuring device to allow for small variations in the actual length of various specimens. The terminals of the comparator shall be plane, polished and heat-treated. They shall be fitted with collars held in place with set screws. The collars shall extend 0.062 ± 0.003 in. beyond the plane face of the terminal. The collars shall allow free rotation of the gauge stud tips that fit inside the collars and have an inside diameter no more than 0.02 in. larger than the average diameter of that portion of the gauge stud tips that fit into the collars.

5.3.3 The design shall provide a means for checking the measuring device against a reference bar at regular intervals.

5.4 *Reference Bar*, shall have an overall length of 295 ± 3.0 mm or 170 ± 3.0 mm [11⅝ ± ⅛ in. or 6 ⅝ ± ⅛ in.], whichever is appropriate for the specimen in use. The bar shall be of a steel alloy having a coefficient of thermal expansion not greater than two millionths per degree Celsius. Each end of the reference bar shall be fitted with heat treated, hardened, and polished tips machined to the same shape as the contact end of the gauge studs used in test specimens. That portion of the bar that extends into the comparator's collar shall have a diameter of 6 ± 0.25 mm [0.250 ± 0.010 in.], and the length of that portion shall extend beyond the depth of the collar. Except for the tips, which are attached after heat treatment, no part of the reference bar shall be heat treated. The central 100 mm [4 in.] of the length of the reference bar shall be covered by a rubber tube with a wall at least 3 mm [⅛ in.] thick to minimize the effect of temperature change during handling. The reference bar shall be provided near one end with a positioning mark.

NOTE 2—Alloys such as invar lose their low coefficient of thermal expansion properties when heat treated.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

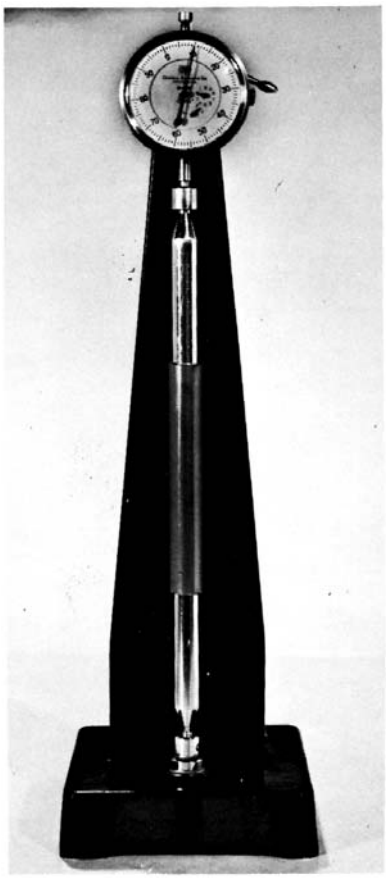

FIG. 3 Type of Suitable Apparatus for Measurement of Length Changes

5.5 Check and document the bar mold dimensions, gauge stud projection into the mold interior, length comparator, and length measuring device for conformance to the design and dimensional requirements of this specification at least every 2½ years.

6. Procedure

6.1 *Preparation of Molds*—Prior to the molding of specimens, the outside joints of the mold and the contact lines of the mold and base plate shall be sealed to prevent loss of mixing water from a freshly molded specimen. Thinly cover the interior surfaces of the mold with mineral oil. After this operation, set the gauge studs, taking care to keep them clean, and free of oil, grease, and foreign matter.

6.2 *Use of Reference Bar*—Place the reference bar in the instrument in the same position each time a comparator reading is taken. Check the dial gauge setting of the measuring device by use of the reference bar at least at the beginning and end of the readings made within a half day when the apparatus is kept in a room maintained at constant temperature. Check it more often when kept in a room where the temperature is not constant.

NOTE 3—The equation given in the section on calculation of length change contemplates that a comparator reading for the reference bar will be recorded each time the reference bar is used and a difference calculated for each test specimen reading. Alternatively, the dial gauge setting can be reset, if necessary, to its original setting with the reference bar in place each time the reference bar is read. Doing so simplifies the calculation of length change by canceling the comparator reading of the reference bar from the values of L_x and L_i. If this procedure is used, care should be taken to ensure that the dial set screw is tightened adequately each time the dial is reset.

6.3 *Obtaining Comparator Readings*—Rotate specimens slowly in the measuring instrument while the comparator reading is being taken. Record the minimum reading of the dial if the rotation causes a change in the dial reading. Place specimens in the instrument with the same end up each time a comparator reading is taken.

6.3.1 *Obtaining Comparator Readings of Specimens Stored Moist*—Clean the hole in the base of the comparator into which the gauge stud on the lower end of the bar fits (this hole tends to collect water and sand and should be cleaned after every reading). Read and record the comparator indication of the length of the reference bar. Take one bar out of immersion, blot the pins, put the bar in the comparator, read, and record the indication. Return the bar to immersion and clean the hole in the base of the comparator. Take out the second bar and treat it in a like manner. Return the second bar to immersion, record the reading, and clean the hole in the base of the comparator. Continue the procedure until all bars have been read, returned to immersion, and the readings recorded, cleaning the hole in the bottom of the comparator each time. After reading the last bar, clean the hole in the comparator base and read and record the reference-bar indication. Blot only around the pins (Note 4).

NOTE 4—The purpose of the minimal blotting of the pins and no blotting of the bars is to avoid drying and shrinkage of the bars. It has been observed that if the pins are blotted, and the bar placed in the comparator and the dial read, and the bar is then wiped gently with a dry cloth, the bar will shrink measurably. Therefore, drying should be minimized.

7. Calculation of Length Change

7.1 Calculate the length change at any age as follows:

$$L = \frac{(L_x - L_i)}{G} \times 100$$

where:

L = change in length at x age, %,
L_x = comparator reading of specimen at x age minus comparator reading of reference bar at x age; in millimetres when using Fig. 1 apparatus, in inches when using Fig. 2 apparatus,
L_i = initial comparator reading of specimen minus comparator reading of reference bar at that same time; in millimetres when using Fig. 1 apparatus, in inches when using Fig. 2 apparatus, and
G = nominal gauge length, 250 mm when using Fig. 1 apparatus, 10 in. when using Fig. 2 apparatus.

7.2 Calculate length change values for each specimen to the nearest 0.001 % and report averages to the nearest 0.01 %.

8. Temperature, Humidity, and Time

8.1 *Molding Room*—The temperature of the molding room and dry materials shall be maintained between 23.0 ± 4 °C. The relative humidity shall be not less than 50 %. The temperature of the mixing water shall be 23.0 ± 2.0 °C.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:24 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.2 *Moist Storage Facility*—The temperature and humidity of the air in the moist storage facility shall conform to the requirements of Specification C511.

8.3 *Time*—Comparator readings shall be taken at specified time intervals or ages. All intervals and ages shall be met within ±2 %.

9. Keywords

9.1 cement paste; comparator; concrete; length change apparatus; molds; mortar

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this practice since the last issue, C490 – 08, that may impact the use of this practice. (Approved December 1, 2009)

(*1*) Moved part of 5.3.3 into new 5.4 and renumbered subsequent paragraphs.

Committee C01 has identified the location of selected changes to this practice since the last issue, C490 – 07, that may impact the use of this practice. (Approved June 1, 2008)

(*1*) Editorially changed the designation to dual editorially to agree with the units statement in the Scope.

(*2*) Revised 5.3.1 and 5.3.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Designation: C494/C494M – 10

Standard Specification for Chemical Admixtures for Concrete[1]

This standard is issued under the fixed designation C494/C494M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers materials for use as chemical admixtures to be added to hydraulic-cement concrete mixtures in the field for the purpose or purposes indicated for the eight types as follows:

1.1.1 *Type A*—Water-reducing admixtures,

1.1.2 *Type B*—Retarding admixtures,

1.1.3 *Type C*—Accelerating admixtures,

1.1.4 *Type D*—Water-reducing and retarding admixtures,

1.1.5 *Type E*—Water-reducing and accelerating admixtures,

1.1.6 *Type F*—Water-reducing, high range admixtures,

1.1.7 *Type G*—Water-reducing, high range, and retarding admixtures, and

1.1.8 *Type S*—Specific performance admixtures.

1.2 This specification stipulates tests of an admixture with suitable concreting materials as described in 11.1-11.3 or with cement, pozzolan, aggregates, and an air-entraining admixture proposed for specific work (11.4). Unless specified otherwise by the purchaser, the tests shall be made using concreting materials as described in 11.1-11.3.

NOTE 1—It is recommended that, whenever practicable, tests be made using the cement, pozzolan, aggregates, air-entraining admixture, and the mixture proportions, batching sequence, and other physical conditions proposed for the specific work (11.4) because the specific effects produced by chemical admixtures may vary with the properties and proportions of the other ingredients of the concrete. For instance, Types F and G admixtures may exhibit much higher water reduction in concrete mixtures having higher cement factors than that listed in 12.1.1.

Mixtures having a high range water reduction generally display a higher rate of slump loss. When high-range admixtures are used to impart increased workability (6 to 8-in. slump [150 to 200–mm]), the effect may be of limited duration, reverting to the original slump in 30 to 60 min depending on factors normally affecting rate of slump loss. The use of chemical admixtures to produce high-slump (flowing) concrete is covered by Specification C1017/C1017M.

NOTE 2—The purchaser should ensure that the admixture supplied for use in the work is equivalent in composition to the admixture subjected to test under this specification (see Section 6, Uniformity and Equivalence).

NOTE 3—Admixtures that contain relatively large amounts of chloride may accelerate corrosion of prestressing steel. Compliance with the requirements of this specification does not constitute assurance of acceptability of the admixture for use in prestressed concrete.

1.3 This specification provides for three levels of testing.

1.3.1 *Level 1*—During the initial approval stage, proof of compliance with the performance requirements defined in Table 1 demonstrates that the admixture meets the requirements of this specification. Admixtures (except for Types B, C, E, and S) shall qualify for provisional compliance when the physical requirements and any of the alternative compressive strength requirements in Table 1 are met. If subsequent test results at 6 months or one year fail to meet the standard requirement of 100 % of reference strength, the compliance of the admixture to this standard is withdrawn and all users of the admixture shall be notified immediately. Uniformity and equivalence tests of Section 6 shall be carried out to provide results against which later comparisons can be made (See Note 4).

NOTE 4—Allowing for provisional compliance while retaining longer term compressive strength requirements promotes more rapid qualification of new materials, but also provides assurance that new admixture technologies will not exhibit unexpected longer term performance. The alternative compressive strength requirements in Table 1 are based on statistical analysis of 103 Specification C494/C494M evaluation tests. The alternative requirements correspond to a 99 % probability of passing subsequent test age requirements.[2]

1.3.2 *Level 2*—Limited retesting is described in 5.2, 5.2.1 and 5.2.2. Proof of compliance with the requirements of Table 1 demonstrates continued conformity of the admixture with the requirements of the specification.

1.3.3 *Level 3*—For acceptance of a lot or for measuring uniformity within or between lots, when specified by the purchaser, the uniformity and equivalence tests of Section 6 shall be used.

1.4 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

Current edition approved Feb. 1, 2010. Published March 2010. Originally approved in 1962. Last previous edition approved in 2008 as C494/C494M–08a. DOI: 10.1520/C0494_C0494M-10.

2.2 *American Concrete Institute Standard:*

ACI 211.1–91 Standard Practice for Selecting Proportions for Normal, Heavyweight, and Mass Concrete[4]

3. Terminology

3.1 *Definitions:*

3.1.1 *accelerating admixture*—an admixture that accelerates the setting and early strength development of concrete.

3.1.2 *retarding admixture*—an admixture that retards the setting of concrete.

3.1.3 *water-reducing admixture*—an admixture that reduces the quantity of mixing water required to produce concrete of a given consistency.

3.1.4 *water-reducing admixture, high range*—an admixture that reduces the quantity of mixing water required to produce concrete of a given consistency by 12 % or greater.

3.1.5 *water-reducing and accelerating admixture*— an admixture that reduces the quantity of mixing water required to produce concrete of a given consistency and accelerates the setting and early strength development of concrete.

3.1.6 *water-reducing and retarding admixture*— an admixture that reduces the quantity of mixing water required to produce concrete of a given consistency and retards the setting of concrete.

3.1.7 *water-reducing, high range, and retarding admixture*—an admixture that reduces the quantity of mixing water required to produce concrete of a given consistency by 12 % or greater and retards the setting of concrete.

3.1.8 *specific performance admixture*—an admixture that provides a desired performance characteristic(s) other than reducing water content, or changing the time of setting of concrete, or both, without any adverse effects on fresh, hardened and durability properties of concrete as specified herein, excluding admixtures that are used primarily in the manufacture of dry-cast concrete products (See Note 5).

NOTE 5—Other specific performance characteristics include, but are not limited to, shrinkage reduction, mitigation of alkali-silica reaction, and viscosity modification. Admixtures used for the purposes of reducing water content or changing the time of setting of concrete are classified within the Type A through Type G grouping. Plasticizing, water-repellent, and efflorescence-controlling admixtures are examples of admixtures that are used in the manufacture of dry-cast concrete products.

4. Ordering Information

4.1 The purchaser shall specify the type of chemical admixture desired, and in the case of a Type S admixture the specific performance characteristic(s) required.

5. General Requirements

5.1 For initial compliance with this specification, test concrete in which each type of admixture shown in 1.1 is used shall conform to the respective requirements prescribed in Table 1.

5.2 The purchaser is allowed to require a limited retesting to confirm current compliance of the admixture to specification requirements. The limited retesting will cover physical properties and performance of the admixture.

5.2.1 The physical properties retesting shall consist of uniformity and equivalence tests for infrared analysis, residue by oven drying and specific gravity.

5.2.2 The performance property retesting shall consist of water content of fresh concrete, setting time and compressive strength at 3, 7 and 28 days. Purchasers having special requirements are allowed to require additional tests currently in this standard.

www.technobetar.ir

5.3 At the request of the purchaser, the manufacturer shall state in writing that the admixture supplied for use in the work is identical in all essential respects, including concentration, to the admixture tested under this specification.

5.4 At the request of the purchaser, when the admixture is to be used in prestressed concrete, the manufacturer shall state in writing the chloride content of the admixture and whether or not chloride has been added during its manufacture.

5.5 At the request of the purchaser, the manufacturer shall provide data to substantiate the specific performance characteristic(s) stated by the manufacturer for a Type S admixture.

5.6 Tests for uniformity and equivalence, as indicated in Section 6, shall be made on the initial sample and the results retained for reference and comparison with the results of tests of samples taken from elsewhere within the lot or subsequent lots of admixture supplied for use in the work.

6. Uniformity and Equivalence

6.1 When specified by the purchaser, the uniformity of a lot, or the equivalence of different lots from the same source shall be established by the use of the following requirements:

6.1.1 *Infrared Analysis*—The absorption spectra of the initial sample and the test sample, obtained as specified in 18.1, shall be essentially similar.

6.1.2 *Residue by Oven Drying (Liquid Admixtures)*—When dried as specified in 18.2, the oven-dried residues of the initial sample and of subsequent samples shall be within ± 12 % of the mid-point of the manufacturer's stated range, but not exceeding the manufacturer's stated limits (See Note 6).

NOTE 6—As an example, for an admixture produced with a residue range from 27 to 35 %, the manufacturer would provide maximum acceptable limits of 27.3 to 34.7 %, representing ± 12 % of the mid-point of the limits, where the mid-point is 31.0 %.

6.1.3 *Residue by Oven Drying (Nonliquid Admixtures)*—When dried as specified in 18.3, the oven-dried residues of the initial sample and of the subsequent samples shall be within a range of variation not greater than ± 4 percentage points.

6.1.4 *Specific Gravity (Liquid Admixtures)*—When tested as specified in 18.4, the specific gravity of subsequent test samples shall not differ from the specific gravity of the initial sample by more than 10 % of the difference between the specific gravity of the initial sample and that of reagent water at the same temperature. If 10 % of the difference between the specific gravity of the initial sample and water is less than 0.01, use the value 0.01 as the maximum allowable difference. Reagent water conforming to Specification D1193, Types III or IV, and prepared by distillation ion exchange, reverse osmosis, electrodialysis, or a combination of these procedures is adequate.

6.2 When the nature of the admixture or the analytical capability of the purchaser make some or all of these procedures unsuitable, other requirements for uniformity and equivalence from lot to lot or within a lot shall be established by agreement between the purchaser and the manufacturer.

7. Packaging and Marking

7.1 When the admixture is delivered in packages or containers, the proprietary name of the admixture, the type under this specification, and the net weight or volume shall be plainly marked thereon. Similar information shall be provided in the shipping advices accompanying packaged or bulk shipments of admixtures.

8. Storage

8.1 The admixture shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weathertight building that will protect the admixture from dampness and freezing.

9. Sampling and Inspection

9.1 Every facility shall be provided the purchaser for careful sampling and inspection, either at the point of manufacture or at the site of the work, as specified by the purchaser.

9.2 Samples shall be either "grab" or "composite" samples, as specified or required by this specification. A grab sample is one obtained in a single operation. A composite sample is one obtained by combining three or more grab samples.

9.3 For the purposes of this specification, it is recognized that samples will be taken for two reasons:

9.3.1 *Quality Tests*—A sample taken for the purpose of evaluating the quality of a source or lot of admixture will be required to meet all the applicable requirements of this specification. Samples used to determine conformance with the requirements of this specification shall be composites of grab samples taken from sufficient locations to ensure that the composite sample will be representative of the lot.

9.3.2 *Uniformity and Equivalence Tests*— When specified by the purchaser, a sample taken for the purpose of evaluating the uniformity of a single lot, or equivalence of different lots from one source shall be tested as provided in Section 6. Such samples shall be composite samples from individual lots when different lots from the same source are being compared. When the uniformity of a single lot is being determined, grab samples shall be used.

9.4 *Liquid Admixtures*—Liquid admixtures shall be agitated thoroughly immediately prior to sampling. Grab samples taken for quality or uniformity tests shall represent a unit shipment or a single production lot. Each grab sample shall have a volume of at least 1 pt [0.5 L]. A minimum of three grab samples shall be taken. Composite samples shall be prepared by thoroughly mixing the grab samples selected and the resultant mixture sampled to provide at least 1 gal [4 L] for quality tests. Grab samples shall be taken from different locations well distributed throughout the quantity to be represented.

9.4.1 Admixtures in bulk storage tanks shall be sampled equally from the upper, intermediate, and lower levels by means of drain cocks in the sides of the tanks or a weighted sampling bottle fitted with a stopper that can be removed after the bottle is lowered to the desired depth.

9.4.2 Samples shall be packaged in impermeable, airtight containers which are resistant to attack by the admixture.

9.5 *Nonliquid Admixtures*—Grab samples taken for quality or uniformity tests shall represent not more than 2 tons [2 Mg] of admixture and shall weigh at least 2 lb [have a mass of at least 1 kg]. A minimum of four grab samples shall be taken. Composite samples shall be prepared by thoroughly mixing the grab samples selected and the resultant mixture sampled to

TABLE 1 Physical Requirements[A]

	Type A, Water Reducing	Type B, Retarding	Type C, Acceler-ating	Type D, Water Reducing and Retarding	Type E, Water Reducing and Accelerating	Type F, Water Reducing, High Range	Type G, Water Reducing, High Range and Retarding	Type S Specific Performance
Water content, max, % of control	95	...	...	95	95	88	88	...
Time of setting, allowable deviation from control, h:min:								
Initial: at least	...	1:00 later	1:00 earlier	1:00 later	1:00 earlier	...	1:00 later	
not more than	1:00 earlier nor 1:30 later	3:30 later	3:30 earlier	3:30 later	3:30 earlier	1:00 earlier nor 1:30 later	3:30 later	1:00 earlier nor 1:30 later
Final: at least	...	...	1:00 earlier	...	1:00 earlier	...	...	
not more than	1:00 earlier nor 1:30 later	3:30 later	...	3:30 later	...	1:00 earlier nor 1:30 later	3:30 later	1:00 earlier nor 1:30 later
Compressive strength, min, % of control:[B]								
1 day	...	...	...	...	...	140	125	...
3 days	110	90	125	110	125	125	125	90
7 days	110	90	100	110	110	115	115	90
28 days	110 (120)[C]	90	100	110 (120)[C]	110	110 (120)[C]	110 (120)[C]	90
90 days	(117)[C]	n/a	n/a	(117)[C]	n/a	(117)[C]	(117)[C]	n/a
6 months	100 (113)[C]	90	90	100 (113)[C]	100	100 (113)[C]	100 (113)[C]	90
1 year	100	90	90	100	100	100	100	90
Flexural strength, min, % control:[B]								
3 days	100	90	110	100	110	110	110	90
7 days	100	90	100	100	100	100	100	90
28 days	100	90	90	100	100	100	100	90
Length change, max shrinkage (alternative requirements):[D]								
Percent of control	135	135	135	135	135	135	135	135
Increase over control	0.010	0.010	0.010	0.010	0.010	0.010	0.010	0.010
Relative durability factor, min[E]	80	80	80	80	80	80	80	80

[A] The values in the table include allowance for normal variation in test results. The object of the 90 % compressive strength requirement for a Type B amd Type S admixture is to require a level of performance comparable to that of the reference concrete.

[B] The compressive and flexural strength of the concrete containing the admixture under test at any test age shall be not less than 90 % of that attained at any previous test age. The objective of this limit is to require that the compressive or flexural strength of the concrete containing the admixture under test shall not decrease with age.

[C] Alternative requirement. If the physical requirements are met and any of the measured relative strengths are greater than the requirement in parentheses, the admixture shall be considered provisionally qualified until the 1-year strength test results are obtained.

[D] Alternative requirements, see 17.1.4, % of control limit applies when length change of control is 0.030 % or greater; increase over control limit applies when length change of control is less than 0.030 %.

[E] This requirement is applicable only when the admixture is to be used in air-entrained concrete which may be exposed to freezing and thawing while wet.

provide at least 5 lb [2.5 kg] for the composite sample. Grab samples shall be taken from different locations well distributed throughout the quantity to be represented.

9.5.1 Samples of packaged admixtures shall be obtained by means of a tube sampler as described in Practice C183.

9.5.2 Samples shall be packaged in moisture-proof, airtight containers.

9.6 Samples shall be thoroughly mixed before testing to ensure uniformity. When recommended by the manufacturer, the entire sample of a nonliquid admixture shall be dissolved in water prior to testing.

10. Rejection

10.1 For initial compliance testing, the purchaser is allowed to reject the admixture if it fails to meet any of the applicable requirements for this specification.

10.2 For limited retesting, the purchaser is allowed to reject the admixture if it fails to meet any of the requirements of the Uniformity and Equivalence Section and of the applicable parts of Table 1.

10.3 An admixture stored at the point of manufacture, for more than 6 months prior to shipment, or an admixture in local storage in the hands of a vendor for more than 6 months, after completion of tests, shall be retested before use when requested by the purchaser and is allowed to be rejected if it fails to conform to any of the applicable requirements of this specification.

10.4 Packages or containers varying more than 5 % from the specified weight or volume are allowed to be rejected. If the average weight or volume of 50 packages taken at random is less than that specified, the entire shipment is allowed to be rejected.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.5 When the admixture is to be used in non-air-entrained concrete, it shall be rejected when the purchaser desires if the test concrete containing it has an air content greater than 3.5 %; when the admixture is to be used in air-entrained concrete, it can be rejected if the test concrete containing it has an air content greater than 7.0 %.

TEST METHODS

NOTE 7—These tests are based on arbitrary stipulations which make possible highly standardized testing in the laboratory and are not intended to simulate actual job conditions.

11. Materials

TESTS NOT FOR A SPECIFIC USE

11.1 *Cement*—The cement used in any series of tests shall be either the cement proposed for a specific use in accordance with 11.4, a Type I or Type II cement conforming to Specification C150, or a blend of two or more cements, in equal parts. Each cement of the blend shall conform to the requirements of either Type I or Type II, Specification C150. If when using a cement other than that proposed for specific work, the air content of the concrete made without admixture, tested as prescribed in 14.3, is more than 3.5 %, select a different cement, or blend, so that the air content of the concrete will be 3.5 % or less.

11.2 *Aggregates*—Except when tests are made in accordance with 11.4 using the aggregates proposed for a specific use, the fine and coarse aggregates used in any series of tests shall come from single lots of well-graded, sound materials that conform to the requirements of Specification C33, except that the grading of the aggregates shall conform to the following requirements:

11.2.1 *Fine Aggregate Grading*:

Sieve	Weight Percent Passing
No. 4 [4.75-mm]	100
No. 16 [1.18-mm]	65 to 75
No. 50 [300 µm]	12 to 20
No. 100 [150 µm]	2 to 5

11.2.2 *Coarse Aggregate Grading*— The coarse aggregate shall meet the requirements for size number 57 of Specification C33. Take care in loading and delivery to avoid segregation.

11.2.3 The coarse aggregate used for each set of reference concrete and comparable test admixture-treated concrete shall be essentially the same. Therefore, a set of test concrete consists of one reference concrete and as many test admixture-containing concretes as are intended to be compared to that one reference. Thus, coarse aggregate for one set shall consist of enough material for one reference concrete, the test admixture-containing concrete to be compared with that reference and the sample for grading analysis testing.

11.2.3.1 Prepare coarse aggregate for a set, comprising a sample large enough for concrete trials, as follows: Fill tared containers, one each for a sample, a batch of reference concrete and one or more test concretes to the required mass from the aggregate stockpile. Accomplish this by starting with a scoopful into the first container and repeat this procedure until all containers have their required mass. Repeat the process for each of the three or more sets needed. One or more spare sets may be needed. See the Appendix of Practice D75, Sampling from Stockpiles, and the Manual of Aggregate and Concrete TestingManual of Aggregate and Concrete Testing for guidance for conditions and procedures.

11.2.4 Test coarse aggregate samples representing each set by Method C136 requirements for the sieves shown below. Discard any set for which the sample does not comply with size 57. Average test results for samples which comply with size 57 for each sieve size. Discard any set for which the sample deviates from this average by more than the amount shown in column 3. Continue the process of preparation, testing and averaging until sufficient sets of aggregate within tolerance are obtained.

Sieve	Specification C33, No. 57 Percent Passing	Maximum variation from average/passing
1½ in. [37.5-mm]	100	0.0
1.00 in. [25.0-mm]	95 to 100	1.0
½ in. [12.5-mm]	25 to 60	4.0
No. 4 [4.75-mm]	0 to 10	4.0
No. 8 [2.36-mm]	0 to 5	1.0

NOTE 8—All of the results required for demonstrating compliance under this specification are dependent on the uniformity of the aggregate samples prepared and used. Careful, skilled and well-supervised work is essential.

11.3 *Air-Entraining Admixture*—Except when tests are made in accordance with 11.4 using the air-entraining admixture proposed for specific work, the air-entraining admixture used in the concrete mixtures specified in Section 12 shall be a material such that when used to entrain the specified amount of air in the concrete mixture will give concrete of satisfactory resistance to freezing and thawing. The material to be so used will be designated by the person or agency for whom the testing is to be performed. If no material is designated, "neutralized Vinsol resin[5]" shall be used. Accomplish neutralization by treating 100 parts of Vinsol resin with 9 to 15 parts of NaOH by mass. In an aqueous solution, the ratio of water to the resinate shall not exceed 12 to 1 by mass.

TESTS FOR SPECIFIC USES

11.4 *Materials for Tests*—The effects of a chemical admixture on the time of setting and water requirement of concrete are known to vary with the time of its addition during the batching and mixing sequence. To test a chemical admixture for use in specific work, the cement, pozzolan, aggregates, and air-entraining admixture used shall be representative of those proposed for use in the work. Add the chemical admixture in the same manner and at the same time during the batching and mixing sequence as it will be added on the job. Proportion the concrete mixtures to have the cement content specified for use in the work. If the maximum size of coarse aggregate is greater than 1 in. [25.0 mm], screen the concrete over a 1-in. [25.0-mm] sieve prior to fabricating the test specimens.

11.4.1 *Other Use Conditions*—Other conditions are known to affect the overall suitability of the concrete mixture for

[5] The sole source of supply of Vinsol resin known to the committee at this time is Hercules Inc., Wilmington, DE. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee [1], which you may attend.

www.technobetar.ir

specific intended uses. These include the temperature of the materials or the surroundings, the humidity, the length of time between mixing and placing, the amount of mixing activity and other factors. These physical conditions may be incorporated into the tests with intention for indicating the potential interactions. These tests would be only for guidance. After incorporation of such test conditions it would not be suitable to expect compliance with this specification requirement.

11.5 *Preparation and Batching*—Prepare all material and make all weighings as prescribed in Practice C192/C192M.

12. Proportioning of Concrete Mixtures

12.1 *Proportions*—Except when tests are being made for specific uses, all concrete shall be proportioned using ACI 211.1–91 to conform to the requirements described in 12.1.1-12.1.4. After evaluation of the trial mixtures, aggregate proportions shall be adjusted as needed to obtain workable, cohesive mixtures with the correct yield to obtain the required contents. Unless otherwise specified, the admixture shall be added with the first increment of mixing water that is added to the mixer.

12.1.1 The cement content shall be 517 ± 5 lb/yd ^{3}[307 ± 3 kg/m^3].

12.1.2 For the first trial mixture, refer to the table on volume of coarse aggregate per unit volume of concrete in ACI 211.1–91 for guidance on the amount of coarse aggregate to use, given the nominal maximum size of the aggregate and the fineness modulus of the fine aggregate being used (see Note 9

NOTE 9—Values in the referenced table of ACI 211.1–91 are intended to ensure workable mixtures with the least favorable combinations of aggregate likely to be used. It is suggested, therefore, that for a closer approximation of the proportions required for this test, the values selected from this table be increased by about 7 for the first trial mixture.

12.1.3 For the non-air-entrained mixtures, the air content used in calculating the proportions shall be 1.5, as shown in Table number 5.3.3 of ACI 211.1–91. For the air-entrained mixtures, the air content used for this purpose shall be 5.5.

12.1.4 Adjust the water content to obtain a slump of 3½ ± ½ in. [90 ± 15 mm]. The workability of the concrete mixture shall be suitable for consolidation by hand rodding and the concrete mixture shall have the minimum water content possible. Achieve these conditions by final adjustments in the proportion of fine aggregate to total aggregate or in the amount of total aggregate, or both, while maintaining the yield and slump in the required ranges.

12.2 *Conditions*—Prepare concrete mixtures both with and without the admixture under test. Refer herein to the concrete mixture without the chemical admixture as the reference or control concrete mixture. Except in the case of a Type S admixture, add the admixture in the manner recommended by the manufacturer and in the amount necessary to comply with the applicable requirements of the specifications for water reduction or time of setting, or both. When desired by the person or agency for whom the tests are being performed, the admixture is allowed to be added in an amount such as to produce a specific time of setting of the concrete mixture within the limits of the applicable provisions of this specification. A Type S admixture shall be tested at a dosage within the range recommended by the manufacturer for field use.

12.2.1 *Non-Air-Entrained Concrete*—When the admixture is to be tested for use only in non-air-entrained concrete, the air content of both the mixture containing the admixture under test and the reference concrete mixture shall be 3.5 % or less, and the difference between the air contents of the two mixtures shall not exceed 1.0. If necessary, the air-entraining admixture shall be added to the reference concrete mixture. Tests for resistance to freezing and thawing shall not be made.

12.2.2 *Air-Entrained Concrete*—When the admixture is to be tested for use only in air-entrained concrete, the air-entraining admixture shall be added to the reference concrete mixture and, if necessary, to the concrete mixture containing the admixture under test in sufficient amounts to produce air contents in the range 3.5 to 7.0 %, except that for tests for resistance to freezing and thawing, the range shall be 6.0 ± 1.0 %. In both cases the difference between the air content of the reference concrete and that of the concrete containing the admixture under test shall not exceed 0.5.

13. Mixing

13.1 Machine mix the concrete as prescribed in Practice C192/C192M.

14. Tests and Properties of Freshly Mixed Concrete

14.1 Samples of freshly mixed concrete from at least three separate batches for each condition of concrete shall be tested in accordance with the methods described in 14.2-14.5.

14.2 *Slump*—Test Method C143/C143M.

14.3 *Air Content*—Test Method C231.

14.4 *Time of Setting*—Test Method C403/C403M, except that the temperature of each of the ingredients of the concrete mixtures, just prior to mixing, and the temperature at which the time-of-setting specimens are stored during the test period shall be 73 ± 3 °F [23.0 ± 2.0 °C].

14.5 *Water Content*:

14.5.1 Report the water-cement ratio of the concrete, computed to the nearest 0.001, as follows: Determine the net water content of the batch as the weight of water in the batch in excess of that present as absorbed water in the aggregates. Calculate the actual volume of concrete in the batch by determining the density of concrete in the batch as prescribed in Test Method C138/C138M. Determine the water-cement ratio by dividing the net weight of water by the weight of cement in the batch.

14.5.2 Calculate the relative water content of the concrete containing the admixture under test as a percentage of the water content of the reference concrete as follows: Divide the average water content of all batches of concrete containing the admixture under test by the average water content of all batches of the reference concrete and multiply the quotient by 100.

15. Preparation of Test Specimens

15.1 Make specimens for tests of hardened concrete, representing each test and age of test and each condition of concrete being compared, from at least three separate batches, and the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

minimum number of specimens shall be as prescribed in Table 2. On a given day make at least one specimen for each test and age of test from each condition of concrete, except make at least two specimens for the freezing and thawing test from each condition of concrete. If desired, the preparation of all specimens can be completed in one, two, or three days of mixing, provided the test concrete and its reference are made on the same day.

15.2 *Manifestly Faulty Specimens*—Visually examine each group of specimens representing a given test or a given age of test, including tests of freshly mixed concrete, before or during the test, or both, whichever is appropriate. Discard any specimen found to be manifestly faulty by such examination without testing. Visually examine all specimens representing a given test at a given age after testing, and should any specimen be found to be manifestly faulty the test results thereof shall be disregarded. Should more than one specimen representing a given test at a given age be found manifestly faulty either before or after testing, the entire test shall be disregarded and repeated. The test result reported shall be the average of the individual test results of the specimens tested or, in the event that one specimen or one result has been discarded, it shall be the average of the test results of the remaining specimens.

16. Test Specimens of Hardened Concrete

16.1 *Number of Specimens*—Six or more test specimens for the freezing and thawing test and three or more test specimens for each other type of test and age of test specified in Table 2 shall be made for each condition of concrete to be compared.

16.2 *Types of Specimens*—Specimens made from concrete with and without the chemical admixture under test shall be prepared in accordance with the following:

16.2.1 *Compressive Strength*—Make and cure test specimens in accordance with Practice C192/C192M.

16.2.2 *Flexural Strength*—Make and cure test specimens in accordance with Practice C192/C192M.

TABLE 2 Types and Minimum Number of Specimens and Tests

	Number of Types of Specimens[A]	Number of Test Ages	Number of Conditions of Concrete[B]	Number of Specimens, min
Water content	...	1	2	[C]
Slump	1	1	2	C
Air content	1	1	2	C
Time of setting	1	[D]	2	6
Compressive strength				
Types B, C, and E	1	5	2	30
Types A, D, and S	1	6	2	36
Types F and G	1	7	2	42
Flexural strength	1	3	2	18
Freezing and thawing	1	1	2	12
Length change	1	1	2	6
Water reducing, high range	...	6	...	36
Water reducing, high —range and retarding	...	6	...	36

[A] See Section 14 and 16.2.
[B] See 12.2.
[C] Determined on each batch of concrete mixed.
[D] See 14.4.

16.2.3 *Resistance to Freezing and Thawing*— Test specimens shall consist of prisms made and cured in accordance with the applicable requirements of Practice C192/C192M. Test specimen dimensions shall be as required by Test Method C666/C666M. Make one set of specimens from the concrete mixture containing the chemical admixture under test and from the reference concrete mixture, the air content of each mixture being as specified in 12.2.2.

16.2.4 *Length Change*—Make and cure test specimens in accordance with Test Method C157/C157M. The moist-curing period, including the period in the molds, shall be 14 days.

17. Tests on Hardened Concrete

17.1 Test specimens of hardened concrete (see Table 1) in accordance with the following methods :

17.1.1 *Compressive Strength*—Test Method C39/C39M. Test specimens at ages of 1 (Types F and G only), 3, 7, and 28 days, 6 months, and 1 year. Test specimens at 90 days if compliance to the alternative requirement for provisional compliance is desired. Calculate the compressive strength of the concrete containing the admixture under test as a percentage of the compressive strength of the reference concrete as follows:

17.1.1.1 Divide the average compressive strength of the specimens made from the concrete containing the admixture under test at a given age of test by the average compressive strength of the specimens made from the reference concrete at the same age of test and multiply the quotient by 100.

17.1.1.2 When tests are conducted with materials representative of those proposed for a specific use in accordance with 11.4, and if the results of the tests are required in a period of time that will not permit curing of specimens to ages of 6 months and 1 year, the tests at those ages are permitted to be waived.

17.1.2 *Flexural Strength*—Test Method C78. Test specimens at ages 3, 7, and 28 days. Calculate the flexural strength of the concrete containing the admixture under test as a percentage of the flexural strength of the reference concrete as follows:

17.1.2.1 Divide the average flexural strength of the specimens made from the concrete containing the admixture under test at a given age of test by the average flexural strength of the specimens made from the reference concrete at the same age of test, and multiply the quotient by 100.

17.1.3 *Resistance to Freezing and Thawing*— Comparison tests of the concrete containing the admixture under test with the reference concrete mixture shall be made concurrently using Procedure A of Test Method C666/C666M. Place specimens under test at the age of 14 days. Calculate the relative durability factors as shown in Specification C260.

17.1.4 *Length Change*—Test specimens shall consist of molded prisms made and tested in accordance with Test Method C157/C157M except that the moist curing period, including the period in the molds, shall be 14 days. Then store the specimens in air under conditions specified in the section on Air Storage of Test Method C157/C157M for a period of 14 days, at which time determine the length change of the specimen. Consider the drying shrinkage to be the length

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:28 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

change during the drying period, based on an initial measurement at the time of removal of the specimen from the mold, and express it as percent to the nearest 0.001 % based on the specimen gage length. If the length change of the reference concrete after 14 days of drying is 0.030 % or greater, the length change on drying of concrete containing the admixture under test, expressed as percent of the length change of the reference concrete, shall not exceed the maximum specified in Table 1. If the length change of the reference concrete after 14 days of drying is less than 0.030 %, the length change on drying of concrete containing the admixture under test shall be not more than 0.010 percentage units greater than that of the reference concrete.

NOTE 10—Because the specific effects produced by chemical admixtures may vary with the properties of the other ingredients of the concrete, results of length change tests using aggregates of such a nature that the length change on drying is low may not accurately indicate relative performance to be expected with other aggregates having properties such as to produce concrete of high length change on drying.

18. Uniformity and Equivalence Tests

18.1 *Infrared Analysis*—This test procedure is intended to compare qualitatively the composition of different samples and results should not be interpreted quantitatively. Sections 18.1.1, 18.1.2, and 18.1.3 give a general procedure for the infrared analysis of admixtures (see Note 11).

18.1.1 *Liquid Admixtures*—Determine the dissolved solids concentration by 18.2 and dilute an aliquot of the liquid admixture sample with distilled water to yield a dissolved solids concentration of about 0.015 g/mL, for example, a 5-mL aliquot diluted to 200 mL. Pipet 5 mL of above solution and add it to a petri dish with 2.5 g of potassium bromide of a grade suitable for use in infrared analysis and 5 mL of distilled water. Stir and mix to dissolve. Place in a drying oven (18.2.1.1) and dry for 17 ± ¼ h at 105 ± 3 °C. Cool and transfer the dried residue to a mortar and grind to a fine powder. Work quickly to avoid moisture pick-up. Weigh 0.1 g of the powder and 0.4 g of potassium bromide of a grade suitable for use in infrared analysis. Mix in an electric amalgamator for 30 s using stainless steel capsule and balls. Proceed in accordance with 18.1.3.

18.1.2 *Non-liquid Admixtures*—Grind 10 g to a fine powder with mortar and pestle. Transfer the sample to a petri dish, place in a drying oven (18.2.1.1) and dry for 17 ± ¼ h at 105 ± 3 °C. Weigh approximately 0.005 g of the dry powder and 0.995 g of potassium bromide of a grade suitable for use in infrared analysis. Mix in an electric amalgamator for 30 s using stainless steel capsule and balls. Proceed in accordance with 18.1.3.

18.1.3 To prepare a disk for infrared analysis, weigh 0.300 g of the mixture prepared in 18.1.1 or 18.1.2 and transfer into a suitable die. If an evacuable die is used, apply vacuum for 2 min prior to pressing. Continue vacuum and press at a suitable force for 3 min, producing a disk about 1 mm thick. Remove the disk from the die, insert into the infrared spectrophotometer and obtain infrared absorption spectra.

NOTE 11—It is important that the same procedures be used on all samples to be compared with each other and preferably that they be conducted by the same analyst. Major changes in infrared spectra may result from (*a*) water content differences due to drying variations, (*b*) water picked up by hygroscopic materials, (*c*) reaction between the potassium bromide and some other compound present, and (*d*) differences in time between formation of the disk and its use. Also, the threshold for detection of individual components by infrared absorption varies widely, depending upon the identity and concentration of accompanying substances. For example, significant amounts of saccharides may be present in a lignosulfonate admixture without their presence being indicated by this method.

18.2 *Residue by Oven Drying* (Liquid Admixtures):

18.2.1 Place 25 to 30 g of standard Ottawa sand (20 to 30 mesh) in a wide-mouth, low-form (about 60 mm inside diameter and 30 mm in height) glass weighing bottle provided with a ground-glass stopper. Place the weighing bottle and stopper, with stopper removed, in a drying oven (18.2.1.1) and dry for 17 ± ¼ h at 105 ± 3 °C (Note 10). Insert the stopper in the weighing bottle, transfer to a desiccator, cool to room temperature, and weigh to the nearest 0.001 g. Remove the stopper and, using a pipet, evenly distribute 4 ml of the liquid admixture over the sand. Immediately insert the stopper to avoid loss by evaporation and weigh to the nearest 0.001 g. Remove the stopper and place both the bottle and stopper in a drying oven (18.2.1.1). Dry for 17 ± ¼ h at 105 ± 3 °C. At the end of the drying period, stopper the weighing bottle, transfer to a desiccator, cool to room temperature, and weigh to the nearest 0.001 g.

18.2.1.1 *Drying Oven*—The drying oven shall be either a forced circulation type or one with provision for free access of air. There shall be precise control of temperature and time of drying so that the degree of volatilization of the material other than water from sample to sample will not vary.

18.2.2 *Calculation*:

18.2.2.1 Record the following masses:

m_1 = mass of stoppered bottle with sand and sample,
m_2 = mass of stoppered bottle with sand,
m_3 = $m_1 - m_2$ = mass of sample,
m_4 = mass of stoppered bottle with sand and dried residue, and
m_5 = $m_4 - m_2$ = mass of dried residue.

18.2.2.2 Calculate the residue by using the following equation:

$$\text{Residue by oven drying (percent by mass)} = (m_5 \times 100)/m_3 \quad (1)$$

NOTE 12—For laboratories conducting this test as a routine operation, previously dried sand and weighing bottles can be maintained in desiccators so that they are immediately available for use when a sample is to be tested.

18.2.3 *Precision Statement*—The maximum multilaboratory coefficient of variation for residue by oven drying (liquid admixtures) has been found to be 1.25 %. Therefore, results of tests by two different laboratories on identical samples of an admixture are not expected to differ from each other by more than 3.5 % of their average (Note 13). The maximum single-operator coefficient of variation has been found to be 0.6 %. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 1.7 %.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 13—The precision statements are based on the maximum variation of tests made in 18 laboratories on sets of three duplicate samples of two different admixtures.

NOTE 14—Testing Type C and E admixtures, which commonly contain calcium salts, for oven-dried residue using the oven-dry method can yield inconsistent values. This is because these salts can retain bound water of hydration in an unpredictable manner upon drying. Purchasers and users of these types of chemical admixtures should preferably use the specific gravity test to determine uniformity and equivalence.

18.3 *Residue by Oven Drying* (Nonliquid Admixtures):

18.3.1 Place about 3 g of the nonliquid admixture into a dried and tared glass-stoppered weighing bottle (similar to the one described in 18.2.1). Stopper and determine the mass of the bottle and contents to the nearest 0.001 g. Remove the stopper and immediately place both bottle and stopper in a drying oven (18.2.1.1). Dry for 17 ± ¼ h at 105 ± 3 °C. At the end of the drying period, stopper the weighing bottle, transfer to the desiccator, cool to room temperature, and weigh to the nearest 0.001 g.

18.3.2 *Calculation*:

18.3.2.1 Record the following masses:

m_1 = mass of tared stoppered weighing bottle and sample before drying,
m_2 = mass of empty, stoppered weighing bottle,
m_3 = mass of sample = $(m_1 - m_2)$,
m_4 = mass of tared stoppered weighing bottle and sample after drying, and
m_5 = mass of oven-dried residue = $m_4 - m_2$.

18.3.2.2 Calculate the oven-dried residue by using the following equation:

$$\text{Residue by oven drying (mass percent)} = [m \times 100]/m_3 \quad (2)$$

18.3.3 *Precision Statement*—The maximum multilaboratory coefficient of variation for residue by oven-drying (non-liquid admixture) has been found to be 1.40 %. Therefore, results of tests by two different laboratories on identical samples of an admixture are not expected to differ from each other by more than 4.0 % of their average. The maximum single-operator coefficient of variation for residue by oven drying (non-liquid admixture) has been found to be 0.48 %. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 1.4 % of their average. Note 13 also applies to 18.3.3.

18.4 *Specific Gravity* (Liquid Admixtures):

18.4.1 Determine the specific gravity at 25 ± 1 °C of a liquid admixture using hydrometers complying with Specification E100. Hydrometers No. 112H through 117H will cover the range for most determinations. A250-mL graduated cylinder, and a water bath capable of maintaining 25 ± 1 °C will also be required.

18.4.2 Place a sample in the 250-mL graduated cylinder and put in the hydrometer in such a manner that it floats free and does not touch the side of the cylinder. Place the cylinder with sample and hydrometer in the constant-temperature bath until the temperature of the cylinder, hydrometer, and sample is uniform at 25 ± 1 °C. If all are at proper temperature prior to insertion of the hydrometer, approximately 10 min should be allowed for equilibrium. If the sample shows evidence of foaming, hydrometer reading should be continued until constant readings are obtained. Read the hydrometer at the base of the meniscus to the nearest 0.005.

18.4.2.1 If foaming is encountered during transfer of the admixture to the cylinder, sufficient time shall be allowed for the foam to dissipate or rise to the surface, where it shall be removed before inserting the hydrometer. Crusting of the admixture on the hydrometer stem due to evaporation during temperature adjustment shall be avoided.

18.4.3 *Precision Statement*—The maximum multilaboratory coefficient of variation for specific gravity (liquid admixtures) has been found to be 0.316 %. Therefore, results of two different laboratories on identical samples of an admixture are not expected to differ from each other by more than 0.9 % of their average (Note 13). The maximum single-operator coefficient of variation has been found to be 0.09 %. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 0.275 %.

19. Report

19.1 Report the following:

19.1.1 Results of the tests specified in Sections 6, 14, and 17, and the relevant specification requirements with which they are compared,

19.1.2 Brand name, manufacturer's name, and lot number, character of the material, and quantity represented by the sample of the admixture under test,

19.1.3 Brand name, manufacturer's name, and other pertinent data on the material used as the air-entraining admixture,

19.1.4 Brand name, manufacturer's name, type, and test data on the portland cement or cements used,

19.1.5 Description of, and test data on the fine and coarse aggregates used,

19.1.6 Detailed data on the concrete mixtures used, including amounts and proportions of admixtures used, actual cement factors, water-cement ratios, unit water contents, ratios of fine to total aggregate, slump, and air content, and

19.1.7 In the event that, in accordance with the provisions of 17.1.1.2, some of the tests have been waived, the circumstances under which such action was taken shall be stated.

19.1.8 For a Type S admixture and when required by the purchaser, a report on the performance characteristics of the admixture in accordance with 5.5.

20. Keywords

20.1 accelerating; chemical admixtures; concrete; physical requirements; retarding; specific performance; testing; water reducing

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C494/C494M–08a, that may impact the use of this specification. (Approved February 1, 2010)

(*1*) Added new Note 14.

Committee C09 has identified the location of selected changes to this specification since the last issue, C494/C494M – 08, that may impact the use of this specification. (Approved September 1, 2008)

(*1*) Added Type S admixture to Scope in new paragraph 1.1.8.

(*2*) Added new paragraph 3.1.8, definition of Type S admixture.

(*3*) Added new Note 5 and renumbered subsequent notes.

(*4*) Revised paragraph 4.1, ordering information.

(*5*) Added new paragraph 5.5 regarding provision of data, at the request of the purchaser, to substantiate specific performance claim(s) for a Type S admixture, and renumbered subsequent paragraphs.

(*6*) Revised 12.2 to include a test dosage for a Type S admixture.

(*7*) Added new paragraph 19.1.8 to require the attachment of a report on the specific performance characteristic offered by a Type S admixture to the Specification C494/C494M test report.

(*8*) Addition of specific performance to keywords.

(*9*) Added physical requirements for Type S admixture in Table 1.

(*10*) Revised Table 2 to include Type S admixture.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 495 – 07

Standard Test Method for Compressive Strength of Lightweight Insulating Concrete[1]

This standard is issued under the fixed designation C 495; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the preparation of specimens and the determination of the compressive strength of lightweight insulating concrete having an oven-dry density not exceeding 50 lb/ft^3 (800 kg/m^3) as determined by the procedures described herein. This test method covers the preparation and testing of molded 3 by 6-in. (75 by 150-mm) cylinders.

1.2 The values stated in inch-pound units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens

C 88 Test Method for Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars(Using 2-in. or [50-mm] Cube Specimens)

C 172 Practice for Sampling Freshly Mixed Concrete

C 617 Practice for Capping Cylindrical Concrete Specimens

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Significance and Use

3.1 This test method provides standardized requirements for sampling, molding, curing, and testing lightweight insulating concretes for the purpose of determining compliance with compressive strength and density specifications.

4. Apparatus

4.1 *Testing Machine*—Use a testing machine as prescribed in Test Method C 39/C 39M.

4.2 *Scales and Weights*—Use scales and weights in weighing specimens that conform to those specified in the Apparatus Section of Test Method C 109/C 109M.

4.3 *Drying Oven*—Use an oven as specified in Test Method C 88.

4.4 *Molds*—Use molds made of nonabsorbent materials or of materials treated to reduce absorption, that are watertight, and not subject to distortion of more than 1/16 in. (1.6 mm) in any dimension during molding and early curing of specimens. Coat all mold surfaces that will be in contact with concrete except single use plastic molds with wax or mineral oil, prior to use. Use molds having a diameter of 3 ± 1/16 in. (75 ± 1.6 mm) and a length of 6 ± 1/8 in. (150± 3 mm).

5. Sampling

5.1 Sample fresh lightweight insulating concrete in accordance with applicable provisions of Practice C 172, with the following exceptions:

5.1.1 *Sampling from Pump Equipment*—Fill a bucket of approximately 10-qt (9-dm^3) capacity by passing through the discharge stream of the concrete pump hose being used to place the concrete, at the point of placement of the concrete. Exercise care to ensure that the sample is representative of the pour, avoiding the beginning or ending of the discharge from the equipment. Prepare the test specimens as described in Section

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.21 on Lightweight Aggregates and Concrete.

Current edition approved July 15, 2007. Published August 2007. Originally approved in 1962. Last previous edition approved in 1999 as C 495 – 99a.

www.technobetar.ir

6, by filling them with a scoop of lightweight insulating concrete dipped from the bucket.

5.1.2 *Remixing Sample*—Do not remix the sample.

6. Test Specimens

6.1 *Size and Shape*—Use cylindrical test specimens 3 ± 1⁄16 in. (75 ± 1.6 mm) in diameter and 6 ± 1⁄8 in. (150 ± 3 mm) in length, with the base of each specimen perpendicular to the longitudinal axis within the limits prescribed in 6.8.

6.2 *Number*—Obtain at least four test specimens for compressive strength tests from each sample of lightweight insulating concrete.

6.3 *Molding*—In molding the specimens, place the concrete in two approximately equal layers. Tap the sides of the mold lightly with a rubber mallet after placing each layer until the surface of the layer has subsided approximately to a plane. Over fill the mold when placing the second layer. Do not rod the concrete.

6.4 *Finishing Surface*—Strike off the specimens immediately after filling the molds. Cover them in such a manner as to prevent evaporation without marring the surface (Note 1). If desired, cover the filled mold with a glass or metal plate to obtain a surface that will be suitable for testing without capping and with a minimum of grinding.

NOTE 1—It is desirable to place the filled mold in a moist room if one is available. If this is done, protect the surface from dripping water.

6.5 *Removal from Molds*—Do not remove specimens from molds until danger of damage to the specimens is past. In any event, remove specimens from the molds within 7 days after molding.

6.6 *Curing*—For the first 24 h after molding, maintain the specimens at a temperature of 70 ± 10 °F (21.1 ± 5.5 °C). After 24± 2 h, store the specimens in a moist condition (Note 2) at a temperature of 73.4 ± 3 °F (23.0 ± 1.7 °C) (Note 3). Do not expose specimens to a stream of running water nor store in water, unless a saturated lime (calcium hydroxide) solution is used. After 7 days, store the specimens at a temperature of 70 ± 10 °F and a relative humidity of 50 ± 30 % for 18 days. Twenty-five days after molding, dry the specimens in an oven at 140 ± 5 °F (60 ± 2.8 °C) for 3 days (Note 4). Cool specimens to room temperature and test for compressive strength at an age of 28 days.

NOTE 2—A moist condition is that in which free water is maintained on the surfaces of the specimens at all times.

NOTE 3—The temperature within damp sand and under wet burlap or similar materials will always be lower than the temperature in the surrounding atmosphere if evaporation takes place.

NOTE 4—Caution must be observed in loading the oven so that the moisture content of the specimen at time of test does not exceed 5 % of the oven-dry density determined in accordance with 9.1.

6.7 *Preparation for Testing*—Check the surfaces of the specimen that will be in contact with the bearing surfaces of the testing machine within 0.02 in. (0.5 mm). If the bearing surfaces depart from a plane more than 0.02 in. (0.5 mm), grind them to conform to this tolerance or cap in accordance with Practice C 617. Cap surfaces to be plane within 0.002 in. (0.05 mm). Check the planeness of the bearing surface of the specimen by means of a straightedge and feeler gage, making a minimum of three measurements on different diameters of the specimen. Make sure the surface of the specimen in contact with the lower bearing block of the testing machine does not depart from perpendicularity with the longitudinal axis of the cylinder by more than 1° (approximately equivalent to 0.1 in. in 6 in. (2.5 mm in 150 mm)) or the combined departure of the two bearing surfaces from perpendicularity by more than 3°.

6.8 *Measurement of Specimen*—Determine the diameter of the specimens to the nearest 0.01 in. (0.3 mm) by averaging two diameters measured at right angles to each other at about midheight of the specimen. Use these dimensions in computing the cross-sectional areas. Determine the height of the specimen to the nearest 0.01 in.

7. Procedure

7.1 *Placing of Specimen*—Wipe clean the bearing faces of the upper and lower bearing blocks of the compression test machine and of the test specimen and place the test specimen on the lower bearing block. Carefully align the axis of the specimen with the center of thrust of the spherically seated block. As the spherically seated block is brought to bear on the specimen, gently rotate its movable portion by hand so that uniform seating is obtained.

7.2 *Rate of Loading*—Continuously apply the load without shock at a constant rate such that the maximum load will be reached in 65 ± 15 s. Record the maximum load sustained by the specimen. Note the type of failure and the appearance of the concrete.

8. Calculation

8.1 Calculate the unit compressive strength of the concrete by dividing the maximum load by the average cross-sectional area and record to the nearest 10 psi (69 kPa).

9. Oven-Dry Density

9.1 When the oven-dry unit density is desired, mold two companion specimens for this purpose at the same time as the compressive strength specimens. Cure the companion specimens the same as the compressive strength specimens, except dry the companion specimens at the age of 28 days in an oven at 230 ± 18 °F (110 ± 10 °C) and weigh at 24-h intervals until the loss in weight does not exceed 1 % in a 24-h period. Determine the mass and dimensions of the oven-dry specimens and calculate the density from the average data obtained.

10. Report

10.1 For each specimen tested report the following information where applicable:

10.1.1 Identification number,

10.1.2 Dimensions of test specimen, in inches (millimetres),

10.1.3 The cross-sectional area in square inches (square centimetres),

10.1.4 Type of cap,

10.1.5 Maximum load, in pounds-force (or kilonewtons),

10.1.6 Unit compressive strength in pounds-force per square inch (or kilopascals),

10.1.7 Type of fracture and appearance of the concrete following determination of compressive strength,

10.1.8 Defects in either specimen or caps,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:15:30 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.1.9 Age of specimen, in days,

10.1.10 Calculated oven-dry density, if determined,

10.1.11 Average ambient temperature and average relative humidity at which specimens were stored during the 18-day curing period, and

10.1.12 Summation of tests of specimens from same sample with average of test results. This summation shall be shown on the report of the last specimen tested and should be referenced in reports of other specimens.

11. Precision and Bias

11.1 *Precision*:

11.1.1 The single operator standard deviation for a test result (where a test result is, as defined in this test method, the average of four separate compressive strength measurements) has been found to be 21 psi (Note 5). Therefore, results of two properly conducted tests (each consisting of the average of four individual measurements) by the same operator on concrete samples from the same batch should not differ by more than 59 psi (Note 5). The range (difference between highest and lowest) of the four individual measurements used in calculating the average should not exceed 155 psi (Note 6).

11.1.2 The multilaboratory standard deviation for a test result has been found to be 29 psi (Note 5). Therefore, results of two properly conducted tests (each consisting of the average of four individual measurements) by two different laboratories on concrete samples from the same batch should not differ by more than 83 psi (Note 5).

NOTE 5—These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

NOTE 6—Calculated as described in 3.4.3 of Practice C 670.

11.2 *Bias*—The bias of this test method cannot be determined because compressive strength can only be defined in terms of this test method.

12. Keywords

12.1 compressive strength; density; lightweight insulating concrete; oven-dry density

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 495 – 99a, that may impact the use of this test method. (Approved July 15, 2007)

(*1*) Replaced “weight” with “density” in 1.1, Note 4, the title of Section 9, 9.1, and Section 12.

(*2*) Replaced “weight” with “mass” in 9.1, and corrected the citation in Note 4 from 8.1 to 9.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 496/C 496M – 04$^{\epsilon 1}$

Standard Test Method for Splitting Tensile Strength of Cylindrical Concrete Specimens[1]

This standard is issued under the fixed designation C 496/C 496M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

ε[1] NOTE—Footnote 3 was reinserted editorially to correct a typo in December 2006.

1. Scope*

1.1 This test method covers the determination of the splitting tensile strength of cylindrical concrete specimens, such as molded cylinders and drilled cores.

1.2 The values stated in either inch-pound or SI units are to be regarded separately as standard. The SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this standard references notes that provide explanatory material. These notes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Summary of Test Method

3.1 This test method consists of applying a diametral compressive force along the length of a cylindrical concrete specimen at a rate that is within a prescribed range until failure occurs. This loading induces tensile stresses on the plane containing the applied load and relatively high compressive stresses in the area immediately around the applied load. Tensile failure occurs rather than compressive failure because the areas of load application are in a state of triaxial compression, thereby allowing them to withstand much higher compressive stresses than would be indicated by a uniaxial compressive strength test result.

3.2 Thin, plywood bearing strips are used to distribute the load applied along the length of the cylinder.

3.3 The maximum load sustained by the specimen is divided by appropriate geometrical factors to obtain the splitting tensile strength.

4. Significance and Use

4.1 Splitting tensile strength is generally greater than direct tensile strength and lower than flexural strength (modulus of rupture).

4.2 Splitting tensile strength is used in the design of structural lightweight concrete members to evaluate the shear resistance provided by concrete and to determine the development length of reinforcement.

5. Apparatus

5.1 *Testing Machine*—The testing machine shall conform to the requirements of Test Method C 39/C 39M and be of a type with sufficient capacity that will provide the rate of loading prescribed in 7.5.

5.2 *Supplementary Bearing Bar or Plate*—If the diameter or the largest dimension of the upper bearing face or the lower bearing block is less than the length of the cylinder to be tested, a supplementary bearing bar or plate of machined steel shall be used. The surfaces of the bar or plate shall be machined to within ± 0.001 in. [0.025 mm] of planeness, as measured on any line of contact of the bearing area. It shall have a width of at least 2 in. [50 mm], and a thickness not less than the distance

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved Feb. 1, 2004. Published March 2004. Originally approved in 1962. Last previous edition approved in 1996 as C 496 – 96.

www.technobetar.ir

from the edge of the spherical or rectangular bearing block to the end of the cylinder. The bar or plate shall be used in such manner that the load will be applied over the entire length of the specimen.

5.3 *Bearing Strips*—Two bearing strips of nominal ⅛ in. [3.2 mm] thick plywood, free of imperfections, approximately 1 in. [25 mm] wide, and of a length equal to, or slightly longer than, that of the specimen shall be provided for each specimen. The bearing strips shall be placed between the specimen and both the upper and lower bearing blocks of the testing machine or between the specimen and supplemental bars or plates, when used (see 5.2). Bearing strips shall not be reused.

6. Test Specimens

6.1 The test specimens shall conform to the size, molding, and curing requirements set forth in either Practice C 31/C 31M (field specimens) or Practice C 192/C 192M (laboratory specimens). Drilled cores shall conform to the size and moisture-conditioning requirements set forth in Test Method C 42/C 42M. Moist-cured specimens, during the period between their removal from the curing environment and testing, shall be kept moist by a wet burlap or blanket covering, and shall be tested in a moist condition as soon as practicable.

6.2 The following curing procedure shall be used for evaluations of light-weight concrete: specimens tested at 28 days shall be in an air-dry condition after 7 days moist curing followed by 21 days drying at 73.5 ± 3.5°F [23.0 ± 2.0°C] and 50 ± 5 % relative humidity.

7. Procedure

7.1 *Marking*—Draw diametral lines on each end of the specimen using a suitable device that will ensure that they are in the same axial plane (see Fig. 1, Fig. 2 and Note 1), or as an alternative, use the aligning jig shown in Fig. 3 (Note 2).

NOTE 1—Figs. 1 and 2 show a suitable device for drawing diametral lines on each end of a 6 in. by 12 in. [150 mm by 300 mm] cylinder in the same axial plane. The device consists of three parts as follows:

(1) A length of 4-in. [100-mm] steel channel, the flanges of which have been machined flat,

(2) A section, part a, that is grooved to fit smoothly over the flanges of the channel and that includes cap screws for positioning the vertical member of the assembly, and

(3) A vertical bar, part b, for guiding a pencil or marker,

The assembly (part a and part b) is not fastened to the channel and is positioned at either end of the cylinder without disturbing the position of the specimen when marking the diametral lines.

NOTE 2—Fig. 4 is a detailed drawing of the aligning jig shown in Fig. 3 for achieving the same purpose as marking the diametral lines. The device consists of:

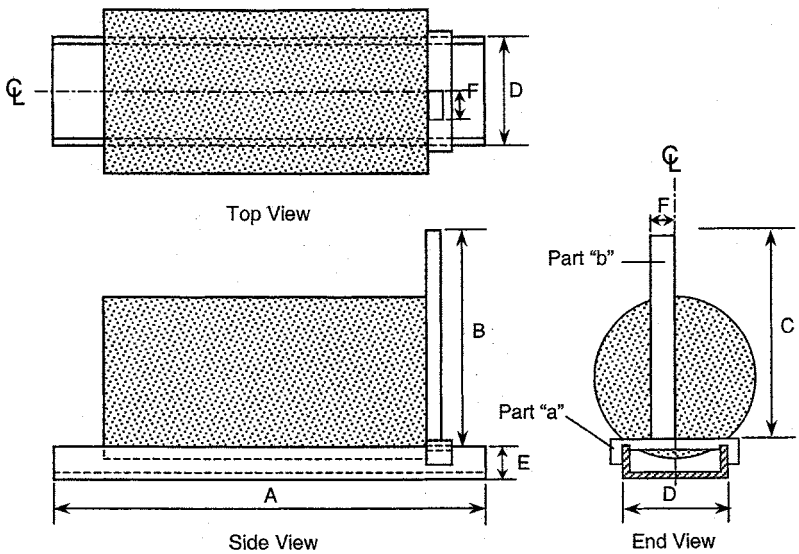
(1) A base for holding the lower bearing strip and cylinder,

(2) A supplementary bearing bar conforming to the requirements in Section 5 as to critical dimensions and planeness, and

(3) Two uprights to serve for positioning the test cylinder, bearing strips, and supplementary bearing bar.

7.2 *Measurements*—Determine the diameter of the test specimen to the nearest 0.01 in. [0.25 mm] by averaging three diameters measured near the ends and the middle of the specimen and lying in the plane containing the lines marked on the two ends. Determine the length of the specimen to the nearest 0.1 in. [2 mm] by averaging at least two length measurements taken in the plane containing the lines marked on the two ends.

7.3 *Positioning Using Marked Diametral Lines*—Center one of the plywood strips along the center of the lower bearing block. Place the specimen on the plywood strip and align so that the lines marked on the ends of the specimen are vertical and centered over the plywood strip. Place a second plywood strip lengthwise on the cylinder, centered on the lines marked on the ends of the cylinder. Position the assembly to ensure the following conditions:



A	B	C	D	E	F
16 in	8 ¼ in.	8 in.	4 in.	1 ¼ in.	1 in.
400 mm	205 mm	200 mm	100 mm	32 mm	25 mm

100 mm	25 mm	20 mm	13 mm	6 mm	4.8 mm	3.2 mm

FIG. 2 Detailed Plans for a Suitable Apparatus for Marking End Diameters Used for Aligning the Specimen

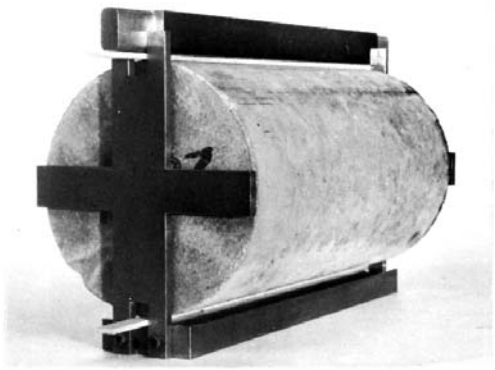

FIG. 3 Jig for Aligning Concrete Cylinder and Bearing Strips

7.3.1 The projection of the plane of the two lines marked on the ends of the specimen intersects the center of the upper bearing plate, and

7.3.2 The supplementary bearing bar or plate, when used, and the center of the specimen are directly beneath the center of thrust of the spherical bearing block (see Fig. 5).

7.4 *Positioning by Use of Aligning Jig*—Position the bearing strips, test cylinder, and supplementary bearing bar by means of the aligning jig as illustrated in Fig. 3 and center the jig so that the supplementary bearing bar and the center of the specimen are directly beneath the center of thrust of the spherical bearing block.

7.5 *Rate of Loading*—Apply the load continuously and without shock, at a constant rate within the range 100 to 200 psi/min [0.7 to 1.4 MPa/min] splitting tensile stress until failure of the specimen (Note 3). Record the maximum applied load indicated by the testing machine at failure. Note the type of failure and the appearance of the concrete.

NOTE 3—The relationship between splitting tensile stress and applied load is shown in Section 8. The required loading range in splitting tensile stress corresponds to applied total load in the range of 11 300 to 22 600 lbf [50 to 100 kN]/min for 6 by 12-in. [150 by 300-mm] cylinders.

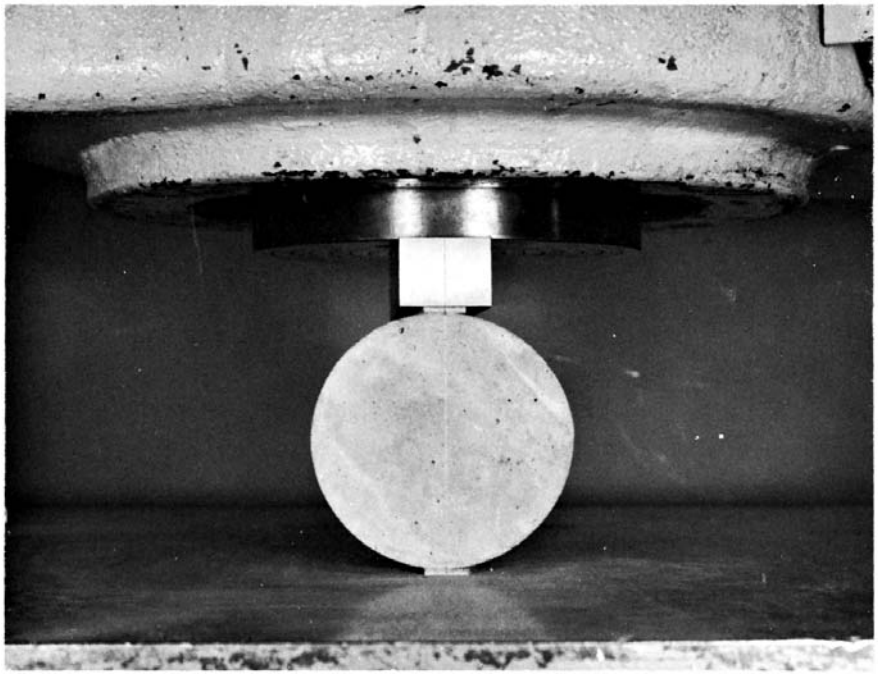

FIG. 5 Specimen Positioned in a Testing Machine for Determination of Splitting Tensile Strength

8. Calculation

8.1 Calculate the splitting tensile strength of the specimen as follows:

$$T = 2P/\pi ld \quad (1)$$

where:

T = splitting tensile strength, psi [MPa],
P = maximum applied load indicated by the testing machine, lbf [N],
l = length, in. [mm], and
d = diameter, in. [mm].

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9. Report

9.1 Report the following information:
9.1.1 Identification number,
9.1.2 Diameter and length, in. [mm],
9.1.3 Maximum load, lbf [N],
9.1.4 Splitting tensile strength calculated to the nearest 5 psi [0.05 MPa],
9.1.5 Estimated proportion of coarse aggregate fractured during test,
9.1.6 Age of specimen,
9.1.7 Curing history,
9.1.8 Defects in specimen,
9.1.9 Type of fracture, and
9.1.10 Type of specimen.

10. Precision and Bias

10.1 *Precision*—An interlaboratory study of this test method has not been performed. Available research data,[3] however, suggests that the within batch coefficient of variation is 5 % (see Note 4) for 6 × 12-in. [150 × 300-mm] cylindrical specimens with an average splitting tensile strength of 405 psi [2.8 MPa]. Results of two properly conducted tests on the same material, therefore, should not differ by more than 14 % (see Note 4) of their average for splitting tensile strengths of about 400 psi [2.8 MPa].

NOTE 4—These numbers represent, respectively, the (1s %) and (d2s %) limits as defined in Practice C 670.

10.2 *Bias*—The test method has no bias because the splitting tensile strength can be defined only in terms of this test method.

11. Keywords

11.1 cylindrical concrete specimens; splitting tension; tensile strength

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 496 – 96, that may impact the use of this test method. (Approved February 1, 2004)

(*1*) Revised 1.2.
(*2*) Added 1.4.
(*3*) Revised 5.1, 6.1, Section 2, and Note 1 to correct references.
(*4*) Revised 5.2, 6.2, 7.2, 7.5, 10.1, and Note 4 by metrication rules.
(*5*) Revised Section 4.
(*6*) Revised 3.2 and 5.3.
(*7*) Revised Note 2.
(*8*) Figs. 1, 2, and 4 were revised and redrawn.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. from the edge of the spherical or rectangular bearing block to the end of the cylinder. The bar or plate shall be used in such manner that the load will be applied over the entire length of the specimen.

5.3 *Bearing Strips*—Two bearing strips of nominal ⅛ in. [3.2 mm] thick plywood, free of imperfections, approximately 1 in. [25 mm] wide, and of a length equal to, or slightly longer than, that of the specimen shall be provided for each specimen. The bearing strips shall be placed between the specimen and both the upper and lower bearing blocks of the testing machine or between the specimen and supplemental bars or plates, when used (see 5.2). Bearing strips shall not be reused.

6. Test Specimens

6.1 The test specimens shall conform to the size, molding, and curing requirements set forth in either Practice C 31/C 31M (field specimens) or Practice C 192/C 192M (laboratory specimens). Drilled cores shall conform to the size and moisture-conditioning requirements set forth in Test Method C 42/C 42M. Moist-cured specimens, during the period between their removal from the curing environment and testing, shall be kept moist by a wet burlap or blanket covering, and shall be tested in a moist condition as soon as practicable.

6.2 The following curing procedure shall be used for evaluations of light-weight concrete: specimens tested at 28 days shall be in an air-dry condition after 7 days moist curing followed by 21 days drying at 73.5 ± 3.5°F [23.0 ± 2.0°C] and 50 ± 5 % relative humidity.

7. Procedure

7.1 *Marking*—Draw diametral lines on each end of the specimen using a suitable device that will ensure that they are in the same axial plane (see Fig. 1, Fig. 2 and Note 1), or as an alternative, use the aligning jig shown in Fig. 3 (Note 2).

NOTE 1—Figs. 1 and 2 show a suitable device for drawing diametral lines on each end of a 6 in. by 12 in. [150 mm by 300 mm] cylinder in the same axial plane. The device consists of three parts as follows:

(1) A length of 4-in. [100-mm] steel channel, the flanges of which have been machined flat,

(2) A section, part a, that is grooved to fit smoothly over the flanges of the channel and that includes cap screws for positioning the vertical member of the assembly, and

(3) A vertical bar, part b, for guiding a pencil or marker,

The assembly (part a and part b) is not fastened to the channel and is positioned at either end of the cylinder without disturbing the position of the specimen when marking the diametral lines.

NOTE 2—Fig. 4 is a detailed drawing of the aligning jig shown in Fig. 3 for achieving the same purpose as marking the diametral lines. The device consists of:

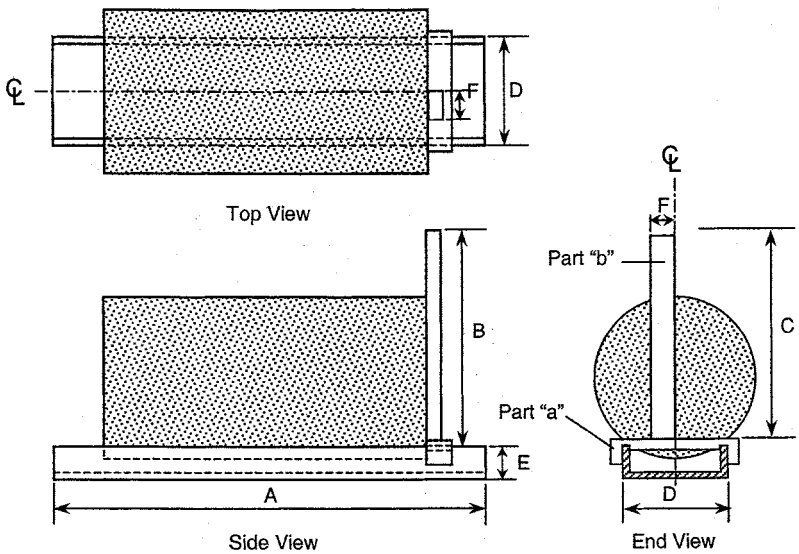
(1) A base for holding the lower bearing strip and cylinder,

(2) A supplementary bearing bar conforming to the requirements in Section 5 as to critical dimensions and planeness, and

(3) Two uprights to serve for positioning the test cylinder, bearing strips, and supplementary bearing bar.

7.2 *Measurements*—Determine the diameter of the test specimen to the nearest 0.01 in. [0.25 mm] by averaging three diameters measured near the ends and the middle of the specimen and lying in the plane containing the lines marked on the two ends. Determine the length of the specimen to the nearest 0.1 in. [2 mm] by averaging at least two length measurements taken in the plane containing the lines marked on the two ends.

7.3 *Positioning Using Marked Diametral Lines*—Center one of the plywood strips along the center of the lower bearing block. Place the specimen on the plywood strip and align so that the lines marked on the ends of the specimen are vertical and centered over the plywood strip. Place a second plywood strip lengthwise on the cylinder, centered on the lines marked on the ends of the cylinder. Position the assembly to ensure the following conditions:



A	B	C	D	E	F
16 in	8 ¼ in.	8 in.	4 in.	1 ¼ in.	1 in.
400 mm	205 mm	200 mm	100 mm	32 mm	25 mm

FIG. 2 Detailed Plans for a Suitable Apparatus for Marking End Diameters Used for Aligning the Specimen

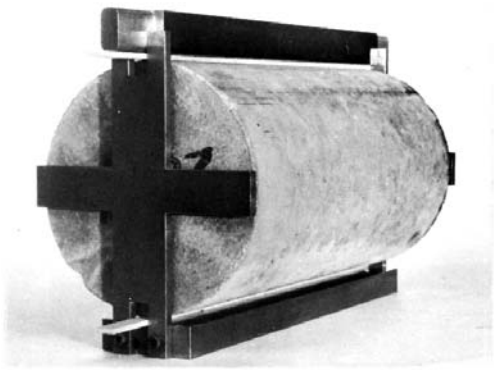

FIG. 3 Jig for Aligning Concrete Cylinder and Bearing Strips

7.3.1 The projection of the plane of the two lines marked on the ends of the specimen intersects the center of the upper bearing plate, and

7.3.2 The supplementary bearing bar or plate, when used, and the center of the specimen are directly beneath the center of thrust of the spherical bearing block (see Fig. 5).

7.4 *Positioning by Use of Aligning Jig*—Position the bearing strips, test cylinder, and supplementary bearing bar by means of the aligning jig as illustrated in Fig. 3 and center the jig so that the supplementary bearing bar and the center of the specimen are directly beneath the center of thrust of the spherical bearing block.

7.5 *Rate of Loading*—Apply the load continuously and without shock, at a constant rate within the range 100 to 200 psi/min [0.7 to 1.4 MPa/min] splitting tensile stress until failure of the specimen (Note 3). Record the maximum applied load indicated by the testing machine at failure. Note the type of failure and the appearance of the concrete.

NOTE 3—The relationship between splitting tensile stress and applied load is shown in Section 8. The required loading range in splitting tensile stress corresponds to applied total load in the range of 11 300 to 22 600 lbf [50 to 100 kN]/min for 6 by 12-in. [150 by 300-mm] cylinders.

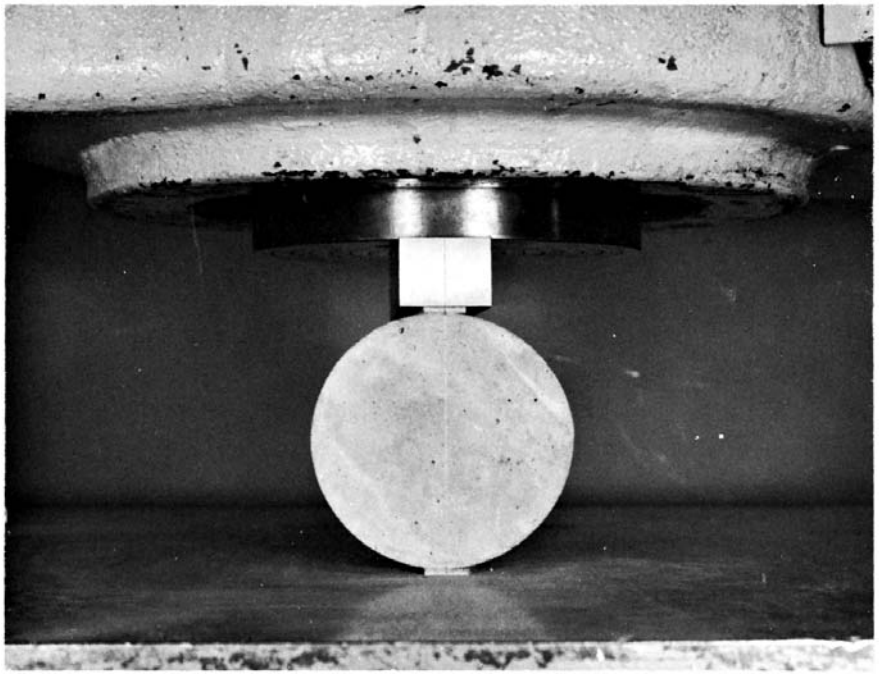

FIG. 5 Specimen Positioned in a Testing Machine for Determination of Splitting Tensile Strength

8. Calculation

8.1 Calculate the splitting tensile strength of the specimen as follows:

$$T = 2P/\pi ld \quad (1)$$

where:

T = splitting tensile strength, psi [MPa],
P = maximum applied load indicated by the testing machine, lbf [N],
l = length, in. [mm], and
d = diameter, in. [mm].

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9. Report

9.1 Report the following information:
9.1.1 Identification number,
9.1.2 Diameter and length, in. [mm],
9.1.3 Maximum load, lbf [N],
9.1.4 Splitting tensile strength calculated to the nearest 5 psi [0.05 MPa],
9.1.5 Estimated proportion of coarse aggregate fractured during test,
9.1.6 Age of specimen,
9.1.7 Curing history,
9.1.8 Defects in specimen,
9.1.9 Type of fracture, and
9.1.10 Type of specimen.

10. Precision and Bias

10.1 *Precision*—An interlaboratory study of this test method has not been performed. Available research data,[3] however, suggests that the within batch coefficient of variation is 5 % (see Note 4) for 6 × 12-in. [150 × 300-mm] cylindrical specimens with an average splitting tensile strength of 405 psi [2.8 MPa]. Results of two properly conducted tests on the same material, therefore, should not differ by more than 14 % (see Note 4) of their average for splitting tensile strengths of about 400 psi [2.8 MPa].

NOTE 4—These numbers represent, respectively, the (1s %) and (d2s %) limits as defined in Practice C 670.

10.2 *Bias*—The test method has no bias because the splitting tensile strength can be defined only in terms of this test method.

11. Keywords

11.1 cylindrical concrete specimens; splitting tension; tensile strength

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 496 – 96, that may impact the use of this test method. (Approved February 1, 2004)

(*1*) Revised 1.2.
(*2*) Added 1.4.
(*3*) Revised 5.1, 6.1, Section 2, and Note 1 to correct references.
(*4*) Revised 5.2, 6.2, 7.2, 7.5, 10.1, and Note 4 by metrication rules.
(*5*) Revised Section 4.
(*6*) Revised 3.2 and 5.3.
(*7*) Revised Note 2.
(*8*) Figs. 1, 2, and 4 were revised and redrawn.

Designation: C 511 – 09

Standard Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes[1]

This standard is issued under the fixed designation C 511; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification includes requirements for mixing rooms where paste and mortar specimens are prepared; and for moist cabinets, moist rooms, and water storage tanks where paste, mortar, and concrete specimens are stored.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard. Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and rounding given in Standard IEEE/ASTM SI 10, of measurements made in other units.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

E 77 Test Method for Inspection and Verification of Thermometers

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Terminology

3.1 *Definitions:*

3.1.1 *mixing room*, *n*—a room with controlled temperature and relative humidity where cement paste and mortar specimens are prepared.

3.1.2 *moist cabinet*, *n*—a compartmented storage facility of moderate dimensions with controlled temperature and relative humidity.

3.1.3 *moist room*, *n*—a "walk-in" storage facility with controlled temperature and relative humidity, commonly called a fog room when the prescribed relative humidity is achieved by the atomization of water.

4. Requirements for Cement Mixing Rooms

4.1 The temperature of the air in the vicinity of the mixing slab, molds, and base plates shall be maintained at 23.0 ± 4.0 ° C and at a relative humidity of not less than 50 %.

4.2 The temperature of the mixing water used to prepare cement paste and mortar specimens shall be 23.0 ± 2.0 °C.

5. Temperature Measuring Devices

5.1 *Reference Temperature Measuring Device*—used to verify the temperature recorder, must be accurate and readable to 0.5 ºC. A copy of the certificate or report which verifies the accuracy shall be available in the laboratory.

NOTE 1—The ice-point method described in Test Method E 77 may be used to ensure that no damage to the reference thermometer has occurred during shipping.

5.2 *Temperature Recorder*—shall record temperatures every 15 min or less and shall be accurate and readable to 1 º C. The data from the recorder shall be evaluated at a minimum of once each week. A record of this evaluation documenting the date checked, a confirmation that the data is within the required temperature range, and the name of the individual performing this evaluation shall be maintained in the laboratory. (Note 2)

NOTE 2—This requirement may be satisfied by an initialed and dated temperature recorder chart. Brief changes in the temperature due to door openings should be ignored.

5.2.1 The temperature recorder shall be verified at least every six months or whenever there is a question of accuracy.

5.2.1.1 For moist cabinets and rooms, position the reference temperature measuring device in a readable position in air as near as practical to the temperature recorder probe. Keep the door closed for at least 5 min prior to taking readings. Record the temperature readings of both the temperature recorder and

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the reference temperature measuring device. When taking these readings, the reference temperature measuring device shall remain in the moist cabinet or room and read immediately upon opening the door.

5.2.1.2 For water storage tanks, position the reference temperature measuring device in a readable position in water as near as practical to the temperature recorder probe. Without removing the reference temperature measuring device from the water, record the temperature readings of both the temperature recorder and the reference temperature measuring device after the temperatures have stabilized.

5.2.1.3 Verify the accuracy of the temperature recorder by comparing the reading of the temperature recorder with that of the reference temperature measuring device during the normal operation of the moist cabinet, moist room or water storage tanks. If the difference between the temperature readings is greater than 1 ºC, the temperature recorder shall be adjusted to within 0.5 ºC of the reference temperature measuring device.

6. Requirements for Moist Cabinets and Moist Rooms

6.1 *General*—Except during those times when specimens are being placed into or removed from storage, maintain the atmosphere in a moist cabinet or moist room at a temperature of 23.0 ± 2.0 °C and a relative humidity of not less than 95 %. Maintain atmospheric conditions within a moist cabinet or moist room such that test specimens in storage are saturated with moisture to the degree needed to ensure that the exposed surfaces of all specimens in storage both look moist and feel moist (See Note 5). Equip all moist cabinets and moist rooms with a temperature recorder. The use of humidity recording devices is optional. Keep shelves on which fresh specimens are placed level.

6.1.1 The air temperature inside the moist cabinet or moist room shall be controlled with provisions made for heating or cooling, or both, as may be necessary. This shall be accomplished in one of two ways:

6.1.1.1 Thermostatically control the air temperature within the moist cabinet or moist room when surrounding space is not conditioned. In this case the sensing element for the controls shall be located inside the moist cabinet or moist room.

6.1.1.2 Thermostatically control the space surrounding the moist cabinet or moist room and manually control the temperature within the moist cabinet or moist room.

6.1.2 In either of the preceding cases, the laboratory shall demonstrate the ability of the controls to maintain the required temperature in the moist cabinet or moist room over an extended period of time. Data from the temperature recorder that indicates that the temperatures are within the temperature limits specified in 6.1 shall be required as evidence of this ability.

6.2 *Moist Cabinets*—A moist cabinet shall be constructed of durable materials and the doors shall be tight-fitting. The specified relative humidity shall be maintained by the use of one or more fog sprays, water sprays, or curtains of water on the inner walls that are so directed that the discharge will collect in a pool at or near the bottom of the moist storage section.

6.3 *Moist Rooms*:

6.3.1 *General*—The walls of a moist room shall be constructed of durable materials, and all openings shall be provided with tight-fitting doors or windows (Note 3). The specified relative humidity may be maintained in any convenient and suitable manner (Note 4).

NOTE 3—Well insulated walls will substantially help maintain necessary conditions.

NOTE 4—A fog spray found suitable for this purpose is shown in Fig. 1.

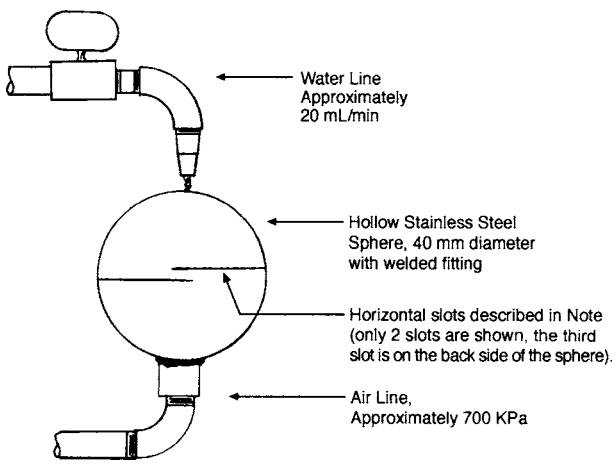
6.3.2 *Moist Rooms Used in Cement Testing*—Durable shelving that is properly shielded to prevent droplets of water from falling on the surfaces of freshly molded specimens shall be available within each moist room.

6.3.3 *Moist Rooms Used in Concrete Testing*—Maintain atmospheric conditions within each moist room such that test specimens in storage both look moist and feel moist (See Note 5). Do not expose specimens to dripping or running water.

NOTE 5—Maintenance of adequate water spray(s) and adequate spray distribution in the moist room will result in stored specimens looking and feeling moist and will maintain the required humidity. Inadequate numbers of spray nozzles, partially obstructed spray nozzles, or disturbances in the moist air system such as open doors, air-conditioning or heating drafts, or overly crowded shelf space may result in relative dry spots. Specimen surface texture and age can influence the surface appearance and should be considered when specimens in localized areas do not look and feel moist.

7. Requirements for Water Storage Tanks

7.1 *General*—Tanks shall be constructed of non-corroding materials. Provision for automatic control of water temperature at 23.0 ± 2.0 °C shall be made where a tank is located in a room not having temperature controlled within that range and in any other instance where difficulty in maintaining temperatures within the specified range is encountered. With the exception of water storage tanks located in a moist room or moist cabinet, all water storage tanks shall be equipped with a



NOTE 1—Cut three horizontal air slots around circumference of hollow sphere using a 0.20 mm thick diamond lapidary saw covering 120° to 150° each and spaced approximately 5 mm apart. Air passing through these slots strikes the water (which is flowing over the outer surface of the sphere) to produce a spray.

FIG. 1 Example of a Fog Spray for Maintaining Relative Humidity in Moist Rooms (Full Scale)

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

temperature recorder with its sensing element in the storage water. For the purpose of temperature recording, a group of water storage tanks may be considered one tank if the following three conditions are met: (*1*) all the tanks are interconnected with tubing that allows the water to flow between the tanks, (*2*) some means of circulation is provided between tanks, and (*3*) temperature variation between the tanks must not exceed 1.0 °C when checked and recorded weekly. The water in a storage tank shall be saturated with calcium hydroxide to prevent leaching of calcium hydroxide from the specimens (Note 6). Water not saturated with calcium hydroxide (high-calcium hydrated lime) may affect test results due to leaching of lime from the test specimens and shall not be used in storage tanks. To maintain saturation with calcium hydroxide, excess calcium hydroxide shall be present. For the purposes of lime saturation to prevent leaching, lime means high-calcium hydrated lime, not calcium carbonate (limestone)—see Terminology C 51. The water in the storage tank shall be thoroughly stirred at intervals not to exceed one month to help replace calcium ions that have depleted. Tanks shall be cleaned and refilled with water containing 3 g/L of calcium hydroxide at intervals not to exceed 24 months (Note 7).

NOTE 6—pH is not a reliable indicator of lime saturation in storage tank water since severe reductions in dissolved calcium ions can occur before pH values are significantly reduced.

NOTE 7—The 3 g/L level is intended to provide a quantity of calcium hydroxide approximately two times that required for initial saturation.

7.2 Do not use continuously running fresh water or demineralized water in storage tanks because it may effect test results due to excessive leaching. A closed system, circulating the saturated lime water between or among storage tanks, may be used.

8. Keywords

8.1 cement paste; concrete; mixing room; moist cabinets; moist rooms; mortar; water storage tanks

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C 511 – 06, that may impact the use of this specification. (Approved June 1, 2009)

(*1*) Revised 6.1.
(*2*) Deleted old 6.1.1 and renumbered subsequent sections
(*3*) Revised 6.3.3.
(*4*) Added new Note 5 and renumbered subsequent notes.

Designation: C 512 – 02

Standard Test Method for Creep of Concrete in Compression[1]

This standard is issued under the fixed designation C 512; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the creep of molded concrete cylinders subjected to sustained longitudinal compressive load. This test method is limited to concrete in which the maximum aggregate size does not exceed 2 in. (50 mm).

1.2 The values stated in inch-pound units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 39/C 39M Test Method for Compressive Strength of Cylindrical Concrete Specimens[2]

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory[2]

C 470/C 470M Specification for Molds for Forming Concrete Test Cylinders Vertically[2]

C 617 Practice for Capping Cylindrical Concrete Specimens[2]

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials[2]

3. Significance and Use

3.1 This test method measures the load-induced time-dependent compressive strain at selected ages for concrete under an arbitrary set of controlled environmental conditions.

3.2 This test method can be used to compare creep potentials of different concretes. A procedure is available, using the developed equation (or graphical plot), for calculating stress from strain data within massive non-reinforced concrete structures. For most specific design applications, the test conditions set forth herein must be modified to more closely simulate the anticipated curing, thermal, exposure, and loading age conditions for the prototype structure. Current theories and effects of material and environmental parameters are presented in ACI SP-9, Symposium on Creep of Concrete.[3]

3.3 In the absence of a satisfactory hypothesis governing creep phenomena, a number of assumptions have been developed that have been generally substantiated by test and experience.

3.3.1 Creep is proportional to stress from 0 to 40 % of concrete compressive strength.

3.3.2 Creep has been conclusively shown to be directly proportional to paste content throughout the range of paste contents normally used in concrete. Thus, the creep characteristics of concrete mixtures containing aggregate of maximum size greater than 2 in. (50 mm) may be determined from the creep characteristics of the minus 2-in. (minus 50-mm) fraction obtained by wet-sieving. Multiply the value of the characteristic by the ratio of the cement paste content (proportion by volume) in the full concrete mixture to the paste content of the sieved sample.

3.4 The use of the logarithmic expression (Section 8) does not imply that the creep strain-time relationship is necessarily an exact logarithmic function; however, for the period of one year, the expression approximates normal creep behavior with sufficient accuracy to make possible the calculation of parameters that are useful for the purpose of comparing concretes.

3.5 There are no data that would support the extrapolation of the results of this test to tension or torsion.

4. Apparatus

4.1 *Molds*—Molds shall be cylindrical conforming to the provisions of Practice C 192/C 192M, or to the provisions of Specification C 470/C 470M. If required, provisions shall be made for attaching gage studs and inserts, and for affixing integral bearing plates to the ends of the specimen as it is cast.

4.1.1 Horizontal molds shall conform to the requirements of the section on horizontal molds for creep test cylinders of Practice C 192/C 192M. A horizontal mold that has proven satisfactory is shown in Fig. 1.

4.2 *Loading Frame*, capable of applying and maintaining the required load on the specimen, despite any change in the dimension of the specimen. In its simplest form the loading

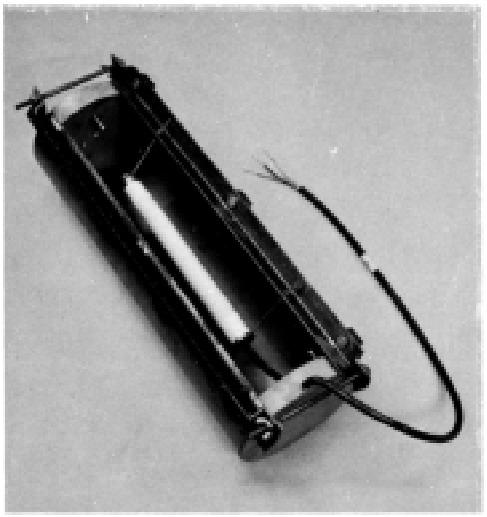

FIG. 1 Horizontal Mold for Creep Specimens

frame consists of header plates bearing on the ends of the loaded specimens, a load-maintaining element that is either a spring or a hydraulic capsule or ram, and threaded rods to take the reaction of the loaded system. Bearing surfaces of the header plates shall not depart from a plane by more than 0.001 in. (0.025 mm). In any loading frame, it is not prohibited to stack several specimens for simultaneous loading. The length between header plates shall not exceed 70 in. (1780 mm). When a hydraulic load-maintaining element is used, several frames may be loaded simultaneously through a central hydraulic pressure-regulating unit consisting of an accumulator, a regulator, indicating gages, and a source of high pressure, such as a cylinder of nitrogen or a high-pressure pump. Springs such as railroad car springs may be used to maintain the load in frames similar to those described above; the initial compression shall be applied by means of a portable jack or testing machine. When springs are used, care should be taken to provide a spherical head or ball joint, and end plates rigid enough to ensure uniform loading of the cylinders. Fig. 2 shows an acceptable spring-loaded frame. Means shall be provided for measuring the load to the nearest 2 % of total

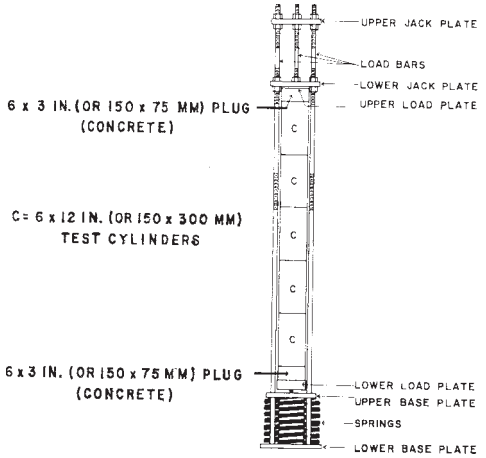

FIG. 2 Spring-Loaded Creep Frame

applied load. It is not prohibited to use a permanently installed hydraulic pressure gage or a hydraulic jack and a load cell inserted in the frame when the load is applied or adjusted.

4.3 *Strain-Measuring Device*—Suitable apparatus shall be provided for the measurement of longitudinal strain in the specimen to the nearest 10 millionths. It is not prohibited for the apparatus to be embedded, attached, or portable. If a portable apparatus is used, gage points shall be attached to the specimen in a positive manner. Attached gages relying on friction contact are not permissible. If an embedded device is used, it shall be situated so that its strain movement occurs along the longitudinal axis of the cylinder. If external devices are used, strains shall be measured on not less than two gage lines spaced uniformly around the periphery of the specimen. The gages may be instrumented so that the average strain on all gage lines can be read directly. The effective gage length shall be at least three times the maximum size of aggregate in the concrete. The strain-measuring device shall be capable of measuring strains for at least 1 year without change in calibration.

NOTE 1—Systems in which the varying strains are compared with a constant-length standard bar are considered most reliable, but unbonded electrical strain gages are satisfactory.

5. Test Specimens

5.1 *Specimen Size*—The diameter of each specimen shall be 6 ± 1/16 in. (or 150 ± 1.6 mm), and the length shall be at least 11½ in. (292 mm). When the ends of the specimen are in contact with steel bearing plates, the specimen length shall be at least equal to the gage length of the strain-measuring apparatus plus the diameter of the specimen. When the ends of the specimen are in contact with other concrete specimens similar to the test specimen, the specimen length shall be at least equal to the gage length of the strain-measuring apparatus plus 1½ in. (38 mm). Between the test specimen and the steel bearing plate at each end of a stack, a supplementary noninstrumented cylinder whose diameter is equal to that of the test cylinders and whose length is at least half its diameter shall be installed.

5.2 *Fabricating Specimens*—The maximum size of aggregate shall not exceed 2 in. (50-mm) (Section 3). Vertically cast cylinders shall be fabricated in accordance with the provisions of Practice C 192/C 192M. The ends of each cylinder shall meet the planeness requirements described in the scope of Practice C 617 (Note 2). Horizontally cast specimens shall be consolidated by the method appropriate to the consistency of the concrete as indicated in the methods of consolidation section of Practice C 192/C 192M. Care must be taken to ensure that the rod or vibrator does not strike the strain meter. When vibration is used, the concrete shall be placed in one layer and the vibrating element shall not exceed 1¼ in. (32 mm) in diameter. When rodding is used, the concrete shall be placed in two approximately equal layers and each layer shall be rodded 25 times evenly along each side of the strain meter. After consolidation, the concrete shall be struck off with trowel or float, then trowelled the minimum amount to form the concrete in the opening concentrically with the rest of the specimen. It is not prohibited to use a template curved in the radius of the specimen as a strikeoff to shape and finish the

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

concrete more precisely in the opening. When cylinders are to be stacked, lapping of ends is strongly recommended.

NOTE 2—Requirements for planeness may be met by capping, lapping, or, at the time of casting, fitting the ends with bearing plates normal to the axis of the cylinder.

5.3 *Number of Specimens*—No fewer than six specimens (Note 3) shall be made from a given batch of concrete for each test condition; two shall be tested for compressive strength, two shall be loaded and observed for total deformation, and two shall remain unloaded for use as controls to indicate deformations due to causes other than load. Each strength and control specimen shall undergo the same curing and storage treatment as the loaded specimen.

NOTE 3—It is recommended that specimens be tested in triplicate although duplicate specimens are acceptable.

6. Curing and Storage of Specimens

6.1 *Standard Curing*—Before removal from the molds, specimens shall be stored at 73.4 ± 3.0°F (23.0 ± 1.7°C) and covered to prevent evaporation. The specimens shall be removed from the molds not less than 20 nor more than 48 h after molding and stored in a moist condition at a temperature of 73.4 ± 3.0°F until the age of 7 days. A moist condition is that in which free water is maintained on the surfaces of the specimens at all times. Specimens shall not be exposed to a stream of running water nor be stored in water. After the completion of moist curing the specimens shall be stored at a temperature of 73.4 ± 2.0°F (23.0 ± 1.1°C) and at a relative humidity of 50 ± 4 % until completion of the test.

6.2 *Basic Creep Curing*—If it is desired to prevent the gain or loss of water during the storage and test period, specimens shall at the time of fabrication or stripping be enclosed and sealed in moistureproof jackets (for example, copper or butyl rubber) to prevent loss of moisture by evaporation and shall remain sealed throughout the period of storage and testing.

6.3 *Variable Curing Temperature Regimen*—When it is desired to introduce the effect of temperature on the elastic and inelastic properties of a concrete (as, for example, the adiabatic temperature conditions existing in massive concrete or temperature conditions to which concrete is subjected during accelerated curing), temperatures within the specimen storage facility shall be controlled to correspond to the desired temperature history. The user shall be responsible for establishing the time-temperature history to be followed and the permissible range of deviation therefrom.

6.4 *Other Curing Conditions*—Other test ages and ambient storage conditions may be substituted when information is required for specific applications. The storage conditions shall be carefully detailed in the report.

7. Procedure

7.1 *Age at Loading*—When the purpose of the test is to compare the creep potential of different concretes, initially load the specimens at an age of 28 days. When the complete creep behavior of a given concrete is desired, prepare the specimens for initial loading in the following ages: 2, 7, 28, and 90 days, and 1 year. If information is desired for other ages of loading, include the age in the report.

7.2 *Loading Details*—Immediately before loading the creep specimens, determine the compressive strength of the strength specimens in accordance with Test Method C 39/C 39M. At the time unsealed creep specimens are placed in the loading frame, cover the ends of the control cylinders to prevent loss of moisture (Note 4). Load the specimens at an intensity of not more than 40 % of the compressive strength at the age of loading. Take strain readings immediately before and after loading, 2 to 6 h later, then daily for 1 week, weekly until the end of 1 month, and monthly until the end of 1 year. Before taking each strain reading, measure the load. If the load varies more than 2 % from the correct value, it must be adjusted (Note 5). Take strain readings on the control specimens on the same schedule as the loaded specimens.

NOTE 4—In placing creep specimens in the frame, take care in aligning the specimens to avoid eccentric loading. When cylinders are stacked and external gages are used, it may be helpful to apply a small preload such that the resultant stress does not exceed 200 psi (1380 kPa) and note the strain variation around each specimen, after which the load may be removed and the specimens realigned for greater strain uniformity.

NOTE 5—Where springs are used to maintain the load, the adjustment can be accomplished by applying the correct load and tightening the nuts on the threaded reaction rods.

8. Calculation

8.1 Calculate the total load-induced strain per pound per square inch (or kilopascal) at any time as the difference between the average strain values of the loaded and control specimens divided by the average stress. To determine creep strain per pound-force per square inch (or kilopascal) for any age, subtract from the total load-induced strain per pound-force per square inch (or kilopascal) at that age the strain per pound-force per square inch (or kilopascal) immediately after loading. If desired, plot total strain per pound-force per square inch (or kilopascal) on semilog coordinate paper, on which the logarithmic axis represents time, to determine the constants $1/E$ and F (K) for the following equation:

$$\epsilon = (1/E) + F(K)\ln(t + 1) \quad (1)$$

where:

ϵ = total strain psi (or kPa),
E = instantaneous elastic modulus, psi (or kPa),
$F(K)$ = creep rate, calculated as the slope of a straight line representing the creep curve on the semilog plot, and
t = time after loading, days.

The quantity $1/E$ is the initial elastic strain per pound per square inch (or kilopascal) and is determined from the strain readings taken immediately before and after loading the specimen. If loading was not accomplished expeditiously, some creep may have occurred before the after-loading strain was observed, in which event extrapolation to zero time by the method of least squares may be used to determine this quantity.

9. Report

9.1 Report the following information:

9.1.1 Cement content, water-cement ratio, maximum aggregate size, slump, and air content,

9.1.2 Type and source of cement, aggregate, admixture, and mixing water (if other than fresh water is used),

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:21:58 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.1.3 Position of cylinder when cast,
9.1.4 Storage conditions prior to and subsequent to loading,
9.1.5 Age at time of loading,
9.1.6 Compressive strength at age of loading,
9.1.7 Type of strain measuring device,
9.1.8 Magnitude of any preload,
9.1.9 Intensity of applied load,
9.1.10 Initial elastic strain,
9.1.11 Creep strain per pound per square inch (or kilopascal) at designated ages up to 1 year, and
9.1.12 Creep rate, *F* (*K*), if determined.

10. Precision and Bias

10.1 *Precision*—The single-operator single-batch coefficient of variation has been found to be 4.0 %[4], and the single-operator-multi-batch coefficient of variation has been found to be 9.0 % [4], over the range of creep strains from 250 to 2000 millionths. The results of two properly conducted tests by the same operator on the same material should not differ by more than 6 %[5] of their average. The results of two properly conducted tests by the same operator on material cast from different batches should not differ by more than 13 %[5] of their average.

10.2 *Bias*—This test method has no bias because the values determined can only be defined in terms of the test method.

11. Keywords

11.1 compression; concrete; creep; creep strain; elastic strain

Designation: C 514 – 04 (Reapproved 2009)ε1

Standard Specification for Nails for the Application of Gypsum Board[1]

This standard is issued under the fixed designation C 514; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

ε[1] NOTE—The units statement in 1.3 was revised editorially in May 2009.

1. Scope

1.1 This specification covers requirements for steel wire nails suitable for use in the application of gypsum board.

1.2 Details of construction for a specific assembly to achieve the required fire resistance shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing laboratories.

1.3 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.4 The following precautionary caveat pertains only to the test method portion, Sections 7 and 8, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

E 4 Practices for Force Verification of Testing Machines

3. Materials

3.1 *Steel Wire*, used in the manufacture of nails, shall be of hard-drawn low or medium-low-carbon steel, entirely suitable for the purpose intended. Before fabrication it shall be sufficiently ductile to withstand cold-bending, without fracture, through 180° over a radius not greater than the diameter of the wire (see Section 8).

4. Physical Properties

4.1 *Ductility*—The nail shall be sufficiently ductile to withstand cold bending without fracture when tested according to Section 8.

4.2 *Withdrawal Resistance*—The average withdrawal resistance, both immediate and delayed, shall be at least equal to that provided by 12.5 gage (0.099 ± 0.003 in.) (2.515 ± 0.08 mm) bright, smooth shank, nails with a medium diamond point, when tested according to 8.2.

5. Dimensions and Permissible Variations

5.1 *Heads*—Shall be not less than 0.2375 in. (6.0 mm) and not more than 0.3875 in. (9.8 mm) in diameter, shall be not more than 1/64 in. (0.4 mm) thick at the peripheral edge, shall be uniformly tapered to a small fillet around the shank, shall be either flat or concave, and shall be free from protrusions and sharp, irregular edges.

5.2 *Shanks*—Diameter shall not vary more than ± 0.003 in. (0.08 mm) for shank diameters 0.076 in. (1.93 mm) or larger.

5.3 *Points*—The nails shall have medium to long diamond or needle points.

5.4 *Clearance*—Where a deformation process produces other than a smooth shank nail, a clearance area (round and smooth), measured from the top of the head to the deformed section, shall be provided equal to the nominal thickness of the gypsum board for which the nails are specified.

6. Workmanship, Finish, and Appearance

6.1 The nails shall be bright, or chemically treated, or coated with rust inhibiting material provided that such chemical treatment or rust inhibitor does not adversely affect the performance of the nail as specified in Section 4. The nails

www.technobetar.ir

shall also be compatible with the joint compound and decoration. Nails shall be neatly formed and free from injurious defects or deformations.

7. Number of Tests

7.1 At least five nails from each lot of 100 individual containers shall be examined to determine conformance to the requirements of this specification.

8. Test Methods

8.1 *Bend Test*:

8.1.1 *Significance and Use*—This test method is performed to determine the ductility of a nail, and used to determine compliance with this specification.

8.1.2 *Procedure*—Hold the test nail in a vise and bend by means of a clamp or similar device attached to the free end of the nail through 90° over a radius not greater than the diameter of the nail.

8.1.3 *Precision and Bias*—Neither the precision nor the bias of the nail bend test have been determined.

8.2 *Withdrawal Resistance*

8.2.1 *Significance and Use*—This test method determines the resistance to withdrawal from a wood block of the test nail compared to a standard nail. It is used to determine compliance with this specification.

8.2.2 *Apparatus*:

8.2.2.1 *Testing machine*—The testing machine shall be of any type that is of sufficient capacity and that is capable of applying a tensile load at the strain rate prescribed in 8.2.3.2. The load platform shall be of sufficient size to accept the block of wood described in 8.2.2.5. The testing machine shall be power operated and shall apply the load continuously and without shock.

8.2.2.2 The test apparatus shall be verified according to Practices E 4, Sections 16 through 18.

8.2.2.3 *Load Indicating Equipment*, capable of reading to 1 lbf (4.45 N) increments shall be provided for the test apparatus. A means shall be provided to indicate the maximum load attained during the test.

8.2.2.4 A means of securing the blocks of wood to the platform or lower cross head shall be provided so that the nails are aligned with the direction of pull. A device shall be attached to the upper cross head to grasp the nail head securely and hold it during the test for the purpose of pulling the nail from the block of wood.

8.2.2.5 *Wood Nailing Blocks*—Nominal 2 by 6 in. (38 by 140 mm) Douglas Fir, construction grade, containing at least 16 %, but not more than 19 %, free moisture as determined by a suitable moisture meter. Required wood blocks for a test series shall be cut from a single piece of lumber creating blocks free of knots.

8.2.3 *Procedure*:

8.2.3.1 Alternately use twenty of the standard 12.5 gage nails and twenty of the nails being tested and hammer drive to a depth of ⅞ in. (22.2 mm) into the longitudinal center line of one edge and one side face of the wood blocks. Space nails 3 in. (76 mm) apart. Determine the comparative performance as follows:

8.2.3.2 *Immediate*—Withdraw alternate samples of each type of nail from each face, ten of each nail, at the rate of 0.06 in. (1.5 mm)/min.

8.2.3.3 *Delayed*—Condition the lumber, into which the nails are driven, at 50 ± 2 % relative humidity and 70 ± 5 °F (21.1 ± 3 °C) to constant weight, after which withdraw the remaining nails.

8.2.4 *Precision and Bias*—Neither the precision nor the bias have been determined for the nail withdrawal test method.

9. Certification

9.1 When specified in the purchase order a producer's or supplier's certification shall be furnished to the purchaser that the material is in compliance with this specification.

10. Packaging and Package Marking

10.1 Unless otherwise specified, nails shall be packaged in substantial commercial containers of the type, size, and kind commonly used for the purpose, so constructed as to preserve the contents in good condition and to ensure acceptance and safe delivery by common or other carriers, at the lowest rate, to the point of delivery. In addition, the containers shall be so made that the contents can be partially removed without destroying the container's ability to serve as a receptacle for the remainder of the contents.

10.2 Unless otherwise specified, individual packages and shipping containers shall be marked with the type and length of nail and the name of the manufacturer or distributor. Individual packages shall also be marked with the name of the manufacturer or distributor and the net mass.

11. Keywords

11.1 gypsum board; nail; points; shanks; wire heads

Designation: C 535 – 09

Standard Test Method for Resistance to Degradation of Large-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine[1]

This standard is issued under the fixed designation C 535; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers testing sizes of coarse aggregate larger than 19 mm (¾ in.) for resistance to degradation using the Los Angeles testing machine (Note 1).

NOTE 1—A procedure for testing coarse aggregate smaller than 37.5 mm (1½ in.) is covered in Test Method C 131.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in SI units are to be regarded as the standard. The inch-pound values given in parentheses are for information only.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 131 Test Method for Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 702 Practice for Reducing Samples of Aggregate to Testing Size

D 75 Practice for Sampling Aggregates

E 11 Specification for Woven Wire Test Sieve Cloth and Test Sieves

3. Terminology

3.1 For definitions of terms used in this test method, refer to Terminology C 125.

4. Summary of Test Method

4.1 This test is a measure of degradation of mineral aggregates of standard gradings resulting from a combination of actions including abrasion or attrition, impact, and grinding in a rotating steel drum containing 12 steel spheres. As the drum rotates, a shelf plate picks up the sample and the steel spheres, carrying them around until they are dropped to the opposite side of the drum, creating an impact-crushing effect. The contents then roll within the drum with an abrading and grinding action until the shelf plate picks up the sample and the steel spheres, and the cycle is repeated. After the prescribed number of revolutions, the contents are removed from the drum and the aggregate portion is sieved to measure the degradation as percent loss.

5. Significance and Use

5.1 The test has been widely used as an indicator of the relative quality or competence of various sources of aggregate having similar mineral compositions. The results do not automatically permit valid comparisons to be made between sources distinctly different in origin, composition, or structure. Assign specification limits with extreme care in consideration of available aggregate types and their performance history in specific end uses.

6. Apparatus

6.1 *The Los Angeles Machine* shall conform to the requirements of Test Method C 131.

6.1.1 The operation and maintenance of the machine shall be as prescribed in Test Method C 131.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved July 1, 2009. Published August 2009. Originally approved in 1964. Last previous edition approved in 2003 as C 535 – 03$^{\varepsilon 1}$.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

6.2 *Sieves*, conforming to Specification E 11.

6.3 *Balance*—A balance or scale accurate within 0.1 % of test load over the range required for this test

6.4 *Charge*—The charge (Note 2) shall consist of 12 steel spheres averaging approximately 47 mm (1 27/32 in.) in diameter, each having a mass between 390 and 445 g, and having a total mass of 5000 ± 25 g.

NOTE 2—Steel ball bearings 46.0 mm (1 13/16 in.) and 47.6 mm (1 7/8 in.) in diameter, having a mass approximately 400 and 440 g each, respectively, are readily available. Steel spheres 46.8 mm (1 27/32 in.) in diameter having a mass approximately 420 g may also be obtainable. The charge may consist of a mixture of these sizes conforming to the total mass tolerance of 6.4.

7. Sampling

7.1 Obtain the field sample in accordance with Practice D 75 and reduce to an adequate sample size in accordance with Practice C 702.

8. Test Sample Preparation

8.1 Wash the reduced sample and oven dry at 110 ± 5°C (230 ± 9°F) to substantially constant mass, separate into individual size fractions, and recombine to the grading of Table 1 most nearly corresponding to the range of sizes in the aggregate as furnished for the work. Record the mass of the sample prior to test to the nearest 1 g.

9. Procedure

9.1 Place the test sample and charge in the Los Angeles testing machine and rotate the machine at 30 to 33 r/min for 1000 revolutions (Note 3). After the prescribed number of revolutions, discharge the material from the machine and make a preliminary separation of the sample on a sieve coarser than the 1.70-mm (No. 12) sieve. Sieve the finer portion on a 1.70-mm sieve in a manner conforming to Test Method C 136. Wash the material coarser than the 1.70-mm sieve and oven dry at 110 ± 5°C (230 ± 9°F) to substantially constant mass, and determine the mass to the nearest 1 g .

9.1.1 If the aggregate is essentially free of adherent coatings and dust, the requirement for washing after the test is optional. However, in the case of referee testing, the washing procedure shall be performed. Elimination of washing after test will seldom reduce the measured loss by more than about 0.2 % of the original sample mass.

NOTE 3—Valuable information concerning the uniformity of the sample under test may be obtained by determining the loss after 200 revolutions. This loss should be determined by dry sieving the material on the 1.70-mm (No. 12) sieve without washing. The ratio of the loss after 200 revolutions to the loss after 1000 revolutions should not greatly exceed 0.20 for material of uniform hardness. When this determination is made, take care to avoid losing any part of the sample; return the entire sample, including the dust of fracture, to the testing machine for the final 800 revolutions required to complete the test.

10. Calculation

10.1 Calculate the loss (the difference between the original mass and the final mass of the test sample) as a percentage of the original mass of the test sample (Note 4).

NOTE 4—The percent loss determined by this method has no known consistent relationship to the percent loss for the same material when tested by Test Method C 131.

11. Report

11.1 Report the following information:

11.2 Identification of the aggregate as to source, type, and nominal size, and

11.3 Grading designation from Table 1 used for the test, and

11.4 Loss by abrasion and impact of the sample expressed to the nearest 1 % by mass.

12. Precision

12.1 *Repeatability*—Based on four replicate tests by a single operator on one aggregate at a single laboratory using the same equipment, the average degradation (abrasion) loss, with a No. 1 grading was found to be 38.8 % and the standard deviation was 1.8 %

12.2 *Bias*—No statement is being made about the bias of this Test Method since there is no accepted reference material suitable for determining the bias of this procedure.

13. Keywords

13.1 abrasion; aggregate (coarse; large size); degradation; impact; Los Angeles machine

TABLE 1 Gradings of Test Samples

APPENDIX

(Nonmandatory Information)

X1. MAINTENANCE OF SHELF

X1.1 The shelf of the Los Angeles machine is subject to severe surface wear and impact. With use, the working surface of the shelf is peened by the balls and tends to develop a ridge of metal parallel to and about 32 mm (1¼ in.) from the junction of the shelf and the inner surface of the cylinder. If the shelf is made from a section of rolled angle, not only may this ridge develop but the shelf itself may be bent longitudinally or transversely from its proper position.

X1.2 The shelf should be inspected periodically to determine that it is not bent either lengthwise or from its normal radial position with respect to the cylinder. If either condition is found, the shelf should be repaired or replaced before further tests are made. The influence on the test result of the ridge developed by peening of the working face of the shelf is not known. However, for uniform test conditions, it is recommended that the ridge be ground off if its height exceeds 0.1 in. (2 mm).

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 535 – 03$^{\varepsilon 1}$, that may impact the use of this test method. (Approved July 1, 2009)

(*1*) Revised 12.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 563 – 07

Standard Test Method for Approximation of Optimum SO_3 in Hydraulic Cement Using Compressive Strength[1]

This standard is issued under the fixed designation C 563; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method describes the determination of approximate optimum SO_3 for maximum compressive strength at 24 h, 3 days, or 7 days by measuring the change in strength produced in hydraulic cement mortar as a result of substituting calcium sulfate for a portion of the cement.

1.2 This test method refers to the sulfur trioxide (SO_3) content of the cement only. Slag cements and occasionally other hydraulic cements can contain sulfide or other forms of sulfur. The determination of SO_3 content by rapid methods may include these other forms, and may therefore produce a significant error. If a significant error occurs, analyze the cement for SO_3 content using the reference test method of Test Methods C 114 for sulfur trioxide.

1.3 Values stated as SI units are to be regarded as standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

C 595 Specification for Blended Hydraulic Cements

C 778 Specification for Standard Sand

C 1157 Performance Specification for Hydraulic Cement

C 1437 Test Method for Flow of Hydraulic Cement Mortar

3. Significance and Use

3.1 The purpose of this test method is to estimate the SO_3 content for a hydraulic cement that gives maximum compressive strength in mortar made and cured at 23 °C. The value obtained is used to establish an appropriate level of sulfate in the manufacture of cements specified in Specifications C 150, C 595 and C 1157. In Specifications C 150 and C 595 it is used to justify exceeding the prescriptive limits for SO_3.

3.2 The SO_3 content of a cement giving maximum compressive strength is different at different ages of mortar; typically this SO_3 content is higher at 3 days than the 24-h, and often higher for 7 days than that for 3 days. A manufacturer can choose the age of 24-h, 3 days or 7 days for specimens at which to determine optimum SO_3 content.

3.3 This test method indicates optimum SO_3 content for cement in mortar made and cured at a standard temperature of 23.0 ± 2.0 °C (73.5 ± 3.5 °F). The optimum SO_3 increases with increasing temperature and may increase when water-reducing admixtures are used.

3.4 It should not be assumed that the optimum SO_3 estimated in this test method is the same SO_3 content for optimum performance of a concrete prepared from the cement.

3.5 The test method is applicable to cements specified in Specifications C 150, C 595, and C 1157.

4. Apparatus

4.1 Use the apparatus as specified in Test Method C 109/C 109M.

5. Materials

5.1 *Calcium Sulfate*—Use calcium sulfate for addition to the cement that is either a high-grade natural gypsum having an SO_3 content of at least 46 %, or the calcium sulfate from the source used for the intended plant production. Grind the

www.technobetar.ir

calcium sulfate to 100 % passing the 75-μm (No. 200) sieve, and at least 800 m^2/kg Blaine fineness (Test Method C 204). If the SO_3 content of the calcium sulfate is unknown, analyze it in accordance with Test Methods C 471M.

5.2 *Blended Standard Sand*—Use graded sand conforming to Specification C 778.

6. Test Specimens

6.1 Make six specimens from each batch of mortar. Make two rounds of three mixtures of mortar as described in 6.3. Make both rounds during the same day if possible. Make only complete rounds on any given day.

6.2 *Preparing Specimen Molds*—Prepare molds in accordance with the section on Preparation of Specimen Molds of Test Method C 109/C 109M.

6.3 *Proportioning, Consistency, and Mixing of Mortar*—Proportion the dry material for the standard mortar as one part of cement to 2.75 parts graded sand by mass. Mix the following quantities of dry materials at one time for a 6-cube batch:

Mixture No. 1—	500 g cement
	1375.0 g graded sand
Mixture No. 2—	494.6 g cement
	5.3 g calcium sulfate
	1375.0 g graded sand
Mixture No. 3—	489.2 g cement
	10.6 g calcium sulfate
	1375.0 g graded sand

6.3.1 Use an amount of mixing water to produce a flow of 110 ± 5 using 25 drops of the table as determined in the section on Procedures in Test Method C 1437 for all types of cement.

6.3.2 Mix mechanically in accordance with the section on Procedure for Mixing Mortars of Practice C 305, except as follows:

6.3.2.1 Add the calcium sulfate to the water; then start the mixer and mix at slow speed (140 ± 5 rpm) for 15 s; then stop the mixer and add the cement to the water; then start the mixer and mix at slow speed (140 ± 5 rpm) for 30 s.

6.4 *Molding of Test Specimens*—Mold specimens in accordance with the Procedure Section of Test Method C 109/C 109M.

6.5 *Storage of Test Specimens*—Immediately upon completion of molding, place the test specimens in the moist closet or moist room. Keep all test specimens, immediately after molding, in the molds on the base plates in the moist closet or moist room for 20 to 24 h with their upper surfaces exposed to the moist air but protected from dripping water. If the specimens are removed from the molds before 24 h, keep them on the shelves of the moist closet or moist room until they are 24-h old and then immerse the specimens, except those for the 24-h test, in saturated lime water in storage tanks constructed of noncorroding materials until the age chosen for the test. Keep the storage water clean by changing as required.

7. Temperature and Humidity

7.1 The temperature and humidity of the moist cabinet or moist room shall be as specified in Specification C 511.

7.2 The temperature and humidity of the mixing room shall be as specified in Test Method C 109/C 109M.

8. Procedure

8.1 Test the specimens at the age of 24 ± ¼ h, 3 days ± 1 h, or 7 days ± 3 h, from the time the cement and water made contact during mixing, immediately after removal from storage in accordance with Test Method C 109/C 109M. If more than one specimen at a time is removed from storage, keep these specimens covered with a damp cloth until time of testing. Note and observe precautions regarding testing and retesting given in the applicable sections of Test Method C 109/C 109M.

9. Calculation

9.1 Calculate and record the strength of specimens as described in the section on Calculation in Test Method C 109/C 109M.

9.1.1 Calculate the indicated optimum SO_3 content as follows:

$$G = [a/(a - b)]\, c + d + c/2$$

where:

G = optimum percent SO_3,
a = average strength both rounds of Mixture No. 2 minus Mixture No. 1,
b = average strength both rounds of Mixture No. 3 minus Mixture No. 2,
c = (percent SO_3 in calcium sulfate)/100, and
d = percent SO_3 in test cement.

10. Retest

10.1 Regard the results obtained as suspect and repeat the test under any of the following conditions:

10.1.1 If a and b both are positive and the ratio a/b is less than 2.00,

10.1.2 If a and b both are negative and the ratio a/b is greater than 0.500, or

10.1.3 If a is negative and b is positive.

11. Report

11.1 If repeat tests confirm that the ratio of a/b departs from the limiting values as stated above, report the SO_3 content of the cement as "above optimum" or "below optimum" as the data may indicate, but without stating the numerical value of optimum SO_3.

11.2 If the test data indicate that the cement is "below optimum" but do not permit a computation of the percentage of SO_3 required for optimum, an additional series of tests involving greater substitutions of gypsum for part of the cement should yield results that will permit an acceptable calculation of the percentage of SO_3 required for optimum. If the test data indicate that the cement is "above optimum" but do not permit a computation of the percentage of SO_3 required for optimum, in order to establish the required percentage of SO_3 for optimum, it is necessary to make tests of a new sample of similar cement but having an original SO_3 content lower than that of the original cement.

11.3 Report the age of the test specimens.

12. Precision and Bias

12.1 *Precision*—The coefficient of variation for this test method, using 6 cubes per batch, is very similar to that for Test

www.technobetar.ir

Method C 109/C 109M compression cubes tested at later ages. Refer to Test Method C 109/C 109M for suitable values.

12.2 *Bias*—Since there is no accepted reference material suitable for determining optimum SO_3, bias has not been determined.

13. Keywords

13.1 blended hydraulic cement; calcium sulfate; cement; compressive strength; gypsum; hydraulic cement; optimum sulfate content (of cement); portland cement; strength (of cement); sulfate content (of cement)

APPENDIX

(Nonmandatory Information)

X1. DISCUSSION OF THE TERM "OPTIMUM"

X1.1 The scope statement notes that this test method determines the optimum SO_3 content in cements in mortar at a particular temperature and age. Usually, but not always, the SO_3 content that produces the highest 24-h strength at 23 °C also produces approximately the lowest expansion in water and the lowest contraction in air at that temperature.

X1.2 The "optimum" determined by this test is approximate. The "optimum" SO_3 content will vary with changes in mortar proportions; between cement paste, mortars and concrete; will vary with the source of SO_3; with the age of test; with the use of chemical admixtures; and with the use of supplementary cementitious materials. Thus, the term "optimum SO_3" refers to an approximate value.

X1.3 The age for determining the optimum is typically chosen by the manufacturer based on experience with local concrete materials.

X1.4 For convenience, the method uses the compressive strength of specimens at three different SO_3 contents for the cement. If the strength results are plotted against SO_3 content, the three points are assumed to give a curve in the shape of a parabola, and the calculation used assumes this shape. If more points are used with smaller SO_3 content increments, the shape of the curve is seen to be that of a "sawtooth," with a decreasing slope up to the apex at maximum strength, followed by a precipitous fall in strength immediately after the apex. The apex represents the actual optimum SO_3 content, and is typically higher than that calculated using three points. Therefore, this affords a small "cushion" when targeting the calculated optimum SO_3 (determined using three points) during manufacture to allow for variation in the process.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 563 – 04, which may impact the use of this test method. (Approved April 1, 2007)

(*1*) Changed the titled to add the word "Approximate" and remove "24-h."

(*2*) Added 3- and 7-day testing options.

(*3*) Added an appendix to provide a home for explanatory information, and moved appropriate text into the appendix.

(*4*) Changed 6.5 to match Test Method C 109/C 109M provisions for storage, and made the corresponding change to Section 8.

Designation: C 566 – 97 (Reapproved 2004)

Standard Test Method for Total Evaporable Moisture Content of Aggregate by Drying[1]

This standard is issued under the fixed designation C 566; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the determination of the percentage of evaporable moisture in a sample of aggregate by drying both surface moisture and moisture in the pores of the aggregate. Some aggregate may contain water that is chemically combined with the minerals in the aggregate. Such water is not evaporable and is not included in the percentage determined by this test method.

1.2 The values stated in SI units are to be regarded as the standard. The values stated in parentheses are provided for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific precautionary statements, see 5.3.1, 7.2.1, and 7.3.1.

D 75 Practice for Sampling Aggregates

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

2.2 *Other Document:*

National Research Council Report SHRP-P-619[3]

3. Terminology

3.1 *Definitions:*

3.1.1 For definitions of terms used in this test method, refer to Terminology C 125.

4. Significance and Use

4.1 This test method is sufficiently accurate for usual purposes, such as adjusting batch quantities of ingredients for concrete. It will generally measure the moisture in the test sample more reliably than the sample can be made to represent the aggregate supply. In cases where the aggregate itself is altered by heat, or where more refined measurement is required, the test should be conducted using a ventilated, controlled temperature oven.

4.2 Large particles of coarse aggregate, especially those larger than 50 mm (2 in.), will require greater time for the moisture to travel from the interior of the particle to the surface. The user of this test method should determine by trial if rapid drying methods provide sufficient accuracy for the intended use when drying large size particles.

5. Apparatus

5.1 *Balance*—A balance or scale accurate, readable, and sensitive to within 0.1 % of the test load at any point within the range of use. Within any interval equal to 10 % of the capacity of the balance or scale used to determine mass, the load indication shall be accurate within 0.1 % of the difference in masses.

5.2 *Source of Heat*—A ventilated oven capable of maintaining the temperature surrounding the sample at 110 ± 5°C (230 ± 9°F). Where close control of the temperature is not required (see 4.1), other suitable sources of heat may be used, such as an electric or gas hot plate, electric heat lamps, or a ventilated microwave oven.

5.3 *Sample Container*—A container not affected by the heat, of sufficient volume to contain the sample without danger of spilling, and of such shape that the depth of sample will not exceed one fifth of the least lateral dimension.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.20 on Normal Weight Aggregates.

Current edition approved February 1, 2004. Published March 2004. Originally approved in 1965. Last previous edition approved in 1997 as C 566 – 97.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

5.3.1 **Precaution**—When a microwave oven is used, the container shall be nonmetallic.

NOTE 1—Except for testing large samples, an ordinary frying pan is suitable for use with a hot plate, or any shallow flat-bottomed metal pan is suitable with heat lamps or oven. Note the precaution in 5.3.1.

5.4 *Stirrer*—A metal spoon or spatula of convenient size.

6. Sampling

6.1 Sample in accordance with Practice D 75, except for the sample size.

6.2 Secure a sample of the aggregate representative of the moisture content in the supply being tested and having a mass not less than the amount listed in Table 1. Protect the sample against loss of moisture prior to determining the mass.

7. Procedure

7.1 Determine the mass of the sample to the nearest 0.1 %.

7.2 Dry the sample thoroughly in the sample container by means of the selected source of heat, exercising care to avoid loss of any particles. Very rapid heating may cause some particles to explode, resulting in loss of particles. Use a controlled temperature oven when excessive heat may alter the character of the aggregate, or where more precise measurement is required. If a source of heat other than the controlled temperature oven is used, stir the sample during drying to accelerate the operation and avoid localized overheating. When using a microwave oven, stirring of the sample is optional.

7.2.1 **Caution—**When using a microwave oven, occasionally minerals are present in aggregates that may cause the material to overheat and explode. If this occurs it can damage the microwave oven.

7.3 When a hot plate is used, drying can be expedited by the following procedure. Add sufficient anhydrous denatured alcohol to cover the moist sample. Stir and allow suspended material to settle. Decant as much of the alcohol as possible without losing any of the sample. Ignite the remaining alcohol and allow it to burn off during drying over the hot plate.

7.3.1 **Warning**—Exercise care to control the ignition operation to prevent injury or damage from the burning alcohol.

7.4 The sample is thoroughly dry when further heating causes, or would cause, less than 0.1 % additional loss in mass.

TABLE 1 Sample Size for Aggregate

Nominal Maximum Size of Aggregate, mm (in.)[A]	Mass of Normal Weight Aggregate Sample, min, kg[B]
4.75 (0.187) (No. 4)	0.5
9.5 (⅜)	1.5
12.5 (½)	2
19.0 (¾)	3
25.0 (1)	4
37.5 (1½)	6
50 (2)	8
63 (2½)	10
75 (3)	13
90 (3½)	16
100 (4)	25
150 (6)	50

[A] Based on sieves meeting Specification E 11.

[B] Determine the minimum sample mass for lightweight aggregate by multiplying the value listed by the dry-loose unit mass of the aggregate in kg/m^3(determined using Test Method C 29/C 29M) and dividing by 1600.

7.5 Determine the mass of the dried sample to the nearest 0.1 % after it has cooled sufficiently not to damage the balance.

8. Calculation

8.1 Calculate total evaporable moisture content as follows:

$$p = 100\,(W - D)/D \quad (1)$$

where:

p = total evaporable moisture content of sample, percent,
W = mass of original sample, g, and
D = mass of dried sample, g.

8.2 Surface moisture content is equal to the difference between the total evaporable moisture content and the absorption, with all values based on the mass of a dry sample. Absorption may be determined in accordance with Test Method C 127 or Test Method C 128.

9. Precision and Bias

9.1 *Precision*:

9.1.1 The within-laboratory single operator standard deviation for moisture content of aggregates has been found to be 0.28 % (Note 2). Therefore, results of two properly conducted tests by the same operator in the same laboratory on the same type of aggregate sample should not differ by more than 0.79 % (Note 2) from each other.

9.1.2 The between-laboratory standard deviation for moisture content of aggregates has been found to be 0.28 % (Note 2). Therefore, results of properly conducted tests from two laboratories on the same aggregate sample should not differ by more than 0.79 % (Note 2) from each other.

9.1.3 Test data used to derive the above precision indices were obtained from samples dried to a constant mass in a drying oven maintained at 110 ± 5°C. When other drying procedures are used, the precision of the results may be significantly different than that indicated above.

NOTE 2—These numbers represent, respectively, the 1s and 2s limits as described in Practice C 670.

9.2 *Bias*:

9.2.1 When experimental results are compared with known values from accurately compounded specimens, the following has been derived.

9.2.1.1 The bias of moisture tests on one aggregate material has been found to have a mean of +0.06 %. The bias of individual test values from the same aggregate material has been found with 95 % confidence to lie between −0.07 % and +0.20 %.

9.2.1.2 The bias of moisture tests on a second aggregate material has been found to have a mean of < +0.01 %. The bias of individual test values from the same aggregate material has been found with 95 % confidence to lie between −0.14 % and +0.14 %.

9.2.1.3 The bias of moisture tests overall on both aggregate materials has been found to have a mean of +0.03 %. The bias of individual test values overall from both aggregate materials has been found with 95 % confidence to lie between −0.12 % and +0.18 %.

9.2.2 Test data used to derive the above bias statements were obtained from samples dried to a constant mass in a

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

drying oven maintained at 110 ± 5°C. When other drying procedures are used, the bias of the results may be significantly different than that indicated above.

NOTE 3—These precision and bias statements were derived from aggregate moisture data provided by 17 laboratories participating in the SHRP Soil Moisture Proficiency Sample Program which is fully described in the National Research Council Report SHRP-P-619. The samples tested which relate to these statements were well-graded mixtures of fine and coarse aggregate with moisture contents ranging from air dry to saturated surface dry.

10. Keywords

10.1 aggregate; drying; moisture content

Designation: C 567 – 05a

Standard Test Method for Determining Density of Structural Lightweight Concrete[1]

This standard is issued under the fixed designation C 567; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method provides procedures to determine the oven-dry and equilibrium densities of structural lightweight concrete.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

C 172 Practice for Sampling Freshly Mixed Concrete

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 470/C 470M Specification for Molds for Forming Concrete Test Cylinders Vertically

E 104 Practice for Maintaining Constant Relative Humidity by Means of Aqueous Solutions

3. Terminology

3.1 Terminology used in this test method is defined in Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *equilibrium density*, *n*—the density as determined in 8.2 reached by structural lightweight concrete after exposure to relative humidity of 50 ± 5 % and a temperature of 23 ± 2 °C (73.5 ± 3.5 °F) for a period of time sufficient to reach constant mass.

3.2.2 *oven-dry density*—the density as determined in 8.3 reached by structural lightweight concrete after being placed in a drying oven at 110 ± 5 °C (230 ± 9 °F) for a period of time sufficient to reach constant mass.

4. Summary of Test Method

4.1 This test method provides procedures for determining the oven-dry and equilibrium densities of structural lightweight concrete, by calculation or measurement. The calculated oven-dry density is determined from batch quantities and volume of a given batch of concrete. The calculated equilibrium density is approximated by adding a fixed quantity to the oven-dry density. Measured densities are obtained from determinations of the mass of cylindrical specimens after specified treatments.

5. Significance and Use

5.1 The measured or calculated equilibrium density of structural lightweight concrete determines whether specified density requirements have been met. Unless otherwise specified, determine equilibrium density by calculation using the procedures in 9.2.

5.2 Test Method C 138/C 138M shall be used to determine the density of freshly mixed lightweight concrete for compliance with concrete placement specifications.

NOTE 1—The fresh density of lightweight aggregate concrete is a function of mixture proportions, air content, water demand, and the specific density and moisture content of the lightweight aggregate. Decrease in density of a specific lightweight concrete is due to moisture loss that, in turn, is a function of aggregate moisture content, ambient conditions, and the ratio of the surface area to the volume of the concrete member. For most structural lightweight concretes, equilibrium density is approached at about 90 days. For most high-strength lightweight concretes, equilibrium density is approached at about 180 days. Extensive tests demonstrate that despite variations in the initial moisture content of lightweight aggregate, the equilibrium density will be approximately 50 kg/m^3 (3.0 lb/ft^3) greater than the oven-dry density.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.21 on Lightweight Aggregates and Concrete.

Current edition approved Dec. 15, 2005. Published January 2006. Originally approved in 1965. Last previous edition approved in 2005 as C 567 – 05.

6. Apparatus

6.1 *Tamping Rod, Mallet, Measure, Balance, and Molds*—These shall conform to the requirements of Test Method C 138/C 138M and Specification C 470/C 470M.

6.1.1 *Measure*—A 14-L (0.5-ft^3) measure shall be the standard (see Note 3).

6.2 *Controlled Humidity Enclosure*—A room controlled at 50 ± 5 % relative humidity and 23 ± 2 °C (73.5 ± 3 °F) or a small chamber meeting the requirements of Practice E 104.

6.3 *Drying Oven*—An oven of appropriate size capable of maintaining a uniform temperature of 110± 5 °C (230 ± 9 °F), and an average evaporation rate of at least 25 g/h. Determine evaporation rate in accordance with Test Method C 88.

7. Sampling, and Making, and Curing Test Specimens

7.1 *Sampling*—Sample field-mixed concrete in accordance with Practice C 172.

7.2 *Specimens for Determining Equilibrium Density and Oven-dry Density*—Determine the equilibrium density and oven-dry density on 150 by 300-mm (6 by 12-in.) concrete cylinders.

7.2.1 Make test cylinders in accordance with Practice C 192/C 192M or C 31/C 31M, whichever is applicable. Make three cylinders for equilibrium density measurements, and make three cylinders for oven-dry density measurements.

7.3 *Curing Specimens*:

7.3.1 Unless otherwise specified, test cylinders used for the determination of equilibrium density shall be cured in accordance with Practice C 192/C 192M or the standard curing procedure in Practice C 31/C 31M.

NOTE 2—Cylinders may be stripped after 24 h and wrapped securely with a plastic sheet or bag to prevent loss of moisture, or may remain in covered molds until the time of test.

7.3.2 Unless otherwise specified, for the first 24 h or until the time of test, store the test cylinders used for the determination of oven-dry density under conditions that maintain a temperature adjacent to the cylinders in the range from 16 to 27 °C (60 to 80 °F) and that prevent loss of moisture from the cylinders.

8. Procedure

8.1 *Measurement of Freshly Mixed Concrete Density*—Determine the density of the freshly mixed concrete in accordance with Test Method C 138/C 138M.

NOTE 3—Numerous observations indicate that the same compactive effort used on smaller concrete specimens will cause the fresh densities to be higher. The fresh density as determined from measurements on 150 by 300-mm (6 by 12-in.) cylinders of lightweight concrete consolidated by rodding, in accordance with Practice C 192/C 192M or Practice C 31/C 31M will average 40 kg/m^3 (2.5 lb/ft^3) higher than the fresh density as measured using a 14-L (0.5-ft^3) measure in accordance with Test Method C 138/C 138M.

8.2 *Measurement of Equilibrium Density*—To measure the equilibrium density, remove the cylinders from their curing condition on the seventh day after molding and immerse in water at 23 ± 2 °C (73.5 ± 3.5 °F) for 24 h. Measure the apparent mass of the cylinders while suspended and completely submerged in water and record as "C," the mass of the suspended-immersed cylinder. Remove from the water and allow to drain for 1 min by placing the cylinder on a 9.5-mm (⅜-in.) or coarser sieve cloth. Remove visible water with a damp cloth, determine the mass and record as "B," the mass of the saturated-surface-dry cylinder. Dry the cylinders with all surfaces exposed, in a controlled humidity enclosure as described in 6.2 until the mass of the specimen changes not more than 0.5 % (gain or loss) in successive determinations of mass 28 days apart. Determine the mass of the dried cylinders and record as "A," the mass of the dried cylinder. Calculate the equilibrium density of the concrete from Eq 1 and 2.

$$E_m\,(Density,\, kg/m^3) = (A \times 997) / (B-C) \quad (1)$$

$$E_m\,(Density,\, lb/ft^3) = (A \times 62.3) / (B-C)) \quad (2)$$

where:

E_m = measured equilibrium density, kg/m^3(lb/ft^3,
A = mass of cylinder as dried, kg (lb),
B = mass of saturated surface-dry cylinder, kg (lb), and
C = apparent mass of suspended-immersed cylinder, kg (lb).

8.3 *Measurement of Oven-Dry Density*—After 24 h but not to exceed 32 h, remove the cylinders from the mold (see Note 4). Measure the apparent mass of the cylinders while suspended and completely submerged in water and record as "G" the mass of the suspended-immersed cylinders. Remove from the water and allow to drain for 1 min by placing the cylinders on a 9.5-mm (⅜-in.) or coarser sieve cloth. Remove visible water with a damp cloth, determine the mass and record as "F," the mass of the saturated surface-dry cylinders. Place the cylinders in the drying oven at 110 ± 5 °C (230 ± 9 °F) for 72 h. Allow cylinders to cool for at least thirty minutes but not more than 1 hour and determine the mass. Repeat oven-drying, cooling, and determination of mass at 24-h intervals until the change in mass is not more than 0.5 %. Record this mass as "D", the mass of the oven-dried cylinder. Determine the oven-dry density from Eq 3 and 4.

$$O_m(Density,\, kg/m^3) = (D \times 997) / (F-G) \quad (3)$$

$$O_m\,(Density,\, lb/ft^3) = (D \times 62.3) / (F-G)) \quad (4)$$

where:

O_m = measured oven-dry density, kg/m^3(lb/ft^3),
D = mass of oven-dry cylinder, kg (lb),
F = mass of saturated surface-dry cylinder, kg (lb), and
G = apparent mass of suspended-immersed cylinder, kg (lb).

NOTE 4—Determination of oven-dry density may be specified to begin at an age other than 24-h.

9. Calculation

9.1 *Calculation of Oven-Dry Density*—Where mixture quantities, aggregate moisture content, and the volume of the concrete batch are known, calculate an oven-dry density using Eq 5.

$$O_c = (M_{df} + M_{dc} + 1.2\,M_{ct}) / V \quad (5)$$

where:

O_c = calculated oven-dry density, kg/m^3 (lb/ft^3),

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:24:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

M_{df} = mass of dry fine aggregate in batch, kg(lb),
M_{dc} = mass of dry coarse aggregate in batch, kg(lb),
M_{ct} = mass of cement in batch, kg (lb),
1.2 = factor to approximate the mass of cement plus chemically combined water, and
V = volume of concrete produced by the batch m^3 (ft^3).

9.2 *Calculation of Approximate Equilibrium Density*—Using the oven-dry density determined in accordance with 8.3 or 9.1, calculate the approximate equilibrium density from Eq 6 and 7.

$$E_c = O_c + 50 \text{ kg/m}^3 \ (3 \text{ lb/ft}^3) \quad (6)$$

or

$$E_c = O_m + 50 \text{ kg/m}^3 \ (3 \text{ lb/ft}^3) \quad (7)$$

where:
E_c = calculated equilibrium density (see Note 1).

10. Report

10.1 When oven-dry and equilibrium densities are determined by measurements, the report shall include following information:

10.1.1 Fresh density, kg/m^3 (lb/ft^3).
10.1.2 Mass of suspended-immersed cylinder, kg (lb).
10.1.3 Mass of saturated surface dry cylinder, kg (lb).
10.1.4 Mass of cylinder after reaching equilibrium, kg (lb).
10.1.5 Equilibrium density reported to nearest 10 kg/m^3 (0.5 lb/ft^3).
10.1.6 Age at which equilibrium was reached, days.
10.1.7 Mass of oven-dry cylinder, kg (lb).
10.1.8 Oven-dry density rounded to the nearest 10 kg/m^3 (0.5 lb/ft^3).

10.2 When oven-dry and approximate equilibrium densities are determined by calculation, report the following information:

10.2.1 Fresh density, kg/m^3 (lb/ft^3).
10.2.2 Mass of cement and dry aggregates, batched, kg (lb).
10.2.3 Volume of concrete produced from the batch, m^3 (ft^3).
10.2.4 Calculated oven-dry density, to the nearest 10 kg/m^3 (0.5 lb/ft^3).
10.2.5 Calculated approximate equilibrium density, to the nearest 10 kg/m^3 (0.5 lb/ft^3).

11. Precision and Bias

11.1 *Precision*—The precision of this test method has not yet been determined, but an industry-wide multilaboratory testing program is being coordinated. The precision statements will be included when the data is compiled and reviewed.

11.2 *Bias*—Bias for this test method cannot be determined since there is no reference standard available for comparison.

12. Keywords

12.1 equilibrium density; lightweight concrete; oven-dry density

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 586 – 05

Standard Test Method for Potential Alkali Reactivity of Carbonate Rocks as Concrete Aggregates (Rock-Cylinder Method)[1]

This standard is issued under the fixed designation C 586; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the determination of the expansion of a specimen of carbonate rock while immersed in a solution of sodium hydroxide (NaOH) at room temperature. The length changes occurring during such immersion indicate the general level of reactivity of the rock and whether tests should be made to determine the effect of aggregate prepared from the rock upon the volume change in concrete.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in SI units are to be regarded as the standard. The inch-pound units in parentheses are provided for information only.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 294 Descriptive Nomenclature for Constituents of Concrete Aggregates

C 295 Guide for Petrographic Examination of Aggregates for Concrete

C 1105 Test Method for Length Change of Concrete Due to Alkali-Carbonate Rock Reaction

D 75 Practice for Sampling Aggregates

D 1248 Specification for Polyethylene Plastics Extrusion Materials for Wire and Cable

E 177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods

3. Terminology

3.1 For definitions of terms relating to aggregates used in this test method, refer to Descriptive Nomenclature C 294.

4. Summary of Test Method

4.1 Small rock cylinders are immersed in a solution of NaOH except when removed for determination of length change. The length change of each specimen is periodically determined.

5. Significance and Use

5.1 This test method is intended to give a relatively rapid indication of the potential expansive reactivity of certain carbonate rocks that may be used as concrete aggregates. The test method has been successfully used in (*1*) research and (*2*) preliminary screening of aggregate sources to indicate the presence of material with a potential for deleterious expansion when used in concrete.

5.2 The test method is intended as a research and screening method rather than as the basis of a specification requirement. It is intended to supplement data from field service records, petrographic examinations according to Guide C 295, and tests of aggregate in concrete according to Test Method C 1105.

5.3 Alkalies participating in the expansive reactions with aggregate constituents in concrete usually are derived from the hydraulic cement; under certain circumstances they may be derived from other constituents of concrete or from external sources. Two types of alkali reactivity of aggregates are recognized: (*1*) alkali-silica reaction involving certain siliceous rocks, minerals, and artificial glasses, and (*2*) alkali carbonate reaction involving dolomite in certain calcitic dolomites, dolomitic limestones, and dolostones. This test method is not suitable as a means to detect alkali-silica reaction.

6. Apparatus and Reagents

6.1 *1 N Sodium Hydroxide Solution*—Dissolve 40 ± 1 g of reagent-grade sodium hydroxide (NaOH) in distilled water, dilute to 1 L and store in a polyethylene bottle.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C 09.26 on Chemical Reactions.

Current edition approved May 15, 2005. Published June 2005. Originally approved in 1966. Last previous edition approved in 1999 as C 586 – 99.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.2 *Sawing, Drilling, and Grinding Equipment*, suitable for preparing test specimens of the dimensions given in Section 8. This will require one or more rock saws, depending upon the size of the original sample, a drill press equipped with a small diamond core barrel for removing the cylindrical core, and a lap, grinder, or suitable modified lathe for shaping the ends of the specimens.

6.3 *Storage Bottles*, approximately 50 to 100-mL capacity with caps and openings of sufficient size to facilitate removal of specimens. The polyethylene bottle shall be selected to ensure that the solution will not be modified by reaction with the material composing the container, including pigments or other additives or by transpiration of phases through the walls of the container. Bottles with wall thickness not less than 0.50 mm (0.020 in.) and composed of high density polyethylene meeting the requirements of Specification D 1248 for materials of Type III, Class A, are suitable.

6.4 *Length Comparator*, for convenient and rapid measurement of lengths of specimens, the comparator shall be of such design as to provide, permit, or include the following characteristics. One type of comparator which has been found satisfactory is shown in Fig. 1.

6.4.1 A positive means of contact with the conical ends of the specimen to ensure reproducible measurement of length. A

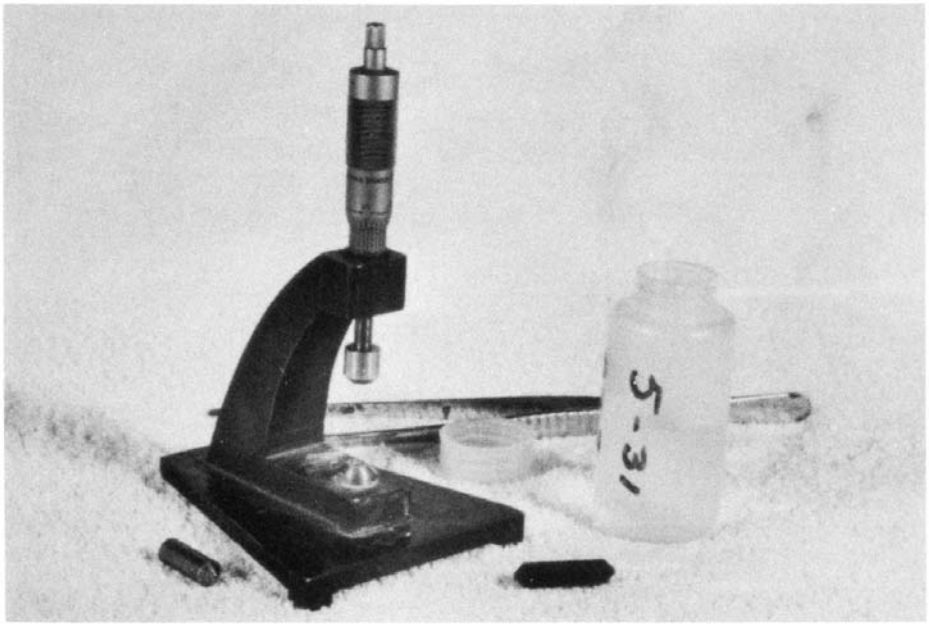

FIG. 1 A Typical Length Comparator

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

variety of contact points have been used successfully. Care should be exercised to ensure that when using specimens with conical ends as described in 8.3, contact is made on the end along a circle which is concentric about the long axis of the specimen. If the measuring device is a barrel micrometer, it shall have a ratchet stop to produce a constant pressure on the specimen,

6.4.2 A high-grade barrel or dial micrometer graduated to read in 0.001 or 0.002–mm (0.0001–in.) units, and accurate within 0.002 mm (0.0001 in.) in any 0.020–mm (0.0010–in.) range, and within 0.004 mm (0.0002 in.) in any 0.200–mm (0.0100–in.) range. The measuring device should be calibrated throughout its range to determine both periodic and cumulative errors for proper correction of observed data.

6.4.3 A sufficient range to allow for small differences among gage lengths of various specimens. If care is taken in the fabrication of the specimens, a measuring device with a travel of not less than 7.5 mm (0.3 in.) provides ample range in the instrument, and

6.4.4 A standard or reference shall be used for checking the measuring device at regular intervals. The bar that serves as a reference for the length comparator shall have an over-all length of 35 ± 2 mm (1.38 ± 0.08 in.) The length of the bar shall be known to an accuracy of 0.002 mm (0.0001 in.). The bar shall be fused silica or a steel alloy having a coefficient of thermal expansion not greater than 1.0×10^{-6}°C. Each end shall be machined to the same shape as that of the rock specimens. If a steel alloy is used, it shall be polished (See Note 1). The reference bar shall be placed in the instrument in the same position each time a length measurement is made. The micrometer setting of the measuring device shall be checked by use of the reference bar at least at the beginning and end of the readings made within a half day when the apparatus is kept in a room maintained at constant temperature. It shall be checked more often when kept in a room where temperature is not constant.

NOTE 1—Steel alloys with low thermal expansion coefficient should not be heat treated because they lose their low coefficient of thermal expansion when so treated.

7. Sampling

7.1 Sample the rock in accordance with the applicable requirements of Practice D 75, except that the sample mass of each discernable stratum shall be at least 1 kg, and individual pieces shall be not less than 75 × 75 × 75 mm in size.

7.2 Sampling should be under the direction of an individual capable of distinguishing differences in lithology, and the sample of rock should be taken to represent only the particular lithology under consideration bearing in mind the limitations and significance of this method as stated in Section 5. Each sample of rock should be in one piece of sufficient size for preparing the necessary test specimens.

7.3 One test specimen will sufficiently represent the sample of rock unless shale seams or other discontinuities are present or the bedding is not discernible. In these cases, prepare and test 3 mutually perpendicular specimens. Of such three specimens that one showing the greatest length change after 28 days of immersion in alkali solution as determined in 9.7 shall be used. Discard the remaining two.

8. Test Specimens

8.1 Test specimens shall be in the form of right circular cylinders or square prisms with conical or plane parallel ends, unless otherwise specified.

8.2 The specimen shall have an over-all length of 35 ± 5 mm (1.38 ± 0.20 in.) and a diameter or sides of 9 ± 1 mm (0.35 ± 0.04 in.) for cylinders and prisms respectively. Care shall be exercised in the preparation of the specimens to avoid alteration of the cylindrical surface by polishing or with materials which will affect the rate of entry of alkali solution into the rock.

8.3 The included angle of the conical ends shall be approximately 120°.

8.4 Fabricate specimens having flat–end faces in such a manner as to ensure that the faces are parallel to each other and perpendicular to the major axis of the specimen (see Note 2).

NOTE 2—End faces parallel to each other and perpendicular to the major axis of the specimen can be made by turning the specimen in a small lathe and using tool steel to cut the ends.

9. Procedure

9.1 Place a position mark on the specimen to permit placing the specimen in the comparator in the same position during subsequent measurements.

9.2 Measure the length of the test specimen.

9.3 Immerse the specimen in distilled water at a room temperature in the range of 20 to 27.5 °C (68 to 81.5 °F).

9.4 At intervals, remove the specimen, blot to remove excess surface water and measure until the change in length during a 24-h water immersion period does not exceed 0.02 % as calculated in 10.1. The length when in this condition is taken as the reference length. The reference length is usually achieved after 1 to 4 days of immersion.

9.5 Immerse the water-saturated specimens in a bottle containing a minimum of 35 mL of 1*N* NaOH solution per specimen at room temperature and seal. Immerse no more than two specimens in a bottle.

9.6 Measure the length of the specimens after 7, 14, 21, and 28 days of immersion in NaOH solution and at 4-week intervals thereafter. If the tests continue beyond 1 year, make measurements at 12-week intervals.

9.7 When measurements are made, remove the specimen from the bottle, rinse with distilled water, blot to remove excess surface water and determine its length in the same position as during the initial measurement.

9.8 After measurement, immediately return the specimen to the bottle and reseal.

9.9 Replace the solution every 6 months during the testing period.

10. Calculation

10.1 Calculate the length change to the nearest 0.01 % of the reference length as follows:

$$\Delta l = [(l_1 - l_0)/l_0] \times 100 \quad (1)$$

where:

Δl = % length change at test age,

l_1 = length in mm (in.) at test age, and

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:24:10 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

l_0 = reference length after equilibrium in water, as outlined in 9.4.

11. Report

11.1 Report the following:

11.1.1 Identification number,

11.1.2 Type and source of rock,

11.1.3 Specimen shape and dimensions if other than right circular cylinder,

11.1.4 Length change in percent to the nearest 0.01 % at each time of measurement. Where no times of measurement are specifically requested, data should be presented for at least the following ages: 1, 4, 8, and 16 weeks and the age at the final measurement.

11.1.5 Significant features revealed by examination of specimen during and after storage in alkali solution, such as cracking, warping, splitting, etc., and

11.1.6 Other significant information as deemed necessary, such as petrographic and chemical analyses.

12. Precision and Bias

12.1 *Precision*:

12.1.1 If the results of replicate specimens measured by the same operator and which presumably represent the same material, differ by more than 0.10 percentage point for expansions less than 1.0 %, it is highly probable that the specimens represent rocks that are significantly different in chemical composition, texture, or both.

12.1.2 The single-operator, single-comparator, single-specimen precision has been found to be ±0.02 percentage point (3S) as defined in Practice E 177.

12.1.3 The multi-operator, single-comparator, single-specimen precision has been found to be ±0.03 percentage point (3S) as defined in Practice E 177.

12.1.4 The multi-operator, multi-comparator, single-specimen precision has been found to be ±0.05 percentage point (3S) as defined in Practice E 177.

12.1.5 In a single laboratory, single operator study of the range of expansion of pairs of rock cylinders from 29 samples of rock from a single quarry (each pair of cylinders cut from a different sample block approximately 75 × 75 × 50 mm in size), the following data were found:

12.1.5.1 For pairs of specimens giving average expansion of less than 0.50 %, the average standard deviation was found to be 0.0255 %[3]; therefore, the difference in expansion between pairs of cylinders cut from a single block should only exceed 0.072 %[3] one time in twenty when the average expansion is less than 0.50 %.

12.1.5.2 For pairs of specimens giving average expansion of more than 0.50 %, the average standard deviation was found to be 0.095 %[3]; therefore, the difference in expansion between pairs of cylinders cut from a single block should only exceed 0.269 %[3] one time in twenty when the average expansion is more than 0.50 %.

12.2 *Bias*—The procedure in this test method for measuring expansion has no bias because the expansion can be defined only in terms of this test method.

13. Keywords

13.1 aggregate; alkali reactivity; carbonate rocks; concrete; deleterious expansion

[3] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

APPENDIX

(Nonmandatory Information)

X1. Interpretation of Results

X1.1 Since the expansion caused by reactions between cement alkalies and carbonate aggregates is sensitive to subtle changes in aggregate lithology, the results of measurements should be interpreted with full recognition of the variables which would affect the results obtained. The acceptance or rejection of aggregate sources based solely on the results of this test is not recommended since, in commercial production, expansive and nonexpansive materials may occur in close proximity and the securing of samples adequately representative of the variability of the production of the source is a difficult task and requires the efforts of an individual trained to distinguish differences in lithology.

X1.2 The relationship of the test results to the behavior of large quantities of rock from a given source will depend upon the degree to which the petrographic and chemical properties of the rock vary within the source.

X1.3 Research results have indicated that the expansive behavior of aggregate in concrete is qualitatively predicted by the results of the rock cylinder test. Quantitative prediction of the expansion of concrete containing reactive aggregate depends upon (*1*) the degree of aggregate reactivity, (*2*) the amount of reactive constituent, (*3*) the alkali content of the cement, and (*4*) the environment. Appreciable expansion should indicate the need for further testing. In the light of current knowledge, it appears that expansions in excess of 0.10 % are indicative of chemical reaction and should warrant additional testing preferably in concrete using Test Method C 1105. Usually expansive tendencies are evident after 28 days of immersion in alkali, however, exceptions to this have been noted. Deleterious expansion of concrete appears to depend

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

upon the magnitude and rate of aggregate expansion and the time at which it begins; however, quantitative predictions of concrete expansion in service solely from results of this test method are not possible.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 587 – 04

Standard Specification for Gypsum Veneer Plaster[1]

This standard is issued under the fixed designation C 587; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers calcined gypsum mixed at the mill with other ingredients to control working quality and setting time; specifically designed as a veneer plaster to be applied over gypsum base for veneer plasters, masonry or concrete surfaces to a maximum thickness of ¼ in. (6.4 mm) providing a surface ready for decoration.

NOTE 1—Specification C 843 contains application procedures for gypsum veneer plaster.

1.2 This specification covers test methods for determining the physical properties of gypsum veneer plasters and sets forth minimum requirements that must be met.

1.3 The values stated in inch-pound units are to be regarded as the standard. The SI (metric) values given in parentheses are approximate and are provided for information purposes only.

1.4 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

1.5 The following safety hazards caveat applies only to the Test Methods portion, Section 5 of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 473 Test Methods for Physical Testing of Gypsum Panel Products

C 843 Specification for Application of Gypsum Veneer Plaster

C 1396/C 1396M Specification for Gypsum Board

3. Terminology

3.1 *Definitions:*

3.1.1 Definitions of terms shall be in accordance with Terminology C 11 and Specification C 843.

3.2 *Definition of Term Specific to This Standard:*

3.2.1 *gypsum veneer plaster systems*, *n*—veneer plaster applied in accordance with Specification C 843 to gypsum base for veneer plasters.

4. Physical Properties

4.1 *Joint Strength*—Gypsum veneer plaster systems applied in accordance with Specification C 843 shall be tested in accordance with 5.9. The breaking load shall be not less than the parallel to surfacing loads specified in Specification C 1396/C 1396M.

4.2 *Bond Strength*—The bond strength of the gypsum veneer plaster to the gypsum veneer base and, where applicable, between the base coat plaster and the finish coat shall not delaminate when tested in accordance with 5.6.

4.3 *Impact Strength*—Gypsum veneer plaster systems shall not crack or lose bond beyond the impact area when tested in accordance with 5.7.

4.4 *Flexure*—Gypsum veneer plaster systems shall exhibit crack resistance within the field of the gypsum base for veneer plasters such that radial or random cracking shall extend not more than ½ in. (13 mm) from the break line at failure when tested in accordance with 5.8. At rupture of the panel the veneer plaster shall be securely bonded to the face paper.

5. Test Methods

5.1 *Materials*—Gypsum Base for Veneer Plaster, see Specification C 1396/C 1396M.

5.2 *Sampling*—Sample not less than 1 % of the packages, but not less than 5 packages. Select packages to be sampled at random. Take samples both from the outer portion and the center of each package. Thoroughly mix the materials so obtained to provide a composite sample of not less than 15 lb

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Dec. 1, 2004. Published December 2004. Originally approved in 1966. Last previous edition approved in 2002 as C 587 – 02.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

(6.8 kg). Place this composite sample immediately in a clean, dry, airtight container for delivery to the laboratory.

5.3 *Test Unit Preparation*—From the sample, prepare panels of veneer plaster system and cut four 2 ft (600 mm) square, and three 12 by 16 in. (300 by 400 mm) specimens.

5.4 *Conditioning*—Condition specimens to constant weight at a temperature of 85 ± 15 °F (29.5 ± 8.5 °C) and relative humidity of 50 ± 2 % (see Note 2). Test specimens individually after constant weight is reached.

NOTE 2—Laboratory test results indicate that conditioning temperatures may range from 70 to 100 °F (21 to 38 °C) without significantly affecting the results. However, relative humidity is critical. Therefore, specimens shall be tested within 10 min upon removal from the conditioning chamber.

5.5 *Number of Tests*—Run each test in triplicate.

5.6 *Bond Strength*:

5.6.1 *Significance and Use*—The bond strength test is designed to evaluate the bond of veneer plaster to veneer plaster base and between the base coat and finish coat. The degree of correlation between these test methods and service performance has not been determined.

5.6.2 *Procedure*—Select three 2 ft (600 mm) square specimens. Raise each specimen and slam the back side (face not treated with veneer plaster) on a bare concrete floor repeatedly until the specimen is broken.

5.6.3 *Report*—Report whether the sample passes or fails the bond test. The sample fails if the bond to the veneer base or between the finish coast and base coat delaminates on any one of the specimens.

5.6.4 *Precision and Bias*—No information is presented about either the precision or bias of the bond test since the test result is nonquantitative.

5.7 *Impact Strength*:

5.7.1 *Significance and Use*—The impact strength is designed to test the effect of impact from a hard object on the surface of the veneer plaster. The degree of correlation between this test method and service performance has not been determined.

5.7.2 *Apparatus*:

5.7.2.1 A stand with a solid, flat base at least 2 ft (600 mm) square with a means of holding the steel ball and releasing it from a height of 36 in. above the base, without imparting additional force.

5.7.2.2 A 1½ in. (38 mm) diameter polished steel ball weighing 7.8 ± 0.1 oz (221 ± 3 g).

5.7.3 *Procedure*—Select one 2 ft (600 mm) square. Place the specimen horizontally, with the plaster surface face up, on the base of the apparatus . Drop the steel ball three times onto different areas of the panel surface.

5.7.4 *Report*—Report whether the sample passes or fails the impact test. The sample fails if there is a loss of bond or cracking beyond the impact area on any one of the drops.

5.7.5 *Precision and Bias*—No information is presented about either the precision or bias of the impact test since the test result is nonquantitative.

5.8 *Flexure*:

5.8.1 *Significance and Use*—The flexure test is designed to test the effect on the resistance to cracking and bond of the veneer plaster to the veneer plaster base while being flexed. The degree of correlation between this test method and service performance has not been determined.

5.8.2 *Apparatus*—Use the apparatus described in Test Methods C 473 for Method B.

5.8.3 *Procedure*—Select three 12 by 16 in. (300 by 400 mm) specimens. Subject each specimen to a continuous, midpoint, loading applied at a rate of 1 in./min ± 5 s (25 mm/min ± 5 s) downward to the back of the panel (plaster surface in tension) supported over a clear span of 14 in. (356 mm) until failure.

5.8.4 *Report*—Report whether the sample passes or fails the flexure test. The sample fails if any one of the specimens shows cracking more than ½ in. (13 mm) from the break line or if the bond of the veneer plaster to the paper fails.

5.8.5 *Precision and Bias*—No information is presented about either the precision or bias of the flexure test since the test result is nonquantitative.

5.9 *Joint Strength*:

5.9.1 *Significance and Use*—The joint strength test is designed to test strength of the joint between two adjacent gypsum veneer panels that have been covered with veneer plaster. The degree of correlation between this test method and service performance has not been determined.

5.9.2 *Apparatus*—Use the apparatus described in Test Methods C 473 for Method B.

5.9.3 *Specimen Preparation*—Cut two 8 by 12-in. (200 by 300-mm) pieces of gypsum base for veneer plaster for each specimen to be tested. One 12-in. edge of each piece shall be the paper-bound edge. Place the two pieces of gypsum base for veneer plaster face down with the paper-bound edges forming the joint. Apply a pregummed tape over the joint. (The tape will keep the joint from flexing during the specimen preparation.) Turn face up and apply joint tape and gypsum veneer plaster in accordance with Specification C 843 using the method titled "Reinforcement Secured and Embedded with Veneer Plaster."

5.9.4 *Procedure*—Condition the specimen and determine the flexural strength in accordance with Test Methods C 473 Method B. Apply the load parallel to and directly over the back of the joint.

5.9.5 *Report*—Calculate and report the average breaking load in pound-force or newtons, rounded to the nearest 1 lbf (N).

5.9.6 *Precision and Bias*—The precision and bias for measuring joint strength are essentially as specified in Test Methods C 473.

6. Inspection

6.1 Inspection of the gypsum veneer plaster shall be agreed upon between the purchaser and the supplier as part of the purchase agreement.

7. Rejection and Rehearing

7.1 Rejection of gypsum veneer plaster that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:24:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

rejection shall contain a statement documenting how the gypsum veneer plaster has failed to conform to the requirements of this specification.

8. Certification

8.1 When specified in the purchase agreement, a manufacturer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

9. Packaging and Package Marking

9.1 Gypsum veneer plaster shall be dry and free from lumps, and shall be shipped in packages.

9.2 When shipped for resale, the following information shall be legibly marked on each package or on a tag of suitable size attached thereto:

9.2.1 Name of producer or supplier,

9.2.2 Brand,

9.2.3 Description, and

9.2.4 Net or gross weight, or both, of package.

10. Keywords

10.1 gypsum; gypsum veneer plaster; plaster; veneer plaster

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 587 – 02, which may impact the use of this specification. (Approved December 1, 2004)

(*1*) Replaced Specification C 588/C 588M with Specification C 1396/C 1396M throughout.

Designation: C 593 – 06

Standard Specification for Fly Ash and Other Pozzolans for Use With Lime for Soil Stabilization[1]

This standard is issued under the fixed designation C 593; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the qualification of fly ash and other pozzolans for use with lime in plastic, nonplastic mixtures and other mixtures that affect lime pozzolanic reaction required by soil stabilization. Evaluation of pozzolans containing available lime, such as Class C fly ash, is given consideration. Pozzolans covered include artificial pozzolans such as fly ash, and natural pozzolans, such as diatomite and pumicite, in either raw or calcined state.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 311 Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 821 Specification for Lime for Use with Pozzolans

D 1557 Test Methods for Laboratory Compaction Characteristics of Soil Using Modified Effort (56,000 ft-lbf/ft^3(2,700 kN-m/m^3))

3. Terminology

3.1 For definitions of terms specific to this specification, see Terminology C 51.

4. Physical Properties

4.1 Pozzolans for use with lime in plastic mixtures, when tested in accordance with the procedures of Sections 7-9, shall conform to the requirements prescribed in Table 1.

4.2 Pozzolans for use with lime in nonplastic mixtures shall conform to the requirements of Table 1, except the lime-pozzolan strength requirement, and in addition shall be tested in accordance with the procedures of Section 10.

NOTE 1—If the minimum value of the vacuum saturation strength specified in 4.2 of this specification is reduced, sufficient documentation shall be provided to the user to enable the determination of a satisfactory minimum residual strength for the given material in its intended use. Such documentation should include at least the following: (*1*) determination of a minimum residual strength requirement that will enable the material to perform its structural function in the pavement system; and (*2*) a rational analysis, using actual climatic data, that will show the severity of exposure of the material to cyclic freeze-thaw action.

TABLE 1 Physical Requirements

Water-soluble fraction, max, %	10.0
Fineness, amount retained, when wet sieved:	
No. 30 (600-μm) sieve, max, %	2.0
No. 200 (75-μm) sieve, max, %	30.0
Lime-pozzolan strength, minimum compressive strength, psi (MPa):	
At 7 days, 130 ± 3 °F (54 ± 2 °C)	600 (4.1)
After additional 21 days, 73± 3 °F (23 ± 2 °C)	600 (4.1)
Compressive strength, min, psi (MPa)	400 (2.8)
Vacuum saturation strength, min, psi (MPa)	400 (2.8)

5. Sampling

5.1 Sample pozzolan in accordance with the applicable provisions of Test Methods C 311, except take one 10-lb (4.5-kg) sample from approximately each 400 tons (350 metric tons) of pozzolan.

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved Nov. 15, 2006. Published December 2006. Originally approved in 1966. Last previous edition approved in 2005 as C 593 – 05.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

5.2 The sampling procedures and techniques shall be consistent from original sample to project completion.

TEST METHODS

6. Significance and Use

6.1 This test method states various procedures that are recommended to quantify various aspects of the lime enhanced pozzolanic reaction. These tests are intended to qualify sources of fly ash and other pozzolans to meet specified job or project criteria as related to soil stabilization.

7. Water-Soluble Fraction

7.1 *Procedure*—Place 10 g of a dried pozzolan sample (dried to constant weight in an oven at 221 to 230 °F (105 to 110 °C)) in a 200-mL Erlenmeyer flask and add 100 mL of distilled water at 73 ± 3 °F (23 ± 2 °C). Shake well by hand until no lumps can be observed; then with a mechanical shaker or stirring device, agitate at laboratory room temperature for a period of 1 h. Pour the material into a weighed Gooch or sintered-glass crucible, and wash all residue from the flask into the crucible with distilled water from a wash bottle. Wash the residue in the crucible free of adhering solution by repeated washings with distilled water. Dry the crucible to constant weight in an oven at 221 °F (105 °C).

7.2 *Calculation*—Calculate the percentage of water-soluble fraction by multiplying the loss in weight in grams by 10.

8. Fineness

8.1 Test in accordance with Test Methods C 110, except that the sample shall be 100 g of the dried pozzolan.

9. Lime-Pozzolan Strength Development

9.1 Test the pozzolan in accordance with the applicable portions of Test Method C 109/C 109M and Practice C 305, and in accordance with the following:

9.2 *Apparatus*:

9.2.1 *Oven*, closed, vapor-type.

9.3 *Materials*:

9.3.1 *Hydrated Lime*—Where possible, the lime shall be the same as that to be used on the job and shall meet the requirements of Specification C 821.

9.3.2 *Sand*—The sand shall be graded standard sand as required by Test Method C 109/C 109M.

9.4 *Number of Test Specimens*—Three specimens shall be prepared for each age at which a strength test is desired.

9.5 *Proportioning, Consistency, and Mixing*—Batches shall be of a size sufficient to make six specimens and shall consist of proportions of dry materials as follows:

Hydrated lime	180 g
Pozzolan (dry basis)	360 g
Graded standard sand	1480 g

9.5.1 The amount of mixing water, measured in millilitres, shall be such as to produce a flow of 65 to 75 as determined in accordance with 9.6, and shall be expressed as weight percent of the combined lime and pozzolan. The lime and pozzolan shall be blended together in a closed container. Mixing shall be done in accordance with the procedure described in Practice C 305, except that it shall be amended to read "Add the blended lime and pozzolan to the water and allow it to stand for 1 min. Then start the mixer and mix at slow speed (140 ± 5 rpm) for 30 s."

9.6 *Determination of Flow*—Determine the flow in accordance with Test Method C 109/C 109M, except that the number of drops of the flow table shall be 10 drops in 6 s instead of 25 drops in 15 s. If the flow is less than the specified limit, the material used for the flow test may be returned to the mixing bowl and additional water added, the batch mixed for 1½ min, and a new flow taken. This operation may be repeated until a flow within the specified range is obtained. If the flow exceeds the range specified, discard the batch and give a new batch a new trial until a flow within range is obtained.

9.7 *Molding Test Specimens*—Immediately after the completion of the flow test, mold specimens in accordance with Test Method C 109/C 109M.

9.8 *Storage of Test Specimens*—When molding is completed, place the filled mold in the vapor immediately above water at 130 ± 3 °F (54 ± 2 °C) in a closed vapor oven with the top surface protected from the drip. Allow the specimens in the molds to remain in the vapor for a period of 7 days, after which remove them from the vapor and cool to 73 ± 3 °F (23 ± 2 °C) in air saturated sufficiently that no drying takes place during the cooling. When the specimens are cool, remove them from the molds, and store them at 73 ± 3 °F (23 ± 2 °C) at 95 to 100 % relative humidity until time of the compressive strength test.

10. Compressive Strength Development and Freeze-Thaw Resistance of Nonplastic Mixtures

10.1 *Materials*:

10.1.1 *Hydrated Lime*—Where possible, the lime shall be the same as that to be used on the job and shall meet the applicable requirements of Specification C 821. Prior to usage, the lime shall be stored in a sealed container to prevent carbonation.

10.1.2 *Pozzolan*—The pozzolan used in this test shall be the same as intended for use on the job.

10.1.3 *Aggregate*—Where possible, the aggregate used in this test shall be the same as intended for use on the job. When using job aggregates, discard the material, if any, retained on the ¾-in. (19.0-mm) sieve. If the aggregate fraction between the ¾-in. and No. 4 (4.75-mm) sieve does not contain free surface moisture, then that fraction of the aggregate shall be soaked for 24 h and towel dried to obtain a saturated surface dry condition. If job aggregates are not available, graded standard sand as specified in Test Method C 109/C 109M shall be used.

10.2 *Number of Specimens*—Three specimens shall constitute one test for the compressive strength test with three additional specimens for the freeze-thaw test.

10.3 *Proportioning*—The proportion of dry materials by weight shall be, where possible, the same proportions as intended for use on the job. If graded standard sand is used as the aggregate, the proportions of dry materials by weight shall be as follows:

Hydrated lime	4 %
Pozzolan	24 %
Graded standard sand	72 %

www.technobetar.ir

The amount of mixing water shall be the optimum moisture content as determined by Method C of Test Methods D 1557, except that the 5-lift requirement is replaced with 3 lifts and Note 1 is not to be used. In determining the moisture-density relationship, mix dry materials in a Lancaster PC Mixer, or its equivalent, for 1 min, or until the mixture is uniform in color and texture, plus an additional 3 min after the water is added in order to obtain the first point on the moisture-density curve. The original sample may be reused for subsequent trials. The batch shall be mixed for an additional minute after the water has been added for each subsequent trial.

10.4 *Mixing and Molding Test Specimens*— After the optimum moisture content is obtained by the above procedure, a batch large enough to make three 4.0 by 4.6-in. (102 by 117-mm) cylinders (approximately 15 lb (7 kg)) shall be mixed in the following manner: Mix the dry materials in a Lancaster PC Mixer, or its equivalent, for 1 min or until the mixture is uniform in color and texture, followed by the addition of water that will give optimum moisture content and an additional 3 min of mixing. Mold the specimens immediately in accordance with Method C of Test Methods D 1557, except as previously noted. Each layer should be scarified to a depth of ¼ in. (6 mm) before the next layer is compacted in order to assure a good bond between the layers. Weigh a representative sample of the mixture, using a container with a tight lid to assure that no moisture is lost while determining the weight of the sample. Dry to constant weight and calculate the actual moisture content of the sample. After molding, weigh each sample in the mold to determine the uniformity of molded weights of the specimens and then carefully remove from the mold by the use of a sample extruded, such as a jack or lever frame.

10.5 *Curing of Test Specimens*—Immediately after the specimens are removed from the mold, reweigh the specimens and place in a sealed container (½-gal (2-L) or 1-gal (4-L) can with double friction lids) to prevent loss of moisture. Place the specimens in the sealed containers carefully in a room or cabinet with forced-air circulation maintained at 100 ± 3 °F (38 ± 2 °C) for a 7-day period. After this period, remove the specimens from the container, reweigh, and allow to cool to room temperature. Submerge the specimens for compressive strength testing in water for 4 h, remove, allow to drain on a nonabsorbent surface, and cap and test within 1 h of the time of removal from the water.

10.6 *Number of Test Specimens*:

10.6.1 Three specimens shall be tested in accordance with Test Method C 39/C 39M; no *l*/*d* correction will be considered in the computation of the compressive strength.

10.6.2 Three specimens shall be tested for freeze-thaw resistance after being cured in accordance with 10.5 (without the 4-h soaking period) by means of the vacuum saturation strength testing procedure described in Section 11.

11. Vacuum Saturation Strength Testing Procedure

11.1 *Equipment*:

11.1.1 *Vacuum Saturation Chamber*—The vacuum saturation chamber is a 12-in. (305-mm) high by 12-in. inside diameter stainless steel cylindrical section welded to a ½-in. (12.7-mm) thick by 14-in. (356-mm) diameter stainless steel base plate. The wall thickness of the cylindrical section is ⅜ in. (9.5 mm). The lid of the vacuum saturation chamber is a poly(methylmethacrylate) (PMMA) plate 1 in. (13 mm) thick and 14 in. in diameter. Both the PMMA lid and top of the vacuum cylinder are grooved for a ¼-in. (6.4-mm) circular O-ring seal having an inside diameter of 12⅛ in. (308 mm). The lid is fastened to the chamber by six equally spaced threaded ¼-in. rods which pass along the outside wall of the cylindrical section and thread into the base plate.

11.1.1.1 A sketch of the vacuum saturation chamber described above is shown in Fig. 1. A vacuum saturation chamber

www.technobetar.ir

of equivalent size and capability is permitted under this specification. Vacuum desiccators can also be used for this purpose.

11.1.1.2 A ¼-in. (6.4-mm) vacuum line connection is located 1 in. (13 mm) below the top of the vacuum chamber and a ⅜-in. (9.5-mm) water line connection with control valve is located at the base of the vacuum chamber. The vacuum line is connected to a commercial vacuum pump and the water line is connected to a reservoir of desired water. The vacuum is controlled by a pressure valve at the vacuum pump.

11.1.1.3 The specimen support plate inside of the chamber is constructed of ½-in. (12.7-mm) thick PMMA which is 11½ in. (292 mm) in diameter. The support plate sits on three 1½-in. (38.1-mm) long legs which elevate it off of the bottom of the chamber. The specimen support plate is perforated (approximately ten ⅛-in. (3.2-mm) diameter holes per square inch) so as to allow complete access of water to the specimens during saturation. For an equivalent size vacuum saturation chamber, a specimen support plate similar to that described above must be provided.

11.1.1.4 The vacuum saturation chamber must be of sufficient size to hold the same number of Proctor-sized specimens for vacuum saturation testing as the number of specimens tested for compressive strength.

11.1.2 *Vacuum System*—A system capable of maintaining a vacuum of 24 in. Hg (11.8 psi) for a minimum of 30 min is required.

11.2 *Procedure*:

11.2.1 At the end of the curing period, remove the specimens from the curing room and allow approximately 2 h to reach equilibrium with room temperature. The specimens should remain sealed in the containers during this 2-h equilibration period in order to prevent moisture loss.

11.2.2 Place the cured specimens in an upright position on the specimen support plate within the vacuum chamber. Place the lid on the vacuum chamber and evacuate the chamber to a pressure of 24 in. Hg gradually over a period of not less than 45 s and hold for 30 min in order to remove air from the voids in the specimens. After the 30-min de-airing period, flood the vacuum chamber with water at room temperature to a depth sufficient to cover the specimens. Remove the vacuum and then soak the specimens for 1 h at atmospheric pressure.

11.2.3 At the end of the soaking period, remove the specimens from the water and allow to drain for approximately 2 min on a nonabsorptive surface. After the free surface water has drained, immediately test the specimens for unconfined compressive strength in accordance with Test Method C 39/C 39M.

11.3 *Report*—Report of the compressive strength and vacuum saturation strength tests shall include the following:

11.3.1 Identification of each material used in the preparation of the specimens,

11.3.2 Percentage by dry weight of each of the constituents,

11.3.3 Actual percentage moisture content of mixture,

11.3.4 Actual dry unit weight of each specimen, nearest lb/ft^3 or g/cm^3,

11.3.5 Percentage of maximum dry unit weight of each specimen,

11.3.6 Cross-sectional area of each specimen, in. ^{2} or cm^2,

11.3.7 Maximum failure load of each specimen, lbf or N,

11.3.8 Compressive strength of each specimen, to nearest 5 psi or 50 kPa, and

11.3.9 Vacuum saturation strength of each specimen, to nearest 5 psi or 50 kPa.

11.3.10 The average compressive strength of the three specimens tested shall be designated as the test value for evaluation by this specification. The average vacuum saturation strength of the three specimens tested shall be designated as the test value for evaluation by this specification.

12. Available Lime Index of Fly Ash

12.1 The available lime index may be determined using the Available Lime Index Method of Test Methods C 25 (Hydrated Lime Procedure). See also Practice C 50, Terminology C 51, and Specification C 821.

12.2 The precision for pulverized coal fly ash, using the procedure of 12.1, is as follows:

12.2.1 The single operator standard deviation has been found to be 0.095 %.[3] Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 0.268 %.[3]

12.2.2 The multilaboratory standard deviation has been found to be 0.264 %.[3] Therefore, results of two properly conducted tests from two different laboratories on identical samples should not differ by more than 0.75 %.[3]

13. Storage and Inspection

13.1 Pozzolans shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment. Reasonable facilities shall be provided the purchaser for careful sampling and inspection either at the source or at the site of the work, as may be specified by the purchaser.

14. Rejection

14.1 Pozzolan may be rejected if it fails to meet any of the requirements of this specification.

14.2 Packages varying more than 5 % from the stated weight may be rejected; and if the average weight of the packages in any shipment, as shown by weighing 50 packages taken at random, is less than that specified, the entire shipment may be rejected.

15. Packaging and Package Marking

15.1 When pozzolan is delivered in packages, the name and brand and the weight of material contained therein shall be plainly marked on each package. Similar information shall be provided in shipping invoices accompanying the shipment of packaged or bulk pozzolans.

16. Keywords

16.1 compressive strength; fly ash; freeze-thaw resistance; lime; pozzolan; soil stabilization

[3] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

SUMMARY OF CHANGES

Committee C07 has identified the location of selected changes to this specification since the last issue, C 593 – 05, that may impact the use of this specification. (Approved November 15, 2006)

(*1*) Replaced reference to Type N Lime (Specification C 207) to Lime Used with Pozzolans (Specification C 821) in 9.3.1 and 10.1.1.

(*2*) Revised 1.2, 9.5, and 9.7 to change the safety caveat and remove references to mortar.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 595/C 595M – 09

Standard Specification for Blended Hydraulic Cements[1]

This standard is issued under the fixed designation C 595/C 595M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification pertains to blended hydraulic cements for both general and special applications, using slag or pozzolan, or both, with portland cement or portland cement clinker or slag with lime.

NOTE 1—This specification prescribes ingredients and proportions, with some performance requirements whereas Performance Specification C 1157 is a hydraulic cement specification in which performance criteria alone govern the products and their acceptance.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. Values in SI units [or inch-pound units] shall be obtained by measurement in SI units [or inch-pound units] or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units [or SI units]. Values are stated in only SI units when inch-pound units are not used in practice.

1.3 The text of this standard refers to notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) are not requirements of the standard.

C 1157 Performance Specification for Hydraulic Cement
IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): the Modern Metric System

3. Terminology

3.1 *Definitions*—The terms used in this specification are defined in Terminology C 219, except for the following terms:

3.1.1 *binary blended cement*, *n*—a blended hydraulic cement consisting of portland cement with either a slag cement or a pozzolan.

3.1.2 *ternary blended cement*, *n*—a blended hydraulic cement consisting of portland cement with either a combination of two different pozzolans, or slag cement and a pozzolan.

4. Classification

4.1 This specification applies to the following types of blended cement that generally are intended for use as indicated.

4.1.1 Blended hydraulic cements for general concrete construction.

4.1.1.1 *Type IS*—Portland blast-furnace slag cement.

4.1.1.2 *Type IP*—Portland-pozzolan cement.

4.1.1.3 *Type IT*—Ternary blended cement.

4.2 *Reporting*:

4.2.1 The naming practice for blended cements shall be made by adding the suffix (X) to the type designation under 4.1.1, where (X) equals the targeted percentage of slag or pozzolan in the product expressed as a whole number by mass of the final blended product, within the allowable variation as stated in 14.3.

4.2.2 The naming practice for ternary blended cements shall be made by adding the suffixes (AX) and (BY) to the Type IT designation under 4.1.1, where:

A is either "S" for slag cement, or "P" for pozzolan, whichever is present in larger amount by mass, and
X is the targeted percentage by mass of constituent A, and
B is either "S" for slag cement, or "P" for pozzolan, and
Y is the targeted percentage by mass of constituent B.

Both X and Y values are expressed as a whole number by mass of the final blended product, within the allowable variation as stated in 14.3. If X and Y are the same, the order is interchangeable.

NOTE 2—Examples of the naming practice per 4.2.1 and 4.3 are shown below (all percentages by mass):

Binary blended cement with 80 % portland cement and 20 % slag cement = IS(20).
Binary blended cement with 85 % portland cement and 15 % pozzolan = IP(15).
Ternary blended cement with 70 % portland cement, 20 % slag cement and 10 % pozzolan = IT(S20)(P10).
Ternary blended cement with 65 % portland cement, 25 % of one pozzolan and 10 % of another pozzolan = IT(P25)(P10).

4.2.3 A simplified naming practice is used in this standard for practicality and clarity when referring to specific requirements for binary and ternary blended cements that are applicable to a range of products or in ternary blended cements when requirements are applicable to only one constituent within a specific range (%). (See Note 3)

NOTE 3—Examples of the simplified naming practices per 4.2.3 are shown below:

1) An example when requirements are applicable to a range of products can be found in Table 1, where the maximum SO_3 content of 3 % applies to: binary blended cements with slag cement contents <70 %, indicated as IS(<70); ternary blended cements with a pozzolan content less than the slag cement content and the slag cement content is less than 70 %, indicated as IT(P<S<70).

2) An example when requirements are applicable to only one constituent within a specific range (%) of that constituent can be found in 8.2, where testing is required only when the slag cement content is <25 %. Because the requirement is based on the slag cement content only with no relation to the pozzolan content, a simplified naming practice is employed and the range of ternary blended cements are indicated as Type IT(S<25).

4.3 *Special Properties*:

4.3.1 Air-entraining cement, when desired by the purchaser, shall be specified by adding the suffix (A) to any of the above types. The air-entraining option is specified in combination with any of the other special properties where required.

NOTE 4—A given mass of blended cement has a larger absolute volume than the same mass of portland cement. This should be taken into consideration in purchasing cements and in proportioning concrete mixtures.

4.3.2 Moderate sulfate resistance or moderate heat of hydration, or both, when desired by the purchaser, shall be specified by adding the suffix (MS) or (MH), respectively, to the type designation under 4.1.1.

4.3.3 High sulfate resistance, when desired by the purchaser, shall be specified by adding the suffix (HS) to the type designation under 4.1.1.

NOTE 5—Special characteristics attributable to slag or pozzolan will vary based on quantities contained within the blended cements.

4.3.4 Low heat of hydration, when desired by the purchaser, shall be specified by adding the suffix (LH) to the type designation under 4.1.1.

TABLE 1 Chemical Requirements

Cement Type[A,B]	Applicable Test Method	IS(< 70), IT(P<S<70)	IS(≥ 70), IT(S≥70)	IP, IT(P>S)
Magnesium oxide (MgO), max, %	C 114	...	...	6.0
Sulfate reported as SO_3, max, %[C]	C 114	3.0	4.0	4.0
Sulfide reported as S^{2-}, max, %	C 114	2.0	2.0	...
Insoluble residue, max, %	C 114	1.0	1.0	...
Loss on ignition, max, %	C 114	3.0	4.0	5.0

[A] The chemical requirements in this table are applicable to all air-entrained cement equivalents.
[B] The requirements of Type IT(P>S) shall apply to ternary blended cements with equal pozzolan and slag cement contents.
[C] When it has been demonstrated by Test Method C 563 that the optimum SO_3 exceeds a value 0.5 % less than the specification limit, an additional amount of SO_3 is permissible provided that, when the cement with the additional calcium sulfate is tested by Test Method C 265, the calcium sulfate in the hydrated mortar at 24 ± ¼ h, expressed as SO_3, does not exceed 0.50 g/L. When the manufacturer supplies cement under this provision, he will, upon request, supply supporting data to the purchaser.

5. Ordering Information

5.1 Orders for material under this specification shall include the following:

5.1.1 Specification number,

5.1.2 Type or types required,

5.1.2.1 Indicate allowable slag or pozzolan % maximum or minimum, or both, if required.

5.1.3 Optional special properties required (see 4.3):

5.1.3.1 MS if moderate sulfate resistance is required;

5.1.3.2 HS if high sulfate resistance is required;

5.1.3.3 MH if moderate heat of hydration is required;

5.1.3.4 LH if low heat of hydration is required;

5.1.3.5 A if air entraining is required;

5.1.3.6 Accelerating addition, if required;

5.1.3.7 Retarding addition, if required;

5.1.3.8 Water reducing addition, if required;

5.1.3.9 Water reducing and accelerating addition, if required; and

5.1.3.10 Water reducing and retarding addition, if required.

5.1.4 Certification, if desired (see Section 14).

NOTE 6—It is important to check for availability of various options. Some multiple options are mutually incompatible or unattainable.

6. Materials and Manufacture

6.1 *Blast-Furnace Slag*—Blast-Furnace slag shall be the nonmetallic product, consisting essentially of silicates and aluminosilicates of calcium and other bases, that is developed in a molten condition simultaneously with iron in a blast furnace.

6.2 *Granulated Blast-Furnace Slag*—Granulated blast-furnace slag shall be the glassy granular material formed when molten blast-furnace slag is rapidly chilled, as by immersion in water.

6.3 *Slag Cement*—See Terminology C 219.

6.4 *Portland Cement*—See Terminology C 219. For purposes of this specification, portland cement meeting the requirements of Specification C 1157 or Specification C 150 are suitable. Portland cement or other hydraulic materials, or both, containing high free lime are not prohibited from use as long as the autoclave test limits for the blended cement are met.

6.5 *Portland Cement Clinker*—Portland cement clinker shall be partially fused clinker consisting primarily of hydraulic calcium silicates.

6.6 *Pozzolan*—Pozzolan shall be a siliceous or siliceous and aluminous material, which in itself possesses little or no cementitious value but which will, in finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties.

6.7 *Hydrated Lime*—Hydrated lime used as part of a blended cement shall meet the requirements of Specification C 821, except that when interground in the production process there shall be no minimum fineness requirement.

6.8 *Air-Entraining Addition*—When air-entraining cement is specified, an addition meeting the requirements of Specification C 226 shall be used.

6.9 When processing additions are used in the manufacture of cement, they shall have been shown to meet the requirements of Specification C 465 in the amounts used or greater, (see Section 14.2).

6.10 When functional additions (used at the sole option of the purchaser) are used they shall have been shown to meet the requirements of Specification C 688 when tested with the cement to be used, in the amount used or greater, (see Section 14.2).

6.11 *Other Additions*—The cement covered by this specification shall contain no additions except as provided for above except that water or calcium sulfate (see Terminology C 219), or both, if added, shall be in amounts so that the limits shown in Table 1 for sulfate reported as SO_3 and loss on ignition are not exceeded.

6.12 *Binary Blended Cement*—Binary blended cement shall be a hydraulic cement consisting of an intimate and uniform blend (see Note 7) produced either by intergrinding portland cement clinker with a pozzolan or a granulated blast-furnace slag, or a slag cement, or by blending portland cement with a pozzolan or a slag cement, or a combination of intergrinding and blending. The maximum constituent requirements of 6.14 and 6.16 shall apply.

6.13 *Ternary Blended Cement*—Ternary blended cement shall be a hydraulic cement consisting of an intimate and uniform blend (see Note 7) produced either by intergrinding portland cement clinker with 1) two different pozzolans, 2) granulated blast-furnace slag or slag cement and a pozzolan; or by blending portland cement with 1) two different pozzolans or 2) slag cement and a pozzolan, or 3) a combination of intergrinding and blending. The maximum constituent requirements of 6.14 and 6.16 shall apply.

6.14 *Portland Blast-Furnace Slag Cement*—Portland blast-furnace slag cement shall be a hydraulic cement in which the slag cement constituent is up to 95 % by mass of the blended cement. Binary or ternary blended cement with a slag cement content equal to or exceeding 70 % by mass, is permitted to contain hydrated lime.

NOTE 7—The attainment of an intimate and uniform blend of two or more types of fine materials is difficult. Consequently, adequate equipment and controls must be provided by the manufacturer. The purchasers should assure themselves of the adequacy of the blending operation.

6.15 *Air-Entraining Portland Blast-Furnace Slag Cement*—Air-entraining portland blast-furnace slag cement shall be portland blast-furnace slag cement to which sufficient air-entraining addition has been added so that the resulting product complies with the air content of mortar requirements.

6.16 *Portland-Pozzolan Cement*—Portland-pozzolan cement shall be a hydraulic cement in which the pozzolan constituent is up to 40 % by mass of the blended cement.

6.17 *Air-Entraining Portland-Pozzolan Cement*—Air-entraining portland-pozzolan cement shall be portland-pozzolan cement to which sufficient air-entraining addition has been added so that the resulting product complies with the air content of mortar requirements.

www.technobetar.ir

7. Chemical Composition

7.1 Cement of the type specified shall conform to the applicable chemical requirements prescribed in Table 1.

7.2 If the purchaser has requested the manufacturer to state in writing the composition of the blended cement purchased, the composition of the cement furnished shall conform to that shown in the statement within the following tolerances (see Note 8).

	Tolerance, ± %
Silicon dioxide (SiO_2)	3
Aluminum oxide (Al_2O_3)	2
Calcium oxide (CaO)	3

NOTE 8—This means that if the manufacturer's statement of the composition says" SiO_2: 32 %," the cement when analyzed, shall be found to contain between 29 and 35 % SiO_2.

8. Physical Properties

8.1 *Blended Cement*—Blended cement of the type specified shall conform to the applicable physical requirements prescribed in Table 2.

8.2 *Pozzolan or Slag*—Pozzolan or granulated blast-furnace slag or slag cement that is to be blended with cement shall be tested in the same state of subdivision as that in which it is to be blended. Pozzolan shall conform to the fineness requirement and the activity index requirement of Table 3. Slag cement that is to be used for portland blast-furnace slag cements Type IS(< 25) or ternary blended cements Type IT(S<25) shall conform to the activity index requirement of Table 3. Such pozzolan, or granulated blast-furnace slag, or slag cement that is to be interground with portland cement clinker shall, before testing for conformance with requirements of Table 3, be ground in the laboratory to a fineness at which it is believed to be present in the finished cement. It is the manufacturer's responsibility to decide on the fineness at which the testing is to be carried out, and when requested to do so by a purchaser, to report the information upon which the decision was based.

8.3 Pozzolan for use in the manufacture of portland-pozzolan cement, Type IP(< 15) and IP(< 15)-A or ternary blended cements Type IT(P<15) and Type IT(P<15)-A, shall meet the requirements of Table 3 when tested for mortar expansion of pozzolan as described in 10.1.13. If the alkali content of the clinker to be used for the production lots changes by more than 0.2 % total as equivalent Na_2O, calculated as $Na_2O + 0.658\ K_2O$, from that of the clinker with which the acceptance tests were carried out, the pozzolan shall be retested to show compliance with the requirements of Table 3.

9. Sampling

9.1 Sample the materials in accordance with the following methods:

9.1.1 *Sampling Blended Cements*—Practice C 183.

9.1.1.1 When the purchaser desires that the cement be sampled and tested to verify compliance with this specification, perform sampling and testing in accordance with Practice C 183.

9.1.1.2 Practice C 183 is not designed for manufacturing quality control and is not required for manufacturer's certification.

9.1.2 *Sampling Pozzolan*—Test Methods C 311. One 2 kg [4 lb] sample shall be taken from approximately each 360 Mg [400 tons] of pozzolan.

10. Test Methods

10.1 Determine the applicable properties enumerated in this specification in accordance with the following test methods:

10.1.1 *Chemical Analysis*—Test Methods C 114, with the special provisions noted therein applicable to blended cement analyses.

10.1.2 *Fineness by Sieving*—Test Method C 430.

10.1.3 *Fineness by Air-Permeability Apparatus*—Test Method C 204.

10.1.4 *Autoclave Expansion*—Test Method C 151, except that, in the case of portland blast-furnace slag cement IS(≥70) or ternary blended cement IT(S≥70), the test specimens shall remain in the moist cabinet for a period of 48 h before being measured for length, and the neat cement shall be mixed for not less than 3 min nor more than 3½ min.

10.1.5 *Time of Setting*—Test Method C 191.

10.1.6 *Air Content of Mortar*—Test Method C 185, using the actual specific gravity of the cement, if it differs from 3.15 by more than 0.05, in calculating the air content.

10.1.7 *Compressive Strength*—Test Method C 109/C 109M.

10.1.8 *Heat of Hydration*—Test Method C 186.

10.1.9 *Normal Consistency*—Test Method C 187, except that in the case of portland blast-furnace slag cement IS(≥70) or ternary blended cement IT(S≥70), the paste shall be mixed for not less than 3 min nor more than 3½ min.

10.1.10 *Specific Gravity*—Test Method C 188.

10.1.11 *Water Requirement*—The mass of mixing water added to the six-cube batch in accordance with Test Method C 109/C 109M, as a percentage of the total cementing ingredients.

10.1.12 *Mortar Expansion of Blended Cement*—Test Method C 227, using crushed Pyrex glass No. 7740[3] as aggregate and the grading prescribed in Table 4.

10.1.13 *Mortar Expansion of Pozzolan for Use in Portland-Pozzolan Cement Types IP(< 15) and IP(< 15)-A or Ternary Blended Cement Types IT(P<15) and IT(P<15)-A*—Using the pozzolan and the clinker or cement that are to be used together in the production of the blended cement, prepare portland-pozzolan cements Types IP(< 15) and IP(< 15)-A or Ternary Blended Cement Types IT(P<15) and IT(P<15)-A containing 2.5, 5, 7.5, 10, 12.5, and 15 mass % of the pozzolan. These blends shall be tested in accordance with Test Method C 227 using a sand judged to be a nonreactive by the mortar bar test in Test Method C 227. The expansion of the mortar bars shall be measured at 91 days, and all the six blends shall meet the expansion requirement in Table 3.

10.1.14 *Drying Shrinkage*—Test Method C 157/C 157M. Make three specimens using the proportion of dry materials of

[3] Pyrex Glass No. 7740 is available as lump cullet from the Corning Glass Works, Corning, NY; this is the sole source of supply of the apparatus known to the committee at this time. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee,[1] which you may attend.

8 weeks,		0.060	0.060	0.060	0.060	0.060
Sulfate resistance, max, %:[I]	C 1012					
Expansion at 180 days		(0.10)[J]	0.10	0.05	...	(0.10)[J]
Expansion at 1 year				0.10	...	

[A] Air-entrained cements shall have a mortar air content of 19 ± 3 % by volume and the minimum compressive strength shall be no less than 80 % of the comparable non-air-entrained cement type.
[B] The requirements of Type IT(P>S), including MS, HS, or LH, as appropriate, shall apply to ternary blended cements with equal pozzolan and slag cement contents.
[C] Applicable only when higher strengths at early ages are not required or when low heat is required.
[D] Both amount retained when wet sieved on 45-μm (No. 325) sieve and specific surface by air permeability apparatus, m^2/kg, shall be reported on all mill test reports requested under 14.4.
[E] The specimens shall remain firm and hard and show no signs of distortion, cracking, checking, pitting, or disintegration when subjected to the autoclave expansion test.
[F] Time of setting refers to initial setting time in Test Method C 191. The time of setting of cements containing a user-requested accelerating or retarding functional addition need not meet the limits of this table, but shall be stated by the manufacturer.
[G] Applicable only when moderate (MH) or low (LH) heat of hydration is specified, in which case the strength requirements shall be 80 % of the values shown in the table.
[H] The test for mortar expansion is an optional requirement to be applied only at the purchaser's request and is not required unless the cement will be used with alkali-reactive aggregate.
[I] In the testing of HS cement, testing at one year shall not be required when the cement meets the 180-day limit. An HS cement failing the 180-day limit shall not be rejected unless it also fails the one-year limit.
[J] Optional sulfate resistance criterion that applies only if specifically invoked.

TABLE 3 Requirements for Pozzolan for Use in Blended Cements and for Slag for Use in Portland Blast-Furnace Slag Cement Type IS(< 25) and Ternary Blended Cement Type IT(S<25)

Pozzolan and Slag, as applicable	Applicable Test Method	
Fineness:	C 430	
Amount retained when wet-sieved on 45-μm (No. 325) sieve, max, %		20.0
Alkali reactivity of pozzolan for use in Types IP(< 15); IT(P<15) and IP(< 15)-A; IT(P<15)-A cements, six tests, mortar bar	C 227	
expansion at 91 days, max, %		0.05
Activity index with portland cement, at 28 days, min, %	(see Annex A1)	75

1 part of cement to 2.75 parts of Test Method C 109/C 109M graded Ottawa sand. Use a curing period of 6 days and an air storage period of 28 days. Report the linear contraction during air storage based on an initial measurement after the 6-day water-curing period.

10.1.15 *Activity Index with Portland Cement*—Test in accordance with Annex A1.

10.1.16 *Sulfate Resistance*—see Test Method C 1012.

11. Testing Time Requirements

11.1 The following periods from time of sampling shall be allowed for the completion of testing:

3-day test	8 days
7-day test	12 days
14-day test	19 days
28-day test	33 days
8-week test	61 days

12. Inspection

12.1 Facilities shall be provided to the purchaser for careful inspection and sampling of the finished cement. Inspection and sampling of finished cement shall be at the mill or distribution site controlled by the manufacturer, or at any other location as agreed by the purchaser and seller.

12.2 The manufacturer shall provide suitable facilities to enable the inspector to check the relative masses of the constituents used, and the intergrinding or blending operation used to produce the cement. The plant facilities for intergrinding or blending and inspection shall be adequate to ensure compliance with the provisions of this specification.

13. Rejection

13.1 At the option of the purchaser, cement shall be rejected if it fails to meet any of the requirements of this specification applicable to the cement. Such rejection shall apply to an optional requirement only if that option has been invoked for the cement.

13.2 When the purchaser requires, cement in bulk storage for a period greater than six months shall be resampled and retested and, at the option of the purchaser, shall be rejected if it fails to meet any of the applicable requirements of this specification. Cement so rejected shall be the responsibility of the owner of record at the time of sampling for retest.

13.3 When the purchaser requires, packages more than 2 % below the mass marked thereon shall be rejected; or if the average mass of packages in any shipment, as shown by determining the mass of 50 packages taken at random, is less than that marked on the packages, the entire shipment, at the option of the purchaser, shall be rejected.

TABLE 4 Aggregate Grading Requirements for Mortar Expansion Test

Sieve Size		Weight %
Passing	Retained on	
4.75-mm (No. 4)	2.36-mm (No. 8)	10
2.36-mm (No. 8)	1.18-mm (No 16)	25
1.18-mm (No. 16)	600-μm (No. 30)	25
600-μm (No. 30)	300-μm (No. 50)	25
300-μm (No. 50)	150-μm (No. 100)	15

14. Certification

14.1 At the request of the purchaser, the manufacturer shall state in writing the source, amount, and composition of the essential constituents used in manufacture of the finished cement and the composition of the blended cement purchased.

14.2 At the request of the purchaser, the manufacturer shall state in writing the nature, amount, and identity of any processing, functional, or air-entraining addition used; and also, if requested, shall supply test data showing compliance of any such processing addition with the provisions of Specification C 465 and of any such functional addition with the provisions of Specification C 688, and of any such air-entraining addition with the provisions of Specification C 226.

14.3 At the request of the purchaser, the manufacturer shall also state in writing that the amount of pozzolan or slag in the finished cement will not vary more than ± 5.0 mass % of the finished cement from lot to lot or within a lot.

14.4 Upon request of the purchaser in the contract or order, a manufacturer's certification shall be furnished indicating that the material was tested during production or transfer in accordance with this specification, that it complies with this specification, and a report of the test results shall be furnished at the time of shipment (to include both amount retained on the 45-μm (No. 325) sieve and specific surface by the air permeability method).

15. Packaging and Package Marking

15.1 When the cement is delivered in packages, the words, "portland blast-furnace slag cement," "portland-pozzolan cement," or "ternary blended cement" as appropriate; the type of cement, name and brand of the manufacturer, and the mass of the cement contained therein, shall be plainly marked on each package. When the cement contains a functional addition listed in 5.1.3.5-5.1.3.10, the type of functional addition shall be plainly marked on each package. Similar information shall be provided in the shipping documents accompanying the shipment of packaged or bulk cement. All packages shall be in good condition at the time of inspection.

16. Storage

16.1 The cement shall be stored in such a manner as to permit easy access for proper inspection and identification of

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:24:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

each shipment, and in a suitable weathertight building that will protect the cement from dampness and minimize warehouse set.

17. Keywords

17.1 blended hydraulic cement; fly ash cement; hydraulic cement; portland blast-furnace slag cement; portland pozzolan cement; pozzolanic cement; slag; granulated blast furnace slag

ANNEX

(Mandatory Information)

A1. ACTIVITY INDEX WITH PORTLAND CEMENT

A1.1 Specimen Preparation

A1.1.1 Mold, cure, and test the specimens from a control mix and from a test mix in accordance with Test Method C 109/C 109M. The portland cement used in the control mix shall meet the requirements of Specification C 150, and shall be the type, and if available, the brand of cement to be used in the work. Make three-cube batches as follows: (For 6- or 9-cube batches, double or triple, respectively, the amounts of dry ingredients.)

A1.1.1.1 *Control Mix*:

250 g of portland cement
687.5 g of graded Ottawa sand
X mL of water required for flow of 100 to 115

A1.1.1.2 *Pozzolan Test Mix*:

162.5 g of portland cement
g of pozzolan:
87.5 × sp gr of the sample/sp gr of the portland cement
687.5 g of graded Ottawa sand
Y mL of water required for flow of 100 to 115

A1.1.1.3 *Slag Test Mix*:

75 g of portland cement
g of slag:
175 × sp gr of the slag/sp gr of the portland cement
687.5 g of graded Ottawa sand
Z mL of water required for flow of 100 to 115

A1.2 Storage of Specimens

A1.2.1 After molding, place the specimens and molds (on the base plates) in the moist room or closet at 23.0 ± 2.0 °C [73.5 ± 3.5 °F] for 20 to 24 h. While in the moist room or closet, protect the surface from dripping water. Remove the molds from the moist room or closet and remove the cubes from the molds. Place the cubes in close-fitting metal or glass containers (Note A1.1), seal the containers airtight, and store at 38.0 ± 2.0 °C [100.0 ± 3.5 °F] for 27 days. Allow the specimens to cool to 23.0 ± 2.0 °C [73.5 ± 3.5 °F] before testing.

NOTE A1.1—Use any metal container having a capacity of three cubes if it can be sealed airtight by soldering. Containers of light-tinned sheet metal with inside dimensions of 52 by 52 by 160 mm [2 by 2 by 6.25 in.] have been found to be satisfactory. Wide-mouth Mason jars of 1-L capacity have been found to be satisfactory, provided care is taken to prevent breakage.

(**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[4]

A1.3 Compressive Strength Test

A1.3.1 Determine the compressive strength of the three specimens of the control mix and of the test mix at an age of 28 days in accordance with Test Method C 109/C 109M.

A1.4 Calculation

A1.4.1 Calculate the activity index with portland cement as follows:

$$\text{Activity index with portland cement} = (A/B) \times 100 \qquad \text{(A1.1)}$$

where:

A = average compressive strength of test mix cubes, MPa, and
B = average compressive strength of control mix cubes, MPa.

A1.5 Precision and Bias

A1.5.1 *Precision*—Single operator precision, on blended cements using fly ash is essentially the same as on fly ash/cement blends in Research Report C09-1001[5] and it was found to have 3.8 % coefficient of variation (1s %). This indicates that results of two properly conducted tests by the same operator are not expected to differ by more than 10.7 % (d2s) of the average of two results. Since the test is performed solely for the purpose of manufacturer certification of raw material quality, no multilaboratory precision is applicable.

A1.5.2 *Bias*—Since there are no standard reference materials, bias cannot be determined.

[4] Section on Safety, Manual of Cement Testing, *Annual Book of ASTM Standards*, Vol 04.01.

[5] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1001.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C 595 – 08a, that may impact the use of this specification. (Approved June 15, 2009)

(*1*) Revised Sections 3, 4, 6, 8, 10, 15, and Tables 1-3.

(*2*) Revised the standard as a dual-units specification.

Committee C01 has identified the location of selected changes to this specification since the last issue, C 595 – 08, that may impact the use of this specification. (Approved December 15, 2008)

(*1*) Revised 6.10.

(*2*) Deleted old Note 5 and renumbered subsequent notes.

(*3*) Revised the "IP(LH)" value for "Compressive strength, min: 28 days" in Table 2.

Committee C01 has identified the location of selected changes to this specification since the last issue, C 595 – 07, that may impact the use of this specification. (Approved January 1, 2008)

(*1*) Revised Table 1.

(*2*) Revised A1.2.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 596 – 09

Standard Test Method for Drying Shrinkage of Mortar Containing Hydraulic Cement[1]

This standard is issued under the fixed designation C 596; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method determines the change in length on drying of mortar bars containing hydraulic cement and graded standard sand.

1.2 The values stated in SI units are to be regarded as standard. When combined standards are referenced, the selection of measurement system is at the user's discretion subject to the requirements of the referenced standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—*Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure).*[2]

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C157/C157M Test Method for Length Change of Hardened Hydraulic-Cement Mortar and Concrete

C219 Terminology Relating to Hydraulic Cement

C305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C490/C490M Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C778 Specification for Standard Sand

C1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

C1437 Test Method for Flow of Hydraulic Cement Mortar

E177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods

3. Terminology

3.1 The term "drying shrinkage" is defined as the decrease in length of the test specimen, where the decrease is caused by any factor other than externally applied forces under stated conditions of temperature, relative humidity and evaporation rate in the environment; the term includes the net effect of a variety of phenomena tending to bring about both increases and decreases in length during the period in which the test specimens under consideration are stored in the environment and in which a number of processes, including hydration of the cement, are taking place at a variety of rates.

3.2 Other terms used in this test method are defined in Terminology C219.

4. Significance and Use

4.1 This test method establishes a selected set of conditions of temperature, relative humidity and rate of evaporation of the environment to which a mortar specimen of stated composition shall be subjected for a specified period of time during which its change in length is determined and designated "drying shrinkage".

4.2 The drying shrinkage of mortar as determined by this test method has a linear relation to the drying shrinkage of concrete made with the same cement and exposed to the same drying conditions.[4] Hence this test method may be used when

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.31 on Volume Change.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 1967. Last previous edition approved in 2007 as C 596 – 07.

[2] Section on Safety, *Manual of Cement Testing, Annual Book of Standards,* Vol 04.01.

www.technobetar.ir

it is desired to develop data on the effect of a hydraulic cement on the drying shrinkage of concrete made with that cement.

5. Apparatus

5.1 *Weighing Devices and Weights*—Weighing devices and weights used in determining the mass of materials for mortar mixtures shall conform to the requirements of Specification C1005.

5.2 *Glass Graduates*—Glass graduates of suitable capacities shall conform to the requirements of Specification C1005.

5.3 *Molds*—Molds shall conform to the requirements of Practice C490/C490M for mortars.

5.4 *Trowel*—The trowel shall have a straight-edged steel blade 100 to 150 mm in length.

5.5 *Tamper*—The tamper shall conform to the requirements of Test Method C157/C157M.

5.6 *Demolding Apparatus*—The demolding apparatus shall conform to the requirements of Test Method C157/C157M.

5.7 *Length Comparator*—The length comparator shall conform to the requirements of Practice C490/C490M.

6. Temperature and Humidity

6.1 *Laboratory*—The temperature of the laboratory, dry materials, and mixing water, and the relative humidity of the air in the laboratory shall conform to the requirements of Specification C511.

6.2 *Moist Storage Facility*—The temperature and humidity of the air in the moist storage facility shall conform to the requirements of Specification C511.

6.3 *Drying Room and Controls*—The drying room and controls shall conform to the requirements of Test Method C157/C157M.

7. Graded Standard Sand

7.1 The graded standard sand shall conform to Specification C778.

8. Number of Test Specimens

8.1 Make at least four test specimens (Note 1).

NOTE 1—Although the number of test specimens may consist of four specimens from a single batch of mortar, it is preferable that twelve specimens be made with four specimens being made from each of three batches, with each batch being made on a different day.

9. Preparation of Molds

9.1 Prepare the specimen molds as required by Practice C490/C490M.

10. Preparation of Test Specimens

10.1 *Mortar Proportions*—A batch of mortar shall consist of 750 g of cement, 1500 g of graded standard sand, and an amount of mixing water sufficient to produce a flow of 110 ± 5 %. The flow shall be determined in conformance with the procedure as described in Test Method C1437.

10.2 *Mixing Mortar*—Mix the mortar in a mechanical mixer as required by Practice C305.

10.3 *Molding of Specimens*—Mold the specimens as required by Test Method C157/C157M.

11. Curing, Storage, and Taking Comparator Readings of Test Specimens

11.1 Cure, store, and take comparator readings of the test specimens as required by Test Method C157/C157M, except as follows:

11.1.1 Moist cure the specimens in the molds for 24 h ± 30 min. If the strength of the specimens is insufficient to allow proper removal from the mold at 24 h, moist cure in the mold for 48 h ± 30 min.

11.1.2 Remove the specimens from the molds and cure in lime-saturated water for 48 h. If the specimens have been moist cured in the mold for 48 h, cure in lime-saturated water for 24 h.

11.1.3 At the age of 72 h ± 30 min remove the specimens from water, wipe with damp cloth and immediately obtain a length comparator reading for each specimen. Then place the specimens in air storage for 25 days. Obtain a length comparator reading for each specimen after 4, 11, 18, and 25 days of air storage.

12. Calculation

12.1 Calculate the length change of each specimen at each age of air drying by subtracting the initial comparator reading, taken after removal from water storage, from the comparator reading taken at each age of air drying and express as millionths and as the percent of the effective gage length. Do not prefix a shrinkage value with a minus sign.

12.2 Report the average change in unit length, expressed as millionths, and as a percent of the effective gage length of four specimens from the same batch of mortar as the drying shrinkage of the mortar. If any one test specimen is manifestly faulty, discard it. If more than one test specimen is discarded, do not report the results and repeat the test on a new batch of mortar. If more than one batch of mortar has been tested, report the average result of the individual batches. When the experimenter is clearly aware that a gross deviation from prescribed experimental procedure has taken place, discard the resultant observation, whether or not it agrees with the rest of the data and without recourse to statistical tests for outliers.

NOTE 2—An approximation of ultimate drying shrinkage of mortar may be determined by plotting the shrinkage values as a function of the reciprocal of the time. The time includes the moist curing period. An example of the method is given in Fig. 1 where a logarithmic scale is used for the drying shrinkage values and a reciprocal scale for the total time in weeks.

13. Precision and Bias

13.1 *Precision*:

13.1.1 The single-laboratory-operator multibatch-day precision has been found to be 0.0223 (1S %) and the single-operator multilaboratory-batch-day precision has been found to be 6.6 (R1S %) as defined in Practice E177, therefore 95 % percent of the time two test results (each the average of four determinations of properly conducted tests) obtained by the same operator on different days should not differ by more than 70 millionths, and the test results (each the average of four determinations of properly conducted tests) obtained by two laboratories should not differ by more than 25 % of their mean.

www.technobetar.ir

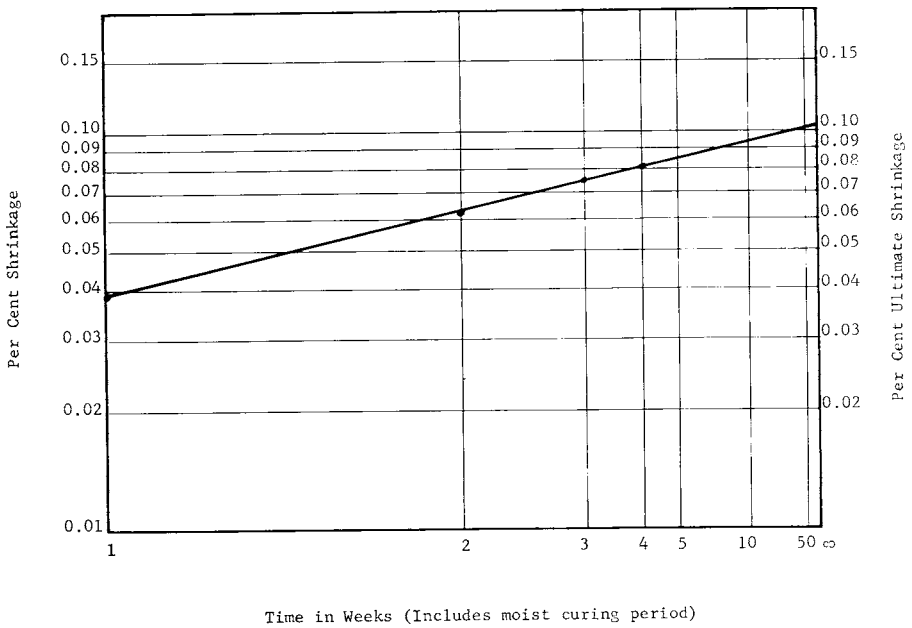

FIG. 1 Ultimate Drying Shrinkage of Mortar

13.1.2 *Repeatability*—Where a test result is the average of four specimens from a single batch, the difference between duplicate results by the same operator should not be considered suspect unless it exceeds 70 millionths. Where a test result is the average of twelve specimens, four specimens being tested from each of three batches, the difference between duplicate results by the same operator should not be considered suspect unless it exceeds 40 millionths.

13.1.3 *Reproducibility*—The average result of four or twelve specimens reported by one laboratory should not be considered suspect unless it differs from that of another laboratory by more than 25 % of their mean.

13.2 *Bias*—No justifiable statement can be made on the bias of this test method since no reference samples are available.

14. Keywords

14.1 drying shrinkage; hydraulic cement; method; mortar

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 596 – 07, that may impact the use of this test method. (Approved December 1, 2009)

(*1*) Revised the standard throughout to remove informational units.

Designation: C597 – 09

Standard Test Method for Pulse Velocity Through Concrete[1]

This standard is issued under the fixed designation C597; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of the propagation velocity of longitudinal stress wave pulses through concrete. This test method does not apply to the propagation of other types of stress waves through concrete.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C125 Terminology Relating to Concrete and Concrete Aggregates

C215 Test Method for Fundamental Transverse, Longitudinal, and Torsional Resonant Frequencies of Concrete Specimens

C823 Practice for Examination and Sampling of Hardened Concrete in Constructions

E1316 Terminology for Nondestructive Examinations

3. Terminology

3.1 *Definitions*—Refer to Terminology C125 and the section related to ultrasonic examination in Terminology E1316 for definitions of terms used in this test method.

4. Summary of Test Method

4.1 Pulses of longitudinal stress waves are generated by an electro-acoustical transducer that is held in contact with one surface of the concrete under test. After traversing through the concrete, the pulses are received and converted into electrical energy by a second transducer located a distance L from the transmitting transducer. The transit time T is measured electronically. The pulse velocity V is calculated by dividing L by T.

5. Significance and Use

5.1 The pulse velocity, V, of longitudinal stress waves in a concrete mass is related to its elastic properties and density according to the following relationship:

$$V = \sqrt{\frac{E\,(1-\mu)}{\rho\,(1+\mu)(1-2\,\mu)}} \quad (1)$$

where:

E = dynamic modulus of elasticity,
μ = dynamic Poisson's ratio, and
ρ = density.

5.2 This test method is applicable to assess the uniformity and relative quality of concrete, to indicate the presence of voids and cracks, and to evaluate the effectiveness of crack repairs. It is also applicable to indicate changes in the properties of concrete, and in the survey of structures, to estimate the severity of deterioration or cracking. When used to monitor changes in condition over time, test locations are to be marked on the structure to ensure that tests are repeated at the same positions.

5.3 The degree of saturation of the concrete affects the pulse velocity, and this factor must be considered when evaluating test results (Note 1). In addition, the pulse velocity in saturated concrete is less sensitive to changes in its relative quality.

NOTE 1—The pulse velocity in saturated concrete may be up to 5 % higher than in dry concrete.[3]

5.4 The pulse velocity is independent of the dimensions of the test object provided reflected waves from boundaries do not complicate the determination of the arrival time of the directly transmitted pulse. The least dimension of the test object must exceed the wavelength of the ultrasonic vibrations (Note 2).

NOTE 2—The wavelength of the vibrations equals the pulse velocity

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.64 on Nondestructive and In-Place Testing.

Current edition approved Dec. 15, 2009. Published February 2010. Originally approved in 1967. Last previous edition approved in 2002 as C597–02. DOI: 10.1520/C0597-09

www.technobetar.ir

divided by the frequency of vibrations. For example, for a frequency of 54 kHz and a pulse velocity of 3500 m/s, the wavelength is 3500/54000 = 0.065 m.

5.5 The accuracy of the measurement depends upon the ability of the operator to determine precisely the distance between the transducers and of the equipment to measure precisely the pulse transit time. The received signal strength and measured transit time are affected by the coupling of the transducers to the concrete surfaces. Sufficient coupling agent and pressure must be applied to the transducers to ensure stable transit times. The strength of the received signal is also affected by the travel path length and by the presence and degree of cracking or deterioration in the concrete tested.

NOTE 3—Proper coupling can be verified by viewing the shape and magnitude of the received waveform. The waveform should have a decaying sinusoidal shape. The shape can be viewed by means of outputs to an oscilloscope or digitized display inherent in the device.

5.6 The results obtained by the use of this test method are not to be considered as a means of measuring strength nor as an adequate test for establishing compliance of the modulus of elasticity of field concrete with that assumed in the design. The longitudinal resonance method in Test Method C215 is recommended for determining the dynamic modulus of elasticity of test specimens obtained from field concrete because Poisson's ratio does not have to be known.

NOTE 4—When circumstances permit, a velocity-strength (or velocity-modulus) relationship may be established by the determination of pulse velocity and compressive strength (or modulus of elasticity) on a number of samples of a concrete. This relationship may serve as a basis for the estimation of strength (or modulus of elasticity) by further pulse-velocity tests on that concrete. Refer to ACI 228.1R[4] for guidance on the procedures for developing and using such a relationship.

5.7 The procedure is applicable in both field and laboratory testing regardless of size or shape of the specimen within the limitations of available pulse-generating sources.

NOTE 5—Presently available test equipment limits path lengths to approximately 50-mm minimum and 15-m maximum, depending, in part, upon the frequency and intensity of the generated signal. The upper limit of the path length depends partly on surface conditions and partly on the characteristics of the interior concrete under investigation. A preamplifier at the receiving transducer may be used to increase the maximum path length that can be tested. The maximum path length is obtained by using transducers of relatively low resonant frequencies (20 to 30 kHz) to minimize the attenuation of the signal in the concrete. (The resonant frequency of the transducer assembly determines the frequency of vibration in the concrete.) For the shorter path lengths where loss of signal is not the governing factor, it is preferable to use resonant frequencies of 50 kHz or higher to achieve more accurate transit-time measurements and hence greater sensitivity.

5.8 Since the pulse velocity in steel is up to double that in concrete, the pulse-velocity measured in the vicinity of the reinforcing steel will be higher than in plain concrete of the same composition. Where possible, avoid measurements close to steel parallel to the direction of pulse propagation.

[4] "In-Place Methods to Estimate Concrete Strength," ACI 228.1R, American Concrete Institute, Farmington Hills, MI.

6. Apparatus

6.1 The testing apparatus, shown schematically in Fig. 1, consists of a pulse generator, a pair of transducers (transmitter and receiver), an amplifier, a time measuring circuit, a time display unit, and connecting cables.

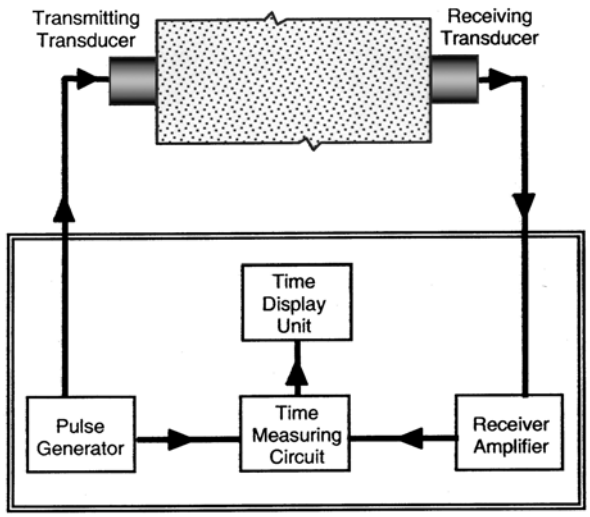
6.1.1 *Pulse Generator and Transmitting Transducer*—The pulse generator shall consist of circuitry for generating pulses of voltage (Note 6). The transducer for transforming these electronic pulses into wave bursts of mechanical energy shall have a resonant frequency in the range from 20 to 100 kHz (Note 7). The pulse generator shall produce repetitive pulses at a rate of at least 3 pulses per second. The time interval between pulses shall exceed the decay time for the transmitting transducer. The transducer shall be constructed of piezoelectric, magnetostrictive, or other voltage-sensitive material, and housed for protection. A triggering pulse shall be produced to start the time measuring circuit.

NOTE 6—The pulse voltage affects the transducer power output and the maximum penetration of the longitudinal stress waves. Voltage pulses of 500 to 1000 V have been used successfully.

NOTE 7—Transducers with higher resonant frequencies have been used successfully in relatively small laboratory specimens.

6.1.2 *Receiving Transducer and Amplifier*—The receiving transducer shall be similar to the transmitting transducer. The voltage generated by the receiver shall be amplified as necessary to produce triggering pulses to the time-measuring circuit. The amplifier shall have a flat response between one half and three times the resonant frequency of the receiving transducer.

6.1.3 *Time-Measuring Circuit*—The time-measuring circuit and the associated triggering pulses shall be capable of providing an overall time-measurement resolution of at least 1 μs. Time measurement is initiated by a triggering voltage from the pulse generator, and the time measuring circuit shall operate at the repetition frequency of the pulse generator. The time-measuring circuit shall provide an output when the received pulse is detected, and this output shall be used to



NOTE 1—It is advantageous to incorporate the pulse generator, time measuring circuit, receiver amplifier, and time display into one unit.

www.technobetar.ir

determine the transit time displayed on the time-display unit. The time-measuring circuit shall be insensitive to operating temperature in the range from 0 to 40°C and voltage changes in the power source of ±15 %.

6.1.4 *Display Unit*—A display unit shall indicate the pulse transit time to the nearest 0.1 µs.

6.1.5 *Reference Bar*—For units that use manual zero-time adjustment, provide a bar of metal or other durable material for which the transit time of longitudinal waves is known. The transit time shall be marked permanently on the reference bar. The reference bar is optional for units that perform automatic zero-time adjustment.

6.1.6 *Connecting Cables*—Where pulse-velocity measurements on large structures require the use of long interconnecting cables, use low-capacitance, shielded, coaxial cables.

6.1.7 *Coupling Agent*—A viscous material (such as oil, petroleum jelly, water soluble jelly, moldable rubber, or grease) to ensure efficient transfer of energy between the concrete and the transducers. The function of the coupling agent is to eliminate air between the contact surfaces of the transducers and the concrete. Water is an acceptable coupling agent when ponded on the surface, or for underwater testing.

7. Procedure

7.1 *Functional Check of Equipment and Zero-time Adjustment*—Verify that the equipment is operating properly and perform a zero-time adjustment.

7.1.1 *Units with Automatic Zero-Time Adjustment*—Apply coupling agent to the transducer faces and press the faces together. The instrument uses a microprocessor to record this delay time, which is subtracted automatically from subsequent transit time measurements.

NOTE 8—A reference bar may be used to verify that the zero-time adjustment has been performed correctly.

7.1.2 *Units with Manual Zero-Time Adjustment*—Apply coupling agent to the ends of the reference bar, and press the transducers firmly against the ends of the bar until a stable transit time is displayed. Adjust the zero reference until the displayed transit time agrees with the value marked on the bar.

7.1.3 Check the zero adjustment on an hourly basis during continuous operation of the instrument, and every time a transducer or connecting cable is changed. If zero-time adjustment cannot be accomplished, do not use the instrument until it has been repaired.

7.2 *Determination of Transit Time*:

7.2.1 For testing existing construction, select test locations in accordance with Practice C823, or follow the requirements of the party requesting the testing, whichever is applicable.

7.2.2 For best results, locate the transducers directly opposite each other. Because the beam width of the vibrational pulses emitted by the transducers is large, it is permissible to measure transit times across corners of a structure but with some loss of sensitivity and accuracy. Measurements along the same surface shall not be used unless only one face of the structure is accessible since such measurements may be indicative only of surface layers, and calculated pulse velocities will not agree with those obtained by through transmission (Note 9).

NOTE 9—One of the sources of uncertainty in surface tests is the lengths of the actual travel paths of the pulses. Hence, individual readings are of little value. Surface tests, however, have been used to estimate the depth of a lower quality surface layer by making multiple measurements of transit time with varying distances between the transducers. From the plot of travel time versus spacing, it may be possible to estimate the depth of the lower quality concrete.[5]

7.2.3 Apply an appropriate coupling agent (such as water, oil, petroleum jelly, grease, moldable rubber, or other viscous materials) to the transducer faces or the test surface, or both. Press the faces of the transducers firmly against the surfaces of the concrete until a stable transit time is displayed, and measure the transit time (Note 10). Determine the straight-line distance between centers of transducer faces.

NOTE 10—The quality of the coupling is critically important to the accuracy and maximum range of the method. Inadequate coupling will result in unstable and inaccurate time measurements, and will significantly shorten the effective range of the instrument. Repeat measurements should be made at the same location to minimize erroneous readings due to poor coupling.

8. Calculation

8.1 Calculate the pulse velocity as follows:

$$V = L/T \quad (2)$$

where:

V = pulse velocity, m/s,
L = distance between centers of transducer faces, m, and
T = transit time, s.

9. Report

9.1 Report at least the following information:

9.1.1 Location of test or identification of specimen.

9.1.2 Location of transducers.

9.1.3 Distance between centers of transducer faces, reported to a precision of at least 0.5 % of the distance.

9.1.4 Transit time, reported to a resolution of at least 0.1 µs.

9.1.5 Pulse velocity reported to the nearest 10 m/s.

10. Precision and Bias

10.1 *Precision*:

10.1.1 Repeatability of results have been investigated using devices with CRT displays. It is expected that the repeatability with digital display devices will be better than stated as follows.

10.1.2 Tests involving three test instruments and five operators have indicated that for path lengths from 0.3 to 6 m through sound concrete, different operators using the same instrument or one operator using different instruments will achieve repeatability of test results within 2 %. For longer path lengths through sound concrete, attenuation of the signal will decrease the absolute repeatability of the transit-time measurement, but the longer transit time involved will result in a calculation of velocity having the same order of accuracy.

10.1.3 In the case of tests through badly cracked or deteriorated concrete, the variation of the results are substantially

[5] Chung, H. W., and Law, K. S., "Assessing Fire Damage of Concrete by the Ultrasonic Pulse Technique," *Cement, Concrete, and Aggregates*, CCAGDP, Vol 7, No. 2, Winter, 1985, pp. 84–88.

www.technobetar.ir

increased. Attenuation is affected by the nature of the deterioration and the resonant frequency of the transducers. Differences between operators or instruments may result in differences in test results as large as 20 %. In such cases, however, calculated velocities will be sufficiently low as to indicate clearly the presence of distress in the concrete tested.

10.2 *Bias*—Bias of this test method has not been determined.

11. Keywords

11.1 concrete; longitudinal stress wave; nondestructive testing; pulse velocity; ultrasonic testing

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C597–02, that may impact the use of this test method. (Approved December 15, 2009)

(*1*) Revised 6.1.1 by adding a requirement that the time interval between pulses has to exceed the decay time of the transmitter, and the listing of transducer materials was deleted.
(*2*) Revised the requirements for the display unit in 6.1.4 and deleted reference to cathode ray tubes.
(*3*) Revised the reporting requirement for transit time in 9.1.4 to a resolution of at least 0.1 μs.
(*4*) Revised the description of the reference bar in 6.1.5 to clarify that the bar is not required with units that use automatic zero-time adjustment.
(*5*) Revised the procedure in 7.1 to address units that use automatic zero-time adjustment and units that use manual zero-time adjustment.

Designation: C 602 – 07

Standard Specification for Agricultural Liming Materials[1]

This standard is issued under the fixed designation C 602; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers agricultural liming materials, such as quicklime (burnt lime), hydrated lime, limestone, (calcitic and dolomitic), marl, shells, and by-products including slag, and other materials.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

C 125 Terminology Relating to Concrete and Concrete Aggregates

D 3176 Practice for Ultimate Analysis of Coal and Coke

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 *Definitions:*

3.1.1 *agricultural liming material*—a product whose calcium and magnesium compounds are capable of neutralizing soil acidity.

3.1.2 *air-cooled blast-furnace slag and granulated blast-furnace slag*—air-cooled blast-furnace slag and granulated blast furnace slag as defined in Terminology C 125.

3.1.3 *calcium carbonate equivalent (C.C.E.)*—the acid-neutralizing capacity (of an agricultural liming material) of the material expressed as weight percent of calcium carbonate.

4. Chemical Classifications

4.1 Agricultural liming materials shall be classified in terms of calcium carbonate equivalent (C.C.E.), as shown in Table 1.

TABLE 1 Agricultural Liming Materials

Material	Calcium Carbonate Equivalent (C.C.E.), percent
Quicklime	not less than 140
Hydrated lime	not less than 110
Limestone	not less than 80
Slag	not less than 80
Shells	not less than 80

NOTE 1—Marl and some by-product liming materials are used for neutralizing soil acidity, but due to their varying composition, their chemical limits are not included. In some economic circumstances limestone, slag, and shells of less than 80 % C.C.E. may be used.

5. Sieve Analysis Classifications for Agricultural Limestone

5.1 Agricultural limestone shall be classified according to the minimum percentages passing the No. 8 (2.36-mm) and No. 60 (250-µm) sieves conforming to Specification E 11, as shown in Table 2.

TABLE 2 Classification for Agricultural Limestone

Class Designation	Passing No. 8 (2.36-mm) Sieve, min, percent	Passing No. 60 (250-µm) Sieve, min, percent
S	100	100
T	99	75
O	95	55
N	90	40
E	80	25

NOTE 2—These classifications apply where the agricultural limestone is obtained by the normal crushing procedure and the product contains the fines of fracture. In some economic circumstances, coarser products are

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved June 15, 2007. Published July 2007. Originally approved in 1967. Last previous edition approved in 2006 as C 602 – 06a.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

Copyright. (C) ASTM International, 100 Barr Harbour Dr., P.O. box C-700 West Conshohocken, Pennsylvania 19428-2959, United States

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

used. The No. 60 (250-µm) sieve was selected because research has shown that this sieve gives a more accurate representation of the particle size distribution of most agricultural limestones presently produced than a finer or coarser sieve. The No. 8 (2.36-mm) sieve is used to control the upper limit on the amount of coarse limestone particles that may be in the product.

6. Sieve Analysis Classifications for Agricultural Slag

6.1 *Air-Cooled Blast-Furnace Slag*—Air-cooled blast-furnace slag shall be classified the same as agricultural limestone as shown in Section 5.

6.2 *Granulated Blast-Furnace Slag*—Granulated blast-furnace slag shall be classified in accordance with the minimum percentages passing the No. 8 (2.36-mm) and the No. 60 (250-µm) sieves.

7. Particle Size Requirements for Hydrated Lime and Quicklime

7.1 Hydrated lime and quicklime for agricultural use shall be classified in accordance with the minimum percentages passing the No. 8 (2.36-mm) and No. 60 (250-µm) sieves, as follows:

	Min. %	
Passing Sieve No.	Hydrated Lime	Quicklime
8 (2.36 mm)	100	95
60 (250 µm)	97	35

8. Sampling

8.1 Sampling shall be conducted using the procedures specified in Practice C 50.

9. Chemical Methods

9.1 Reagent grade chemicals or equivalent and water purity shall be used as specified in Test Methods C 25.

9.2 The analytical sample for chemical methods relative to this standard shall be pulverized to pass a 60 mesh sieve.

9.3 The following chemical parameters are to be determined using the methods as specified in Test Methods C 25.

9.3.1 Calcium carbonate equivalent, and

9.3.2 *Total calcium and magnesium*—determination can be made either gravimetrically or by EDTA titration.

SIEVE ANALYSIS OF AGRICULTURAL LIMING MATERIALS

10. Preparation of Sample

10.1 Dry the sample to constant weight at 110 ± 5 °C and store in an airtight container. Obtain the sample from a larger sample of the material to be tested by the use of a riffle or a sample splitter in accordance with Practice D 3176, or by the method of quartering. The sample for sieve analysis shall have a weight of 100 to 150 g.

10.2 Where limestone contains clay, some agglomeration of fine particles may occur. The agglomerates must be broken by rolling the dry sample with a hard rubber roller on a hard rubber mat or by some equally effective means that does not result in crushing the limestone.

11. Procedure

11.1 Sieve analysis shall be conducted using the procedures in Test Methods C 110. Sieve the sample through No. 8 (2.36-mm) and No. 60 (250-µm) sieves. Determine the weight of liming material passing each sieve on a scale or balance sensitive to at least 0.1 g. Calculate the amount of liming material passing the sieves to the nearest whole percentage of the total weight of the dry sample.

12. Report

12.1 Report the following results for agricultural liming materials:

12.1.1 *Percentage Calcium Carbonate Equivalent*—The percentage calcium carbonate equivalent (C.C.E.) shall be reported on the as-received basis. Calculate as follows:

$$\text{C.C.E. (as-received)} = [1-(\%\ \text{moisture} \div 100)] \times \text{C.C.E. (oven-dry)} \quad (1)$$

12.1.2 *Percentage Moisture*—Calculate as follows:

$$\text{Moisture, \%} = \frac{\text{Weight of sample (as received)} - \text{oven-dry weight}}{\text{Weight of sample (as received)}} \times 100 \quad (2)$$

12.1.3 *Percentage Calcium and Magnesium*—The percentages of elemental calcium and elemental magnesium on the basis of the as-received sample.

12.1.4 *Sieve Analysis*—The amount of dried sample passing the No. 8 (2.36-mm) and No. 60 (250-µm) sieves as a percentage of the total weight of the dried sample with the figures rounded to the nearest whole percentage point.

13. Keywords

13.1 agricultural liming materials; agricultural limestone; calcium carbonate equivalent; hydrated lime; lime by-products; limestone; quicklime; slag

SUMMARY OF CHANGES

Committee C07 has identified the location of selected changes to this specification since the last issue, C 602 – 06a, that may impact the use of this specification. (Approved June 15, 2007)

(*1*) Revised 11.1.

Committee C07 has identified the location of selected changes to this specification since the last issue, C 602 – 06, that may impact the use of this specification. (Approved December 15, 2006)

(*1*) Replaced outdated term “burnt lime” with “quicklime” throughout.

Committee C07 has identified the location of selected changes to this specification since the last issue, C 602 – 95a(2001), that may impact the use of this specification. (Approved July 1, 2006)

(*1*) Revised 1.2.

(*2*) Revised Section 8.

Designation: C 617 – 09a

Standard Practice for Capping Cylindrical Concrete Specimens[1]

This standard is issued under the fixed designation C 617; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This practice covers apparatus, materials, and procedures for capping freshly molded concrete cylinders with neat cement and hardened cylinders and drilled concrete cores with high-strength gypsum plaster or sulfur mortar.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific precaution statements see 4.3.1 and 6.2.4.1.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 150 Specification for Portland Cement

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete

C 595 Specification for Blended Hydraulic Cements

C 1231/C 1231M Practice for Use of Unbonded Caps in Determination of Compressive Strength of Hardened Concrete Cylinders

2.2 *ANSI Standard:*[3]

B46.1 Standard for Surface Texture (Surface, Roughness, Waviness and Lay)

3. Significance and Use

3.1 This practice describes procedures for providing plane surfaces on the ends of freshly molded concrete cylinders, hardened cylinders, or drilled concrete cores when the end surfaces do not conform with the planeness and perpendicularity requirements of applicable standards. Practice C 1231/C 1231M describes alternative procedures using unbonded caps or pad caps.

4. Capping Equipment

4.1 *Capping Plates*—Neat cement caps and high-strength gypsum-plaster caps shall be formed against a glass plate at least ¼ in. (6 mm) thick, a machined metal plate at least 0.45 in. (11 mm) thick, or a polished plate of granite or diabase at least 3 in. (76 mm) thick. Sulfur mortar caps shall be formed against similar metal or stone plates except that the recessed area which receives molten sulfur shall not be deeper than ½ in. (12 mm). In all cases, plates shall be at least 1 in. (25 mm) greater in diameter than the test specimen and the working surfaces shall not depart from a plane by more than 0.002 in. (0.05 mm) in 6 in. (152 mm). The surface roughness of newly finished metal plates shall not exceed that set forth in Table 4 of American National Standard B46.1, or 125 µin. (3.2 µm) for any type of surface and direction of lay. The surface, when new, shall be free of gouges, grooves, or indentations beyond those caused by the finishing operation. Metal plates that have been in use shall be free of gouges, grooves, and indentations greater than 0.010 in. (0.25 mm) deep or greater than 0.05 in.^{2}(32 mm^2) in surface area.

NOTE 1—A Rockwell hardness of 48 HRC is suggested for capping plates of devices used to form sulfur mortar caps.

4.2 *Alignment Devices*—Suitable alignment devices, such as guide bars or bull's-eye levels, shall be used in conjunction with capping plates to ensure that no single cap will depart from perpendicularity to the axis of a cylindrical specimen by more than 0.5° (approximately equivalent to ⅛ in. in 12 in. (3.2 mm in 305 mm)). The same requirement is applicable to

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved July 1, 2009. Published August 2009. Originally approved in 1968. Last previous edition approved in 2009 as C 617 – 09.

www.technobetar.ir

the relationship between the axis of the alignment device and the surface of a capping plate when guide bars are used. In addition, the location of each bar with respect to its plate must be such that no cap will be off-centered on a test specimen by more than 1/16 in. (2 mm).

4.3 *Melting Pots for Sulfur Mortars*—Pots used for melting sulfur mortars shall be equipped with automatic temperature controls and shall be made of metal or lined with a material that is nonreactive with molten sulfur.

4.3.1 **Warning**—Melting pots equipped with peripheral heating will ensure against accidents during reheating of cooled sulfur mixture that have a crusted-over surface. When using melting pots not so equipped, a build-up of pressure under the hardened surface crust on subsequent reheating may be avoided by use of a metal rod that contacts the bottom of the pot and projects above the surface of the fluid sulfur mix as it cools. The rod should be of sufficient size to conduct enough heat to the top on reheating to melt a ring around the rod first and thus avoid the development of pressure. A large metal ladle can be substituted for the rod.

4.3.1.1 Use sulfur melting pots in a hood to exhaust the fumes to outdoors. Heating over an open flame is dangerous because the flash point of sulfur is approximately 440 °F (227 °C) and the mixture can ignite due to overheating. Should the mixture start to burn, covering will snuff out the flame. The pot should be recharged with fresh material after the flame has been extinguished.

5. Capping Materials

5.1 The strength of the capping material and the thickness of the caps shall conform to the requirements of Table 1.

5.1.1 If sulfur mortar, high strength gypsum plaster and other materials except neat cement paste are to be used to test concrete with a strength greater than 7000 psi (50 MPa), the manufacturer or the user of the material must provide documentation:

5.1.1.1 That the average strength of 15 cylinders capped with the material is not less than 98 percent of the average strength of 15 companion cylinders capped with neat cement paste or 15 cylinders ground plane to within 0.002 in. (0.05 mm).

5.1.1.2 That the standard deviation of the strengths of the capped cylinders is not greater than 1.57 times that of the standard deviation of the reference cylinders.

5.1.1.3 That the cap thickness requirements were met in the qualification tests, and

TABLE 1 Compressive Strength and Maximum Thickness of Capping Materials

Cylinder Compressive Strength psi (MPa)	Minimum Strength of Capping Material	Maximum Average Thickness of Cap	Maximum Thickness Any Part of Cap
500 to 7000 psi (3.5 to 50 MPa)	5000 psi (35 MPa) or cylinder strength whichever is greater	1/4 in. (6 mm)	5/16 in. (8 mm)
greater than 7000 psi (50 MPa)	Compressive strength not less than cylinder strength, except as provided in 5.1.1	1/8 in. (3 mm)	3/16 in. (5 mm)

5.1.1.4 Of the hardening time of the caps used in the qualification tests.

5.1.2 Additionally, the qualification test report must include the compressive strength of 2 in. cubes of the material qualified and of neat cement paste cubes, if used. Capping materials conforming to these requirements is permitted to be used for cylinders with strengths up to 20 percent greater than the concrete tested in these qualification tests. The manufacturer must requalify lots of material manufactured on an annual basis or whenever there is a change in the formulation or the raw materials. The user of the material must retain a copy of the qualification results, and the dates of manufacture of material qualified and of the material currently being used. See Table 2.

5.1.3 The compressive strength of capping materials shall be determined by testing 2 in. cubes following the procedure described in Test Method C 109/C 109M. Except for sulfur mortars, molding procedures shall be as in Test Method C 109/C 109M unless other procedures are required to eliminate large entrapped air voids. See Test Methods C 472 for alternative compaction procedures. Cure cubes in the same environment for the same length of time as the material used to cap specimens.

5.1.4 The strength of the capping material shall be determined on receipt of a new lot and at intervals not exceeding three months. If a given lot of the capping material fails to conform to the strength requirements, it shall not be used, and strength tests of the replacement material shall be made weekly until four consecutive determinations conform to specification requirements.

5.2 *Neat Hydraulic Cement Paste*:

5.2.1 Make qualification tests of the neat hydraulic cement paste prior to use for capping to establish the effects of water-cement ratio and age on compressive strength of 2 in. (50 mm) cubes.

NOTE 2—The cements used generally conform to Specification C 150 Types I, II or III; however, Specification C 595 blended cements, calcium aluminate or other hydraulic cements producing acceptable strength may be used.

5.2.2 Mix the neat cement paste to the desired consistency at a water-cement ratio equal to or less than that required to produce the required strength, generally 2 to 4 h before the paste is to be used (Note 3). Remix as necessary to maintain acceptable consistency (Note 4). Some retempering of the paste is acceptable if the required water-cement ratio is not exceeded. Optimum consistency is generally produced at water-cement ratios of 0.32 to 0.36 by mass for Type I and Type II cements and 0.35 to 0.39 by mass for Type III cements.

NOTE 3—Freshly mixed pastes tend to bleed, shrink, and make unacceptable caps. The 2 to 4 h period is generally appropriate for portland cements.

NOTE 4—The required consistency of the paste is determined by the appearance of the cap when it is stripped. Fluid paste results in streaks in the cap. Stiff paste results in thick caps.

5.3 *High-Strength Gypsum Cement Paste*:

5.3.1 No fillers or extenders may be added to neat high-strength gypsum cement paste subsequent to the manufacture of the cement. (Note 5) Qualification tests shall be made to

TABLE 2 Sample Report of Qualification of a Capping Material

NOTE—Manufacturer: Testing Supplies Co.
Capping Material: Super Strong AAA-Sulfor mortar
Lot: 12a45 Date Tested: 11/3/98
Signed by:_____ (testing agency and responsible official)

Item	Capping Material	Control Cylinders	Ratio	Criteria	Pass/Fail
		Concrete Cylinder Test Data			
Type of capping material	Sulfur	Ground			
Average Concrete Strength, psi [MPa]	11 061 (76.2)	11 008 (75.9)	1.005	>0.98 Xc	Pass
Standard Deviation, psi [MPa]	376 (2.59)	250 (1.72)	1.504	≤1.57 C	Pass
Number of cylinders tested	15	15			
Cap age when cylinders tested	7 days	na			
		Capping Material Test Data			
Average cap thickness, in. [mm]	0.11 (2.8)	na			
Compressive strength of 2 in. [50 mm] cubes, psi (MPa)	12 195 (91)				
Cube age when tested.	7 days				
Maximum concrete strength qualified, psi (MPa)				1.2 Av. Str = 13 273 (91.5)[A]	

[A] Nominally a specified strength of 11 000 psi (75 MPa) and perhaps somewhat higher.

determine the effects of water-cement ratio and age on compressive strength of 2 in. (50 mm) cubes. Retarders may be used to extend working time, but their effects on required water-cement ratio and strength must be determined. (Note 6)

NOTE 5—Low-strength molding plaster, plaster of paris, or mixtures of plaster of paris and portland cement are unsuitable for capping.

NOTE 6—The water-gypsum cement ratio should be between 0.26 and 0.30. Use of low water-cement ratios and vigorous mixing will usually permit development of 5000 psi (35 MPa) at ages of 1 or 2 h. Higher water-gypsum cement ratios extend working time, but reduce strength.

5.3.2 Mix the neat gypsum cement paste at the desired water-cement ratio and use it promptly since it sets rapidly.

5.4 *Sulfur Mortar*:

5.4.1 Proprietary or laboratory prepared sulfur mortars are permitted if allowed to harden a minimum of 2 h before testing concrete with strength less than 5000 psi (35 MPa). For concrete strengths of 5000 psi or greater, sulfur mortar caps must be allowed to harden at least 16 h before testing, unless a shorter time has been shown to be suitable as specified in 5.1.1.

5.4.2 *Determination of Compressive Strength*—Prepare test specimens using a cube mold and base plate conforming to the requirements of Test Method C 109/C 109M and a metal cover plate conforming in principle to the design shown in Fig. 1 (Note 7). Bring the various parts of the apparatus to a temperature of 68 to 86 °F (20 to 30 °C), lightly coat the surfaces that will be in contact with the sulfur mortar with mineral oil, and assemble near the melting pot. Bring the temperature of the molten-sulfur mortar in the pot within a range of 265 to 290 °F (129 to 143 °C), stir thoroughly, and

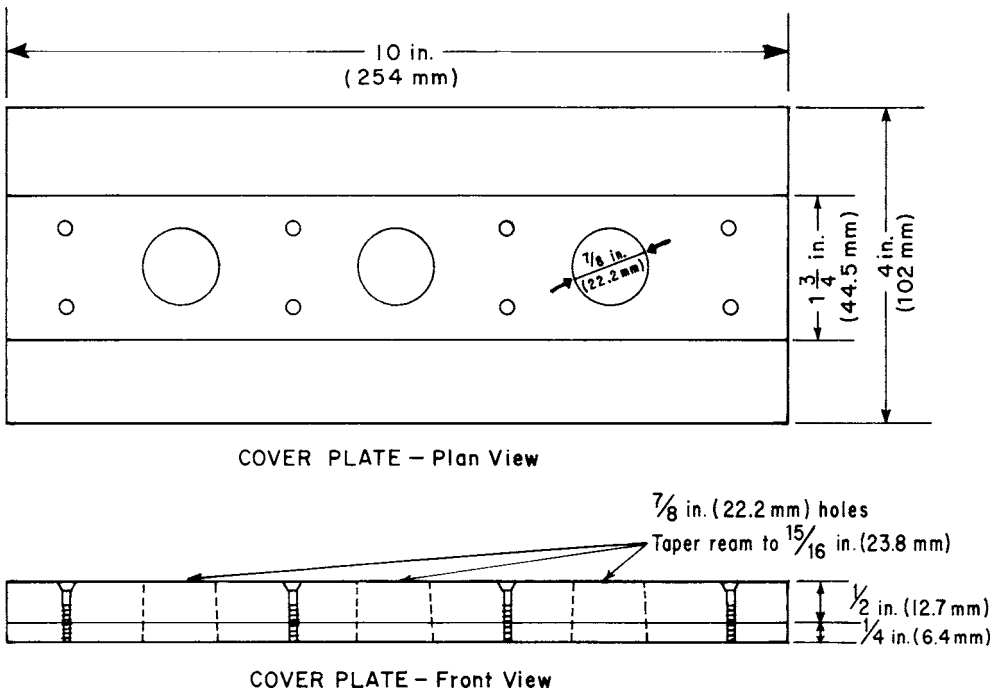

FIG. 1 Sketch of Cover Plate for 2-in. (50-mm) Cube Mold

www.technobetar.ir

begin casting cubes. Using a ladle, or other suitable pouring device, quickly fill each of the three compartments until the molten material reaches the top of the filling hole. Allow sufficient time for maximum shrinkage, due to cooling, and solidification to occur (approximately 15 min) and refill each hole with molten material (Note 8). After solidification is complete, remove the cubes from the mold without breaking off the knob formed by the filling hole in the cover plate. Remove oil, sharp edges, and fins from the cubes and check the planeness of the bearing surfaces in the manner described in Test Method C 109/C 109M. After storage at room temperature to the desired age, but not less than 2 h, test cubes in compression following the procedure described in Test Method C 109/C 109M, and calculate the compressive strength.

NOTE 7—If desired, a plane phenol formaldehyde (bakelite) plate of ⅛-in. (3-mm) thickness, provided with three appropriately spaced filling holes, may be inserted between the cover plate and the mold to slow the rate of cooling of test specimens.

NOTE 8—The second filling helps to prevent the formation of a large void or shrinkage pipe in the body of a cube. However, such defects may occur no matter how much care is exercised, and it therefore is advisable to inspect the interior of tested sulfur mortar cubes for homogeneity whenever the strength values obtained are significantly lower than anticipated.

6. Capping Procedures

6.1 *Freshly Molded Cylinders*—Use only neat portland cement pastes (Note 9) to cap freshly molded cylinders. Make caps as thin as practicable. Do not apply the neat paste to the exposed end until the concrete has ceased settling in the molds, generally from 2 to 4 h after molding. During the molding of the cylinder, strike off the upper end even with or slightly below the plane of the rim of the mold. Remove free water and laitance from the top of the specimen immediately before capping. Form the cap by placing a conical mound of paste on the specimen and then gently pressing a freshly oiled capping plate on the conical mound until the plate contacts the rim of the mold. A very slight twisting motion may be required to extrude excess paste and minimize air voids in the paste. The capping plate must not rock during this operation. Carefully cover the capping plate and mold with a double layer of damp burlap and a polyethylene sheet to prevent drying. Removal of the capping plate after hardening may be accomplished by tapping the edge with a rawhide hammer in a direction parallel to the plane of the cap.

NOTE 9—Type I neat cement caps generally require at least 6 days to develop acceptable strength and Type III neat cement caps at least 2 days. Dry concrete specimens will absorb water from freshly mixed neat cement paste and produce unsatisfactory caps. Neat cement paste caps will shrink and crack on drying and, therefore, should be used only for specimens that are to be moist cured continuously until time of testing.

NOTE 10—High-strength gypsum caps soften and deteriorate on contact with water and cannot be used on freshly mixed concrete or stored in a moist room for more than very brief periods.

6.2 *Hardened Concrete Specimens*:

6.2.1 *General*—If an end of a specimen has a coating or deposit of oily or waxy materials that would interfere with the bond of the cap, remove such coatings or deposits. If necessary, the ends of a specimen may be slightly roughened with a steel file or wire brush to produce proper adhesion of the cap. If desired, capping plates may be coated with a thin layer of mineral oil or grease to prevent the capping material from adhering to the surface of the plate.

6.2.2 *End Condition*—The distance of any point on an uncapped end from a plane that passes through the highest point of the end surface and is perpendicular to the axis of the cylinder shall not exceed ⅛ in. (3 mm) (Note 11). If the end exceeds this limit, the end of the cylinder shall be cut, lapped or ground prior to capping.

NOTE 11—This provision is to control the difference between the thickest and thinnest parts of a cap. The distance may be checked using a square with one blade touching the cylinder parallel to the cylinder axis and the other blade touching the highest point on the end of the cylinder. The distance between the blade of the square and the lowest point on the end of the cylinder is measured.

6.2.3 *Capping with High-Strength Gypsum Plaster or Neat Cement Paste*—Mix the paste as described in 5.2 and 5.3. Do not exceed the water-cement ratio determined in qualification tests. Form the caps as described in 6.1 using capping plates described in 4.1 to achieve the alignment required in 4.2 (Note 12). Generally, capping plates may be removed within 45 min with gypsum cement pastes and after 12 h with neat cement paste, without visibly damaging the cap.

NOTE 12—A number of methods have been used to obtain the desired perpendicularity of the cap to the axis of the cylinder. A mound of paste can be placed on a capping plate and the specimen lowered into it. A bull's-eye level on the top of the cylinder helps obtain alignment. A mound of paste can be placed on top of the cylinder and a capping plate pressed into it, again using the bull's-eye level. A better system is to make a half-height mold with a vertical split so that it can be slipped over the hardened cylinder. A clamp is used to position the mold and to ensure the required cap thickness. The mound of paste can then be placed either on a capping plate or on top of the cylinder and pressed until the plate contacts the mold. As Noted earlier, very stiff paste may require excessive pressure and produce thick or defective caps.

6.2.4 *Capping with Sulfur Mortar*—Prepare sulfur mortar for use by heating to a temperature between 265 and 290 °F (129 to 143 °C) as determined by an all-metal thermometer inserted near the center of the mass. Check the temperature at approximately hourly intervals during capping. Empty the pot and recharge with fresh material at intervals to ensure that the oldest material in the pot has not been used more than five times. When capping concrete cylinders with a compressive strength of 5000 psi (35 MPa) or greater, it is not permitted to reuse compound recovered from the capping operation or old caps. Fresh sulfur mortar must be dry at the time it is placed in the pot as dampness may cause foaming. Keep water away from molten sulfur mortar for the same reason. The capping plate or device should be warmed before use to slow the rate of hardening and permit the production of thin caps. Oil the capping plate lightly and stir the molten sulfur mortar immediately prior to pouring each cap. The ends of moist cured specimens shall be dry enough at the time of capping to preclude the formation of steam or foam pockets under or in the cap larger than ¼ in. (6 mm) in diameter. Replace caps with steam pockets or voids larger than ¼ in. (6 mm) (Note 13). To ensure that the cap is bonded to the surface of the specimen, the end of the specimen shall not be oiled prior to the application of the cap. When using a vertical device, pour

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:25:06 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the mortar onto the surface of the capping plate, lift the cylinder above the plate and contact the cylinder sides with the guides, slide the cylinder down the guides onto the capping plate while keeping constant contact with the alignment guides. The cylinder end should continue to rest on the capping plate with cylinder sides in positive contact with the alignment guides until the mortar has hardened. Use sufficient material to cover the cylinder end after the sulfur mortar solidifies.

NOTE 13—Periodically, the sulfur mortar cap should be examined after testing for air or steam pockets in the cap. Before testing, the cap can be tapped with a coin or rubbed with a light metal implement to see if a hollow sound can be detected. Caps with hollow areas should be removed and recapped.

6.2.4.1 **Warning**—Hydrogen sulfide gas may be produced during capping when sulfur mortar is contaminated with organic materials such as paraffin or oil. The gas is colorless and has a notoriously bad odor of rotten eggs; however, the odor should not be relied upon as a warning sign, since the sensitivity to the odor disappears rapidly on exposure. High concentrations are lethal and less concentrated dosages may produce nausea, stomach distress, dizziness, headache, or irritation of the eyes. For this and other reasons, the melting pot must be located under a hood with an exhaust fan and that capping area must be well ventilated.

6.2.5 *Daily Check*:

6.2.5.1 During each day's capping operation, check the planeness of the caps prior to compression testing on at least three specimens, selected at random, representing the start, middle, and end of the run. Check planeness with a straightedge and feeler gage, making a minimum of three measurements on different diameters to ensure that the surface of the caps do not depart from a plane by more than 0.002 in. (0.05 mm). Check also for hollow areas (Note 13). Record the results of these determinations in the quality control documentation for the laboratory. If caps fail to satisfy the planeness requirement or have hollow areas, remove and reapply the caps.

6.2.5.2 During each day's compressive strength testing operation, check the thickness of caps on at least three specimens, selected at random, from the start, middle, and end of that day's operation. After completing the compression test, recover at least six pieces of capping material from the top of the selected specimen (Note 14). The pieces shall be selected at random and be distributed over the entire area of the cap. The selected pieces shall have debonded completely from the concrete. Measure and record the thicknesses of the pieces to the nearest 0.01 in. (0.2 mm) using a micrometer, caliper or other thickness measurement device. Compare the average and maximum thicknesses with the values in Table 1. Record the results of the thickness determinations in the quality control documentation for the laboratory.

NOTE 14—Caps may be removed by using a hammer and sharp chisel. Place the chisel tip at the bond line and nearly parallel with the plane of the cap so as to create a wedging action when the chisel is struck with the hammer. Recovery of the entire cap may be simplified by placing duct tape over the cap prior to attempting its removal. The tape will keep the pieces of capping material from being dispersed during removal and will simplify the selection of pieces uniformly distributed over the cap area.

7. Protection of Specimens After Capping

7.1 Maintain moist cured specimens in a moist condition between the completion of capping and the time of testing by returning them to moist storage or wrapping them with a double layer of wet burlap. Do not store specimens with gypsum plaster caps immersed in water or for more than 4 h in a moist room. Protect plaster caps from dripping water.

7.2 Do not test capped specimens before the capping material has sufficient time to develop the strength required in 5.1.

8. Keywords

8.1 capping; concrete; compressive strength; cores; cylinders; gypsum cement paste; neat hydraulic cement paste; sulfur mortar

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 617 – 09, that may impact the use of this practice. (Approved July 1, 2009)

(*1*) Revised 6.2.4 to provide the acceptable temperature range for the molten sulfur mortar.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 617 – 98(2003), that may impact the use of this practice. (Approved May 1, 2009)

(*1*) Revised 6.2.3.

Designation: C 618 – 08a

Standard Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete[1]

This standard is issued under the fixed designation C 618; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers coal fly ash and raw or calcined natural pozzolan for use in concrete where cementitious or pozzolanic action, or both, is desired, or where other properties normally attributed to fly ash or pozzolans may be desired, or where both objectives are to be achieved.

NOTE 1—Finely divided materials may tend to reduce the entrained air content of concrete. Hence, if a fly ash or natural pozzolan is added to any concrete for which entrainment of air is specified, provision should be made to ensure that the specified air content is maintained by air content tests and by use of additional air-entraining admixture or use of an air-entraining admixture in combination with air-entraining hydraulic cement.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 The text of this standard references notes and footnotes, which provide explanatory information. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 311 Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete

3. Terminology

3.1 *Definitions:*

3.1.1 The terms used in this specification are defined in Terminology C 125.

3.1.2 *fly ash*—the finely divided residue that results from the combustion of ground or powdered coal and that is transported by flue gasses.

NOTE 2—This definition of fly ash does not include, among other things, the residue resulting from: (*1*) the burning of municipal garbage or any other refuse with coal; (*2*) the injection of lime directly into the boiler for sulfur removal; or (*3*) the burning of industrial or municipal garbage in incinerators commonly known as "incinerator ash."

4. Classification

4.1 *Class N*—Raw or calcined natural pozzolans that comply with the applicable requirements for the class as given herein, such as some diatomaceous earths; opaline cherts and shales; tuffs and volcanic ashes or pumicites, calcined or uncalcined; and various materials requiring calcination to induce satisfactory properties, such as some clays and shales.

4.2 *Class F*—Fly ash that meets the applicable requirements for this class as given herein. This class of fly ash has pozzolanic properties.

4.3 *Class C*—Fly ash that meets the applicable requirements for this class as given herein. This class of fly ash, in addition to having pozzolanic properties, also has some cementitious properties.

NOTE 3—Class F fly ash is typically produced from burning anthracite or bituminous coal, but may also be produced from subbituminous coal and from lignite. Class C fly ash is typically produced from burning lignite or subbituminous coal, and may also be produced from anthracite or bituminous coal. Class C fly ashes contain total calcium contents, expressed as calcium oxide (CaO), higher than 10 %.

5. Ordering Information

5.1 The purchaser shall specify any supplementary optional physical requirements.

5.2 The purchaser shall indicate which procedure, A or B, shall be used when specifying requirements for effectiveness in contribution to sulfate resistance under Table 3.

6. Chemical Composition

6.1 Fly ash and natural pozzolans shall conform to the requirements as to chemical composition prescribed in Table 1.

NOTE 4—The chemical component determinations and the limits placed

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.24 on Supplementary Cementitious Materials.

Current edition approved Oct. 1, 2008. Published October 2008. Originally approved in 1968. Last previous edition approved in 2008 as C 618–08.

	N	F	C
Silicon dioxide (SiO_2) plus aluminum oxide (Al_2O_3) plus iron oxide (Fe_2O_3), min, %	70.0	70.0	50.0
Sulfur trioxide (SO_3), max, %	4.0	5.0	5.0
Moisture content, max, %	3.0	3.0	3.0
Loss on ignition, max, %	10.0	6.0[A]	6.0

[A]The use of Class F pozzolan containing up to 12.0 % loss on ignition may be approved by the user if either acceptable performance records or laboratory test results are made available.

TABLE 2 Physical Requirements

	Class		
	N	F	C
Fineness:			
Amount retained when wet-sieved on 45 μm (No. 325) sieve, max, %	34	34	34
Strength activity index: [A]			
With portland cement, at 7 days, min, percent of control	75[B]	75[B]	75[B]
With portland cement, at 28 days, min, percent of control	75[B]	75[B]	75[B]
Water requirement, max, percent of control	115	105	105
Soundness: [C]			
Autoclave expansion or contraction, max, %	0.8	0.8	0.8
Uniformity requirements:			
The density and fineness of individual samples shall not vary from the average established by the ten preceding tests, or by all preceding tests if the number is less than ten, by more than:			
Density, max variation from average, %	5	5	5
Percent retained on 45-μm (No. 325), max variation, percentage points from average	5	5	5

[A] The *strength* activity index with portland cement is not to be considered a measure of the compressive strength of concrete containing the fly ash or natural pozzolan. The mass of fly ash or natural pozzolan specified for the test to determine the *strength* activity index with portland cement is not considered to be the proportion recommended for the concrete to be used in the work. The optimum amount of fly ash or natural pozzolan for any specific project is determined by the required properties of the concrete and other constituents of the concrete and is to be established by testing. *Strength* activity index with portland cement is a measure of reactivity with a given cement and is subject to variation depending on the source of both the fly ash or natural pozzolan and the cement.

[B] Meeting the 7 day or 28 day *strength* activity index will indicate specification compliance.

[C] If the fly ash or natural pozzolan will constitute more than 20 % by mass of the cementitious material in the project mixture, the test specimens for autoclave expansion shall contain that anticipated percentage. Excessive autoclave expansion is highly significant in cases where water to cementitious material ratios are low, for example, in block or shotcrete mixtures.

on each do not predict the performance of the fly ash or natural pozzolan with hydraulic cement in concrete, but collectively help describe composition and uniformity of the material.

7. Physical Properties

7.1 Fly ash and natural pozzolans shall conform to the physical requirements prescribed in Table 2. Supplementary optional physical requirements are shown in Table 3.

8. Methods of Sampling and Testing

8.1 Sample and test the fly ash or natural pozzolan in accordance with the requirements of Test Methods C 311.

8.2 Use cement of the type proposed for use in the work and, if available, from the mill proposed as the source of the cement, in all tests requiring the use of hydraulic cement.

9. Storage and Inspection

9.1 The fly ash or natural pozzolan shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment.

9.2 Inspection of the material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

10. Rejection

10.1 The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer or supplier promptly and in writing.

10.2 The purchaser has the right to reject packages varying more than 5 % from the stated weight. The purchaser also has the right to reject the entire shipment if the average weight of the packages in any shipment, as shown by weighing 50 packages taken at random, is less than that specified.

10.3 The purchaser has the right to require that material in storage prior to shipment for a period longer than 6 months after testing be retested. The purchaser has the right to reject such material if it fails to meet the fineness requirements.

TABLE 3 Supplementary Optional Physical Requirements

NOTE 1—These optional requirements apply only when specifically requested.

	Class		
	N	F	C
Increase of drying shrinkage of mortar bars at 28 days, max, difference, in %, over control[A]	0.03	0.03	0.03
Uniformity Requirements:			
In addition, when air-entraining concrete is specified, the quantity of air-entraining agent required to produce an air content of 18.0 vol % of mortar shall not vary from the average established by the ten preceding tests or by all preceding tests if less than ten, by more than, %	20	20	20
Effectiveness in Controlling Alkali-Silica Reaction:[B]			
Expansion of test mixture as percentage of low-alkali cement control, at 14 days, max, %	100	100	100
Effectiveness in Contributing to Sulfate Resistance:[C]			
Procedure A:			
Expansion of test mixture:			
For moderate sulfate exposure after 6 months exposure, max, %	0.10	0.10	0.10
For high sulfate exposure after 6 months exposure, max, %	0.05	0.05	0.05
Procedure B:			
Expansion of test mixture as a percentage of sulfate resistance cement control after at least 6 months exposure, max,%	100	100	100

[A] Determination of compliance or noncompliance with the requirement relating to increase in drying shrinkage will be made only at the request of the purchaser.

[B] Fly ash or natural pozzolans meeting this requirement are considered as effective in controlling alkali silica reactions as the use of the low-alkali control cement used in the evaluation. However, the fly ash or natural pozzolan shall be considered effective only when used at percentages by mass of the total cementitious material equal to or exceeding that used in the tests and when the alkali content of the cement to be used does not exceed that used in the tests by more than 0.05 %. See Appendix XI, Test Methods C 311.

[C] Fly ash or natural pozzolan shall be considered effective only when the fly ash or natural pozzolan is used at percentages, by mass, of the total cementitious material within 2 % of those that are successful in the test mixtures or between two percentages that are successful, and when the C_3A content of the project cement is less than, or equal to, that which was used in the test mixtures. See Appendix X2 of Test Method C 311.

11. Packaging and Package Marking

11.1 When the fly ash or natural pozzolan is delivered in packages, the class, name, and brand of the producer, and the weight of the material contained therein, shall be plainly marked on each package. Similar information shall be provided in the shipping invoices accompanying the shipment of packaged or bulk material.

12. Keywords

12.1 fly ash; natural pozzolan; pozzolans

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 618 – 08, that may impact the use of this specification. (Approved October 1, 2008)

(*1*) Revised Table 3 to remove the optional requirement for the multiple factor and the associated table footnote A.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 618 – 05, that may impact the use of this specification. (Approved March 1, 2008)

(*1*) Revised 4.2, 4.3, Note 3, and Footnote C of Table 3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 631 – 09

Standard Specification for Bonding Compounds for Interior Gypsum Plastering[1]

This standard is issued under the fixed designation C 631; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers minimum requirements for bonding compounds for adhering interior gypsum plaster to structurally sound surfaces.

1.2 This specification also covers test methods for determining performance requirements and physical properties.

1.3 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.4 The following safety hazards caveat pertains only to the test methods described in this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 28/C 28M Specification for Gypsum Plasters

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

3. Terminology

3.1 *Definitions*—For definitions relating to gypsum and related building materials and systems, see Terminology C 11.

4. Physical Properties

4.1 *General*—The bonding compound shall be a film forming, non-oxidizing, non-toxic, non-flammable composition suitable for application by brush, roller, and spray. The compound shall be tinted to show, by visual inspection, where it has been applied. The tinting material shall not show through the material being bonded. The surfaces to which bonding compounds are applied shall be relatively smooth, clean, and dry. Surface coatings shall be removed if their nature indicates an unsatisfactory condition. Surfaces shall be prepared in accordance with the manufacturer's directions.

4.2 *Consistency*—The bonding compound shall be of a homogeneous nature with no settling of the solids. The compound shall be free of foreign matter, and when applied in accordance with the manufacturer's directions, shall cover evenly.

4.3 *Film Characteristics*—A dry film of the bonding compound shall be uniform and smooth and shall remain flexible. The film shall not be noticeably affected by mild acid or alkali.

5. Performance Requirements

5.1 *Bonding Capability*—A dry film of bonding compound shall be capable of bonding gypsum plaster immediately after drying and 10 days after drying when tested as specified in Section 12.

5.2 *Degradation*—Bonding compound that separates shall be able to be re-mixed to a uniform consistency when tested as specified in Section 10.

5.3 *High Temperature Stability*—The bond strength shall be not less than 20 psi (138 kPa) when tested as specified in Section 9.

5.4 *Freeze-Thaw Stability*—The bond strength shall be not less than 20 psi (138 kPa) when tested as specified in Section 11.

5.5 *Bond Strength*—Bond strength of a fresh sample or a 30 day old sample shall be not less than 20 psi (138 kPa) when tested as specified in Section 12.

6. Sampling

6.1 Take a sample of not less than 1 kg from each shipment or consignment for analysis and tests. Except in special cases, take the sample from not less than three separate containers,

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved May 1, 2009. Published May 2009. Originally approved in 1988. Last previous edition approved in 2004 as C 631 – 95a(2004).

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

www.technobetar.ir

chosen at random. In addition, take samples from containers that appear to be nonrepresentative, and test separately. Immediately place the samples in airtight glass containers and transport to the testing laboratory in these containers. Take precautions to reduce evaporation or drying to a minimum. Thoroughly mix the bonding compound in the container if there is a tendency for liquid phase separation.

7. Apparatus

7.1 *Moist Cabinet*—Specification C 511.

7.2 *Oven*—A forced draft type oven, having a temperature controlled at 140 ± 5 °F (60 ± 3 °C) for high temperature tests and 100 ± 5 °F (38 ± 3 °C) for drying of the briquets.

7.3 *Freezer*—A freezer having a controlled temperature of – 10 ± 2 °F (-23 ± 1 °C).

7.4 *Balance*—A balance capable of weighing at least 2500 g at a precision of 0.1 g.

7.5 *Timing Device*—A standard clock or watch with second hand.

7.6 *Tamper*—A tamper made up of a nonabsorptive, nonabrasive, non-brittle material and having a cross section of ½ in. by 1 in. (13 by 25 mm) and approximately 5 to 6 in. (130 to 150 mm) long. The tamping face shall be flat and at right angles to the length of the tamper.

7.7 *Straight Edge*—A steel straight edge not less than 4 in. (100 mm) long and not less than 1⁄16 in. (1.6 mm) nor more than ⅛ in. (3.2 mm) in thickness.

7.8 *Spatula*—A spatula with a metal blade 6 in. (150 mm) in length and ½ in. (13 mm) in width, with straight edges.

7.9 *Paint Brush*—A standard 1 in. (25 mm) wide brush, with natural or synthetic bristles.

7.10 *Testing Machine*—Any type that is of sufficient capacity and that is capable of applying the load continuously and without shock at the rate of 0.05 in. (1.27 mm)/min, with provision for adjustment of the rate of loading.

7.11 *Briquet Molds*—The molds for making test specimens shall be made of metal not attacked by the plaster mortar and shall have sufficient material in the sides to prevent spreading during molding. Gang molds, when used, shall be of the type shown in Fig. 1. The dimensions of the briquet molds shall conform to the following requirements: width of mold, between inside faces, at waist line of the briquet, 1 in. (25.4 mm) with permissible variations of ±0.01 in. (0.25 mm) for molds in use and ±0.005 in. (0.13 mm) for new molds; thickness of molds measured at the point of greatest thickness on either side of the mold at the waist line, 1 in. (25.4 mm) with permissible variations of + 0.004 in. (0.10 mm) and – 0.002 in. (0.05 mm) for new molds and – 0.02 in. (0.5 mm) for molds in use. The inside faces at the waist line shall have a vertical slot 0.03 in. (0.75 mm) wide by 0.06 in. (1.5 mm) deep to accept the divider. The briquet specimens shall conform to the dimensional requirements shown in Fig. 2.

7.12 *Divider*—Sheet brass 0.02 in. (0.05 mm) thick, 1.1 in. (27.8 mm) wide by 1 in. (25.4 mm) high.

7.13 *Clips for Briquet Testing Machine*— The clips for holding the tension test specimen shall be in accordance with Fig. 3.

8. Conditioning

8.1 *Room Temperature and Humidity*— Maintain the air temperature in the vicinity of the mixing and testing area, 70 ± 5 °F (21 ± 3 °C). Maintain the relative humidity at 50 ± 2 %.

8.2 *Temperature of the Mixing Water*— 72 ± 2 °F (22 ± 1 °C).

9. High Temperature Test

9.1 *Significance and Use*—This test method provides procedures for evaluating the bond strength of adhesives after being exposed to accelerated aging at high temperature.

9.2 *Specimen Preparation*—For each test specimen, transfer the bonding compound, taken from the sample obtained, into a standard 1 pt (400 mL) glass container.

9.3 *Procedure*—Place the specimen in the oven for 30 days. Remove the container, allow the compound to cool to room temperature, mix the compound to a uniform consistency, and test as specified in Section 12.

9.4 *Test and Retests*—Test six briquets and report the average of the test results. If the result of any one of the six tests varied more than 15 % from the average, reject it and report the average of the other five tests. If the results from more than two tests vary more than 15 % from the average, reject the series and retest.

9.5 *Precision and Bias*—The precision and bias of the High Temperature Test for determining bond strength after exposure to high temperature is essentially the same as specified in the test method for bond strength, 12.7.

10. Degradation Test

10.1 *Significance and Use*—This test method simulates the effects of high temperature storage on the physical properties of bonding compound.

10.2 *Specimen Preparation*—For each test, transfer the bonding compound, from the sample obtained, into a standard 1 pt (400 mL) glass container.

10.3 *Procedure*—Place the specimen in the oven for 15 days. Remove the container from the oven and examine the

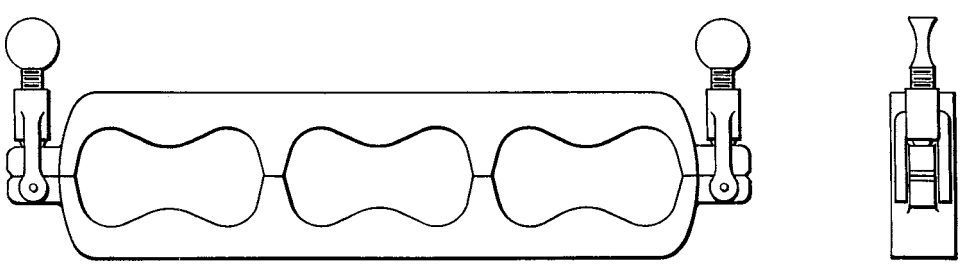

FIG. 1 Briquet Gang Mold

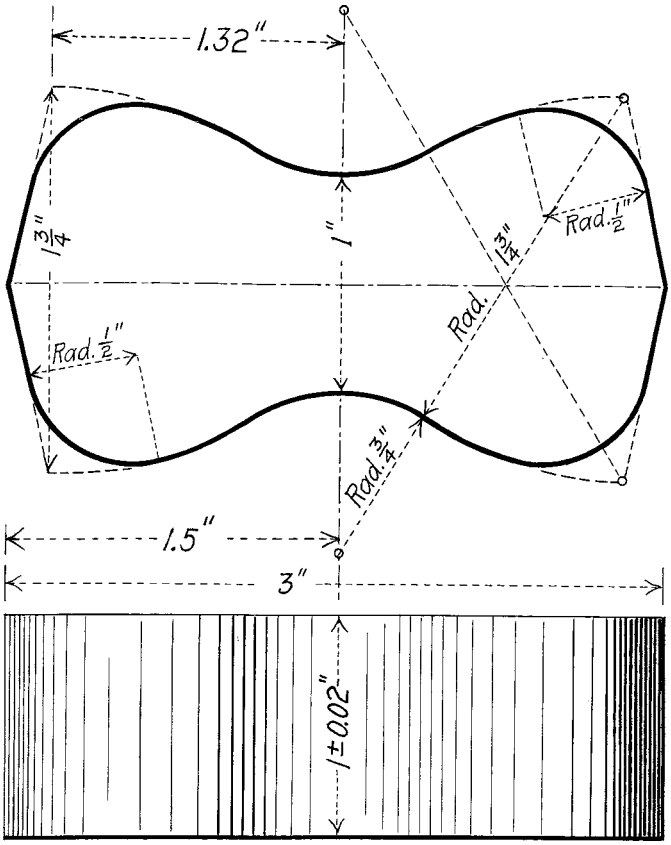
www.technobetar.ir



NOTE 1—1 in. = 25.4 mm

FIG. 2 Briquet Specimen for Tensile Strength Test

contents for settling and separation. Place the container back in the oven for an additional 15 days. Remove the container and examine the contents again for settling and separation. Allow the compound to come to room temperature, and mix to a uniform consistency. Mix by hand, stirring with a wood, metal, or plastic paddle for not more than 5 min.

10.4 *Tests and Retests*—Bonding compound that fails to be remixed to a uniform consistency shall be considered to have failed the test.

10.5 *Report*—Determine the extent of settling and separation by measuring, and report as a percentage of the height of the specimen in the clear glass container, represented by the location of the liquid/solid interface.

10.6 *Precision and Bias*—No information is presented about either the precision or bias of the degradation test for measuring settling, separation, or the ability to be mixed to a uniform consistency since the test result is nonquantitative.

11. Freeze-Thaw Cycle Test

11.1 *Significance and Use*—This test method provides procedures for determining the bond strength of bonding compounds after being exposed to accelerated storage conditions of alternate freezing and thawing.

11.2 *Specimen Preparation*—For each test specimen, transfer the bonding compound, taken from the sample obtained, into a standard 1 pt (400 mL) glass container having a screw on or friction fit cover.

11.3 *Procedure*—Place a covered specimen in the freezer for 16 h. Remove the specimen and allow to thaw at room temperature for 8 h. Repeat this procedure for 5 cycles. After the fifth cycle, allow the compound to come to room temperature, and then test as specified in Section 12.

11.4 *Tests and Retests*—Test six briquets and report the average of the test results. If the result of any one of the six tests varies more than 15 % from the average, reject it and report the average of the other five tests. If the results from more than two tests vary more than 15 % from the average, reject the series and retest.

11.5 *Precision and Bias*—The precision and bias of the freeze-thaw cycle test for determining bond strength after exposure to alternate freezing and thawing are essentially the same as specified in the test method for bond strength, 12.7.

12. Bond Strength Test

12.1 *Significance and Use*—This test method provides a method for determining the relative ability of bonding compound, after being subject to various simulated conditions of aging and exposure to temperature extremes, to adhere cementitious materials to a properly prepared substrate.

12.2 *Materials*:

12.2.1 *Gauging Plaster*—Specification C 28/C 28M, at normal consistency (Test Methods C 472).

12.2.2 *Retarder*—Sodium citrate.

12.3 *Preparation of Briquets*:

12.3.1 Prepare not less than six briquets for each series of tests.

12.3.2 Partition the briquet molds by placing the divider in the slots formed at the waist of the mold.

12.3.3 Add the plaster to the required amount of water and allow to soak for 30 s. Add approximately 0.1 g of retarder per 100 g of plaster to achieve a 2 to 3 h plaster set.

12.3.4 Prepare the molds by coating them with a thin film of mineral oil. Support the molds on a lightly oiled glass or metal plate. Protect the divider from contamination with oil (wrap in plastic food wrap) and carefully insert into the mold slots.

12.3.5 Cast the briquets immediately after completely mixing the mortar; half fill the molds and puddle the mortar uniformly with the tamper, taking care not to displace the divider. Slightly over fill the molds with additional mortar and repeat the puddling. After the mortar has set, cut off the excess to a plane surface flush with the top of the mold, using a broad knife or similar implement.

12.3.6 Immediately after molding, place the molds, on the base plate, into the moist cabinet for not less than 16 h.

12.3.7 Remove the briquets from the mold and store them at room temperature and humidity for not less than 48 h.

12.3.8 Examine the specimens, and discard any that have air holes or excessively rough surfaces.

12.4 *Procedure*:

12.4.1 Apply the bonding compound, in accordance with the producer's directions, to the flat waist surface of the briquet by means of a paint brush.

12.4.2 Remove the divider from the mold. Place the half briquet, coated with bonding compound, into the mold. Fill the remaining space in the mold with gypsum plaster, mixed and molded as specified in 12.2.

7	Guide	2	* *	Ditto
8	Flat Head Mach. Scr.	4	Brass	#10-24 Thd. A.S.M.E.

NOTE 1—1 in. = 25.4 mm

FIG. 3 Clips for Briquet Testing Machine

12.4.3 The time between coating the briquet with compound and casting the plaster against it shall be immediately after the compound has dried, or as recommended by the manufacturer, except when otherwise specified for a ten day waiting period.

12.4.4 Place the filled briquet mold in the moist cabinet for not less than 16 h. Remove the briquets from the molds as soon as they are thoroughly hardened, but retain them in the moist cabinet for not less than 16 h.

12.4.5 The briquets are then dried to constant weight in a forced draft oven maintained at 100 ± 5 °F (38 ± 3 °C) and a relative humidity not more than 50 %.

12.5 *Test Method*—Test the briquets immediately after removing them from the oven. Remove any loose particles or flash from the surfaces that will be in contact with the clips of the testing machine. Make sure the bearing surfaces of the clips are clean and free of sand, and the roller bearings are lubricated and maintained to ensure freedom of turning. Keep the stirrups supporting the clips free of accumulations. Keep the pivots in proper adjustment so that the clips swing freely on the pivots without binding the stirrups. Carefully center the briquets in the clips and apply the load continuously at the rate of 0.05 in. (1.27 mm)/min.

12.6 *Tests and Retests*—Test six briquets and report the average of the test results. If the result of any one of the six tests varies more than 15 % from the average, reject it and report the average of the other five tests. If the results from more than two tests vary more than 15 % from the average, reject the series and retest.

12.7 *Precision and Bias*—Precision and bias have not been determined for the test method specified.

13. Inspection

13.1 Inspection of the bonding compound shall be agreed upon between the producer or purchaser and the supplier as part of the purchase agreement.

14. Rejection

14.1 Rejection of bonding compound that fails to conform to the requirements of this specification shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the product has failed to conform to the requirements of this specification.

15. Certification

15.1 When specified in the purchase agreement, the producer or supplier shall furnish a report certifying that, at the time of shipment, the bonding compound is in compliance with the requirements of this specification.

16. Packaging and Package Marking

16.1 *Packaging*—The bonding compound shall be packed in standard commercial containers. The containers shall be so constructed as to ensure acceptance by common or other carriers for safe transportation to the point of delivery, unless otherwise specified in the purchase order.

16.2 *Marking*—Shipping containers shall be marked with the name of the bonding compound, the quantity contained therein, the name, brand, or trademark of the producer or supplier, the shelf life, the batch number, and the ASTM designation.

Designation: C637 – 09

Standard Specification for Aggregates for Radiation-Shielding Concrete[1]

This standard is issued under the fixed designation C637; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers special aggregates for use in radiation-shielding concretes in which composition or high specific gravity, or both, are of prime consideration.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 The following precautionary caveat pertains only to the test method portion, Section 8, of this specification:*This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

C131 Test Method for Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine

C136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C535 Test Method for Resistance to Degradation of Large-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine

C638 Descriptive Nomenclature of Constituents of Aggregates for Radiation-Shielding Concrete

3. Classification

3.1 Aggregates covered by this specification include:

3.1.1 Natural mineral aggregates of either high density or high fixed water content, or both. These include aggregates that contain or consist predominately of materials such as barite, magnetite, hematite, ilmenite, and serpentine.

3.1.2 Synthetic aggregates such as iron, steel, ferrophosphorus and boron frit or other boron compounds (see Descriptive Nomenclature C638).

3.1.3 Fine aggregate consisting of natural or manufactured sand including high-density minerals. Coarse aggregate may consist of crushed ore, crushed stone, or synthetic products, or combinations or mixtures thereof.

4. Composition and Relative Density (Specific Gravity)

4.1 Table 1 gives data on chemical composition and relative density (specific gravity) of aggregate materials covered by this specification.

4.2 The purchaser shall specify the minimum specific gravity for each size and type of aggregate.

4.2.1 *Uniformity of Specific Gravity*—The relative density (specific gravity) SSD (saturated surface-dry) of successive shipments of aggregate shall not differ by more than 3 % from that of the sample submitted for source approval tests. The average specific gravity of the total shipment shall be equal to or greater than the specified minimum.

4.3 The purchaser shall specify the minimum fixed water content of hydrous ores. If the design temperature, *T,* is different from that given in 8.1.3.5, the purchaser shall specify the value of *T.*

4.3.1 *Uniformity of Fixed Water Content*—For hydrous aggregates the fixed water content of successive shipments of aggregate shall not be less than 95 % of the specified minimum value. The average fixed water content of the total shipment shall be equal to or exceed the specified minimum value.

5. Aggregate Grading

5.1 *Sieve Analysis*—Fine and coarse aggregates for conventionally placed concrete shall be graded within the limits given in Specification C33, except that with the approval of the purchaser, as much as 20 % of the material passing the 9.5-mm

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.41 on Pre-placed Aggregate Concrete for Radiation Shielding.

Current edition approved Dec. 15, 2009. Published February 2010. Originally approved in 1969. Last previous edition approved in 2003 as C637 – 98a(2003). DOI: 10.1520/C0637-09.

TABLE 1 Composition and Relative Density (Specific Gravity) of Aggregates Covered by This Specification

Predominant Constituent	Class of Material	Chemical Composition of Principal Constituent[A]	Relative Density (Specific Gravity) of Available Aggregates
Serpentine[B]	crushed stone, hydrous siliente	$Mg_3Si_2O_5(OH)_4$	2.4 to 2.65
Limonite[C]	crushed stone, hydrous iron ore	$(HFeO_2)_x(H_2O)_y$	3.4 to 3.8
Goethite[C]	crushed stone, hydrous iron ore	$HFeO_2$	3.5 to 4.5
Barite	gravel or crushed stone	$BaSO_4$	4.0 to 4.4
Ilmenite	crushed stone, iron ore	$FeTiO_3$	4.2 to 4.8
Hematite	crushed stone, iron ore	Fe_2O_3	4.6 to 5.2
Magnetite	crushed stone, iron ore	$FeFe_2O_4$	4.6 to 5.2
Iron	manufactured from iron/steel	Fe	6.5 to 7.5
Ferrophosphorous[D]	synthetic	Fe_nP	5.8 to 6.3
Boron Frit[E]	synthetic	B_2O_3, Al_2O_3, SiO_2, CaO	2.6 to 2.8
Boron Carbide	synthetic	B_4C, B_2O_3, C	2.5
Calcium Boride	synthetic	C_aB_6, C	2.5

[A] When it is necessary to minimize the production of long-lived secondary radiation in the shield, or to avoid using materials having inherent radioactivity, the purchaser should specify limits on the contents of objectionable elements.

[B] The fixed water content of serpentine ranges from 10 to 13 percent by weight.

[C] The fixed water content of limonite and goethite ranges from 8 to 12 percent by weight.

[D] Ferrophosphorus when used in Portland cement concrete will generate flammable and possibly toxic gases which can develop high pressures if confined. See Clendenning, T. G., Kellam, B., and MacInnis, C., "Hydrogen Evolution from Ferrophosphorous Aggregate in Portland Cement Concrete," *Journal of the American Concrete Institute, No. 12,* December 1968. (*Proceedings*, Vol 65, pp. 1021–1028), and Mather, Bryant, discussion of Davis, Harold S., "Concrete for Radiation Shielding—In Perspective," and closure by author in "Concrete for Nuclear Reactors," *Journal of the American Concrete Institute* SP-34, Vol 1, 1972, pp. 11–13.

[E] The fixed water content of boron frit is less than 0.5 %.

(⅜ -in.) sieve may also pass the 150-µm (No. 100) sieve, with up to 10 % passing the 75-µm (No. 200) sieve if the material passing the 75-µm (No. 200) sieve is essentially free of clay or shale.

5.1.1 Fine and coarse aggregates for preplaced aggregate concrete shall be graded according to the requirements of Table 2 and as follows:

Relative Density (Specific Gravity) of Fine Aggregate	Grading of Aggregate	
	Coarse Aggregate	Fine Aggregate
Up to 3.0	Grading 1	Grading 1
Greater than 3.0	Grading 1	Grading 2
Full range	Grading 2	Grading 2

TABLE 2 Grading Requirements for Coarse and Fine Aggregates for Preplaced Aggregate Concrete

Sieve Size	Percentage Passing	
	Grading 1 For 37.5-mm (1½ -in.) Nominal Maximum Size Aggregate	Grading 2 For 25-mm (1-in.) Nominal Maximum Size Aggregate
Coarse Aggregate		
50-mm (2-in.)	100	. . .
37.5-mm (1½ in.)	95 to 100	100
25.0-mm (1-in.)	40 to 80	95 to 100
19.0-mm (¾ in.)	20 to 45	40 to 80
12.5-mm (½-in.)	0 to 10	0 to 15
9.5-mm (⅜-in.)	0 to 2	0 to 2
Fine Aggregate		
2.36-mm (No. 8)	100	. . .
1.18-mm (No. 16)	95 to 100	100
600-µm (No. 30)	55 to 80	75 to 95
300-µm (No. 50)	30 to 55	45 to 65
150-µm (No. 100)	10 to 30	20 to 40
75-µm (No. 200)	0 to 10	0 to 10
Fineness modulus	1.30 to 2.10	1.00 to 1.60

5.1.2 When boron frit is used as part of the fine aggregate, the grading shall be such that 100 % passes the 4.75-mm (No. 4) sieve and not more than 5 % passes the 600-µm (No. 30) sieve.

5.2 *Fineness Modulus*—If the fineness modulus of the fine aggregate varies more than 0.2 from the value corresponding to that of the sample submitted for acceptance, the fine aggregate shall be rejected unless suitable adjustments are made in concrete proportions to compensate for the difference in grading.

6. Deleterious Substances

6.1 Fine and coarse aggregates shall meet the requirements of Specification C33.

6.2 Boron frit shall not contain more than 2.0 % of water soluble material.

NOTE 1—This limit is based on concrete mixtures containing no more than 300 kg/m^3(500 lb/yd^3) of boron frit.

7. Abrasion Resistance of Coarse Aggregate

7.1 Coarse aggregate shall have an abrasion loss not greater than 50 % when tested in accordance with Test Method C131, or Test Method C535, as applicable. Coarse aggregate failing to meet this requirement may be used, provided it can be shown that it produces satisfactory strengths in concrete of the proportions selected for the work.

8. Methods of Sampling and Testing

8.1 Sample and test the aggregates in accordance with the methods cited in Specification C33 as applicable, except as follows:

8.1.1 *Relative Density (Specific Gravity)*—Determine the relative density (specific gravity), saturated surface-dry, of fine aggregate in accordance with Test Method C128, and of coarse aggregate in accordance with Test Method C127, except that the mass of the test sample for fine and coarse aggregate shall be approximately the specified mass multiplied by the ratio:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:25:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

relative density (*specific gravity*)/2.65

using for relative density (specific gravity) the higher value given in Table 1.

8.1.2 *Grading* — Test Method C136, except that the mass of the test sample for fine and coarse aggregate shall be approximately the specified mass multiplied by the ratio:

relative density (*specific gravity*)/2.65

using for relative density (specific gravity) the higher value given in Table 1.

8.1.3 *Fixed Water Content*—When 90 % or more of the weight loss on ignition of the aggregate is due to fixed water content, determine the fixed water content, *F,* by the loss-on-ignition test according to 8.1.3.1. When less than 90 % of the loss on ignition is due to fixed water content, determine the fixed water content by the train method (8.1.3.2). In case of dispute, use results obtained by the train method as the basis for acceptance or rejection of the aggregate. Use the train method to demonstrate that 90 % or more of the weight lost during ignition is fixed water. When loss-on-ignition tests are being made on aggregate samples from the same source, also determine the fixed water content of the first sample and each tenth sample thereafter by the train method.

8.1.3.1 For the loss-on-ignition test crush a representative sample of aggregate weighing 20 to 50 g *(W)* to pass the 4.75-mm (No. 4) sieve. Heat the sample to constant weight at a temperature, *T,* in a furnace, open to the atmosphere. Cool the heated sample in a desiccator and then weigh it, (W_t). Place the sample in the oven again, heat at the ignition temperature, *t,* cool in a desiccator, and determine the final weight (W_t). Constant weight may be considered to have been attained when further heating at the design temperature *T* causes or would cause less than 0.1 % additional weight loss.

8.1.3.2 In the train test, heat approximately 1 g *(W′)* of the finely ground sample to constant weight (W'_T) at a temperature of *T.* Then heat the sample W'_T in a stream of argon gas at the ignition temperature *t.* Pass water vapor and gaseous material driven from the heated sample through magnesium perchlorate. The gain in weight (W'_g) of the magnesium perchlorate is an indication of the fixed water content of the sample at temperature *T.* Also determine the dehydrated weight (W'_t) of the sample at the ignition temperature *t.*

8.1.3.3 Compute the fixed water content at temperature *T* by one of the following equations:

Ignition Test:

$$F, \text{ percent} = [(W_T - W_t)/W_T] \times 100 \quad (1)$$

where:
W_T = sample heated to constant weight, g, and
W_t = heated and cooled sample, g.

Train Test:

$$F, \text{ percent} = [(W'_g - W'_T) \times 100 \quad (2)$$

where:
W'_g = gain in weight of sample, g, and
W'_T = dehydrated weight, g.

8.1.3.4 Determine the percent of nonhydrous volatile material, *V,* as follows:

Train Test:

$$V, \text{ percent} = \{[W' - (W'_t + W'_g)]/W'_T\} \times 100 \quad (3)$$

where:
W' = sample weight, g,
W'_t = dehydrated weight of sample, g,
W'_g = gain in weight of sample, g, and
W'_T = sample heated to constant weight, g.

8.1.3.5 Water vapor driven from the sample by heating at temperature *T* is considered as part of the nonhydrous volatile material. Absorbed water at 110°C is not considered as part of the nonhydrous volatile material. Determine percent absorption by Test Methods C127 and C128.

8.1.3.6 Temperature values shall be as follows:

	Design Temperature, *T*	Ignition Temperature, *t*
Hydrous Aggregate	°C	°C
Iron ore	110	500
Serpentine	300	900

Heat the sample until it reaches constant weight at the specified temperature, unless otherwise approved. Determine weights after sample has been cooled in a desiccator to room temperature. Duplicate determinations of fixed water content should check to within 0.3 %.

8.1.4 *Water-Soluble Material in Boron Frit*—Place a 5.00-g sample passing a 600-µm (No. 30) sieve and retained on a 300-µm (No. 50) sieve in contact with 100 mL of distilled water at 20 ± 5°C for 16 h. Filter, wash with about 200-mL of hot (70 ± 5°C) water, and dry at 125 ± 10°C for 1 h. Weigh the residue, *s,* to the nearest 0.01 g. Calculate the percentage of water soluble material (W_s) to the nearest 0.1 % as follows:

$$W_3 = [(5.00 - s)/s] \times 100$$

where:

s = residue, g

9. Precision and Bias

9.1 *Precision* — The following precision statement addresses the test of the water-soluble material in Boron Frit. The precision for fixed water content by either the loss on ignition test or by the train test method has not been evaluated.

9.1.1 Data from one laboratory was available for estimating the precision of water-soluble material in boron frit, therefore, only a within-laboratory estimate of precision is made. The estimate is based on 15 replicate analyses of 5 lots of frit produced by one company. The 15 replicates were determined on 5 separate days, 3 replicates per day. The mean water soluble material ranged from 1.23 to 1.75 % among the 5 lots.

9.1.2 *Within-laboratory Precision*—The within-laboratory standard deviation among individual determinations of water-soluble material in boron frit is 0.224 %.[3] Therefore, two

[3] These numbers represent, respectively, the 1s and d2s limits as described in Practice C670.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

analyses of the same material should differ by no more than 0.627 %[3] in 95 % of cases.

9.2 *Bias*—Since there is no accepted reference material suitable for determining the bias of this test method, no statement on bias is made.

10. Keywords

10.1 aggregates; boron frit; calcium boride; high-density aggregates; high water-content aggregates; hydrous aggregates; radiation shielding concrete

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C637 – 98a(2003), that may impact the use of this specification. (Approved December 15, 2009)

(*1*) Revised the standard throughout to replace all instances of "specific gravity" with "relative density (specific gravity)."

(*2*) Revised 1.2 and 8.1.3.6 to delete non-SI units.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org). Designation: C638 – 09

Standard Descriptive Nomenclature of Constituents of Aggregates for Radiation-Shielding Concrete[1]

This standard is issued under the fixed designation C638; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This descriptive nomenclature is intended to give accurate descriptions of some common or important naturally occurring and synthetic constituents of aggregates for radiation-shielding concrete, that, at the same time, are not common or important constituents of concrete aggregates in general use. While most of the minerals and rocks discussed below may occur in small quantities in aggregates in general use, they are not major constituents of such aggregates. Common constituents of aggregates in general use are described in Descriptive Nomenclature C294. Radiation-shielding concrete often contains such aggregates, but other special aggregates are used in some circumstances.

1.2 The synthetic aggregates included are ferrophosphorus and boron frit.

1.3 The descriptions are not adequate to permit the identification of materials, since accurate identification of natural and synthetic aggregate constituents in many cases can only be made by a qualified geologist, mineralogist, or petrographer, using the apparatus and procedures of those sciences.

1.4 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C294 Descriptive Nomenclature for Constituents of Concrete Aggregates

3. Types of Materials

3.1 Two classes of materials are described below. The first class consists of minerals and rocks formed from them, and synthetic materials, that have high relative density (specific gravity) and in addition contain substantial proportions of atoms of high or moderately high atomic weight. They are referred to as heavy or high-density aggregates. The second class consists of minerals and synthetic glasses of substantial boron content that are particularly effective in absorbing thermal neutrons without producing highly penetrating gamma rays. The boron-frit glasses are included because of their frequent use.

HEAVY AGGREGATES

4. Descriptions of Naturally Occurring Constituents

4.1 Members of this group have higher relative density (specific gravity) than aggregates in general use. Six are iron minerals, of which five are important iron ore minerals and the sixth is an ore of titanium. Two are barium minerals worked as the principal sources of barium salts. The other is ferrophosphorus, a mixture of synthetic iron phosphides.

4.2 The constituents are described below first as minerals, and then as major constituents of ores when their aspect as major constituents of ores affects the behavior of ores as concrete aggregates.

5. Iron Minerals and Ores

5.1 *Hematite (Fe_2O_3)*—Hematite has a hardness of 5 to 6 on Mohs' scale (will be scratched by hard steel), and a relative density (specific gravity) of 5.26 when pure. The color varies from bright red to dull red to steel gray; luster varies from metallic to submetallic to dull; the streak is cherry red or reddish brown; it is nonmagnetic.

5.1.1 *Hematite Ores*—Rocks of which hematite is the major constituent vary from one deposit to another, and within the deposit, in specific gravity, toughness, compactness, amount of impurities, degree of weathering, and suitability for use as concrete aggregate. Hematite appears to be the iron ore mineral most exploited as a source of iron. The ores of the Lake Superior region are banded sedimentary ores consisting of layers rich in hematite, and sometimes goethite, iron silicates, such as stilpnomelane, minnesotaite, greenalite, grunerite, and iron carbonate, alternating with silica-rich layers of chert or fine-grained quartz or a mixture. The Birmingham, AL ores are

[1] This descriptive nomenclature is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.41 on Pre-placed Aggregate Concrete for Radiation Shielding.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 1973. Last previous edition approved in 2002 as C638–92(2002). DOI: 10.1520/C0638-09.

www.technobetar.ir

oolitic with hematite replacements of oölites and fossils in a matrix that ranges from fine-grained earthy hematite, with or without calcite, to crystalline calcite. Hematite ores dust in handling, with the dust ranging in color from moderate red to dusky red to moderate reddish brown (5R 4/6 to 5R 3/4 to 10R 4/6).[3]

5.2 *Ilmenite ($FeTiO_3$ with minor Mg and Mn)*—Ilmenite has a hardness of 5 to 6 and relative density (specific gravity) of 4.72 ± 0.04 when pure. The color is iron black with metallic to submetallic luster; the streak is black; it is feebly magnetic.

5.2.1 *Ilmenite Ores*—These ores consist of crystalline ilmenite with either magnetite or hematite and constituents of the associated gabbroic or anorthositic rocks. Massive ilmenite ores can form coarsely crystalline massive tough rocks but vary, from deposit to deposit, and within a deposit, in relative density (specific gravity), composition, hardness, and suitability for use as concrete aggregate. Many ilmenite ores consist of ilmenite disseminated in rock rather than concentrated as a major rock-forming mineral. Ilmenite concentrated from beach sands is usually altered to a variable degree, and its mechanical properties probably differ from those of unaltered ilmenite. One of the most widely used types of heavy aggregates is ilmenite ore.

5.3 *Lepidocrocite ($FeO(OH)$)*—Lepidocrocite has a hardness of 5 and relative density (specific gravity) of 4.09 when pure. The color varies from ruby red to reddish brown and the streak is dull orange. Lepidocrocite and goethite occur together, and lepidocrocite may be a constituent of goethite and limonite ores.

5.4 *Goethite ($HFeO_2$)*—Goethite has the same chemical composition as lepidocrocite but crystallizes differently. The hardness is 5 to 5½ and the relative density (specific gravity) is 4.28 ± 0.01 when pure and 3.3 to 4.3 in massive goethite. The color varies with the form, from crystals that are blackish brown with imperfect adamantine-metallic luster, to dull or silky luster in fibrous varieties; massive goethite is yellowish brown to reddish brown; clayey material is brownish yellow to ocher yellow. The streak is brownish yellow to ocher yellow.

5.4.1 *Goethite Ores*—These ores range from hard tough massive rocks to soft crumbling earths; these alterations frequently occur within fractions of an inch.

5.5 *Limonite*—A general name for hydrous iron oxides of unknown composition frequently cryptocrystalline goethite with adsorbed and capillary water, and probably mixtures of such goethite with similar lepidocrocite or hematite, or both, with adsorbed and capillary water[4]. The relative density (specific gravity) ranges from 2.7 to 4.3 and the color from brownish black through browns to yellows. Limonite deposits range from recognizable crystalline goethite to dull massive material of indefinite composition, and therefore, properly limonite. Limonites of high iron content are also called brown iron ores. Frequently they contain sand, colloidal silica, clays, and other impurities.

5.6 *Magnetite ($FeFe_2O_4$)*—Magnetite has a hardness of 5½ to 6½ and relative density (specific gravity) of 5.17 when pure. It is strongly magnetic; the color is black with metallic to semimetallic luster; the streak is black.

5.6.1 *Magnetite Ores*—These ores can form dense, tough, usually coarse-grained rocks with few impurities. Magnetite ores are associated with metamorphic or igneous or sedimentary rocks, and therefore, the impurities associated with magnetite ores may include a wide variety of rock-forming and accessory minerals. Magnetite occurs in association with hematite and ilmenite; magnetic ores are widely distributed, but many are not suitable for use as heavy aggregate because the magnetite occurs disseminated through rock rather than as a major rock-forming mineral. One of the most widely used types of heavy aggregates is magnetite ore.

6. Barium Minerals

6.1 *Witherite ($BaCO_3$)*—Witherite has a hardness of 3 to 3½ and a relative density (specific gravity) of 4.29 when pure. The color ranges from colorless to white to grayish or many pale colors. Like calcite and aragonite, witherite is decomposed with effervescence by dilute hydrochloric acid (HCl). Witherite, the second most common barium mineral, occurs with barite and galena. England is the chief producer of witherite, and barium-containing heavy aggregates in Great Britain might be expected to contain witherite as a major constituent.

6.2 *Barite* ($BaSO_4$) (also, but improperly, called barytes)—Barite has a hardness of 3 to 3½ and a relative density (specific gravity) of 4.50 when pure. The color ranges from colorless to white to many usually pale colors.

6.2.1 Barite is the most common barium mineral and the major barium ore. It occurs in veins transecting many kinds of rocks, concentrated in sedimentary rocks, and as residual nodules in clays formed by the solution of sedimentary rocks. In many of its occurrences it is accompanied by clay or a calcium sulfate mineral (gypsum or anhydrite) or both. Although barite from residual deposits is often weathered, it is possible to obtain clean, well-graded barite aggregate.

7. Ferrophosphorus

7.1 Ferrophosphorus, a material produced in the production of phosphorus, consists of a mixture of iron phosphides, and has been used as coarse and fine aggregate in radiation-shielding concrete. Published relative density (specific gravity) range from 5.72 to 6.50 for coarse aggregate. The coarse aggregate is reported to degrade easily and has been associated with extreme retardation of set in concrete. Ferrophosphorus in concrete releases flammable, and possibly toxic, gases which can develop high pressures if confined[5].

7.2 Several iron phosphides are known, including silver gray to blue gray Fe_2P, with relative density (specific gravity)

TABLE 1 Commercially Important Boron Minerals

Name	Chemical Composition	Solubility in Cold Water	Produced
Borax	$Na_2B_4O_7.10H_2O$	1.6g/100 mL at 10°C: 3.86 g/ 100 mL at 30°C	United States, Argentina, Chile
Kernite	$Na_2B_4O_7.4H_2O$	slowly soluble	United Stats, Argentina
Colemanite	$Ca_2B_6O_{11}.5H_2O$	0.09 g/100 mL	United States, Turkey, USSR
Ulexite	$NaCaB_5O_9.8H_2O$	slightly decomposed with loss of Na_2O	United States, Turkey, USSR, Argentina, Chile
Sassolite (boricacid)	H_3BO_3	5.15 g/100mL	Italy
Tncalconite	$Na_2B_4O_7.5H_2O$	like borax	common dehydration product of borax
Priceite	$Ca_4B_{10}O_{19}.7H_2O$	insoluble	Turkey, USSR, United States
Inyoite	$Ca_2B_6O_{11}.13H_2O$	relatively insoluble	USSR, United States
Hydroboracite	$CaMgB_6O_{11}.6H_2O$	relatively insoluble	USSR
Szaibelyite	(Mg, Mn)(BO_2)(OH)	insoluble	USSR

of 6.50, FeP_2 with relative density (specific gravity) of 5.07, and Fe_3P and FeP. Ferrophosphorus aggregates are silver gray but develop some rusty staining on exposure.

BORON-CONTAINING MATERIALS

8. Boron Minerals

8.1 The gamma rays that result from neutron capture by the lighter isotope of boron, boron-10, are much less penetrating than those which result from neutron capture by hydrogen; and for this reason boron and boron compounds are often used in neutron shields. The unusually high capture capability of boron-10 permits its use in relatively small quantities. Boron is most frequently incorporated in the concrete as borate minerals or synthetic boron frits. Both methods of incorporating boron cause some retardation of time of setting of the concrete, which can be counteracted by the use of a suitable accelerator. The experience recorded in the United States suggests that the cost of synthetic frits, which is higher than the cost of borate, may be counterbalanced by uniform composition of the frits, which permits effective control of the properties of the concrete.

8.2 Minerals that are commercially important sources of boron are principally sodium, calcium, and magnesium borate precipitates from waters in arid volcanic regions, or alteration products of such precipitates (Table 1)[6]. These hydrated minerals include some that are easily altered by changes in relative humidity and temperature. Some of them are soluble in or partly decomposed by cold water. Clay, gypsum, and salt are found in borate deposits. The presence of one or more of these in varying unknown amounts in a borate ore used in shielding concrete may cause problems in making concrete with controlled strength, setting time, volume stability, and workability, aside from the problem of varying degrees of retardation as the time composition, and thus the solubility, of the borate ore may range from lot to lot or within a lot.

8.3 Borate production in the United States is virtually limited to borax and borax derivates obtained from natural brines at Searles Lake, CA, and brines produced by treating borates from the Kramer deposit at Boron, CA. California colemanite deposits, which also contain ulexite, are apparently not regularly worked but colemanite ores have been obtained from them for use in shielding concrete. Turkish borate ores, which have been referred to as "borocalcite," but probably are ulexite or colemanite or mixtures of the two, have been used in shielding concrete in Germany and Japan[7].

8.4 Boron minerals that are stable and insoluble are usually not available in large quantities for use as aggregates. The recorded exceptions are described below.

8.4.1 *Paigeite*—$((Fe^{++}Mg)Fe^{+++}BO_5)$—Paigeite has a hardness of 5 and specific gravity ranging from 4.7 at the paigeite end to 3.6 at the ludwigite end of the paigeite-ludwigite series. It is coal black or greenish black and insoluble in water, and tough. It is a high-temperature mineral occurring with magnetite in contact metamorphic deposits. Paigeite has been used as a heavy boron-containing aggregate in Japan.

8.4.2 *Tourmaline* $(Na(Mg, Fe, Mn, Li, Al)_3Al_6[Si_6O_{18}]\cdot(BO_3)_3(OH,F)_4)$—Tourmaline has a hardness of 7 and specific gravity ranging from 3.03 to 3.25; it ranges widely in color, but common varieties are brown or black. It is characteristically a mineral of granites, pegmatites, and pneumatolytic veins, but persists as a detrital mineral in sediments. Concrete having effective neutron-shielding characteristics has been described in which the coarse aggregate was serpentine and the fine aggregate a tourmaline sand concentrate.

9. Boron-Frit Glasses

9.1 Boron-frit glasses are clear, colorless, synthetic glasses produced by fusion and quenching used in making ceramic glazes. They may be obtained in many compositions, but those most useful in shielding concrete contain calcium, relatively high amounts of silica and alumina, and low amounts of alkalies. Increased silica and alumina decrease the solubility of the frits and thus diminish their retarding effect in shielding concrete. When there is a hazard from secondary radiation, limits on allowable proportions of sodium and potassium may be imposed.

10. Keywords

10.1 aggregates; boron; concrete; iron; minerals

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this descriptive nomenclature since the last issue, C638–92(2002), that may impact the use of this descriptive nomenclature. (Approved December 1, 2009)

(*1*) Added units statement in new 1.4.

(*2*) Replaced all instances of "specific gravity" with "relative density (specific gravity)" throughout the standard.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 641 – 09

Standard Test Method for Iron Staining Materials in Lightweight Concrete Aggregates[1]

This standard is issued under the fixed designation C 641; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the testing of lightweight concrete aggregates to evaluate the potential degree of staining from iron compounds.

1.2 The values stated in SI units are to be regarded as the standard. The inch-pound values given in parentheses are provided for information only.

1.3 *This standard does not purport to address the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C330 Specification for Lightweight Aggregates for Structural Concrete

C331 Specification for Lightweight Aggregates for Concrete Masonry Units

C702 Practice for Reducing Samples of Aggregate to Testing Size

D75 Practice for Sampling Aggregates

E11 Specification for Woven Wire Test Sieve Cloth and Test Sieves

E832 Specification for Laboratory Filter Papers

3. Significance and Use

3.1 This test method evaluates the potential degree of staining attributable to the presence of iron compounds in a lightweight aggregate sample primarily by means of a visual classification method. Such compounds may or may not produce stains on the surface of the concrete in which the aggregate is incorporated.

4. Apparatus

4.1 *Balance*—A balance or scale accurate to within 0.1 % of the test load at any point within the range of use.

4.2 *Sieves*— 9.5-mm (⅜-in.) and 600-µm (No. 30) sieves conforming to Specification E11.

4.3 *Filter Paper*—shall comply with Specification E832 class E2 with a minimum diameter of 250 mm.

4.4 *Cheesecloth Wrapping*—Two thicknesses, reagent grade cheesecloth, approximately 457 mm (18 in.) square is sufficient for wrapping each sample.

4.5 *Steam Bath*—Any suitable apparatus that will meet the requirement of the test procedure. Water in the steam bath, and makeup water, shall be iron-free water or distilled water.

NOTE 1—An oven top glassware sterilizer made of nonferrous materials is satisfactory.

5. Reagents

5.1 *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.[3]

5.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean distilled water or water of equal purity.

5.3 *Concentration of Reagents*:

5.3.1 *Concentrated Acid and Ammonium Hydroxide*—When reagents are specified by name it shall be understood that concentrated reagents of the following specific gravity are intended:

Hydrochloric acid (HCl)	sp gr 1.19
Ammonium hydroxide (NH_4OH)	sp gr 0.90

5.3.2 *Diluted acid* is described in terms of the number of volumes of the concentrated reagent to be added to a given number of volumes of water. Thus HCl (1 + 2) means 1 volume of HCl (sp gr 1.19) added to 2 volumes of water.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.21 on Lightweight Aggregates and Concrete.

Current edition approved Oct. 1, 2009. Published November 2009. Originally approved in 1969. Last previous edition approved in 2007 as C 641 – 07. DOI: 10.1520/C0641-09.

6. Sampling

6.1 Sample in accordance with Practice D75.

6.2 After reducing a field sample to an appropriate size in accordance with Practice C702, thoroughly dry the aggregate and prepare by sieving material to pass the 9.5-mm (⅜-in.) sieve and is retained on the 600-µm (No. 30) sieve.

7. Procedure

7.1 Select two portions each weighing 100 g from the aggregate sample prepared for test.

7.2 Crimp the edges of two filter papers to form cup-shaped receptacles approximately 130 mm (5 in.) in diameter and 60 mm (2½ in.) in depth. Place one of the 100-g portions in each filter cup, spreading to a uniform depth. Fold the sides of the cup to the center and press in that position.

7.3 Wrap both portions of the prepared sample, one on top of the other, in cheesecloth. Saturate with distilled water and expose to steam in the steam bath for 16 h, adding distilled water as make-up water as required.

7.4 Remove from the steam bath, and carefully remove the aggregate from the filter papers. Wash both papers in water, place on a watch glass, and oven dry at a temperature of 110 ± 5 °C (230 ± 9 °F). The insoluble products of the decomposition of iron compounds in the aggregate will be deposited on the filter paper as red, green, or black stains.

7.5 Rate the extent of staining on the filter papers by the Visual Classification Method.

7.5.1 *Visual Classification Method*—Evaluate the extent and intensity of the stains on the filter paper in accordance with the photographic stain index reference standards shown in Figs. 1-5: The photographic stain index ranges from No Stain (stain index = 0) to a Very Heavy Stain (stain index = 100).

7.6 When required by Specification C330 and Specification C331, follow the procedure of the Chemical Analysis Method.

7.6.1 Chemical Analysis Method—The iron deposits may be dissolved from the filter papers by careful application of HCl from a dropping bottle and rinsing with hot distilled water from a wash bottle. Otherwise, dissolve the iron compound on the washed and dried filter papers by digesting in HCl (1 + 1) and filtering out the residue of filter pulp washing thoroughly with hot water. Precipitate the iron in the filtrate as ferric hydroxide $Fe(OH)_3$ by adding NH_4OH dropwise to neutralize the acid using methyl red indicator solution. Redissolve the $Fe(OH)_3$ precipitate using 10 cm^3 of HCl (1 + 1) and determine the iron quantitatively as Fe_2O_3 by standard titration procedures.

NOTE 2—The iron may be determined by using other standard quantitative procedures.

8. Calculation

8.1 Calculate the determined Fe_2O_3 to the nearest 0.01 mg (to be reported to the nearest 0.1) as follows:

$$Fe_2O_3, \text{ mg/200 g} = E \times V \quad (1)$$

where:

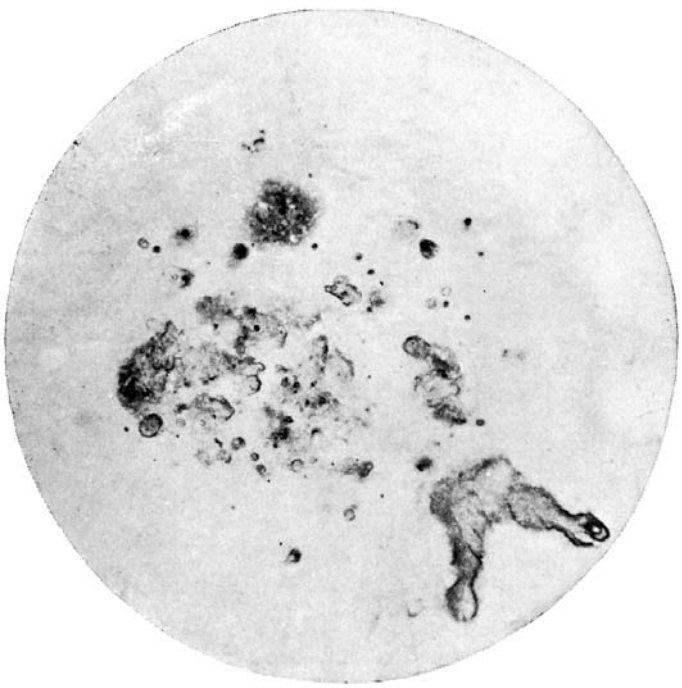
E = Fe_2O_3 equivalent of standard titration solution, mg/mL,

V = millilitres of standard titration solution required by the stains from the 200-g sample.

9. Report

9.1 The report shall include the following:

9.1.1 Identification of the sample,



Stain Index = 100

FIG. 1 Visual Degree of Staining

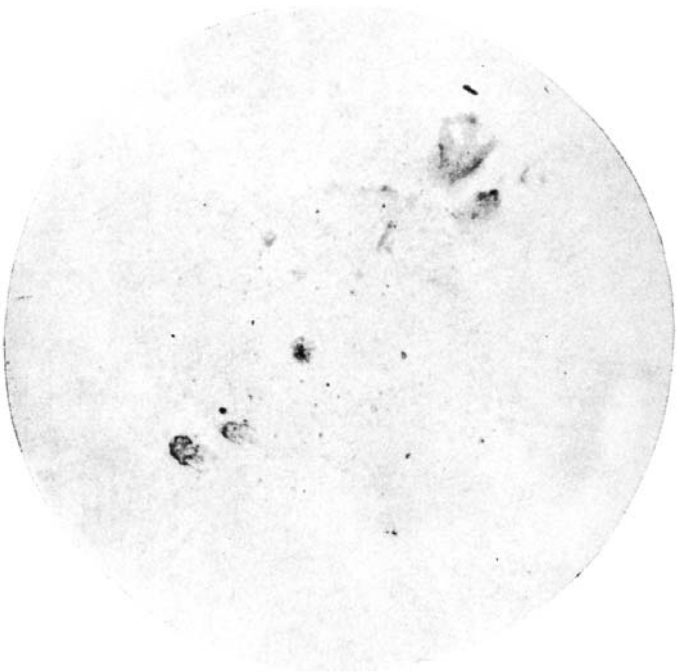
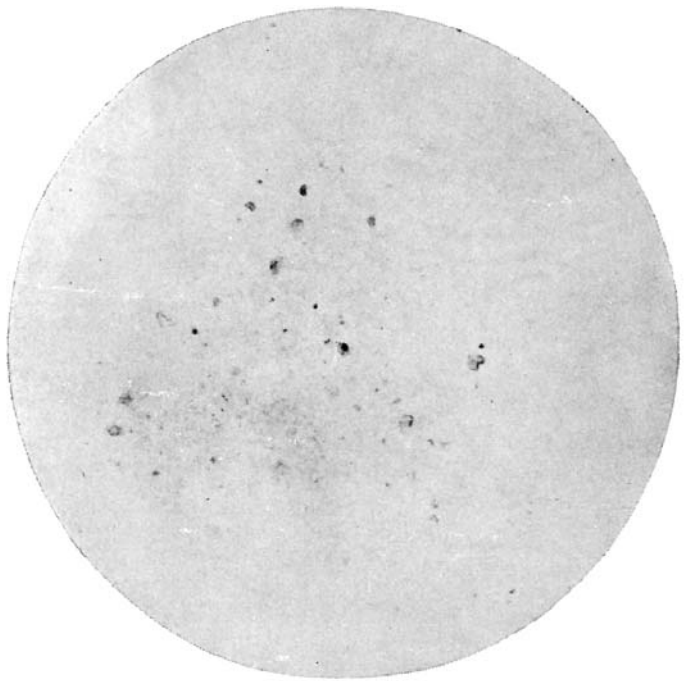
Stain Index = 80

FIG. 2



Stain Index = 60

FIG. 3



Stain Index = 40

FIG. 4

9.1.2 Stain index, as evaluated by the Visual Classification Method, when required, and

9.1.3 Iron content as milligrams of Fe_2O_3 per 200 g of sample evaluated by the Chemical Analysis Method.

10. Precision and Bias

10.1 *Precision*—The precision of this test method has not yet been determined, but an interlaboratory testing program is underway. The precision statements will be included when the data are compiled and reviewed.

10.2 *Bias*—Bias for this test method cannot be determined since there is no reference standard available for comparison.

Designation: C 642 – 06

Standard Test Method for Density, Absorption, and Voids in Hardened Concrete[1]

This standard is issued under the fixed designation C 642; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determinations of denisty, percent absorption, and percent voids in hardened concrete.

1.2 The text of this test method references notes and footnotes which provide explanatory information. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this standard.

1.3 The values stated in SI units are to be regarded as the standard.

2. Significance and Use

2.1 This test method is useful in developing the data required for conversions between mass and volume for concrete. It can be used to determine conformance with specifications for concrete and to show differences from place to place within a mass of concrete.

3. Apparatus

3.1 *Balance*, sensitive to 0.025 % of the mass of the specimen.

3.2 *Container*, suitable for immersing the specimen and suitable wire for suspending the specimen in water.

4. Test Specimen

4.1 Whenever possible, the sample shall consist of several individual portions of concrete, each to be tested separately. The individual portions may be pieces of cylinders, cores, or beams of any desired shape or size, except that the volume of each portion shall be not less than 350 cm^3 (or for normal weight concrete, approximately 800 g); and each portion shall be free from observable cracks, fissures, or shattered edges.

5. Procedure

5.1 *Oven-Dry Mass*—Determine the mass of the portions, and dry in an oven at a temperature of 100 to 110 °C for not less than 24 h. After removing each specimen from the oven, allow it to cool in dry air (preferably in a desiccator) to a temperature of 20 to 25 °C and determine the mass. If the specimen was comparatively dry when its mass was first determined, and the second mass closely agrees with the first, consider it dry. If the specimen was wet when its mass was first determined, place it in the oven for a second drying treatment of 24 h and again determine the mass. If the third value checks the second, consider the specimen dry. In case of any doubt, redry the specimen for 24-h periods until check values of mass are obtained. If the difference between values obtained from two successive values of mass exceeds 0.5 % of the lesser value, return the specimens to the oven for an additional 24-h drying period, and repeat the procedure until the difference between any two successive values is less than 0.5 % of the lowest value obtained. Designate this last value *A*.

5.2 *Saturated Mass After Immersion*—Immerse the specimen, after final drying, cooling, and determination of mass, in water at approximately 21 °C for not less than 48 h and until two successive values of mass of the surface-dried sample at intervals of 24 h show an increase in mass of less than 0.5 % of the larger value. Surface-dry the specimen by removing surface moisture with a towel, and determine the mass. Designate the final surface-dry mass after immersion *B*.

5.3 *Saturated Mass After Boiling*—Place the specimen, processed as described in 5.2, in a suitable receptacle, covered with tap water, and boil for 5 h. Allow it to cool by natural loss of heat for not less than 14 h to a final temperature of 20 to 25 °C. Remove the surface moisture with a towel and determine the mass of the specimen. Designate the soaked, boiled, surface-dried mass *C*.

5.4 *Immersed Apparent Mass*—Suspend the specimen, after immersion and boiling, by a wire and determine the apparent mass in water. Designate this apparent mass *D*.

6. Calculation

6.1 By using the values for mass determined in accordance with the procedures described in Section 5, make the following calculations:

$$\text{Absorption after immersion, \%} = [(B - A)/A] \times 100 \quad (1)$$

$$\text{Absorption after immersion and boiling, \%} = [(C - A)/A] \times 100 \quad (2)$$

$$\text{Bulk density, dry} = [A/(C - D)]\cdot\rho = g_1 \quad (3)$$

$$\text{Bulk density after immersion} = [B/(C - D)]\cdot\rho \quad (4)$$

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.69 on Miscellaneous Tests.

Current edition approved July 1, 2006. Published August 2006. Originally approved in 1969. Last previous edition approved in 1997 as C 642 – 97.

***A Summary of Changes section appears at the end of this standard.**

Copyright © ASTM International, 100 Barr Harbor Drive PO box C-700 West Conshohocken, Pennsylvania 19428-2959, United States

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:25:18 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

$$\text{Bulk density after immersion and boiling} = [C/(C-D)]\cdot\rho \quad (5)$$

$$\text{Apparent density} = [A/(A-D)]\cdot\rho = g_2 \quad (6)$$

$$\text{Volume of permeable pore space (voids), \%} = (g_2 - g_1)/g_2 \times 100 \quad (7)$$

$$\text{or } (C-A)/(C-D) \times 100$$

where:

A = mass of oven-dried sample in air, g
B = mass of surface-dry sample in air after immersion, g
C = mass of surface-dry sample in air after immersion and boiling, g
D = apparent mass of sample in water after immersion and boiling, g
g_1 = bulk density, dry, Mg/m^3 and
g_2 = apparent density, Mg/m^3
ρ = density of water = 1 Mg/m^3 = 1 g/cm^3.

7. Example

7.1 Assume a sample having the following characteristics:

7.1.1 Mass of the solid part of the specimen = 1000 g.

7.1.2 Total volume of specimen (including solids, "permeable" voids, and "impermeable" voids) = 600 cm^3.

7.1.3 Absolute density of solid part of specimen = 2.0 Mg/m^3.

7.1.4 Void space in specimen contains initially only air (no water).

7.2 Then, it follows that there are 500 cm^3 of solids and 100 cm^3 of voids making up the specimen, and the void content is ⅙ = 16.67 %.

7.3 Assume that on immersion 90 mL of water is absorbed.

7.4 Assume that after immersion and boiling 95 mL of water is absorbed.

7.5 Based on the assumptions given in 7.1-7.4 above, the data that would be developed from the procedures given in Section 5 would be as follows:

7.5.1 Oven-dry mass, A = 1000 g.

7.5.2 Mass in air after immersion, B = 1090 g.

7.5.3 Mass in air after immersion and boiling, C = 1095 g.

7.5.4 Apparent mass in water after immersion and boiling, D = 495 g.

NOTE 1—Since loss of mass in water is equal to mass of displaced water, and volume of specimen = 600 cm^3, mass of specimen in water after immersion and boiling is 1095 – 600 = 495 g.

7.6 By using the data given above to perform the calculations described in Section 6, the following results will be obtained (Note 2):

$$\text{Absorption after immersion, \%} = [(B - A(/A] \times 100 = [(1090 - 1000)/1000] \times 100 = 9.0 \quad (8)$$

$$\text{Absorption after immersion and boiling, \%} = [(C - A)/A] \times 100 = [(1095 - 1000)/1000] \times 100 = 9.5 \quad (9)$$

$$\text{Bulk density, dry} = [A/(C-D)]\cdot\rho = [1000/(1095 - 495)] \times 1 = 1.67\ Mg/m^3 = g_1 \quad (10)$$

$$\text{Bulk density after immersion} = [B/(C-D)]\cdot\rho = [1090/(1095 - 495)] \times 1 = 1.82 \quad (11)$$

$$\text{Bulk density after immersion and boiling} = [C/(C-D)]\,\rho = [1095/(1095 - 495)] \times 1 = 1.83\ Mg/m^3 \quad (12)$$

$$\text{Apparent density} = [A/(A-D)]\,\rho = [1000/(1000 - 495)] \times 1 = 1.98\ Mg/m^3 = g_2 \quad (13)$$

$$\text{Volume of permeable voids, \%} \quad (14)$$

$$= [(g_2 - g_1)/g_2] \times 100 = [(1.98 - 1.67)/1.98] \times 100$$

$$= 15.8, \text{ or } [(C - A)/(C - D)] \times 100$$

$$= [(1095 - 1000)/(1095 - 495)] \times 100 = 15.7$$

NOTE 2—This test method does not involve a determination of absolute density. Hence, such pore space as may be present in the specimen that is not emptied during the specified drying or is not filled with water during the specified immersion and boiling or both is considered "impermeable" and is not differentiated from the solid portion of the specimen for the calculations, especially those for percent voids. In the example discussed it was assumed that the absolute density of the solid portion of the specimen was 2.0 Mg/m^3, the total void space was 16.67 %, and the impermeable void space was 5 cm^3. The operations, if performed, and the calculations, if performed as described, have the effect of assuming that there are 95 cm^3 of pore space and 505 cm^3 of solids, and indicate that the solid material, therefore, has an apparent density of 1.98 rather than the absolute density of 2.00 Mg/m^3 and the specimen has a percentage of voids of 15.8 rather than 16.67.

Depending on the pore size distribution and the pore entry radii of the concrete and on the purposes for which the test results are desired, the procedures of this test method may be adequate, or they may be insufficiently rigorous. In the event that it is desired to fill more of the pores than will be filled by immersion and boiling, various techniques involving the use of vacuum treatment or increased pressures may be used. If a rigorous measure of total pore space is desired, this can only be obtained by determining absolute density by first reducing the sample to discrete particles, each of which is sufficiently small so that no impermeable pore space can exist within any of the particles. If the absolute density were determined and designated g_3, then:

$$\text{Total void volume, \%} = (g_3 - g_1)/g_3 \times 100 \quad (15)$$

$$= (2.00 - 1.67)/2.00 \times 100 = 16.5$$

8. Precision and Bias

8.1 *Precision*—At present there are insufficient data available to justify attempting to develop a precision statement for this test method.

8.2 *Bias*—Bias for this test method cannot be determined since there is no reference standard available for comparison.

9. Keywords

9.1 absorption; concrete-hardened; density; voids

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 642 – 97, that may impact the use of this test method. (Approved July 1, 2006)

(*1*) Added new 1.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 645 – 09a

Standard Specification for Nonstructural Steel Framing Members[1]

This standard is issued under the fixed designation C 645; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers nonstructural steel framing members in interior construction assemblies.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 The following safety hazards caveat pertains only to the test methods portion, Sections 9 and 10, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

A653/A653M Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process

A1003/A1003M Specification for Steel Sheet, Carbon, Metallic- and Nonmetallic-Coated for Cold-Formed Framing Members

C11 Terminology Relating to Gypsum and Related Building Materials and Systems

C475/C475M Specification for Joint Compound and Joint Tape for Finishing Gypsum Board

C1396/C1396M Specification for Gypsum Board

C754 Specification for Installation of Steel Framing Members to Receive Screw-Attached Gypsum Panel Products

C1002 Specification for Steel Self-Piercing Tapping Screws for the Application of Gypsum Panel Products or Metal Plaster Bases to Wood Studs or Steel Studs

2.2 *AISI Standard:*

S100 North American Specification for the Design of Cold-Formed Steel Structural Members, 2007 edition[3]

AISI COSP Code of Standard Practice for Cold-Formed Steel Structural Framing Committee on Framing Standards, 2005 Edition[3]

2.3 *ICC-ES Document*[4]

ICC-ES-AC86 Acceptance Criteria for Steel Studs and Gypsum-Board Interior Nonload-Bearing Walls—Complete Construction—AC86—Approved July 1995 (Editorially revised September 2005) (Formerly ICBO AC86 dated July 1995)

3. Terminology

3.1 *Definitions*—Definitions shall be in accordance with Terminology C11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *members*, *n*—in screw application of gypsum board, studs, runners (track), hat furring channels, main beams and cross furring members of grid suspension systems or other items manufactured in accordance with this specification.

3.2.2 *nonstructural wall stud*, *n*—a member in a steel framed wall system which is limited to a lateral (transverse) load of not more than 10 lb/ft^2 (480 Pa), a superimposed vertical load, exclusive of sheathing materials, of not more than 100 lbf/ft (1460 N/m), or a superimposed vertical load of not more than 200 lbs (890 N).

4. Materials and Manufacture

4.1 Members shall be manufactured from steel meeting the requirements of Specification A1003/A1003M.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved Nov. 15, 2009. Published December 2009. Originally approved in 1970. Last previous edition approved in 2009 as C 645 – 09.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

4.2 Members shall have a protective coating conforming to Specification A653/A653M – G 40 minimum or shall have a protective coating with an equivalent corrosion resistance.

4.3 Members shall be manufactured from steel having a minimum thickness, individual measurement of 0.0179 in. (0.455 mm) before application of protective coating.

5. Dimensions and Permissible Variations

5.1 Studs and rigid furring channels shall have a configuration and steel thickness such that the system in which they are used will carry the design transverse loads without exceeding either the allowable stress of the steel or the allowable design deflection. Main beams and cross furring of grid suspension systems shall be limited to a deflection of L/240. The manufacturer shall supply sufficient data for calculating design performance.

NOTE 1—Allowable deflection varies depending on the cladding used and architectural requirements. Detailed requirements shall be specified in application specifications.

5.1.1 Members, except main beams of grid suspension systems, shall be sufficiently rigid to permit penetration of the screw.

5.1.2 Minimum width of face to which gypsum board is screw-attached shall be not less than 1¼ in. (32 mm).

5.1.3 Minimum lip dimension shall be 3⁄16 in. (5 mm). See Fig. 1.

5.2 Members shall be manufactured within the limits as shown in Table 1 and Fig. 2.

5.3 *Rigid Furring Channels*—Minimum depth shall be ⅞ in. (22 mm). Minimum width of furring attachment flanges (see Fig. 3) shall be ½ in. (12.7 mm).

5.4 Grid suspension systems include main beams and cross furring members which mechanically interlock to form a modular supporting network. Length tolerance for grid suspension members shall be ±1⁄16 in. (1.59 mm).

5.5 Runners (track) shall be formed in a U-shaped configuration, having web depth compatible with those of the studs of the same nominal size. The runners (track) shall be designed such that when the studs are placed in both the top and bottom

TABLE 1 Manufacturing Tolerances

Dimension[A]	Item Checked	Drywall Studs, in. (mm)	Drywall Track, in. (mm)
A	length	+ ⅛ (3.18) – ¼ (6.35)	+ 1 (25.40) – ¼ (6.35)
B[B]	web width	+ 1/32 (0.79) – 1/32 (0.79)	+ ⅛ (3.18) – 0 (0)
C	flare overbend	+ 1/16 (1.59) – 1/16 (1.59)	+ 0 (0) – 3/16 (4.76)
D	hole center width	+ ⅛ (3.18) – ⅛ (3.18)	NA
E	hole center length	+ ¼ (6.35) – ¼ (6.35)	NA
F	crown	+ ⅛ (3.18) – ⅛ (3.18)	+ ⅛ (3.18) – ⅛ (3.18)
G	camber	1/32 per ft (0.79) ½ max (12.7)	1/32 per ft (0.79) ½ max (12.7)
H	bow	1/32 per ft (0.79) ½ max (12.7)	1/32 per ft (0.79) ½ max (12.7)
I	twist	1/32 per ft (0.79) ½ max (12.7)	1/32 per ft (0.79) ½ max (12.7)

[A] All measurements shall be taken not less than 1 ft (305 mm) from the end.
[B] Outside dimension for stud; inside for track.

runners (track), they are held by friction. Minimum height of flanges shall be 1 in. (25 mm).

6. Edges

6.1 Members shall be manufactured in such a fashion as to minimize burrs and sharp edges.

7. Cutouts

7.1 Cutouts shall not reduce the performance of the members in the gypsum board construction assembly below the specified performance requirements.

8. Sectional Properties

8.1 The sectional properties of members shall be computed in accordance with AISI S100 (See Tables 2 and 3 and Figs. 1 and 3).

9. Performance Requirements

9.1 *Penetration*—When tested in accordance with Section 10, members shall be capable of pulling the head of the screw below the surface of the gypsum board in less than 2 s without spin out.

9.2 Members that can show certified third party testing in accordance with ICC-ES-AC86 (Approved July 1995—Editorially Revised September 2005) and conform to the limiting height tables in Specification C754 need not meet the minimum thickness limitation set forth in 4.3 or the minimum section properties set forth in 8.1.

10. Penetration Test

10.1 *Significance and Use*—This test method provides a procedure for evaluating the member's ability to pull the head of a screw below the surface of gypsum wallboard. It shall be used to determine compliance with this specification. The degree of performance of this test method with service performance has not been determined.

10.2 *Apparatus shall satisfy the following*:

10.2.1 *Power-Driven Drill Screw Gun*, capable of 4000 rpm (free spindle speed) with a depth-sensitive nose piece, supplied with a screw driving bit to fit the screw used in the test.

10.2.2 *Stop Watch*, capable of being read to the nearest 0.1 s.

10.3 *Materials shall satisfy the following*:

10.3.1 *Gypsum Wallboard*—Specification C1396/C1396M, Type X, 5/8 in. (16 mm) thick.

10.3.2 *Screws*—Specification C1002, Type S, minimum 1 in. (25.4 mm) long.

10.3.3 *Paper Joint Tape*—Specification C475/C475M.

10.4 *Sampling*—One member shall be selected from each bundle or package but not more than ten from any one shipment for testing.

10.5 *Specimen Preparation*:

10.5.1 Each member to be tested shall be cut into test specimens not less than 18 in. (460 mm) long.

10.5.2 For each test, one piece of gypsum wallboard, 6 in. (150 mm) square, shall be cut from not less than 12 in. (300 mm) from the edge or end of the gypsum wallboard.

10.5.3 For each test, four pieces of paper joint tape, 2 in. (50 mm) square shall be cut.

10.6 *Procedure*—

10.6.1 Assemble the member, gypsum wallboard and paper joint tape on a rigid, flat surface. (See Fig. 4 for studs, Fig. 5 for furring channels.)

10.6.2 Prior to performing the test, drive several screws without the paper joint tape to set the depth of the nose piece on the screw gun, allowing the screws to be driven below the surface of the wallboard without breaking the gypsum wallboard face paper.

10.6.3 Drive the screw through the paper joint tape, using the screw gun, while applying a force (dead weight and applied force) of 30 lbf (112.2 N). Drive the screw until the nosepiece of the screw gun has either stopped and seated the screw or the screw spins out. Record if the screw has spun out and if it exceeds 2 s to seat the screw in the gypsum wallboard.

10.7 *Number of Tests and Retests*:

10.7.1 A sample consisting of five specimens of members shall be tested.

10.7.2 If not more than one of the test specimens fails to meet the requirements, the sample has met the requirements.

10.7.3 If two of the five test specimens fail to meet the requirements, two additional test specimens shall be chosen for retesting. If either of the two additional test specimens fail, the sample has failed to meet the requirements of this test.

10.8 *Report*—Report shall indicate the total number of specimens tested and the number of specimens meeting the requirements of this specification.

10.9 *Precision and Bias*—No statement is made about either the precision or bias of this test method since the result merely states whether or not there is conformance to the criteria for success specified in the procedure.

11. Inspection

11.1 Inspection of the members shall be agreed upon between the purchaser and the producer or supplier as part of the purchase agreement.

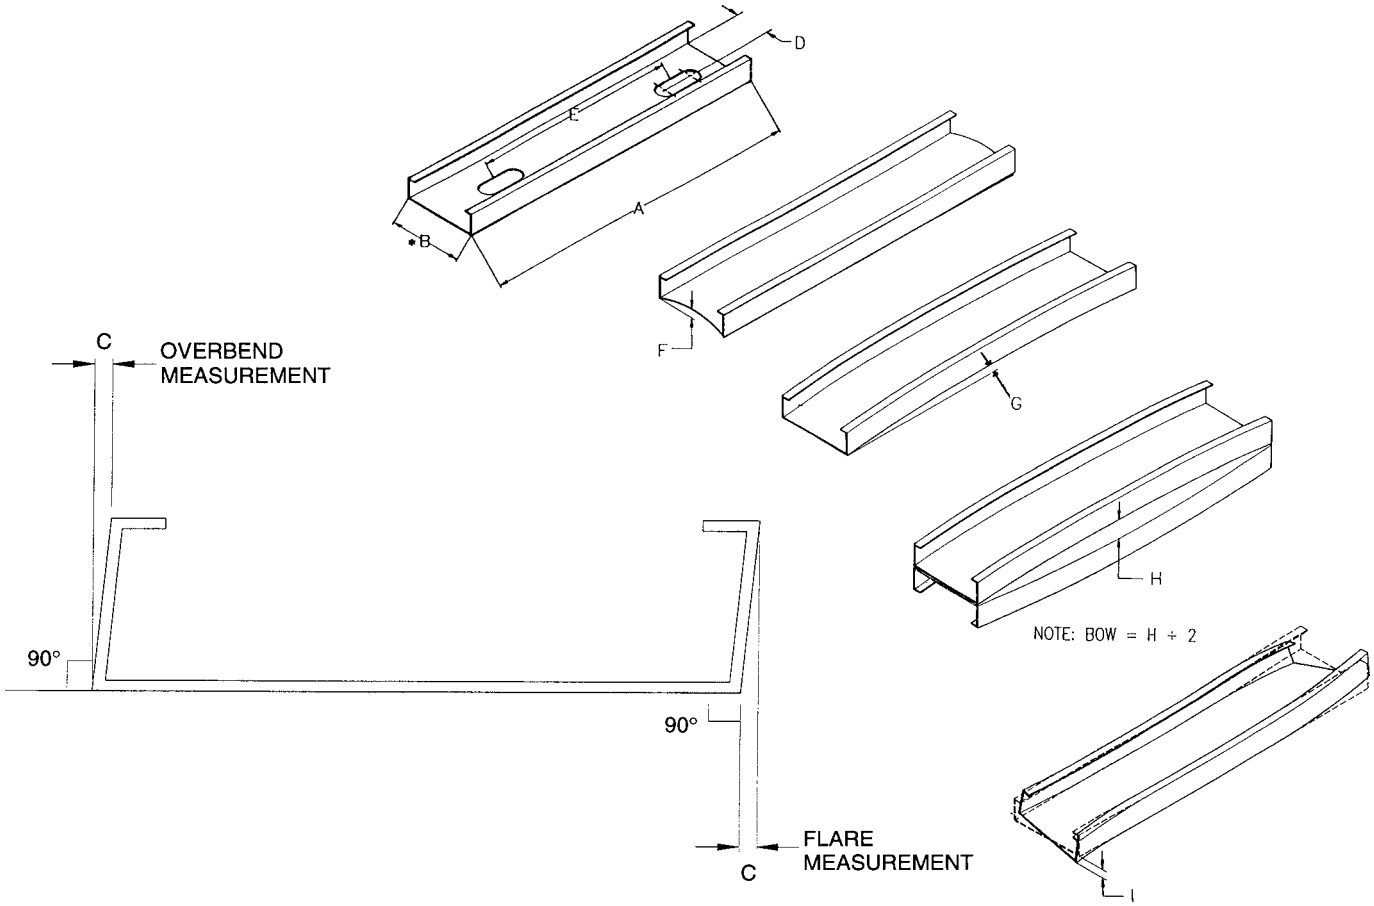

FIG. 2 Manufacturing Tolerances

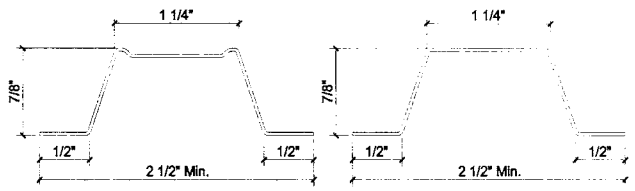

FIG. 3 Hat Furring Channel Cross Section

12. Rejection

12.1 When specified in the purchase agreement, members that fail to conform to the requirements of the specification shall be rejected. Rejection shall be reported to the producer or supplier promptly and in writing. The notice of rejection shall contain a statement documenting how the member has failed to conform to the requirements of this specification and the purchase agreement.

13. Certification

13.1 When specified in the purchase agreement, a producer's or supplier's report shall be furnished at the time of shipment certifying that the product is in compliance with this specification.

14. Marking and Identification

14.1 Groups of like members shall be marked with a label, or a tag attached thereto. Marking shall include the rollformer's identification (name, logo, or initials), length, quantity and rollformer's member designator including member depth, flange size, and minimum steel thickness in mils or inches, exclusive of protective coating.

14.2 In addition to the marking referenced in 14.1, individual members shall have a legible label, stencil, or embossment, at a maximum distance of 96 in. (2440 mm) on center, on the member, with the following minimum information:

14.2.1 The rollformer's identification (that is, name, logo or initials).

14.2.2 The minimum steel thickness, in mils or inches, exclusive of protective coating.

400S125-33	4.000	102	0.0346	0.879	0.0329	0.835	0.228	147	0.524	218	4.01	453
600S125-30	6.000	152	0.0312	0.792	0.0296	0.752	0.268	173	1.223	513	5.39	609
600S125-33	6.000	152	0.0346	0.879	0.0329	0.835	0.297	192	1.378	574	6.32	714

[A] The section designator defines the cold-formed steel framing member dimensions.
Example: 350S125-18
350 designates the member web depth in 100ths of an inch, 350 = 3.50 in. (88.9 mm)
S designates the type of member, S = Stud
125 designates the member flange width in 100ths of an inch, 125 = 1.25 in. (31.8 mm)
–18 designates the minimum base metal thickness in mils, 18 = 0.0179 in. (0.454 mm)
–30 designates the minimum base metal thickness in mils, 30 = 0.0296 in. (0.752 mm)
–33 designates the minimum base metal thickness in mils, 33 = 0.0329 in. (0.836 mm)
[B] Minimum base metal thickness is 95 % of Design Thickness.
[C] Properties are based on a centerline radius of 3⁄32 in. (2.38 mm), see Fig. 1.
[D] Effective properties are calculated in accordance with AISI S100 and are based on a yield strength, Fy = 33 ksi.
[E] Moment of inertia, Ix, given is for deflection calculations.
[F] Allowable moment is taken as the lowest value based on local or distortional buckling. For distortional buckling, K_Φ= 0 and β = 1.
[G] Where noted, member web height-to-thickness ratio exceeds 200, web stiffeners required at supports.

TABLE 3 Hat Furring Channel Section Properties

Design Thickness		Minimum Base Metal Thickness[A]		Gross Area[B]		Effective Properties[B,C,D]			
						I_x[E]		Mn/Ω[F]	
in	(mm)	in	(mm)	in^2	(mm^2)	in^4 [D]	(mm^4)[D]	in-k	(N-m)
0.0188	0.477	0.0179	0.453	0.0702	45.29	0.0086	3563	0.32	36.16
0.0283	0.719	0.0269	0.683	0.1046	67.48	0.0131	5440	0.54	61.02
0.0312	0.792	0.0296	0.752	0.1152	74.32	0.0143	5953	0.61	68.98
0.0346	0.879	0.0329	0.835	0.1270	81.94	0.0157	6531	0.66	74.58

[A] Minimum base metal thickness is 95 % of Design Thickness.
[B] Properties are based on a centerline radius of 3⁄32 in. (2.38 mm).
[C] Effective properties are given as the minimum value for either positive or negative bending.
[D] Effective properties calculated in accordance with AISI S100 and are based on Fy = 33 ksi (227 MPa).
[E] Moment of inertia given is for deflection calculations.
[F] Allowable moment based on local buckling.

14.2.3 The minimum yield strength in ksi (MPa) if other than 33 ksi (230 MPa).

14.2.4 The minimum protective coating weight, G-XX, if other than as specified in Section 4.

15. Protection

15.1 Material shall be protected during shipment as required. When specified in the purchase order, the members shall be packaged in accordance with the purchaser's instructions.

15.2 Material shall be received and stored in accordance with AISI COSP, paragraph F3.

16. Keywords

16.1 furring channels; grid suspension systems; gypsum board; runners; screws; section properties; spinout; studs

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 645 – 09, that may impact the use of this specification. (Approved November 15, 2009)

(*1*) Revised 10.6.3, 10.7, 10.8, Tables 2 and 3 and Referenced Documents.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 645 – 08a, that may impact the use of this specification. (Approved July 15, 2009)

(*1*) Revised Section 10.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 666/C 666M – 03 (Reapproved 2008)

Standard Test Method for Resistance of Concrete to Rapid Freezing and Thawing[1]

This standard is issued under the fixed designation C 666/C 666M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method covers the determination of the resistance of concrete specimens to rapidly repeated cycles of freezing and thawing in the laboratory by two different procedures: Procedure A, Rapid Freezing and Thawing in Water, and Procedure B, Rapid Freezing in Air and Thawing in Water. Both procedures are intended for use in determining the effects of variations in the properties of concrete on the resistance of the concrete to the freezing-and-thawing cycles specified in the particular procedure. Neither procedure is intended to provide a quantitative measure of the length of service that may be expected from a specific type of concrete.

1.2 The values stated in either inch-pound units or SI units shall be regarded separately as standard. The SI units are shown in brackets. The values stated may not be exact equivalents; therefore each system must be used independently of the other. Combining values from the two units may result in nonconformance.

1.3 All material in this test method not specifically designated as belonging to Procedure A or Procedure B applies to either procedure.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

C 233 Test Method for Air-Entraining Admixtures for Concrete

C 295 Guide for Petrographic Examination of Aggregates for Concrete

C 341/C 341M Practice for Length Change of Cast, Drilled, or Sawed Specimens of Hydraulic-Cement Mortar and Concrete

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 494/C 494M Specification for Chemical Admixtures for Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 823 Practice for Examination and Sampling of Hardened Concrete in Constructions

3. Significance and Use

3.1 As noted in the scope, the two procedures described in this test method are intended to determine the effects of variations in both properties and conditioning of concrete in the resistance to freezing and thawing cycles specified in the particular procedure. Specific applications include specified use in Specification C 494/C 494M, Test Method C 233, and ranking of coarse aggregates as to their effect on concrete freeze-thaw durability, especially where soundness of the aggregate is questionable.

3.2 It is assumed that the procedures will have no significantly damaging effects on frost-resistant concrete which may be defined as (*1*) any concrete not critically saturated with water (that is, not sufficiently saturated to be damaged by freezing) and (*2*) concrete made with frost-resistant aggregates

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.67 on Resistance to the Environment.

Current edition approved June 1, 2008. Published September 2008. Originally approved in 1971. Last previous edition approved in 2003 as C 666/C 666M – 03.

and having an adequate air-void system that has achieved appropriate maturity and thus will prevent critical saturation by water under common conditions.

3.3 If as a result of performance tests as described in this test method concrete is found to be relatively unaffected, it can be assumed that it was either not critically saturated, or was made with "sound" aggregates, a proper air-void system, and allowed to mature properly.

3.4 No relationship has been established between the resistance to cycles of freezing and thawing of specimens cut from hardened concrete and specimens prepared in the laboratory.

4. Apparatus

4.1 *Freezing-and-Thawing Apparatus*:

4.1.1 The freezing-and-thawing apparatus shall consist of a suitable chamber or chambers in which the specimens may be subjected to the specified freezing-and-thawing cycle, together with the necessary refrigerating and heating equipment and controls to produce continuously, and automatically, reproducible cycles within the specified temperature requirements. In the event that the equipment does not operate automatically, provision shall be made for either its continuous manual operation on a 24-h a day basis or for the storage of all specimens in a frozen condition when the equipment is not in operation.

4.1.2 The apparatus shall be so arranged that, except for necessary supports, each specimen is: (*1*) for Procedure A, completely surrounded by not less than 1⁄32 in. [1 mm] nor more than 1⁄8 in. [3 mm] of water at all times while it is being subjected to freezing-and-thawing cycles, or (*2*) for Procedure B, completely surrounded by air during the freezing phase of the cycle and by water during the thawing phase. Rigid containers, which have the potential to damage specimens, are not permitted. Length change specimens in vertical containers shall be supported in a manner to avoid damage to the gage studs.

NOTE 1—Experience has indicated that ice or water pressure, during freezing tests, particularly in equipment that uses air rather than a liquid as the heat transfer medium, can cause excessive damage to rigid metal containers, and possibly to the specimens therein. Results of tests during which bulging or other distortion of containers occurs should be interpreted with caution.

4.1.3 The temperature of the heat-exchanging medium shall be uniform within 6 °F [3 °C] throughout the specimen cabinet when measured at any given time, at any point on the surface of any specimen container for Procedure A or on the surface of any specimen for Procedure B, except during the transition between freezing and thawing and *vice versa*.

4.1.3.1 Support each specimen at the bottom of its container in such a way that the temperature of the heat-exchanging medium will not be transmitted directly through the bottom of the container to the full area of the bottom of the specimen, thereby subjecting it to conditions substantially different from the remainder of the specimen.

NOTE 2—A flat spiral of 1⁄8-in. [3-mm] wire placed in the bottom of the container has been found adequate for supporting specimens.

4.1.4 For Procedure B, it is not contemplated that the specimens will be kept in containers. The supports on which the specimens rest shall be such that they are not in contact with the full area of the supported side or end of the specimen, thereby subjecting this area to conditions substantially different from those imposed on the remainder of the specimen.

NOTE 3—The use of relatively open gratings, metal rods, or the edges of metal angles has been found adequate for supporting specimens, provided the heat-exchanging medium can circulate in the direction of the long axis of the rods or angles.

4.2 *Temperature-Measuring Equipment*, consisting of thermometers, resistance thermometers, or thermocouples, capable of measuring the temperature at various points within the specimen chamber and at the centers of control specimens to within 2 °F [1 °C].

4.3 *Dynamic Testing Apparatus*, conforming to the requirements of Test Method C 215.

4.4 *Optional Length Change Test Length Change Comparator*, conforming to the requirements of Specification C 490. When specimens longer than the nominal 11¼ in. [285 mm] length provided for in Specification C 490 are used for freeze-thaw tests, use an appropriate length reference bar, which otherwise meets the Specification C 490 requirements. Dial gage micrometers for use on these longer length change comparators shall meet the gradation interval and accuracy requirements for Specification C 490 for either the inch or millimetre calibration requirements. Prior to the start of measurements on any specimens, fix the comparator at an appropriate length to accommodate all of the specimens to be monitored for length change.

4.5 *Scales*, with a capacity approximately 50 % greater than the mass of the specimens and accurate to at least 0.01 lb [0.5 g] within the range of ±10 % of the specimen mass will be satisfactory.

4.6 *Tempering Tank*, with suitable provisions for maintaining the temperature of the test specimens in water, such that when removed from the tank and tested for fundamental transverse frequency and length change, the specimens will be maintained within -2 °F and +4 °F (-1 °C and +2 °C) of the target thaw temperature for specimens in the actual freezing-and-thawing cycle and equipment being used. The use of the specimen chamber in the freezing-and-thawing apparatus by stopping the apparatus at the end of the thawing cycle and holding the specimens in it shall be considered as meeting this requirement, provided the specimens are tested for fundamental transverse frequency within the above temperature range. It is required that the same target specimen thaw temperature be used throughout the testing of an individual specimen since a change in specimen temperature at the time of length measurement can affect the length of the specimen significantly.

5. Freezing-and-Thawing Cycle

5.1 Base conformity with the requirements for the freezing-and-thawing cycle on temperature measurements of control specimens of similar concrete to the specimens under test in which suitable temperature-measuring devices have been imbedded. Change the position of these control specimens frequently in such a way as to indicate the extremes of temperature variation at different locations in the specimen cabinet.

www.technobetar.ir

5.2 The nominal freezing-and-thawing cycle for both procedures of this test method shall consist of alternately lowering the temperature of the specimens from 40 to 0 °F [4 to -18 °C] and raising it from 0 to 40 °F [-18 to 4 °C] in not less than 2 nor more than 5 h. For Procedure A, not less than 25 % of the time shall be used for thawing, and for Procedure B, not less than 20 % of the time shall be used for thawing (Note 4). At the end of the cooling period the temperature at the centers of the specimens shall be 0 ± 3 °F [-18 ± 2 °C], and at the end of the heating period the temperature shall be 40 ± 3 °F [4 ± 2 °C], with no specimen at any time reaching a temperature lower than -3 °F [-19 °C] nor higher than 43 °F [6 °C]. The time required for the temperature at the center of any single specimen to be reduced from 37 to 3 °F [3 to -16 °C] shall be not less than one half of the length of the cooling period, and the time required for the temperature at the center of any single specimen to be raised from 3 to 37 °F [-16 to 3 °C] shall be not less than one half of the length of the heating period. For specimens to be compared with each other, the time required to change the temperature at the centers of any specimens from 35 to 10 °F [2 to -12 °C] shall not differ by more than one sixth of the length of the cooling period from the time required for any specimen and the time required to change the temperature at the centers of any specimens from 10 to 35 °F [-12 to 2 °C] shall not differ by more than one third of the length of the heating period from the time required for any specimen.

NOTE 4—In most cases, uniform temperature and time conditions can be controlled most conveniently by maintaining a capacity load of specimens in the equipment at all times. In the event that a capacity load of test specimens is not available, dummy specimens can be used to fill empty spaces. This procedure also assists greatly in maintaining uniform fluid level conditions in the specimen and solution tanks.

The testing of concrete specimens composed of widely varying materials or with widely varying thermal properties, in the same equipment at the same time, may not permit adherence to the time-temperature requirements for all specimens. It is advisable that such specimens be tested at different times and that appropriate adjustments be made to the equipment.

5.3 The difference between the temperature at the center of a specimen and the temperature at its surface shall at no time exceed 50 °F [28 °C].

5.4 The period of transition between the freezing-and-thawing phases of the cycle shall not exceed 10 min, except when specimens are being tested in accordance with 8.3.

6. Sampling

6.1 Constituent materials for concrete specimens made in the laboratory shall be sampled using applicable standard methods.

6.2 Samples cut from hardened concrete are to be obtained in accordance with Practice C 823.

7. Test Specimens

7.1 The specimens for use in this test method shall be prisms or cylinders made and cured in accordance with the applicable requirements of Practice C 192/C 192M and Specification C 490.

7.2 Specimens used shall not be less than 3 in. [75 mm] nor more than 5 in. [125 mm] in width, depth, or diameter, and not less than 11 in. [275 mm] nor more than 16 in. [405 mm] in length.

7.3 Test specimens may also be cores or prisms cut from hardened concrete. If so, the specimens should not be allowed to dry to a moisture condition below that of the structure from which taken. This may be accomplished by wrapping in plastic or by other suitable means. The specimens so obtained shall be furnished with gage studs in accordance with Test Method C 341/C 341M.

7.4 For this test the specimens shall be stored in saturated lime water from the time of their removal from the molds until the time freezing-and-thawing tests are started. All specimens to be compared with each other initially shall be of the same nominal dimensions.

8. Procedure

8.1 Molded beam specimens shall be cured for 14 days prior to testing unless otherwise specified. Beam specimens sawed from hardened concrete shall be moisture-conditioned by immersing in saturated lime water at 73.4 ± 3 °F [23.0 ± 2.0 °C] for 48 h prior to testing unless otherwise specified.

8.2 Immediately after the specified curing or conditioning period, bring the specimen to a temperature within -2 °F and +4 °F [-1 °C and +2 °C] of the target thaw temperature that will be used in the freeze-thaw cycle and test for fundamental transverse frequency, determine the mass and average length and cross section dimensions of the concrete specimen within the tolerance required in Test Method C 215, and determine the initial length comparator reading (optional) for the specimen with the length change comparator. Protect the specimens against loss of moisture between the time of removal from curing and the start of the freezing-and-thawing cycles.

8.3 Start freezing-and-thawing tests by placing the specimens in the thawing water at the beginning of the thawing phase of the cycle. Remove the specimens from the apparatus, in a thawed condition, at intervals not exceeding 36 cycles of exposure to the freezing-and-thawing cycles, test for fundamental transverse frequency and measure length change (optional) with the specimens within the temperature range specified for the tempering tank in 4.6, determine the mass of each specimen, and return them to the apparatus. To ensure that the specimens are completely thawed and at the specified temperature place them in the tempering tank or hold them at the end of the thaw cycle in the freezing-and-thawing apparatus for a sufficient time for this condition to be attained throughout each specimen to be tested. Protect the specimens against loss of moisture while out of the apparatus and turn them end-for-end when returned. For Procedure A, rinse out the container and add clean water. Return the specimens either to random positions in the apparatus or to positions according to some predetermined rotation scheme that will ensure that each specimen that continues under test for any length of time is subjected to conditions in all parts of the freezing apparatus. Continue each specimen in the test until it has been subjected to 300 cycles or until its relative dynamic modulus of elasticity reaches 60 % of the initial modulus, whichever occurs first, unless other limits are specified (Note 5). For the optional

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

length change test, 0.10 % expansion may be used as the end of test. Whenever a specimen is removed because of failure, replace it for the remainder of the test by a dummy specimen. Each time the specimen is tested for fundamental frequency (Note 6) and length change, make a note of its visual appearance and make special comment on any defects that develop (Note 7). When it is anticipated that specimens may deteriorate rapidly, they should be tested for fundamental transverse frequency and length change (optional) at intervals not exceeding 10 cycles when initially subjected to freezing and thawing.

NOTE 5—It is not recommended that specimens be continued in the test after their relative dynamic modulus of elasticity has fallen below 50 %.

NOTE 6—It is recommended that the fundamental longitudinal frequency be determined initially and as a check whenever a question exists concerning the accuracy of determination of fundamental transverse frequency, and that the fundamental torsional frequency be determined initially and periodically as a check on the value of Poisson's ratio.

NOTE 7—In some applications, such as airfield pavements and other slabs, popouts may be defects that are a concern. A popout is characterized by the breaking away of a small portion of the concrete surface due to internal pressure, thereby leaving a shallow and typically conical spall in the surface of the concrete through the aggregate particle. Popouts may be observed as defects in the test specimens. Where popouts are a concern, the number and general description should be reported as a special comment. The aggregates causing the popout may be identified by petrographic examination as in Practice C 295.

8.4 When the sequence of freezing-and-thawing cycles must be interrupted store the specimens in a frozen condition.

NOTE 8—If, due to equipment breakdown or for other reasons, it becomes necessary to interrupt the cycles for a protracted period, store the specimens in a frozen condition in such a way as to prevent loss of moisture. For Procedure A, maintain the specimens in the containers and surround them by ice, if possible. If it is not possible to store the specimens in their containers, wrap and seal them, in as wet a condition as possible, in moisture-proof material to prevent dehydration and store in a refrigerator or cold room maintained at 0 ± 3 °F [-18 ± 2 °C]. Follow the latter procedure when Procedure B is being used. In general, for specimens to remain in a thawed condition for more than two cycles is undesirable, but a longer period may be permissible if this occurs only once or twice during a complete test.

9. Calculation

9.1 *Relative Dynamic Modulus of Elasticity*—Calculate the numerical values of relative dynamic modulus of elasticity as follows:

$$P_c = (n_1^2/n^2) \times 100 \quad (1)$$

where:

P_c = relative dynamic modulus of elasticity, after c cycles of freezing and thawing, percent,
n = fundamental transverse frequency at 0 cycles of freezing and thawing, and
n_1 = fundamental transverse frequency after c cycles of freezing and thawing.

NOTE 9—This calculation of relative dynamic modulus of elasticity is based on the assumption that the mass and dimensions of the specimen remain constant throughout the test. This assumption is not true in many cases due to disintegration of the specimen. However, if the test is to be used to make comparisons between the relative dynamic moduli of different specimens or of different concrete formulations, P_c as defined is adequate for the purpose.

9.2 *Durability Factor*—Calculate the durability factor as follows:

$$DF = PN/M \quad (2)$$

where:

DF = durability factor of the test specimen,
P = relative dynamic modulus of elasticity at N cycles, %,
N = number of cycles at which P reaches the specified minimum value for discontinuing the test or the specified number of cycles at which the exposure is to be terminated, whichever is less, and
M = specified number of cycles at which the exposure is to be terminated.

9.3 *Length Change in Percent (optional)*—Calculate the length change as follows:

$$L_c = \frac{(l_2 - l_1)}{L_g} \times 100 \quad (3)$$

where:

L_c = length change of the test specimen after C cycles of freezing and thawing, %,
l_1 = length comparator reading at 0 cycles,
l_2 = length comparator reading after C cycles, and
L_g = the effective gage length between the innermost ends of the gage studs as shown in the mold diagram in Specification C 490.

10. Report

10.1 Report the following data such as are pertinent to the variables or combination of variables studied in the tests:

10.2 *Properties of Concrete Mixture*:

10.2.1 Type and proportions of cement, fine aggregate, and coarse aggregate, including maximum size and grading (or designated grading indices), and ratio of net water content to cement,

10.2.2 Kind and proportion of any addition or admixture used,

10.2.3 Air content of fresh concrete,

10.2.4 Density of fresh concrete,

10.2.5 Consistency of fresh concrete,

10.2.6 Air content of the hardened concrete, when available,

10.2.7 Indicate if the test specimens are cut from hardened concrete, and if so, state the size, shape, orientation of the specimens in the structure, and any other pertinent information available, and

10.2.8 Curing period.

10.3 *Mixing, Molding, and Curing Procedures*—Report any departures from the standard procedures for mixing, molding, and curing as prescribed in Section 7.

10.4 *Procedure*—Report which of the two procedures was used.

10.5 *Characteristics of Test Specimens*:

10.5.1 Dimensions of specimens at 0 cycles of freezing and thawing,

10.5.2 Mass of specimens at 0 cycles of freezing and thawing,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:25:23 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.5.3 Nominal gage length between embedded ends of gage studs, and

10.5.4 Any defects in each specimen present at 0 cycles of freezing and thawing.

10.6 *Results*:

10.6.1 Values for the durability factor of each specimen, calculated to the nearest whole number, and for the average durability factor for each group of similar specimens, also calculated to the nearest whole number, and the specified values for minimum relative dynamic modulus and maximum number of cycles (Note 9),

10.6.2 Values for the percent length change of each specimen and for the average percent length change for each group of similar specimens (Note 10),

10.6.3 Values of mass loss or gain for each specimen and average values for each group of similar specimens, and

10.6.4 Any defects in each specimen which develop during testing, and the number of cycles at which such defects were noted.

NOTE 10—It is recommended that the results of the test on each specimen, and the average of the results on each group of similar specimens, be plotted as curves showing the value of relative modulus of elasticity or percent length change against time expressed as the number of cycles of freezing and thawing.

11. Precision and Bias

11.1 The data used to develop the precision statements were obtained using apparatus and measurements in inch-pound units.

11.2 *Dynamic Modulus*:

11.2.1 *Within-Laboratory Precision (Single Beams)*—Criteria for judging the acceptability of durability factor results obtained by the two procedures in the same laboratory on concrete specimens made from the same batch of concrete or from two batches made with the same materials are given in Table 1. Precision data for length change (optional) are not available at this time.

TABLE 1 Within-Laboratory Durability Factor Precision for Single Beams

NOTE—The values given in Columns 2 and 4 are the standard deviations that have been found to be appropriate for Procedures A and B, respectively, for tests for which the average durability factor is in the corresponding range given in Column 1. The values given in Columns 3 and 5 are the corresponding limits that should not be exceeded by the difference between the results of two single test beams.

Range of Average Durability Factor	Procedure A		Procedure B	
	Standard Deviation[A]	Acceptable Range of Two Results[A]	Standard Deviation[A]	Acceptable Range of Two Results[A]
0 to 5	0.8	2.2	1.1	3.0
5 to 10	1.5	4.4	4.0	11.4
10 to 20	5.9	16.7	8.1	22.9
20 to 30	8.4	23.6	10.5	29.8
30 to 50	12.7	35.9	15.4	43.5
50 to 70	15.3	43.2	20.1	56.9
70 to 80	11.6	32.7	17.1	48.3
80 to 90	5.7	16.0	8.8	24.9
90 to 95	2.1	6.0	3.9	11.0
Over 95	1.1	3.1	2.0	5.7

[A] These numbers represent the (1S) and (D2S) limits as described in Practice C 670.

NOTE 11—The between-batch precision of durability factors has been found to be the same as the within-batch precision. Thus the limits given in this precision statement apply to specimens from different batches made with the same materials and mix design and having the same air content as well as to specimens from the same batch.

NOTE 12—The precision of this method for both procedures has been found to depend primarily on the average durability factor and not on the maximum N or minimum P specified for terminating the test nor on the size of the beams within limits. The data on which these precision statements are based cover maximum N's from 100 to 300 cycles, and minimum P's from 50 to 70 percent of E_0. The indexes of precision are thus valid at least over these ranges.

11.2.1.1 The different specimen sizes represented by the data include the following: 3 by 3 by 16-in [75 by 75 by 405-mm]; 3 by 3 by 16¼-in. [75 by 75 by 420-mm]; 3 by 4 by 16-in. [75 by 100 by 405-mm]; 3½ by 4½ by 16-in. [90 by 115 by 405-mm]; 3 by 3 by 11-in. [75 by 75 by 280-mm]; and 3½ by 4 by 16-in. [90 by 100 by 405-mm]; and 4 by 3 by 16-in. [100 by 75 by 405-mm]. The first dimension given represents the direction in which the specimens were vibrated in the test for fundamental transverse frequency. The most commonly used size was 3 by 4 by 16-in. [75 by 100 by 405-mm].

11.2.2 *Within-Laboratory Precision (Averages of Two or More Beams)*—Specifications sometimes call for comparisons between averages of two or more beams. Tables 2 and 3 give appropriate standard deviations and acceptable ranges for the two procedures for two averages of the number of test beams shown.

11.2.3 *Multilaboratory Precision*—No data are available for evaluation of multilaboratory precision. It is believed that a multilaboratory statement of precision is not appropriate because of the limited possibility that two or more laboratories will be performing freezing-and-thawing tests on the same concretes.

11.3 *Length Change*:

11.3.1 *Within-Laboratory Precision*—The single operator coefficient of variation has been determined to be 29.9 %. Therefore, results of two properly conducted tests by the same operator on samples from the same batch of concrete, using the same freeze-thaw apparatus and the same length comparator, should not differ from each other by more than 84.6 % of the average.

11.3.2 *Multilaboratory Precision*—No data are available for multilaboratory precision. It is believed that a multilaboratory statement of precision is not appropriate because of the limited possibility that two or more laboratories will be performing freezing-and-thawing tests on the same concretes.

11.4 *Bias*—This test method has no bias because the values determined can be defined only in terms of this test method.[3]

12. Keywords

12.1 accelerated testing; concrete-weathering tests; conditioning; freezing and thawing; resistance-frost

[3] Supporting data for the precision statement for length change have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR:C09–1017.

Designation: C 670 – 03

Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials[1]

This standard is issued under the fixed designation C 670; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope *

1.1 This practice supplements Practice E 177, in order to provide guidance in preparing precision and bias statements for ASTM test methods pertaining to certain construction materials (Note 1). Recommended forms for precision and bias statements are included. A discussion of the purpose and significance of these statements for the users of those test methods is also provided.

NOTE 1—Although under the jurisdiction of Committee C-9, this practice was developed jointly by Committees C-1, D-4, and C-9, and has been endorsed by all three committees. It has subsequently been adopted for use by Committee D-18.

2. Referenced Documents

2.1 *ASTM Standards:*

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)[2]

C 802 Practice for Conducting an Interlaboratory Test Program to Determine the Precision of Test Methods for Construction Materials[3]

E 177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods[4]

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.2 *one-sigma limit (1s)*—the fundamental statistic underlying all indexes of precision is the standard deviation of the population of measurements characteristic of the test method when the latter is applied under specifically prescribed conditions (a given system of causes). The terminology "one-sigma limit" (abbreviated (1s)) is used in Practice E 177 to denote the estimate of the standard deviation or sigma that is characteristic of the total statistical population. The one-sigma limit is an indication of the variability (as measured by the deviations above and below the average) of a large group of individual test results obtained under similar conditions.

3.2.1 *single-operator one-sigma limit*—the one-sigma limit for single-operator precision is a quantitative estimate of the variability of a large group of individual test results when the tests have been made on the same material by a single operator using the same apparatus in the same laboratory over a relatively short period of time. This statistic is the basic one used to calculate the single-operator index of precision given in the precision statement for guidance of the operator.

3.2.2 *multilaboratory one-sigma limit*—the one-sigma limit for multilaboratory precision is a quantitative estimate of the variability of a large group of individual test results when each test has been made in a different laboratory and every effort has been made to make the test portions of the material as nearly identical as possible. Under normal circumstances the estimates of one-sigma limit for multilaboratory precision are larger than those for single-operator precision, because different operators and different apparatus are being used in different laboratories for which the environment may be different.

3.2.3 *one-sigma limit in percent (1s%)*—in some cases the coefficient of variation is used in place of the standard deviation as the fundamental statistic. This statistic is termed the "one-sigma limit in percent" (abbreviated (1s%)) and is the appropriate standard deviation (1s) divided by the average of the measurements and expressed as a percent. When it is appropriate to use (1s%) in place of (1s) is discussed in Section 6.

3.3 *Acceptable Range of Results*:

3.3.1 *acceptable difference between two results*—the "difference two-sigma limit (d2s)" or "difference two-sigma limit in percent (d2s%)," as defined in Practice E 177, has been selected as the appropriate index of precision in most precision statements. These indexes indicate a maximum acceptable difference between two results obtained on test portions of the same material under the applicable system of causes described in 4.1.1 and 4.1.2 (or whatever other system of causes is appropriate). The (d2s) index is the difference between two individual test results that would be equaled or exceeded in the

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.94 on Evaluation of Data.

www.technobetar.ir

long run in only 1 case in 20 in the normal and correct operation of the method. The (d2s%) index is the difference between two individual test results expressed as a percent of their average that meets the same requirements. These indexes are calculated by multiplying the appropriate standard deviation (1s) or coefficient of variation (1s%) by the factor $2\sqrt{2}$ (equal to 2.83).

3.3.2 *acceptable range of more than two results*—in cases where the test method calls for more than two test results to be obtained, the range (difference between highest and lowest) of the group of test results must be compared to a maximum acceptable range for the applicable system of causes and number of test results. The range for different numbers of test results including two that would be equaled or exceeded in only 1 case in 20 is obtained by multiplying the appropriate standard deviation (1s) or coefficient of variation (1s%) by the appropriate factor from the second column of Table 1 (Note 2):

NOTE 2—It is important to note that when more than two test results are obtained, an index of precision for the difference between two results can not be used as a criterion for judging acceptability of the range of the group or for other pairs of results selected from the group.

3.3.3 *variations for single operators*—the system of causes designated for obtaining the quantitative guide to acceptable performance by an operator as stated in 4.1.1 leads to single-operator precision, using the system of modifiers given in Practice E 177 (Note 3). When two results by the same operator differ by more than (d2s) or (d2s%) or the range of more than two results exceeds that obtained by the method described in 3.2.2 there is a significantly large probability that an error has occurred and retests should be made as directed in Note 4.

NOTE 3—Single-operator precision is often referred to as "repeatability," and multilaboratory precision is often referred to as "reproducibility."

NOTE 4—It is beyond the scope of this practice to describe in detail what action should be taken in all cases when results occur that differ by more than the (d2s) limits or by more than the maximum allowable range. Such an occurrence is a warning that there may have been some error in the test procedure, or some departure from the prescribed conditions of the test on which the limits appearing in the test method are based; for example, faulty or misadjusted apparatus, improper conditions in the laboratory, etc. In judging whether or not results are in error, information other than the difference between two test results is needed. Often a review of the circumstances under which the test results in question were obtained will reveal some reason for a departure. In this case the data should be discarded and new test results obtained and evaluated separately. If no physical reason for a departure is found, retests should still be made, but the original tests should not be completely ignored. If the second set of results also differs by more than the applicable limit, the evidence is very strong that something is wrong or that a real difference exists between the two samples tested. If the second set produces a result within the limit, it may be taken as a valid test, but the operator or laboratory may then be suspected of producing erratic results, and a closer examination of the procedures would be in order. If knowledge about the test method in question indicates that certain actions may be appropriate in cases where deviant results occur, then such information should be included in the test method, but details of how this should be done will depend upon the particular test method.

9	4.4
10	4.5

[A] Values were obtained from Table A7 of "Order Statistics and Their Use in Testing and Estimation," Vol 1, by Leon Harter, Aerospace Research Laboratories, United States Air Force.

3.3.4 *variations between laboratories*—the system of causes designated for obtaining the quantitative guide for acceptance of results by different laboratories as given in 4.1.2 is multilaboratory precision, using the system of modifiers given in Practice E 177 (Note 3). When results differ by more than (d2s) there is a significantly large probability that one or both laboratories are in error or that a difference exists in the portions of material being used for the tests. In such cases, retests should be made. When possible, newly drawn test samples should be used for such retests as directed in Note 4.

3.4 *Number of Tests*:

3.4.1 *single test results*—the number of tests run must be taken into account when evaluating testing variations. Usually, the statistics used in evaluating precision and the indexes of precision based on them are based on the population distribution of single test results. When this is the case, the index of precision may be used in comparing single tests results only, not averages of two or more tests.

3.4.2 *test results based on averages*—if the precision statement is based on test results that are averages of two or more measurements, then the number of measurements averaged must be stated, and in using the index of precision, averages of exactly that number of measurements must be used. In some cases a test result is defined in the method as the average of two or more individual measurements. In such cases the index of precision for a test result applies to a test result as so defined, although indexes of precision for ranges of individual measurements within a laboratory may also be included as described in 3.3.3.

3.4.3 *precision of individual measurements averaged to obtain a test result*—when two or more measurements are averaged to obtain a test result, the range of the individual measurements may be examined to determine whether the latter meet the criterion of being valid individual measurements under the conditions of the test method. The maximum acceptable range for individual measurements is obtained by multiplying the appropriate standard deviation (1s) or, coefficient of variation (1s%) obtained from averages by the appropriate factor from the second column of Table 2 (Note 5). The maximum acceptable range for individual measurements obtained by this method may be included in the precision statement as an index of precision for individual measurements in the same laboratory as described in Example 8.

NOTE 5—This procedure is only valid if the individual measurements are subject to the same sources of variation as the test result. For example, the single-operator precision of Test Method C 109/C 109M mortar cubes is calculated from test results that include a contribution from variation among batches of mortar. Variation among individual cubes from a single batch does not contain this component of variation. Therefore, differences

[A] Values were calculated from Table 1.

among individual cubes from a single batch cannot be inferred from the single-operator standard deviation given in Test Method C 109/C 109M and the values in Table 2.

3.4.4 *multilaboratory precision expressed as a maximum allowable difference between two averages*—when the test method calls for the reporting of more than one test result, multi-laboratory precision may be expressed as a maximum allowable difference between averages of such groups, one from each laboratory, and both the (d2s) or (d2s%) limit for individual results and this maximum allowable difference of two averages may be included in the multilaboratory precision statement (Note 6). The maximum allowable difference for averages of a given number of test results, *n*, is obtained by dividing the appropriate (d2s) or (d2s%) limit by the square root of *n*.

NOTE 6—Note that this is not the same as the situation where a test result is defined as the average of two or more individual measurements. A given test method may include both features. It is important to bear in mind, however, that when more than one result is obtained in one or both laboratories, the (d2s) or (d2s%) limit may not be used as a criterion for judging the differences between selected pairs of results from the two laboratories.

3.5 *field versus laboratory tests*—precision indexes for ASTM test methods are normally based on results obtained in laboratories by competent operators using well-controlled equipment on test portions of materials for which precautions have been taken to ensure that they are as nearly alike as possible. Such precautions and the same level of competence may not be practicable for the usual quality control or routine acceptance testing. Therefore, the normal testing variation among laboratories engaged in quality control and acceptance testing of commercial materials may be larger than indicated by the relationship derived from the one-sigma limit for multilaboratory precision. In this case it is recommended that studies be made to determine the one-sigma limit for tests made under field conditions and realistic adjustments in specification tolerances be made accordingly.

4. General Concepts

4.1 A precision statement meeting the requirements of this practice normally contains two main elements described as follows:

4.1.1 *Single-Operator Precision*—A measure of the greatest difference between two results that would be considered acceptable when properly conducted repetitive determinations are made on the same material by a competent operator.

4.1.2 *Multilaboratory Precision*—A measure of the greatest difference between two test results that would be considered acceptable when properly conducted determinations are made by two different operators in different laboratories on portions of a material that are intended to be identical, or as nearly identical as possible.

4.2 *Other Measures of Precision*—The two elements described in 4.1.1 and 4.1.2 involve the main systems of causes of interest to users of test methods involving construction materials. In cases where other systems of causes apply, the appropriate statistics for those systems should be used and the appropriate combination of modifiers given in Practice E 177 should be used to describe those statistics.

4.3 *Use of Indexes of Precision in Specifications*—The indexes of precision described in this practice are to be used as guides to determine (with a prescribed degree of certainty) whether a given series of results can be considered as valid tests under the conditions assumed in the test method. Comparisons of test results with specification limits should be made only after there is reasonable assurance that the determinations are adequate. Writers of specifications have the responsibility of recognizing the variability of results characteristic of a given test method in setting specification limits, but indexes of precision of the test method should never be added to specification limits by the users of those specifications for the purpose of judging acceptance or rejection of materials.

4.4 *Use of Indexes of Precision for Qualifying an Operator*—Indexes of single-operator precision are sometimes used as a basis for qualifying an operator. The assumption is that results that do not differ by more than the stated index are indicative of proper performance of the test. However, this assumption is not necessarily correct. Uniform misunderstanding of instructions or maladjustments of equipment may produce consistent but erroneous test results. Thus, tests conducted for the purpose of qualifying an operator should be made on materials for which the measured characteristic is known, whenever possible, so that accuracy as well as precision can be evaluated. (See Practice E 177 for a discussion of the terms precision and accuracy.)

5. Basis for Precision Statement

5.1 In order to be valid the indexes of precision to be included in the precision statement as guides for the operator must be based on estimates of the precision of the test method obtained from a statistically designed interlaboratory series of tests. This series of tests must involve a sufficient number of laboratories, materials, and replicate measurements so that the results obtained provide reliable estimates of the true precision characteristic of the test method (Note 7). The procedures described in this practice are based on the assumption that the proper estimates of precision have already been obtained. Practice C 802 is a companion document to this one and describes techniques for conducting an interlaboratory study to obtain the needed estimates of precision. In the case where an approved standard test method is revised, the subcommittee having responsibility over the test method should determine whether the change(s) affect the validity of the existing

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:25:25 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

precision statement in the standard; and if so, should also revise the precision statement accordingly.

NOTE 7—The requirement of "reliable estimates of the true precision" presupposes an estimate obtained from a properly designed and executed interlaboratory series of tests involving at least 30 degrees of freedom for single-operator precision and at least 10 laboratories.

5.2 For many of the tests under the jurisdiction of Committees C-1, C-9, D-4 and D-18, there is an extensive backlog of interlaboratory test data in the reference sample program of the Cement and Concrete Reference Laboratory (CCRL) and the AASHTO Materials Reference Laboratory (AMRL). Where such data are available, a precision statement can be prepared for each test method based upon a much larger population of data than can normally be assembled in a round-robin program by merely carrying out the mathematical analysis like that illustrated in Appendix X1.

5.3 The Form and Style for ASTM Standards requires that data and details of the experiments used to determine precision and bias be filed as a research report at ASTM International Headquarters.

6. Form of Precision Statement

6.1 *Preface Information*—The Form and Style for ASTM Standards requires that the precision and bias statement include the reference numbers of the research report (paragraph 5.3) and a brief description of the experiments that will permit the user of the test method to judge the reliability of the data. Many precision and bias statements are based on non-SI data that have been converted to SI units. The following examples provide recommended wording for the preface to the precision and bias statement.

6.1.1 *Case 1*—Precision is stated in terms of percentage, such as coefficient of variation. The precision indices are non-dimensional and there would be no need for dual presentations. In this case, it is only necessary to state that the data were obtained in the inch-pound system.

Example 1:

The data used to develop the precision statement were obtained using the/(an earlier) version of this Test Method.

6.1.2 *Case 2*—For a combined standard in which both systems of units are to be used separately:

Example 2:

A. *Inch-pound (SI)*—The data used to develop the precision statement were obtained using the inch-pound version of this Test Method. The precision indices shown in parentheses are exact conversions of the values in inch-pound units.

B. *SI (inch-pound)*—The data used to develop the precision statement were obtained using the inch-pound version of this Test Method. The precision indices shown in SI units are exact conversions of the values in parentheses.

6.1.3 *Case 3*—For a standard that has been hard converted to SI units as standard and the inch-pound units are shown in parentheses for information only:

Example 3:

The data used to develop the precision statement were obtained using the previous inch-pound version of this Test Method. The precision indices are exact conversions of the values shown in parentheses.

6.1.4 *Case 4*—For a standard that has been converted to an SI standard and the inch-pound units have been dropped.

Example 4:

The data used to develop the precision statement were obtained using the previous inch-pound version of this Test Method. The indicated precision indices are exact conversions of the values obtained originally in inch-pound units.

6.2 *Manner of Expression*—If the test data on which the precision statement is to be based indicate that the standard deviation is essentially the same for all levels of the property being tested for which data are available, the one-sigma limit and the difference two-sigma limit shall be given in the precision statement expressed in the units of the measured property.

6.2.1 If the standard deviation is essentially proportional to the average for different levels of the property in question (that is, the coefficient of variation is essentially constant) then the "one-sigma limit in percent" (1s%) and difference two-sigma limit in percent (d2s%) shall be given. "One-sigma limit in percent" is, for the purposes of this practice, the same as the coefficient of variation. It is determined by dividing the standard deviation by the mean (average) value of available results and multiplying by 100. Similarly, "difference two-sigma limit in percent" is obtained by dividing (d2s) by the mean and multiplying by 100. When neither of these conditions is met, the applicable limits for specific ranges of the property shall be stated together with the specific ranges for which they are appropriate. The abbreviations (1s), (1s%), (d2s), and (d2s%) are given in footnotes as shown in the examples.

6.3 *Recommended Form of the Precision Statement*—When the proper estimates of precision are available (Note 7), the precision statement shall be written in the form of the appropriate example as given below for each available estimate of precision (standard deviation or coefficient of variation) and corresponding system of causes.

NOTE 8—Some of the following examples have been taken from test methods current at the time this practice was written and others are hypothetical. None of the examples should be taken as being quantitatively correct, since, even if taken from actual situations, the figures may have been subsequently revised.

6.3.1 *Form of Statements for Which One Estimate of Precision for Each System of Causes Applies*:

Example 1:

Precision—The multilaboratory standard deviation has been found to be 0.75 %[A]. Therefore, results of two properly conducted tests from two different laboratories on samples of the same cement are not expected to differ by more than 2.1 %.[A]

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

Example 2:

Precision—The single-operator standard deviation has been found to be 0.045 %.[A] Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 0.13 %.[A]

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:25:25 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Example 3:

Precision—The multilaboratory coefficient of variation has been found to be 5.0 %.[A] Therefore, results of two different laboratories on identical samples of a material are not expected to differ from each other by more than 14 % of their average.[A]

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

Example 4:

The single-operator coefficient of variation has been found to be 2.5 %.[A] Therefore, results of two properly conducted tests by the same operator on the same sample using the same viscometer are not expected to differ from each other by more than 7.0 % of their average.[A]

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

6.3.2 *Form of Statements for Which the Precision, Measured by Either the Standard Deviation or the Coefficient of Variation, is not Constant over the Range of Values of the Property in Question*:

6.3.2.1 If the precision limit given applies only over a certain range of the property of the material being measured, this shall be indicated by inserting the words "over the range from __ to __ , or "below", or "above" a certain limit after the words "standard deviation" or "coefficient of variation" in the first sentence of the statement. If precision limits have been obtained for more than one range of the property, separate statements shall be written for each range. The applicable range should also be indicated in subparagraph headings if separate subparagraphs are used as follows:

Example 5:

Single-Operator Precision—The single-operator standard deviation has been found to be 1.4°F (0.8°C)[A] for flash points below 220°F (104°C) and 7.1°F (3.9°C)[A] for flash points above 220°F. Therefore, results of two properly conducted tests by the same operator on the same material are not expected to differ from each other by more than 4°F (2.2°C)[A] for flash points below 220°F or by more than 20°F (11.1°C)[A] for flash points above 220°F.

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

Example 6:

Multilaboratory Precision—The multilaboratory standard deviation has been found to be 2.1°F (1.2°C)[A] for flash points below 220°F (104°C) and 8.8°F (4.9°C)[A] for flash points above 220°F. Therefore, results of two properly conducted tests on the same material in two different laboratories are not expected to differ from each other by more than 6°F (3.3°C)[A] for flash points below 220°F or by more than 25°F (13.9°C)[A] for flash points above 220°F.

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

6.3.2.2 If the precision, whether expressed as an absolute limit or a percent, is not constant over the given range or for all the materials tested, but the limit given is the maximum value of the index of precision, the abbreviation "max" shall be inserted after the closing parenthesis of the abbreviation for the type of limit in the footnote: that is (1s) max, or (1s%) max. Also the word" maximum" shall be inserted in the first sentence of the precision statement. This form should rarely be used, and then only as a last resort. See the Irregular or Nonlinear Relationship Between Standard Deviation, Coefficient of Variation and Average Level section in Practice C 802.

Example 7:

Precision—The maximum single-operator-machine-multibatch coefficient of variation has been found to be 4.25 %.[A] Therefore, results of two properly conducted tests by the same operator of concrete cylinders from two different batches are not expected to differ from each other by more than 12 % of their average.[A]

[A] These numbers represent, respectively, the (1s%) and (d2s%) max limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

6.3.2.3 See Examples 11 and 12 for alternative tabular form of precision statements.

6.4 *Form of Statement for Which a Test Result is Defined as the Average of a Specified Number of Measurements*:

Example 8:

Single-Operator Precision—The single-operator standard deviation of a single test result (where a test result is, as defined in this test method, the average of three separate measurements) has been found to be 2.0 %.[A] Therefore, results of two properly conducted tests (each consisting of the average of three individual measurements) are not expected to differ by more than 5.7 %[A] and the range (difference between highest and lowest) of the three individual measurements used in calculating the average are not expected to exceed 11.4 %.[B]

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

[B] Calculated as described in 3.4.3 of Practice C 670.

6.5 *Form of Statements for Which More than One Test Result is Reported*:

Example 9:

Single-Operator Precision—The single-operator standard deviation of a single test result has been found to be 125 psi (861 kPa). Therefore, results of two properly conducted tests by the same operator are not expected to differ by more than 350 psi (2413 kPa).[A] The test method calls for reporting three test results. The range (difference between highest and lowest) of the three test results obtained by the same operator are not expected to exceed 410 psi (2827 kPa).[B]

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

[B] Calculated as described in 3.4.3 of Practice C 670.

Example 10:

Multilaboratory Precision—The multilaboratory standard deviation of a single test result has been found to be 225 psi (1551 kPa). Therefore, results of two properly-conducted tests in different laboratories on the same material are not expected to differ by more than 640 psi (4413 kPa).[A] The averages of three test results in two different laboratories are not expected to differ by more than 370 psi (2551 kPa).[B]

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

[B] Calculated as described in 3.4.3 of Practice C 670.

6.6 *Alternative Form of the Precision Statement*—In cases where separate statements for a number of different materials or a number of different levels of a property are involved, the form recommended in 6.2 may become cumbersome. In such cases, the statement may be written in table form in accordance with the following examples:

Example 11:

Precision—Criteria for judging the acceptability of solubility test results obtained by this method are given as follows:

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 9—The figures given in Column 2 are the standard deviations that have been found to be appropriate for the materials and conditions of test described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests.

Material and Type Index	Standard Deviation[A]	Acceptable Range of Two Results[A]
Single-operator precision:		
Asphalts, solubility more than 99 %[B]	0.035	0.10
Tars, liquid grades[C]	0.11	0.31
Tars, semi-solid[A]	0.17	0.48
Multilaboratory precision:		
Asphalts, solubility more than 99 %[C]	0.090	0.26
Tars, liquid grades[C]	0.22	0.61
Tars, semi-solid[C]	0.83	2.34

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM Practice C 670, for Preparing Precision Statements for Test Methods for Construction Materials.

[B] Applicable when either carbon disulfide, carbon tetrachloride, trichloroethylene, or benzene are used.

[C] Applicable when carbon disulfide is used.

Example 12:

Precision—Criteria for judging the acceptability of viscosity test results obtained by this method are given as follows:

NOTE 10—The figures given in Column 2 are the coefficients of variation that have been found to be appropriate for the materials and conditions of test described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests expressed as a percent of their mean.

Material and Type Index	Coefficient of Variation (percent of mean)[A]	Acceptable Range of Two Results (percent of mean)[A]
Single-operator precision:		
Asphalt Cements at 275°F (135°C)	0.64	1.8
Liquid asphalts at 140°F (60°C):		
below 3000 cSt	0.53	1.5
3000 cSt and above	0.71	2.0
Multilaboratory precision:		
Asphalt cements at 275°F (135°C)	3.1	8.8
Liquid asphalts at 140°F (60°C):		
below 3000 cSt	1.06	3.0
3000 cSt and above	3.11	9.0

[A] These numbers represent, respectively, the (1s%) and (d2s%) limits as described in this Practice.

7. Bias Statement

7.1 Bias is a systematic error inherent in the test method that contributes to the difference between a population mean of the measurements or test results and an accepted reference or true value. In any test method, tolerances are placed on the accuracy of measuring equipment. All tests made with a given set of equipment which has an error within the permitted tolerance will produce results with a small consistent bias, but that bias is not inherent in the test method and is not included in the bias statement for the test method. There are two conditions which permit the bias of a test method to be estimated: (1) a standard reference sample of known value has been tested by the test method, and (2) the test method has been applied to a sample which has been compounded in such a manner that the true value of the property being measured is known, such as may be the case, for example, in a test for cement content of concrete. Judgment is required to determine whether a potential reference sample is suitable for the purpose. For example, a metal bar of accurately known physical properties might not be suitable for establishing the bias of a test for the corresponding concrete properties because the level of values may differ by an order of magnitude. When it is possible to examine bias, it is necessary to determine whether there are enough data to determine statistically that the mean of the test results is significantly different from the true value. When it is, an absolute measure of bias cannot be made, but confidence limits may be placed on the bias.

7.2 For most test methods there is no reference value available. In those cases a statement based on one of the following may be used:

Example 1:

Bias—The test method has no bias because the values determined can be defined only in terms of the test method.

Example 2:

Bias—Since there is no accepted reference material suitable for determining the bias in this test method, no statement on bias is made.

Example 3:

Bias—No justifiable statement can be made on the bias of this test method because (insert here the reason).

7.3 Where it is possible to determine if bias exists, proceed as follows.

7.3.1 Form at least 30 pairs of results in which X_1 is the known reference value and X_2 is the experimental value. Form the quotient

$$\frac{t = \bar{X}_2 - \bar{X}_1}{s/\sqrt{N}} \quad (1)$$

where:

$\bar{X}_1$ = the mean of the reference values,
$\bar{X}_2$ = the mean of the experimental values,
s = the standard deviation of the differences $(X_2 - X_1)$, and
N = the number of pairs.

This quotient has a t distribution with N−1 degrees of freedom. Reject the hypothesis that no bias exists if t < t½ ½ α or t > t1−½ α. Usually α, the level of significance, will be taken as 0.05. For an α of 0.05 and a sample of 30 pairs, the above inequalities reduce to t < − 2.05 or t > 2.05. Thus if the calculated value of t falls between − 2.05 and 2.05, it is concluded that there is no bias.

7.3.2 Where the value of t falls in the rejection range, the confidence limits for bias are:

$$\bar{X}_2 - \bar{X}_1 + t1/2\,\alpha\, s\sqrt{1/N} \text{ and } \bar{X}_2 - {}^{-}X_1 + t1-1/2\,\alpha\, s\sqrt{1/N} \quad (2)$$

NOTE 11—In the above expression the first value of t is always negative.

7.3.3 In some cases the bias may be a function of level of the quantity being measured. If differences in means for

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

different levels are significantly different from each other, the above procedure may be applied to each such level.

7.3.4 Where a test for bias has been made, a statement based on one of the following may be made:

Example 1:

Bias—When experimental results are compared with accepted reference values (or known values from accurately compounded specimens), the test method is found to have no bias.

Example 2:

Bias—When experimental results are compared with accepted reference values (or known values from accurately compounded specimens), the bias of the test method is found with 95 % confidence to lie between 0.0062 and 0.0071.

Example 3:

Bias—When experimental results are compared with accepted reference values (or known values from accurately compounded specimens), the bias of the test method is found with 95 % confidence to lie between − 0.0004 and − 0.0001 in the range of 6 to 10 and between − 0.0006 and − 0.0002 in the range of 10 to 15.

APPENDIX

(Nonmandatory Information)

X1. USE OF CCRL AND AMRL REFERENCE SAMPLE RESULTS FOR PRECISION STATEMENTS

X1.1 *Introduction:*

X1.1.1 Where the test method has been applied to a reference sample distributed by CCRL or AMRL, use the data from Table 1, Summary of Results, analyze them in accordance with Practice C 802, and formulate precision statements conforming to the requirements of this practice.

X1.1.2 The example which follows uses data from Table 1, Summary of Results, of a CCRL reference sample report (shown in Fig. X1.1). Data from tests for AMRL are reported in the same format.

X1.2 *Use of Table I, CCRL Report:*

X1.2.1 The compressive strength data for Samples 35 and 36 are selected for illustrating the use of Table I of the CCRL Reference sample report. They provide four levels of the measured value.

X1.2.2 The procedure consists largely of selecting appropriate values from Table 1of the CCRL report (Fig. X1.1) and placing them in the correct location in the "Approximate Values (Upper 5 % Level) for the Ratio of Highest to Lowest Variance" Table of Practice C 802 (shown in Fig. X1.2).

NOTE X1.1—In this particular example it was necessary to select the most appropriate lines of data to use in CCRL Table I. For the three-day strength results only the complete set of data before elimination of outliers

TABLE 5 (from ASTM C 802)

Material	Average	Standard Deviation		Coefficient of Variation	
		Within-Laboratory	Between-Laboratory	Within-Laboratory	Between-Laboratory
3 day strength (36)	1-2340	5-187	7-224	11-8.00%	15-9.56%
3 day strength (35)	2-3036		8-243	12-6.16%	16-8.01%
7 day strength (36)	3-3498	6-132	9-235	13-3.79%	17-6.73%
7 day strength (35)	4-4257		10-239	14-3.10%	18-5.62%
Average		160	235		

FIG. X1.2 Placement of Selected Data From Table I of CCRL Reference Sample Report into Table 5 of Practice C 802

permitted a statistically valid estimate of within-laboratory standard deviation (or random error). Thus, no choice was possible. For the 7 day test, the random error could be calculated both with and without outliers. The data with outliers removed were considered preferable.

X1.2.3 Place the information indicated by the circles numbered 1, 2, 3, and 4 in Table I, in order, in the "Average" column of the "Approximate Values (Upper 5 % Level) for the Ratio of Highest to Lowest Variance" Table. Items are placed in order of increasing magnitude.

X1.2.4 Place Circles 5 and 6 in "Within-Laboratory Standard Deviation" column of the "Approximate Values (Upper 5 % Level) for the Ratio of Highest to Lowest Variance" Table in the order shown.

X1.2.5 Place Circles 7, 8, 9, and 10 in order in the" Between-Laboratory Standard Deviation" column of the "Approximate Values (Upper 5 % Level) for the Ratio of Highest to Lowest Variance" Table.

X1.2.6 Place Circles 11, 12, 13, and 14 in order in the "Within-Laboratory Coefficient of Variation" column of the "Approximate Values (Upper 5 % Level) for the Ratio of Highest to Lowest Variance" Table.

X1.2.7 Place Circles 15, 16, 17, and 18 in order in the "Between-Laboratory Coefficient of Variation" column of the "Approximate Values (Upper 5 % Level) for the Ratio of Highest to Lowest Variance" Table.

X1.2.8 As discussed in the Determination of Form of Precision Statement section of Practice C 802, examine the" Approximate Values (Upper 5 % Level) for the Ratio of Highest to Lowest Variance" table to determine whether either the standard deviations or coefficients of variation are independent of level of measurement. Note that in this case the standard deviations are essentially constant.

X1.2.9 Write the precision statement based on standard deviation in accordance with the Estimates of Precision section of this practice, as shown in X1.3. In both cases, the standard deviation is multiplied by $2\sqrt{2}$ to obtain the d2s value, where d2s is the "difference two-sigma limit" as defined in Practice E 177.

X1.3 *Sample Precision Statement:*

X1.3.1 The single-operator standard deviation has been found to be 160 psi (1100 kPa) (the "one-sigma" [1s] limit per Practice C 670) throughout the range 2300 to 4300 psi (15 860 to 29 650 kPa). Therefore, results of two properly conducted tests by the same operator on similar batches are not expected to differ by more than 453 psi (3123 kPa) (d2s limit).

X1.3.2 The multilaboratory standard deviation has been found to be 235 psi (1620 kPa) (1s limit) throughout the range 2300 to 4300 psi (15 860 to 29 650 kPa). Therefore, results of two different laboratories on similar batches are not expected to differ from each other by more than 665 psi (4585 kPa) (d2s limit).

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this standard since the last issue (C 670-96) that may impact the use of this standard.

(1) Editorial revisions were made to sample precision statements.

Designation: C 672/C 672M – 03

Standard Test Method for Scaling Resistance of Concrete Surfaces Exposed to Deicing Chemicals[1]

This standard is issued under the fixed designation C 672/C 672M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the resistance to scaling of a horizontal concrete surface exposed to freezing-and-thawing cycles in the presence of deicing chemicals. It is intended for use in evaluating this surface resistance qualitatively by visual examination.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 143/C 143M Test Method for Slump of Hydraulic Cement Concrete

C 156 Test Method for Water Retention by Concrete Curing Materials

C 173/C 173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method

C 233 Test Method for Air-Entraining Admixtures for Concrete

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

3. Significance and Use

3.1 This test method can be used to evaluate the effect of mixture proportioning, surface treatment, curing, or other variables on resistance to scaling.

3.2 This test method is not intended to be used in determining the durability of aggregates or other ingredients of the concrete.

3.3 No relationship has been established between the frost immunity of specimens cut from hardened concrete and specimens prepared in the laboratory.

4. Apparatus

4.1 *Freezing Equipment*—A chest or room of sufficient size to hold the specimens and capable of lowering the temperature of the specimens to −18 ± 3°C [0 ± 5°F] within 16 to 18 h and maintaining this temperature with a full load of specimens.

4.2 *Molds*, of the proper size for the test specimens to be used, and conforming to the requirements of Practice C 192/C 192M.

4.3 *Tamping Rod*, conforming to the requirements of Test Method C 143/C 143M.

4.4 *Small Tools*—Wood strike-off board, steel trowel, and moderately stiff bristle brush suitable for providing the desired texture of the test surface.

4.5 *Slump Cone*, conforming to the requirements of Test Method C 143/C 143M.

4.6 *Air Meter*, conforming to the requirements of Test Method C 173/C 173M or Test Method C 231.

4.7 *Scales*, conforming to the requirements of Practice C 192/C 192M.

4.8 *Concrete Mixer*, conforming to the requirements of Practice C 192/C 192M.

5. Proportioning and Mixing

5.1 *Proportioning*—The air content, cement factor, slump, water-to-cement ratio, and other characteristics of the concrete and its ingredients shall be those appropriate for the purposes for which the tests are to be made. Concrete with the following characteristics has been found useful for the purposes for which this test method is generally used, such as evaluation of a surface treatment for prevention of scaling: (*a*) non-air-entrained; (*b*) cement content, 335 ± 5 kg/m^3[565 ± 10 lb/yd^3]; (*c*) slump, 75 ± 15 mm [3 ± 0.5 in.]; and (*d*) durable

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.67 on Resistance of Concrete to Its Environment.

Current edition approved Dec. 1, 2003. Published January 2004. Originally published as C 672 – 71 T. Last previous edition C 672 – 92.

www.technobetar.ir

aggregate (Note 1) of 25-mm [1-in.] maximum size. If air-entrained concrete is to be used for comparative purposes, it shall have the same proportions as that with which it is being compared and the air content shall be 6 ± 1 % (Note 2).

NOTE 1—Care should be taken to use an aggregate which has a good performance record in freezing and thawing exposure.

NOTE 2—For additional information pertaining to air-entrained concrete proportions, see Test Method C 233.

5.2 *Mixing and Testing of Freshly Mixed Concrete*—Machine mix and test in conformance with the applicable provisions of Practice C 192/C 192M.

6. Specimens

6.1 Specimens shall have a surface area of at least 0.045 m^2[72 $in.^2$] and be at least 75 mm [3.0 in.] in depth. At least two duplicate specimens for each combination of variables to be tested shall be made.

6.2 *Fabrication of Specimens*:

6.2.1 Coat the inside surface of the mold with a light coat of mineral oil or a suitable nonreactive release material just prior to fabrication of the specimens.

6.2.2 Fill the mold in one layer. Rod one time for each 1400 mm^2[2 $in.^2$] of surface, leaving a slight excess of material after the final rodding. Tap the mold to close any voids and spade around the periphery with a flat trowel. Level the surface with several passes of a wood strike-off board.

6.2.3 After the concrete has stopped bleeding, finish the surface with three sawing-motion passes of a wood strike-off board. Brush the surface with a medium-stiff brush as a final finishing operation unless another method of surface finishing such as steel-troweled surface, burlap drag, or a troweled-in surface treatment is to be evaluated.

6.2.4 After the finishing operation, place a dike about 25 mm [1 in.] wide and 20 mm [¾ in.] high along the perimeter of the top surface of the specimens. The dike may be made of any material that will adhere to the specimen and serve to maintain the brine pond on top of the specimen throughout the period of the test. If the dike is of mortar, it shall be applied immediately after the final finishing operation, and the surface where the mortar is to be applied shall be roughened to provide a mechanical bond. If an epoxy mortar dike is to be formed or a proven satisfactory bonding material is used to bond the dike to the surface, the dike may be applied after the concrete has set. Any pre-applied coating shall be removed from the bond area prior to the application of the dike.

6.2.5 Test specimens may also be slabs meeting the test area requirements cut from hardened concrete in a structure. In this case, the specimens shall not be cut or damaged on the surface to be tested and should not be allowed to dry to a moisture condition below that of the structure from which they have been taken. This may be accomplished by wrapping the specimens in some waterproof material or by other suitable means.

7. Curing

7.1 Except where the method of curing is an element of study or is otherwise specified, cover the specimens with a polyethylene sheet immediately after finishing. The sheet shall not be permitted to contact the concrete surface.

7.2 Remove the specimens from the molds at an age of 20 to 24 h after addition of water to the mix and place in moist storage as provided for in Specification C 511.

7.3 If concretes with differing rates of strength gain are to be compared, maintain the specimens in moist storage until such time as the desired strength level has been obtained. When the desired strength level has been reached, remove the specimens from moist storage and store in air for 14 days at 23.0 ± 2.0°C [73.5 ± 3.5°F] and 45 to 55 % relative humidity.

7.4 For all other concretes, remove the specimens from moist storage at the age of 14 days and store in air for 14 days at 23.0 ± 2.0°C [73.5 ± 3.5°F] and 45 to 55 % relative humidity.

8. Protective Coatings

8.1 If protective coatings are to be evaluated, apply them in accordance with the manufacturer's recommendations regarding quantity and method of application at the age of 21 days. When a material proposed as dual-purpose curing compound/protective coating is being evaluated, apply it at the proper time of application for curing compounds, as described in Test Method C 156.

NOTE 3—When evaluating penetration-type coatings for application to pavement surfaces subject to traffic wear, it may be desirable to abrade the treated surface of the test specimens by sufficient wire brushing to break any films remaining on the surface after drying.

9. Procedure

9.1 After completion of moist and air curing, cover the flat surface of the specimen with approximately 6 mm (¼ in.) of a solution of calcium chloride and water, having a concentration such that each 100 mL of solution contains 4 g of anhydrous calcium chloride.

NOTE 4—Other chemical deicers and different concentrations may be used when there is a need to evaluate their specific effect. In addition, a variation in the procedure may be adopted whereby the deicer is added directly to the ice produced by freezing a 6 mm (¼ in.) layer of fresh water during the freezing portion of the cycle, discarding and flushing the resulting solution off the surface at the end of the thawing portion of the cycle and then repeating the cycle. If this procedure is adopted, it should be recognized that about 100 cycles or more will be required to evaluate a surface treatment.

9.2 Place specimens in a freezing environment for 16 to 18 h. At the end of this time remove them from the freezer and place them in laboratory air at 23 ± 2.0°C [73.5 ± 3.5°F] and a relative humidity of 45 to 55 % for 6 to 8 h. Add water between each cycle as necessary to maintain the proper depth of solution. Repeat this cycle daily, flushing off the surface thoroughly at the end of each 5 cycles. After making a visual examination, replace the solution and continue the test.

NOTE 5—Generally, 50 cycles are sufficient to evaluate a surface or surface treatment. However, where comparative tests are being made, it is recommended that the tests be continued beyond the recommended minimum number of cycles if differences have not developed.

9.3 Either keep specimens frozen during any interruption in the daily cycling or maintain them in a damp condition after removal of solution and flushing surfaces.

www.technobetar.ir

10. Report

10.1 Report the following:

10.1.1 Cement content, water-cement ratio, the kind and amount of any admixture, slump, and air content of mix,

10.1.2 Curing and drying if other than standard,

10.1.3 Type of surface treatment, time of application, and rate of application,

10.1.4 Type of deicer, whether solution or solid, concentration of the solution if used, rate of application, and time of application,

10.1.5 Visual rating of the surface after 5, 10, 15, 25, and every 25 cycles thereafter in accordance with the following scale:

Rating	Condition of Surface
0	no scaling
1	very slight scaling (3 mm [⅛ in.] depth, max, no coarse aggregate visible)
2	slight to moderate scaling
3	moderate scaling (some coarse aggregate visible)
4	moderate to severe scaling
5	severe scaling (coarse aggregate visible over entire surface)

10.1.6 If the test specimens are cut from hardened concrete, the size, shape, orientation of the specimens in the structure, and any other pertinent information available shall be included in the report, and

10.1.7 Photographs or a word description of the surface, or both, also should be included where possible.

11. Precision and Bias

11.1 In statistical analyses of data obtained by the use of this test method, it is necessary to recognize that the ratings are ranks, and as such, may not be appropriately subjected to analyses based on the calculation of averages and standard deviations nor to other techniques that assume continuous distribution of measurement on at least an interval scale. If groups of similar specimens are to be reported or compared with other groups, such nonparametric quantities as the median and the range may be used.

12. Keywords

12.1 concrete-weathering tests; deicing chemicals; freezing and thawing; resistance-frost; resistance-scaling

Designation: C 672/C 672M – 03

Standard Test Method for Scaling Resistance of Concrete Surfaces Exposed to Deicing Chemicals[1]

This standard is issued under the fixed designation C 672/C 672M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the resistance to scaling of a horizontal concrete surface exposed to freezing-and-thawing cycles in the presence of deicing chemicals. It is intended for use in evaluating this surface resistance qualitatively by visual examination.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 143/C 143M Test Method for Slump of Hydraulic Cement Concrete

C 156 Test Method for Water Retention by Concrete Curing Materials

C 173/C 173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method

C 233 Test Method for Air-Entraining Admixtures for Concrete

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

3. Significance and Use

3.1 This test method can be used to evaluate the effect of mixture proportioning, surface treatment, curing, or other variables on resistance to scaling.

3.2 This test method is not intended to be used in determining the durability of aggregates or other ingredients of the concrete.

3.3 No relationship has been established between the frost immunity of specimens cut from hardened concrete and specimens prepared in the laboratory.

4. Apparatus

4.1 *Freezing Equipment*—A chest or room of sufficient size to hold the specimens and capable of lowering the temperature of the specimens to −18 ± 3°C [0 ± 5°F] within 16 to 18 h and maintaining this temperature with a full load of specimens.

4.2 *Molds*, of the proper size for the test specimens to be used, and conforming to the requirements of Practice C 192/C 192M.

4.3 *Tamping Rod*, conforming to the requirements of Test Method C 143/C 143M.

4.4 *Small Tools*—Wood strike-off board, steel trowel, and moderately stiff bristle brush suitable for providing the desired texture of the test surface.

4.5 *Slump Cone*, conforming to the requirements of Test Method C 143/C 143M.

4.6 *Air Meter*, conforming to the requirements of Test Method C 173/C 173M or Test Method C 231.

4.7 *Scales*, conforming to the requirements of Practice C 192/C 192M.

4.8 *Concrete Mixer*, conforming to the requirements of Practice C 192/C 192M.

5. Proportioning and Mixing

5.1 *Proportioning*—The air content, cement factor, slump, water-to-cement ratio, and other characteristics of the concrete and its ingredients shall be those appropriate for the purposes for which the tests are to be made. Concrete with the following characteristics has been found useful for the purposes for which this test method is generally used, such as evaluation of a surface treatment for prevention of scaling: (*a*) non-air-entrained; (*b*) cement content, 335 ± 5 kg/m^3[565 ± 10 lb/yd^3]; (*c*) slump, 75 ± 15 mm [3 ± 0.5 in.]; and (*d*) durable

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.67 on Resistance of Concrete to Its Environment.

Current edition approved Dec. 1, 2003. Published January 2004. Originally published as C 672 – 71 T. Last previous edition C 672 – 92.

www.technobetar.ir

aggregate (Note 1) of 25-mm [1-in.] maximum size. If air-entrained concrete is to be used for comparative purposes, it shall have the same proportions as that with which it is being compared and the air content shall be 6 ± 1 % (Note 2).

NOTE 1—Care should be taken to use an aggregate which has a good performance record in freezing and thawing exposure.

NOTE 2—For additional information pertaining to air-entrained concrete proportions, see Test Method C 233.

5.2 *Mixing and Testing of Freshly Mixed Concrete*—Machine mix and test in conformance with the applicable provisions of Practice C 192/C 192M.

6. Specimens

6.1 Specimens shall have a surface area of at least 0.045 m^2[72 $in.^2$] and be at least 75 mm [3.0 in.] in depth. At least two duplicate specimens for each combination of variables to be tested shall be made.

6.2 *Fabrication of Specimens*:

6.2.1 Coat the inside surface of the mold with a light coat of mineral oil or a suitable nonreactive release material just prior to fabrication of the specimens.

6.2.2 Fill the mold in one layer. Rod one time for each 1400 mm^2[2 $in.^2$] of surface, leaving a slight excess of material after the final rodding. Tap the mold to close any voids and spade around the periphery with a flat trowel. Level the surface with several passes of a wood strike-off board.

6.2.3 After the concrete has stopped bleeding, finish the surface with three sawing-motion passes of a wood strike-off board. Brush the surface with a medium-stiff brush as a final finishing operation unless another method of surface finishing such as steel-troweled surface, burlap drag, or a troweled-in surface treatment is to be evaluated.

6.2.4 After the finishing operation, place a dike about 25 mm [1 in.] wide and 20 mm [¾ in.] high along the perimeter of the top surface of the specimens. The dike may be made of any material that will adhere to the specimen and serve to maintain the brine pond on top of the specimen throughout the period of the test. If the dike is of mortar, it shall be applied immediately after the final finishing operation, and the surface where the mortar is to be applied shall be roughened to provide a mechanical bond. If an epoxy mortar dike is to be formed or a proven satisfactory bonding material is used to bond the dike to the surface, the dike may be applied after the concrete has set. Any pre-applied coating shall be removed from the bond area prior to the application of the dike.

6.2.5 Test specimens may also be slabs meeting the test area requirements cut from hardened concrete in a structure. In this case, the specimens shall not be cut or damaged on the surface to be tested and should not be allowed to dry to a moisture condition below that of the structure from which they have been taken. This may be accomplished by wrapping the specimens in some waterproof material or by other suitable means.

7. Curing

7.1 Except where the method of curing is an element of study or is otherwise specified, cover the specimens with a polyethylene sheet immediately after finishing. The sheet shall not be permitted to contact the concrete surface.

7.2 Remove the specimens from the molds at an age of 20 to 24 h after addition of water to the mix and place in moist storage as provided for in Specification C 511.

7.3 If concretes with differing rates of strength gain are to be compared, maintain the specimens in moist storage until such time as the desired strength level has been obtained. When the desired strength level has been reached, remove the specimens from moist storage and store in air for 14 days at 23.0 ± 2.0°C [73.5 ± 3.5°F] and 45 to 55 % relative humidity.

7.4 For all other concretes, remove the specimens from moist storage at the age of 14 days and store in air for 14 days at 23.0 ± 2.0°C [73.5 ± 3.5°F] and 45 to 55 % relative humidity.

8. Protective Coatings

8.1 If protective coatings are to be evaluated, apply them in accordance with the manufacturer's recommendations regarding quantity and method of application at the age of 21 days. When a material proposed as dual-purpose curing compound/protective coating is being evaluated, apply it at the proper time of application for curing compounds, as described in Test Method C 156.

NOTE 3—When evaluating penetration-type coatings for application to pavement surfaces subject to traffic wear, it may be desirable to abrade the treated surface of the test specimens by sufficient wire brushing to break any films remaining on the surface after drying.

9. Procedure

9.1 After completion of moist and air curing, cover the flat surface of the specimen with approximately 6 mm (¼ in.) of a solution of calcium chloride and water, having a concentration such that each 100 mL of solution contains 4 g of anhydrous calcium chloride.

NOTE 4—Other chemical deicers and different concentrations may be used when there is a need to evaluate their specific effect. In addition, a variation in the procedure may be adopted whereby the deicer is added directly to the ice produced by freezing a 6 mm (¼ in.) layer of fresh water during the freezing portion of the cycle, discarding and flushing the resulting solution off the surface at the end of the thawing portion of the cycle and then repeating the cycle. If this procedure is adopted, it should be recognized that about 100 cycles or more will be required to evaluate a surface treatment.

9.2 Place specimens in a freezing environment for 16 to 18 h. At the end of this time remove them from the freezer and place them in laboratory air at 23 ± 2.0°C [73.5 ± 3.5°F] and a relative humidity of 45 to 55 % for 6 to 8 h. Add water between each cycle as necessary to maintain the proper depth of solution. Repeat this cycle daily, flushing off the surface thoroughly at the end of each 5 cycles. After making a visual examination, replace the solution and continue the test.

NOTE 5—Generally, 50 cycles are sufficient to evaluate a surface or surface treatment. However, where comparative tests are being made, it is recommended that the tests be continued beyond the recommended minimum number of cycles if differences have not developed.

9.3 Either keep specimens frozen during any interruption in the daily cycling or maintain them in a damp condition after removal of solution and flushing surfaces.

Designation: C 684 – 99 (Reapproved 2003)

Standard Test Method for Making, Accelerated Curing, and Testing Concrete Compression Test Specimens[1]

This standard is issued under the fixed designation C 684; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers four procedures for making, curing, and testing specimens of concrete stored under conditions intended to accelerate the development of strength. The four procedures are: Procedure A—Warm Water Method, Procedure B—Boiling Water Method, Procedure C—Autogenous Curing Method, and Procedure D—High Temperature and Pressure Method.

1.2 The values stated in SI units are to be regarded as standard. The values given in parentheses are provided for information purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* See Section 9 and Note 9 and Note 14 for specific warnings and precautions.

3. Terminology

3.1 There are no terms in this standard that require new or other than dictionary definitions.

4. Summary of Test Method

4.1 Concrete specimens are exposed to accelerated curing conditions that permit the specimens to develop a significant portion of their ultimate strength within a time period ranging from 5 to 49 h, depending upon the procedure that is used. Procedures A and B utilize storage of specimens in heated water at elevated curing temperatures without moisture loss. The primary function of the moderately heated water used in Procedure A is to serve as insulation to conserve the heat generated by hydration. The temperature level employed in Procedure B provides thermal acceleration. Procedure C involves storage of specimens in insulated curing containers in which the elevated curing temperature is obtained from heat of hydration of the cement. The sealed containers also prevent moisture loss. Procedure D involves simultaneous application of elevated temperature and pressure to the concrete using special containers. Sampling and testing procedures are the same as for normally cured specimens (see Practice C 172 and Test Method C 39, respectively).

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.61 on Testing for Strength.

Current edition approved Nov. 10, 1999. Published February 2000. Originally approved in 1971. Last previous edition approved in 1999 as C 684 – 99.

www.technobetar.ir

4.2 Important characteristics of these procedures are shown in Table 1.

5. Significance and Use

5.1 The accelerated curing procedures provide, at the earliest practical time, an indication of the potential strength of a specific concrete mixture. These procedures also provide information on the variability of the production process for use in quality control.

5.2 The accelerated early strength obtained from any of the procedures in this test method can be used to evaluate concrete strengths in the same way conventional 28-day strengths have been used in the past, with suitable changes in the expected strength values. Since the practice of using strength values obtained from standard-cured cylinders at 28 days is long established and widespread, the results of accelerated strength tests are often used to estimate the later-age strength under standard curing. Such estimates should be limited to concretes using the same materials and mixture proportions as those used for establishing the correlation. Appendix X2 provides a procedure to estimate the 90 % confidence interval of the average later-age strength based on accelerated strength test results.

5.3 Correlation between accelerated strength and strength achieved at some later age by using conventional curing methods depends upon the materials comprising the concrete, the mixture proportions, and the specific accelerated test procedure.

5.4 The user shall choose which procedure to use on the basis of experience and local conditions. These procedures, in general, will be practical when a field laboratory is available to house the curing containers and the testing equipment to measure compressive strength within the specified time limits.

6. Interferences

6.1 When wet sieving of the concrete sample is required prior to molding the test specimens due to maximum aggregate size limitations (such as Procedure D, which is limited to 25 mm maximum), consider the effect of wet sieving on the air content and strength of the test specimens.

7. Apparatus

7.1 Equipment and small tools for fabricating specimens, measuring slump, and determining air content shall conform to Practice C 31/C 31M.

7.2 *Molds*:

7.2.1 Cylinder molds for test specimens used in Procedures A, B, and C shall conform to Specification C 470. Paper molds are excluded. When specimens are to be tested without capping, use only reusable molds with machined end plates that can be securely connected to both top and bottom of the mold. The end plates shall produce specimens with bearing surfaces that are plane within 0.05 mm (0.002 in.) and whose ends do not depart from perpendicularity to the axis of the cylinder by more than 0.5° (approximately equivalent to 10 mm/m (⅛ in. in 12 in.). When assembled, the mold assembly is sufficiently tight to permit the filled mold to be turned from the vertical filling position to a horizontal curing position without loss of mortar or damage to the test specimen.

7.2.2 Cylinder molds for Procedure D shall conform to the following:

7.2.2.1 Made of stainless steel,

7.2.2.2 Equipped with removable top and bottom metal plugs and O-ring seals,

7.2.2.3 Equipped with a heating element capable of raising the concrete temperature within the mold to 150 ± 3°C (300 ± 5°F) within 30 ± 5 min, and are capable of maintaining this temperature throughout the time required by the test procedure,

7.2.2.4 Equipped with devices to measure the temperature within each mold to ascertain that the temperature of the concrete satisfies the temperature requirements stated herein, and

7.2.2.5 Equipped with a companion loading component capable of maintaining a pressure of 10.3 MPa ± 0.2 MPa (1500 ± 25 psi) on the concrete during the curing period.

7.3 *Curing Apparatus*:

7.3.1 *Accelerated Curing Tank for Procedures A and B*:

7.3.1.1 The tank is of any configuration suitable for the number of cylinders to be tested. Arrange the cylinders in any configuration that provides a clearance of at least 50 mm (2 in.) between the side of each cylinder and the side of the tank, and at least 100 mm (4 in.) between adjacent cylinders. Maintain the water level at least 100 mm (4 in.) above the tops of the cylinders.

NOTE 1—Provision for an overflow pipe is a convenience in controlling the maximum depth of water. A number of different tanks have been used successfully. Guidelines are given in Appendix X1.

TABLE 1 Characteristics of Accelerated Curing Procedures

Procedure	Molds	Source of Strength Acceleration	Accelerated Curing Temperature °C (°F)	Age Accelerated Curing Begins	Duration of Accelerated Curing	Age at Testing
A. Warm Water	reusable or single-use	heat of hydration	35 (95)	immediately after casting	23.5 h ± 30 min	24 h ± 15 min
B. Boiling Water	reusable or single-use	boiling water	boiling	23 h ± 30 min after casting	3.5 h ± 5 min	28.5 h ± 15 min
C. Autogenous	single-use	heat of hydration	initial concrete temperature augmented by heat of hydration	immediately after casting	48 h ± 15 min	49 h ± 15 min
D. High-Temperature and Pressure	reusable	external heat and pressure	150 (300)	immediately after casting	5 h ± 5 min	5.25 h ± 5 min[A]

[A] Add 30 min if capping with sulfur compound is used.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.3.1.2 Equip the tank with environmental control element(s) capable of: (*1*) providing the specified water temperature, (*2*) maintaining the water temperature within ±3°C (±5°F) of the specified value at any point in the water, and (*3*) limiting the temperature drop, after immersion of specimens, to less than 3°C (5°F) and returning to the specified water temperature within 15 min. Thermometers or other temperature recording devices are required, independent of the thermostat, to check the temperature of the water.

NOTE 2—Depending upon the design features of the tank, insulation or mechanical agitation, or both, might be necessary to meet the specified temperature requirements. Electrical immersion heaters controlled by a thermostat are one suitable form of heating elements. For a particular procedure, the size of the heating element required will depend upon the size of the tank and the number of specimens to be cured at one time.

7.3.1.3 The plate supporting the specimens is perforated to permit circulation of the water.

7.3.1.4 A close fitting lid to reduce evaporation is required for Procedure B but is optional for Procedure A.

7.3.2 *Curing Container for Procedure C*:

7.3.2.1 The container consists of thermal insulation meeting heat retention requirements of 12.2.1 and closely surrounding the concrete specimen.

7.3.2.2 The container is capable of being opened to permit insertion and withdrawal of the specimen and has an outer casing and inner liner to protect the insulation from mechanical damage.

7.3.2.3 The container has a maximum-minimum recording thermometer which is not insulated from the concrete specimen (see Note 10).

7.3.2.4 The container has a lid or other means to provide secure closure during the specified curing period. The lid includes a heat seal that satisfies the requirements of 12.2.2.

7.3.2.5 The container is capable of holding either one or two specimens.

NOTE 3—Examples of suitable containers are included in Appendix X1. Any configuration is acceptable provided it meets the performance requirements of 12.2.

7.3.3 *Curing Apparatus for Procedure D*:

7.3.3.1 The curing apparatus consists of a loading system to apply the specified pressure to the concrete specimens and special molds to maintain the concrete specimens at the specified temperature during the curing period. The curing apparatus can be of any configuration suitable for the number of cylindrical specimens to be tested. Appendix X1 describes a successful apparatus designed for curing three specimens.

7.4 *Capping Apparatus*:

7.4.1 If capping of the test specimens is required, use the apparatus specified in Practice C 617 or Practice C 1231.

8. Materials

8.1 Capping compound or pad caps for use when the ends of the test specimens are unsuitable for testing without capping.

9. Hazards

9.1 Observe OSHA requirements and standard laboratory and field safety precautions when sampling, molding, curing, and testing concrete.

9.2 Observe the additional safety measures indicated when using Procedure B to prevent scalding or other burns resulting from the use of boiling water as a curing medium.

9.3 Observe the additional safety measures indicated when using Procedure D to prevent injury due to the high temperature and pressure used for curing.

10. Sampling

10.1 Determine the number of tests required from the concrete lot(s) or process. Use a random or systematic plan that provides the number of tests needed to characterize the strength of the concrete used in the construction.

10.2 If the lot(s) or process is stratified into sublots, locate the samples using a stratified random procedure. If circumstances dictate a non-stratified approach, use a random procedure.

NOTE 4—A stratified random sampling procedure can be implemented by dividing each lot of concrete into a number of equal-sized sublots, and randomly selecting a sample from each sublot. The number of sublots equals the number of samples that were scheduled to be taken from the lot. For example, if the job requirements called for each 500 m^3 of concrete to be treated as a lot and that five samples be obtained from each lot to determine compressive strength, divide the lot into five equal-sized sublots of 100 m^3 each. Randomly obtain one sample from each sublot. Test results from the five samples obtained in this manner provide unbiased estimates of the compressive strength of the 500 m^3 lot. This is the most practical approach to ensure that the samples obtained include the entire range of concrete in the production process. If unequal size sublots occur due to the construction process, weighting of the test results may be appropriate to maintain the fairness and defensibility of the sampling procedure.

NOTE 5—Practice D 3665 contains a table of random numbers, including instructions for use. Practices E 105, E 122, and E 141 contain additional information concerning sampling practices.

10.3 Sample the freshly mixed concrete in accordance with Practice C 172. Record in the job records the location at which the sampled batch is used in the structure.

11. Preparation of Apparatus

11.1 *Methods A and B*:

11.1.1 Activate the environmental control elements at least 1 h prior to the start of a scheduled test to allow the temperature of the water and equipment to stabilize.

11.2 *Method C*:

11.2.1 Conduct the proving tests specified in Section 12 prior to scheduling tests.

11.3 *Method D*:

11.3.1 Clean and check the molds and end plugs before starting a test. Standardize the loading system in accordance with Section 12 prior to scheduling tests.

12. Standardization

12.1 For all methods, verify the calibration of temperature measurement, control, and recording components on a frequent periodic basis. Calibrate such components in accordance with the manufacturer's recommendations or standard laboratory practice.

12.2 *Method C Requirements*:

12.2.1 *Heat Retention*—Place a watertight cylindrical container with internal dimensions of 300 mm (12 in.) in height by

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:26:09 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

150 mm (6 in.) in diameter into the autogenous curing container. Fill the container to within 6 mm (¼ in.) of the brim with water at a temperature of 82°C (180°F). Insert a thermocouple into the water and measure the initial temperature of the water with a suitable readout device. Then seal the water container with a cap or plastic bag and close the autogenous container. When the autogenous curing container is stored in still air at 21 ± 1°C (70 ± 2°F), the water temperature requirements are as follows:

Elapsed time, h	°C	°F
12	67 ± 3	152 ± 5
24	58 ± 3	136 ± 6
48	45 ± 4	114 ± 7
72	38 ± 4	100 ± 8

12.2.2 *Tightness Test for Gasket Heat Seal*—When the autogenous curing container is immersed in water to a depth of 150 mm (6 in.) above the joint between the separable parts, no air shall escape through the heat seal within a period of 5 min.

12.2.3 *Stability of the Container*—The container, or any part thereof, shall not display embrittlement, fracturing, or distortion when maintained in an ambient temperature of − 30°C (−20°F) for 72 h, nor softening or distortion when maintained at an ambient temperature of 60°C (140°F) for 72 h. The gasket type heat seal immediately shall recover fully its original thickness after 50 % compression under the temperature conditions specified above.

12.3 *Method D*:

12.3.1 Verify the calibration of the loading component on a periodic basis. If the loading component is also used for compression testing of the specimens, follow the requirements of Test Method C 39.

13. Conditioning

13.1 The relatively short curing periods used for concrete test specimens in this test method require that particular attention be directed to conditioning of equipment and test specimens. Adhere carefully to the specified temperature and time requirements in each method.

14. Procedure

14.1 *Procedure A—Warm Water Method*:

14.1.1 *Preparation of Test Specimens*:

14.1.1.1 Mold the test specimens in accordance with the requirements of Practice C 31/C 31M or Practice C 192/C 192M, whichever is applicable.

14.1.2 *Curing*:

14.1.2.1 If necessary, cover the top of the specimens with a rigid plate to prevent loss of mortar to the water bath.

14.1.2.2 Immediately after molding, place the specimens into the curing tank (Note 6). Maintain the water at the time of immersion and throughout the curing period at 35 ± 3°C (95 ± 5°F).

NOTE 6—If the specimens are cast in molds meeting the requirements of 7.2.1.1 they may be stored horizontally, otherwise they are stored in the curing tank with the long axis vertical.

14.1.2.3 Record the temperature of the curing water either continuously or periodically throughout the curing period.

14.1.2.4 After curing for 23.5 h ± 30 min, remove the specimens from the tank and remove the molds.

14.1.3 *Capping and Testing*:

14.1.3.1 Cap the ends of specimens that are not plane within 0.05 mm (0.002 in.) or that depart from perpendicularity to the central axis by more than 0.5° (approximately equivalent to 10 mm/m (⅛ in. in 12 in.)) as specified in Practice C 617 or Practice C 1231 (see Note 7).

NOTE 7—Grinding of cylinders to achieve the flatness requirements is permitted provided the specimens are tested within the specified time limits.

14.1.3.2 For bonded caps, use capping material that develops, at an age of 30 min when tested in accordance with the provisions of Practice C 617, a strength equal to or greater than the strength of the specimens to be tested.

14.1.3.3 If bonded caps are used, do not test specimens sooner than 30 min after capping.

14.1.3.4 Test the specimens for strength in accordance with Test Method C 39 at the age of 24 h ± 15 min.

14.2 *Procedure B—Boiling Water Method*:

14.2.1 *Preparation of Test Specimens*:

14.2.1.1 Prepare specimens in accordance with 14.1.1.

14.2.2 *Initial Curing*:

14.2.2.1 Cover the specimens to prevent loss of moisture and store so that they will not be disturbed. Maintain the storage area temperature at 21 ± 6°C (70 ± 10°F). Adhere to the requirements of Practice C 31/C 31M in the protection and storage of test specimens.

NOTE 8—Strict attention to the protection and storage of the specimens during this initial period is necessary for meaningful results because of the short total curing period.

14.2.3 *Accelerated Curing*:

14.2.3.1 At 23 h ± 15 min after molding, place the covered molds in the water tank (Note 9). Maintain the temperature of the water at the time of immersion and throughout the curing period at boiling (Note 10).

NOTE 9—**Precaution:** In addition to other precautions, wear appropriate protection for the eyes, face, hands, and arms to prevent injury from the sudden release of steam upon opening the container or immersion of the cyclinder into the boiling water. Lifting tongs are suggested to slowly lower the molds into the boiling water without splashing.

NOTE 10—In confined places, the temperature of the water may be kept just below the boiling point to avoid excessive evaporation. The temperature at which water boils varies because of differences in elevation above sea level. Differences in strengths caused by the differences in temperatures are not believed to be significant, but comparison of results among areas so affected should be supported by appropriate correlations and interpreted with the knowledge of the temperature variations.

14.2.3.2 Record the temperature of the curing water either continuously or periodically throughout the curing period.

14.2.3.3 After curing for 3.5 h ± 5 min, remove the specimens from the boiling water, remove the molds, and allow the specimens to cool at room temperature for at least 1 h prior to capping.

14.2.4 *Capping and Testing*:

14.2.4.1 Cap and test the specimens in accordance with 14.1.3, except that the age at time of test is 28.5 ± 15 min.

14.3 *Procedure C—Autogenous Method*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:26:09 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

14.3.1 *Preparation of Test Specimens*:

14.3.1.1 Prepare specimens in accordance with 14.1.1.

NOTE 11—Metal, reusable molds with end plates and clamps may be impracticable for Procedure C.

14.3.2 *Curing*:

14.3.2.1 Immediately after molding, cover the mold with a metal plate or a tightly fitted cap and place in a heavy-duty plastic bag from which as much of the entrapped air as possible is expelled prior to tying the neck. (Alternatively, a moisture-tight plastic cap may be used.) Use a plastic bag of sufficient strength to resist punctures and serve as a lifting grip for placing and removing the specimen from the autogenous container.

14.3.2.2 Reset the maximum-minimum thermometer, and, after the specimen is inserted into the container, secure the container lid.

14.3.2.3 Clearly record the time of molding to the nearest 15 min and the temperature of the freshly molded concrete on the outside of the curing container.

14.3.2.4 Store the curing container for at least 12 h in a location not subject to disturbance or direct sunlight, and preferably at a temperature of 21 ± 6°C (70 ± 10°F).

14.3.2.5 At the age of 48 h ± 15 min after the specimen was molded, remove the specimen from the container and remove the mold. Allow to stand at room temperature for 30 min.

14.3.2.6 Record the maximum and minimum temperatures in the container indicated on the thermometer.

NOTE 12—Comparison of the maximum and minimum temperatures with the recorded temperature of the fresh concrete will provide an indication of abnormal or interrupted curing which may cause high or low strength results.

14.3.3 *Capping and Testing*:

14.3.3.1 Cap and test the specimens in accordance with 14.1.3, except that the age at the time of test is 49 h ± 15 min.

NOTE 13—Capping and testing may be performed at an age different from that specified in 14.3.3. Agencies using the procedure have, for convenience, established relationships between test results at 24, 72, and 96 h with those obtained by standard moist curing. However, at 24 h, the relationship is less satisfactory than those obtained by accelerated autogenous curing for 48, 72, or 96 h. Where the curing period is other than that specified in 14.3.3, the age at testing should be the curing period plus 1 h. The tolerance of ±15 min should still apply.

14.4 *Procedure D—High Temperature and Pressure Method*:

14.4.1 *Preparation of Test Specimens*:

14.4.1.1 For the curing apparatus described in Appendix X1, the molds are 75 × 150 mm (3 × 6 in.) cylinders. Seal the molds with their bottom plugs before filling with concrete.

14.4.1.2 Procedure D is limited to concrete containing 25-mm (1-in.) maximum size aggregate. Wet sieve concrete containing aggregate larger than 25 mm (1 in.) in accordance with Practice C 172.

14.4.1.3 Place the concrete in the molds in two equal layers and rod each layer 10 times. Screed the top of the concrete with a special tool (see Fig. X1.3) to achieve the level of concrete required to receive the top metal plug that transmits the designated pressure of 10.3± 0.2 MPa (1500 ± 25 psi) to the concrete in the mold.

14.4.2 *Curing*:

14.4.2.1 Immediately after molding, cover each mold with a metal plug to seal the concrete inside the mold during the curing process.

14.4.2.2 Stack the molds vertically and place them in the loading apparatus described in 7.3.3.1. Apply and maintain a pressure of 10.3 ± 0.2 MPa (1500 ± 25 psi) on the concrete within the molds.

14.4.2.3 Activate the heating element specified in 7.2.2 to elevate the temperature of the specimen to 150 ± 3°C (300 ± 5°F) within 30 ± 5 minutes. The curing period begins when the heating element is activated.

14.4.2.4 The curing period lasts 5 h ± 5 min. During the first 3 h, maintain the specimen temperature at 150 ± 3°C (300± 5°F). After 3 h, turn off the heating element and maintain the pressure at 10.3 ± 0.2 MPa (1500 ± 25 psi) for the remainder of the curing period.

14.4.2.5 At the end of the curing period, release the pressure, remove the molds from the loading apparatus, and extrude the specimens from the molds.

NOTE 14—**Precaution:** The use of high temperature and pressure imposes the need for safety measures to prevent scalding or eye burns resulting from sudden escape of steam upon removal of plugs from the molds. In addition to other precautions, wear eye, face, and hand protection, while removing the specimens from the molds. It is suggested that the plugs be removed by prying in a direction away from the operator.

NOTE 15—Polypropylene plastic liners can be used inside the molds to facilitate extrusion of the cured concrete from the molds.

14.4.3 *Capping and Testing*:

14.4.3.1 Normally the specimens do not need to be capped for testing since the metal plugs produce suitably plane bearing surfaces. If the end surfaces do not meet the requirements of 14.1.3.1, cap the specimens in accordance with 14.1.3.

14.4.3.2 Test the specimens for strength in accordance with Test Method C 39 within 15 min after removing the molds. When capping is required, test the specimens 30 min after capping.

NOTE 16—The loading apparatus used for the curing period can also be designed to function as a suitable compression testing machine (see Appendix X1).

15. Interpretation of Results[3]

15.1 Strength requirements in existing specifications and codes are not based upon accelerated curing; therefore, apply results from this test method in the prediction of specification compliance of strengths at later ages with great caution. As stated in Section 17, the variability of the test method is the same or less than that from traditional methods. Thus, results can be used in rapid assessment of variability for process control and signalling the need for indicated adjustments. On the other hand, the magnitude of the strength values obtained is influenced by the specific combination of materials so that the use of the results from either conventional tests at any arbitrary age or those from this test method must be supported by

[3] Carino, N. J., "Prediction of Potential Concrete Strength at Later Ages," ASTM STP 169C, *Significance of Tests and Properties of Concrete and Concrete Making Materials*, 1994, pp. 140–152.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

experience or correlations developed by the specific agency for the existing local conditions and materials.

15.2 When this test method is used as a means to estimate standard-cured strength at a specified age, statistical methods shall be used to account for the various uncertainties associated with making such estimates. Appendix X2 provides an acceptable procedure for this purpose. Prior to using this test method to estimate standard-cured strength, all interested parties shall agree on the statistical procedures to be used and how the results are to be interpreted. If this test method is used for acceptance testing, the acceptance criterion shall be stated in the project documents.

NOTE 17—A recommended criterion for acceptance of concrete on the basis of accelerated strength testing is that the lower limit of the 90 % confidence interval of the estimated average strength of the sample tested should conform to the acceptance criteria for standard moist-cured cylinders.

16. Report

16.1 Report the following for each test specimen:

16.1.1 Identification number,

16.1.2 Diameter (and length, if not standard) in millimetres (or inches),

16.1.3 Cross-sectional area, in square millimetres (or square inches),

16.1.4 Maximum load, in newtons (or pounds-force),

16.1.5 Compressive strength calculated to the nearest 0.1 MPa (10 psi),

16.1.6 Type of fracture, if other than the usual cone,

16.1.7 Defects in either the specimen or the caps (if used),

16.1.8 Age of the specimens,

16.1.9 Accelerated curing procedure used,

16.1.10 Maximum and minimum temperature to the nearest° C (°F) if Procedure C was used.

16.1.11 If applicable, method of transportation used for shipping the specimens to the laboratory, and

16.1.12 Ambient temperature of the specimen during initial curing in Procedure B or of the container during storage for Procedure C.

17. Precision and Bias

17.1 *Precision*:

17.1.1 The data used to prepare the following precision statements was obtained using measurements in the inch-pound system.

17.1.2 The single-laboratory coefficient of variation for specimens cast from the same batch has been determined as 3.6 % for 150 × 300-mm (6 × 12-in.) cylinders (as used in Procedures A, B, and C) and as 6.7 % for 75 × 150-mm (3 × 6-in.) cylinders (as used in Procedure D) (Note 18). Therefore, for 150 × 300-mm (6 × 12-in.) cylinders tested according to Procedures A, B, and C, individual results of two properly conducted strength tests, by the same laboratory on specimens made from the same batch, should not differ more than 10.1 % of their average. For 75 × 150-mm (3 × 6-in.) cylinders tested according to Procedure D, the maximum acceptable difference between three individual test results is 22.1 %.

17.1.3 The single-laboratory, coefficient of variation for test results among batches cast on different days has been determined as 8.7 % for 150 × 300-mm (6 × 12-in.) cylinders as used in Procedures A, B, and C, and as 20 % for 75 × 150-mm (3 × 6-in.) cylinders as used in Procedure D (Note 19). A test result is the average strength of two specimens for Procedures A, B, and C and the average of three specimens for Procedure D. Therefore, results of two properly conducted strength tests from different batches of the same materials cast on different days should differ by no more than 24.4 % of their average for 150 × 300-mm (6 × 12-in.) cylinders and 56.0 % for 75 × 150-mm (3 × 6-in.) cylinders (Note 19).

NOTE 18—These numbers represent the (1s %) limit as described in Practice C 670.

NOTE 19—These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

18. Keywords

18.1 accelerated curing; compressive strength; testing

APPENDIXES

(Nonmandatory Information)

X1. CURING APPARATUS

X1.1 Accelerated Curing Tank (Procedures A and B)

X1.1.1 Curing tanks similar to that shown in Fig. X1.1 have been used successfully.

X1.1.2 Properly designed tanks will ensure an almost uniform temperature throughout the tank without the need for a mechanical stirrer. Locate the immersion heaters centrally in the plan and as near to the bottom of the tank as possible. The water above the heater will then be kept in circulation by convection currents.

X1.1.3 For a tank containing two or three specimens, two coupled elements (1500 and 5000 W) have been found suitable for use with Procedure B. While the smaller elements will maintain the specified curing temperature, the larger element is required as a booster to reestablish boiling within the specified time after the specimens have been immersed. Where the tank is to be used solely for Procedure A, the above heaters are also suitable, but a single 3000-W element has also been found suitable. With the 3000-W element, the tank may be of larger

www.technobetar.ir

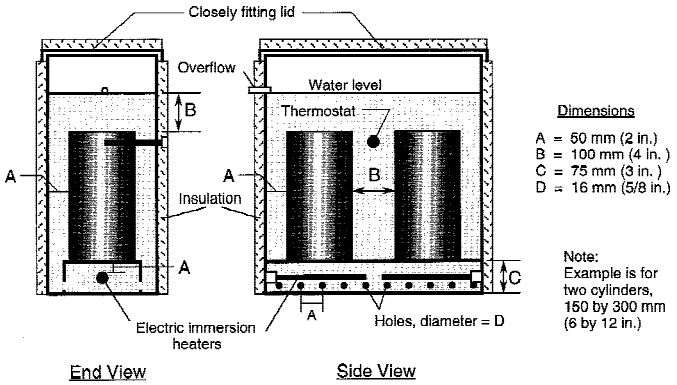

FIG. X1.1 Suggested Design for Accelerated Curing Tank (Procedure A or B)

dimensions to hold more than two or three specimens when used for Procedure A.

X1.1.4 The overflow pipe, closely fitting lid, and exterior insulation are not essential for curing tanks used only for Procedure A.

X1.2 Autogenous Curing Container (Procedure C)

X1.2.1 Satisfactory containers are shown in Fig. X1.2.

X1.2.2 The space for the maximum-minimum thermometer and the means of opening the container, securing when closed, and lifting are not shown.

X1.2.3 A heat seal is required at the joint face between the separable parts of the container. This may be a labyrinth or a gasket type seal provided the requirements of 12.2.1, 12.2.2, and 12.2.3 are met. A suitable gasket is flexible polyurethane foam (32 kg/m^3 or 2 lb/ft^3) maintained when closed at 50 % compression.

X1.2.4 Foamed-in-place closed-cell polyurethane having a density of between 32 and 48 kg/m^3(2 and 3 lb/ft^3) and thermal conductivity equal to or less than 0.02 W/m·K (0.15 Btu·in./h·ft^3°F) in accordance with Test Method C 177 has been found to be a suitable insulating material at the thicknesses specified to meet the heat retention requirements of 12.2.1.

X1.2.5 The maximum-minimum thermometer should cover a range from − 10 to 65°C (20 to 150°F) in 1° increments.

X1.3 High Temperature and Pressure Equipment (Procedure D)

X1.3.1 A satisfactory apparatus for Procedure D is shown in Fig. X1.3.

X1.3.2 Properly designed molds will ensure an almost uniform temperature throughout the concrete. The heater wires are normally spaced closer together near the edges of the mold and further apart in its central region.

X1.3.3 For a 75 × 150-mm (3 × 6-in.) cylindrical mold, a heating element of 100 W will raise and maintain the specified temperature during the curing period. Regular fiberglass insulation with a rating of R20 was found to be sufficient for the suggested heating element and required curing cycle. Each mold has its own electrical circuitry so that if one fails to function, two molds will remain to cure two specimens in a satisfactory manner. The electrical system shall have current indicators, a timer, and a buzzer in order to make the curing procedure automatic and simple to monitor.

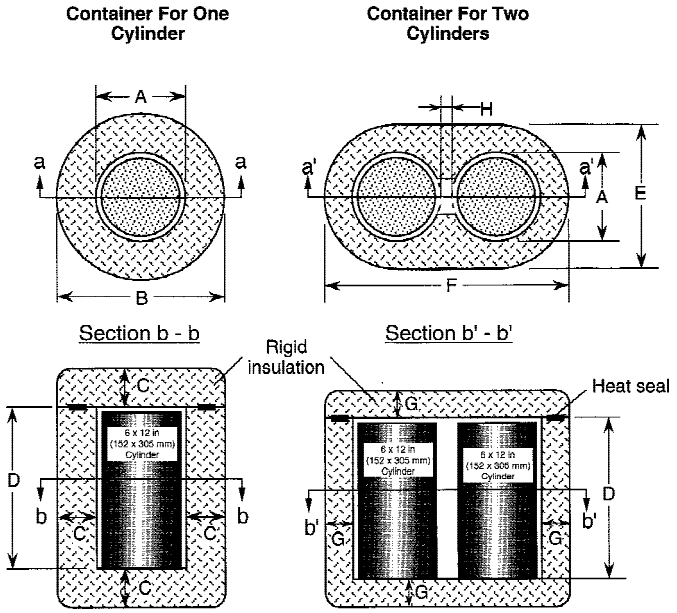

FIG. X1.2 Autogenous Curing Container for One or Two Cylinders (Procedure C)

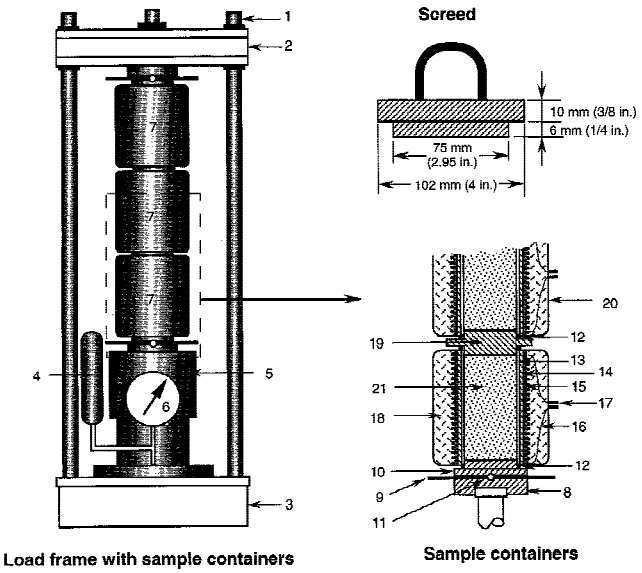

FIG. X1.3 Schematic of High-Temperature and Pressure Curing Apparatus (Procedure D)

www.technobetar.ir

X1.3.4 The hydraulic jack and accumulator shall be equipped with a pressure gage to indicate the pressure being applied to the concrete in the molds. The accumulator shall be calibrated so that it will maintain the required pressure of 10.3 ± 0.2 MPa (1500 ± 25 psi).

X1.3.5 If it is desired to use the apparatus to test the specimens, then the apparatus shall be designed to function as a compression testing machine satisfying the requirements of Test Method C 39.

X2. ESTIMATION OF LATER-AGE STRENGTH

X2.1 Regression Equation

X2.1.1 To estimate the potential later-age strength from a measured early-age accelerated strength, the laboratory must first conduct enough tests to establish the relationship between the two types of strength. This will usually require preparing a series of six to ten mixtures with water-cement ratios varying over the maximum credible range that may be encountered during construction. These mixtures must include similar materials to those that will be used in construction. Ordinary least-squares regression analysis is used to obtain the equation of the line representing the relationship between standard-cured and accelerated strengths **(1,2)**.[4] This relationship is applicable only to the specific materials and accelerated test procedure that were used. To account for the uncertainty in the resulting regression line, confidence bands for the line are established **(1)**. Then, for a new accelerated strength, the confidence interval for the average later-age strength can be estimated. The following procedure and illustrative example are based on earlier work by Wills **(3)** and Carino **(4)**.

X2.1.2 In this discussion, it will be assumed that the relationship between the standard-cured strength (Y) and the accelerated strength (X) can be represented by a straight line with the following equation:

$$Y = a + b\,X \tag{X2.1}$$

However, for some concrete mixtures, the relationship between these two types of strength may not be linear. For these situations, the measured strength values should be transformed by taking their natural logarithms. The natural logarithms of the strengths would be used to obtain the average X and Y values to be used in subsequent calculations. The last step would be to perform exponentiation to convert the computed confidence intervals to strength values.

X2.1.3 Assume that n pairs of (X_i, Y_i) values are obtained from laboratory testing, where X_i and Y_i are the average strengths of accelerated and standard-cured specimens. The intercept, a, and slope, b, of the straight line are determined using the procedure of ordinary least squares **(1)**:

$$b = \frac{S_{xy}}{S_{xx}} \tag{X2.2}$$

$$a = \bar{Y} - b\,\bar{X} \tag{X2.3}$$

where:

$$S_{xy} = \sum (X_i - \bar{X})\,(Y_i - \bar{Y}) \tag{X2.4}$$

$$S_{xx} = \sum (X_i - \bar{X})^2 \tag{X2.5}$$

$$\bar{X} = \sum \frac{X_i}{n} \tag{X2.6}$$

$$\bar{Y} = \sum \frac{Y_i}{n} \tag{X2.7}$$

The residual standard deviation, s_e, of the best-fit line is given by the following:

$$S_e = \sqrt{\frac{1}{n-2}\left(S_{yy} - \frac{S_{xy}^{\,2}}{S_{xx}}\right)} \tag{X2.8}$$

where:

$$S_{yy} = \sum (Y_i - \bar{Y})^2 \tag{X2.9}$$

X2.1.4 To illustrate the procedure, consider the 12 pairs of accelerated and standard-cured, 28-day strengths given in the first two columns of Table X2.1. Each number is the average strength of two cylinders. Using the preceding equations, the following values are to be obtained:

$\bar{X}$ = 16.30 MPa (2366 psi)
$\bar{Y}$ = 38.90 MPa (5646 psi)
S_{xx} = 105.32 (MPa)^2
S_{yy} = 164.14 (MPa)^2
S_{xy} = 125.22 (MPa)^2

The slope of the line is b = 125.22/105.32 = 1.19, and the intercept is a = 38.90 – 1.19× 16.30 = 19.50 MPa (2830 psi).

TABLE X2.1 Values Used in Sample Problem to Illustrate Estimation of Confidence Interval for 28-day Strength

NOTE 1—For an approximate conversion to psi multiply the values by 145.

Accelerated Strength, X_i, MPa	28-day Strength, Y_i, MPa	Estimated Strength, Y, MPa	W_i, MPa	Lower Confidence Limit, MPa	Upper Confidence Limit, MPa
12.06	33.71	33.85	1.50	32.35	35.35
12.15	34.33	33.96	1.48	32.48	35.44
12.96	35.23	34.92	1.30	33.62	36.22
13.85	35.05	35.98	1.12	34.86	37.10

www.technobetar.ir

Therefore, the equation of the relationship between accelerated strength (X) and standard-cured strength (Y) is as follows:

$$Y = 19.50 + 1.19\,X \text{ (MPa)} \quad \text{(X2.10)}$$

Fig. X2.1 shows the 12 data pairs and the calculated best-fit line. The residual standard deviation of the line, s_e, is as follows:

$$s_e = \sqrt{\frac{1}{10}\left(164.14 - \frac{125.22^2}{105.32}\right)} = 1.23 \text{ MPa (178 psi)} \quad \text{(X2.11)}$$

X2.2 Confidence Band for Regression Line

X2.2.1 Because of the uncertainties in the estimates of the slope and the intercept of the line, there will be uncertainty when the line is used to estimate the average standard-cured strength from a measured accelerated strength. This uncertainty may be expressed by constructing the 90 % confidence band for the line **(1,5)**. This band is obtained by calculating Y_i for selected values of X_i using the equation of the line and plotting $Y_i \pm W_i$, versus X_i. The term W_i is the half-width of the confidence band at X_i and is given by the following equation:

$$W_i = s_e \sqrt{2F} \sqrt{\frac{1}{n} + \frac{(X_i - \bar{X})^2}{S_{xx}}} \quad \text{(X2.12)}$$

where:

- s_e = residual standard deviation for the best-fit line (Eq X2.8),
- F = value from F-distribution for 2 and n-2 degrees of freedom and significance level 0.10,
- n = number of data points used to establish regression line,
- X_i = selected value of accelerated strength, and
- $\bar{X}$ = grand average value of accelerated strength for all data used to establish the regression line.

The third column in Table X2.1 lists the estimated average 28-day strengths for the accelerated strengths in Column 1. The value of W_i at each value X_i is listed in the fourth column of Table X2.1. Finally, Columns 5 and 6 list the values of the lower and upper 90 % confidence limits, which are shown in Fig. X2.1. Note that the width of the confidence band is narrowest when X_i equals $\bar{X}$, because the second term under the square root sign in Eq X2.12 equals zero.

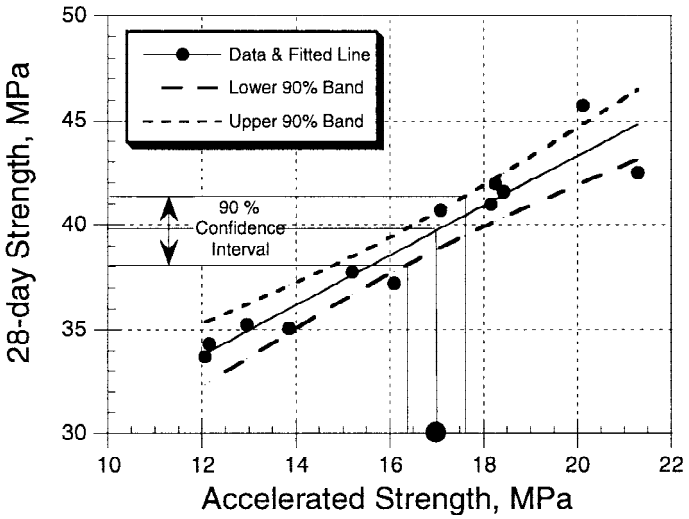

FIG. X2.1 Confidence Bands for the Estimated 28-day Strength Based on Measured Accelerated Strength; 90 % Confidence Interval for an Accelerated Strength of 17.0 MPa are Shown

X2.3 Estimate of Later-Age Strength

X2.3.1 Suppose that the average accelerated strength of two cylinders made in the field from similar concrete is 17.0 MPa (2470 psi). From the regression equation, the estimated average 28-day, standard-cured strength is 39.7 MPa (5760 psi). If the accelerated strength was known without error, the 90 % confidence interval for the average 28-day strength would be 38.8 to 40.6 MPa (5630 to 5890 psi) (see the bottom of Table X2.1). However, the accelerated strength has an uncertainty that is described by the within-batch standard deviation, which can be estimated from the differences between the accelerated strengths of pairs of cylinders **(6)**. Assume that the compressive strengths measured on field-prepared cylinders by the specific accelerated test method has a within-batch coefficient of variation of 3.0 %. Therefore, the standard deviation, s, at an average strength of 17.0 MPa is 0.51 MPa (74 psi). The 90 % confidence interval for the average accelerated strength of the two cylinders is as follows:

$$17.0 \pm z_{0.05}\frac{s}{\sqrt{2}} = 17.0 \pm 1.645 \times 0.51 \times 0.707 = 17.0 \pm 0.6\ MPa\ (2470 \pm 90\ psi) \quad \text{(X2.13)}$$

where $z_{0.05}$ is the value from the standard normal distribution corresponding to 5 % of the area under the curve. Thus the 90 % confidence interval[5] for the average accelerated strength is 16.4 to 17.6 MPa (2380 to 2550 psi). Projecting the limits of this interval to the lower and upper confidence bands of the regression line results in 38.2 to 41.4 MPa (5540 to 6010 psi) for the approximate 90 % confidence interval for the average standard-cured, 28-day strength. Each different measurement of accelerated strength produces a new confidence interval for the average 28-day strength. The use of a personal computer is recommended for implementing the preceding calculations for routine use.

X2.3.2 As the regression equation starts to be used on the project, companion cylinders should be prepared along with cylinders for accelerated testing. The companion cylinders would be subjected to standard curing and tested for compressive strength at the designated age. The measured standard-cured strengths should be compared with the confidence intervals for the estimated strengths based on the companion accelerated strengths. If the measured strengths consistently fall outside the estimated confidence intervals, the reliability of the regression line and its associated statistics is questionable.

[5] The 90 % confidence interval is often interpreted to mean that there is a 90 % probability that the true mean falls within the interval. However, the correct interpretation is as follows: If 100 repeated samples are taken from the same population and the 90 % confidence intervals for the mean are computed in each case, 90 of the intervals would include the true mean. The 90 % confidence band for the regression line has a similar interpretation: If 100 groups of data are taken from the same population and the 90 % confidence bands are computed for the regression equations, 90 % of those bands would include the true regression line for the population. See Mendenhall and Sincich **(7)** for further explanations on the proper interpretation of confidence intervals.

www.technobetar.ir

The new companion results should be added to the data set from the laboratory correlation testing to calculate a new regression line and its corresponding statistics. This new line should be used for subsequent estimates of potential later-age strength. The making of companion sets of accelerated and standard-cured cylinders should be continued until the measured strengths consistently fall within the corresponding calculated confidence intervals. Once the reliability of the procedure has been demonstrated, companion cylinders should be made at random intervals to reconfirm that the procedure continues to be reliable.

X2.4 Summary

X2.4.1 A procedure has been presented to estimate the average standard-cured, 28-day strength from accelerated strength test results. The procedure accounts for the uncertainty in the regression line and in the measured accelerated strength. It is insufficient to simply use the regression equation to convert the accelerated strength to an equivalent 28-day strength. Additional information on the procedure presented in the example may be found in the references by Moore and Taylor **(8)** and in Miller **(5)**. Finally, it is emphasized that a particular regression equation is valid only for a specific accelerated test procedure and combination of materials. Therefore, each laboratory must conduct enough tests with a given set of materials and a certain procedure to establish the regression line and its confidence bands before estimations of standard-cured strengths are possible.

Designation: C685/C685M – 10

Standard Specification for Concrete Made by Volumetric Batching and Continuous Mixing[1]

This standard is issued under the fixed designation C685/C685M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers concrete made from materials continuously batched by volume, mixed in a continuous mixer, and delivered to the purchaser in a freshly mixed and unhardened state as hereinafter specified. Requirements for quality of concrete shall be either as hereinafter specified or as specified by the purchaser. When the requirements of the purchaser differ from this specification, the purchaser's specification shall govern. This specification does not cover the placement, consolidation, finishing, curing, or protection of the concrete after delivery to the purchaser. Tests and criteria for batching accuracy and mixing efficiency are specified herein.

1.2 The values stated in either SI units, shown in brackets, or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 This specification references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this specification.

1.4 *This standard does not purport to address all the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged use.[2])

3. Terminology

3.1 *Definitions:* For definitions of terms used in this specification, refer to Terminology C125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *manufacturer, n—of concrete,* the producer of the concrete.

3.2.2 *purchaser, n—of concrete,* the buyer of the concrete.

4. Basis of Purchase

4.1 The basis of purchase shall be the cubic yard or cubic metre of fresh concrete as it is continuously discharged from the batching and mixing apparatus.

4.2 The volume of fresh concrete in a given batch shall be determined by, or calculated from, a calibrated indicating device driven directly by the batching apparatus.

NOTE 1—It should be understood that the volume of hardened concrete may be, or may appear to be, less than expected due to waste and spillage, over-excavation, spreading forms, some loss of entrained air, or settlement of wet mixtures, none of which are the responsibility of the manufacturer.

5. Materials

5.1 In the absence of designated applicable specifications covering requirements for quality of materials, the following specifications shall govern:

5.1.1 *Cement*—Cement shall conform to Specification C150, Specification C595, or Specification C1157 (Note 2). The purchaser shall specify the type or types required, but if no type is specified, the requirements of Type I as prescribed in Specification C150 shall apply.

NOTE 2—These different cements will produce concretes of different properties and should not be used interchangeably.

5.1.2 *Aggregates*—Normal weight aggregates shall conform to Specification C33. Lightweight aggregates shall conform to Specification C330 and heavyweight aggregates shall conform to Specification C637.

5.1.3 *Water*—Water shall conform to Specification C1602/C1602M.

5.1.4 *Ground Granulated Blast-Furnace Slag*—Ground granulated blast furnace slag shall conform to Specification C989.

5.1.5 *Air-Entraining Admixtures*—Air-entraining admixtures shall conform to Specification C260. (Note 3)

5.1.6 *Chemical Admixtures*—Chemical admixtures shall conform to either Specification C494/C494M or C1017/C1017M, as applicable (Note 3).

NOTE 3—In any given instance, the required dosage of air-entraining, accelerating, and retarding admixtures may vary. Therefore, a range of dosages should be allowed which will permit obtaining the desired effect.

6. Ordering Information

6.1 In the absence of designated applicable general specifications, the purchaser shall specify the following:

6.1.1 Designated size or sizes of coarse aggregate,

6.1.2 Slump or slumps desired at the point of delivery (see 10.3),

6.1.3 When air-entrained concrete is specified, the air content of samples taken at the point of discharge from the transportation unit (see 10.4 and Table 1 for the total air content and tolerances) (Note 4),

6.1.4 When structural lightweight concrete is specified, the density as fresh density, equilibrium density, or oven-dry density (Note 5), and

6.1.5 Which of Options A, B, or C shall be used as a basis for determining the proportions of the concrete to produce the required quality (see 6.2, 6.3, or 6.4).

NOTE 4—In selecting the specified air content, the purchaser should consider the exposure conditions to which the concrete will be subjected. Air contents less than shown in Table 1 may not give the required resistance to freezing and thawing, which is the primary purpose of air-entrained concrete. Air contents higher than the levels shown may reduce strength without contributing any further improvement of durability.

NOTE 5—The density of fresh concrete, which is the only density determinable at the time of delivery, is always higher than the equilibrium density, or oven-dry density. Definitions of, and methods for determining or calculating equilibrium density and oven-dry density, are covered in Test Method C567.

6.2 *Option A*:

6.2.1 When the purchaser requires the manufacturer to assume full responsibility for the selection of the proportions for the concrete mixture, the purchaser shall also specify the following in addition to the requirements of 6.1.1 through 6.1.5:

[4] Available from American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333-9094, http://www.aci-int.org.
[5] Available from Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.
[6] Available from the Volumetric Mixer Manufacturers Bureau, 900 Spring Street, Silver Spring, MD 20910, www.vmmb.org.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:26:11 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.2.1.1 Requirements for compressive strength as determined on samples taken from the mixer at the point of discharge and evaluated in accordance with Section 11. The purchaser shall specify the requirements in terms of the compressive strength of standard specimens cured under standard curing conditions for moist curing. Unless otherwise specified, the age at test shall be 28 days, and

6.2.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of the concrete, furnish a statement to the purchaser, giving the dry mass of cement and saturated surface-dry mass of fine and coarse aggregate and quantities, type, and name of admixtures (if any) and of water per cubic yard or cubic metre of concrete that will be used in the manufacture of each class of concrete ordered by the purchaser. The manufacturer shall also furnish evidence satisfactory to the purchaser that the materials to be used and proportions selected will produce concrete of the quality specified.

6.3 *Option B*:

6.3.1 When the purchaser assumes responsibility for the proportioning of the concrete mixture, the purchaser shall also specify the following in addition to the requirements of 6.1.1 through 6.1.5:

6.3.1.1 Cement content in bags or pounds per cubic yard or kilograms per cubic metre of concrete, or equivalent units,

6.3.1.2 Maximum allowable water content in gallons per cubic yard or litres or kilograms per cubic metre of concrete or equivalent units, including surface moisture on the aggregates, but excluding water of absorption (Note 6), and

6.3.1.3 If admixtures are required, the type, name, and dosage range to be used. Those employed for air-entrainment or for control of set (acceleration, retardation) shall have maximum limitations set as to dosage. Admixtures shall not be used as a substitute for a portion of specified amounts of cement without the written approval of the purchaser.

NOTE 6—The purchaser, in selecting requirements for which he assumes responsibility should give consideration to requirements for workability, placeability, durability, surface texture, and density, in addition to those for structural design. The purchaser is referred to ACI Standard Practice 211.1 for normal weight concrete, and ACI Standard Practice 211.2 for lightweight concrete, for the selection of proportions that will result in concrete suitable for various types of structures and conditions of exposure. The water-cement ratio of most structural lightweight concretes cannot be determined with sufficient accuracy for use as a specification basis.

6.3.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of the concrete, furnish a statement to the purchaser giving the sources, densities, and sieve analyses of the aggregates and the dry mass of cement and saturated surface-dry mass of fine and coarse aggregate and quantities, type, and name of admixture (if any) and of water per cubic yard or cubic metre of concrete that will be used in the manufacture of each class of concrete ordered by the purchaser.

6.4 *Option C*:

6.4.1 When the purchaser requires the manufacturer to assume responsibility for the selection of the proportions for the concrete mixture with the minimum allowable cement content specified, the purchaser shall also specify the following in addition to the requirements of 6.1.1 through 6.1.5:

6.4.1.1 Required compressive strength as determined on samples taken from the mixer at the point of discharge and evaluated in accordance with Section 11. The purchaser shall specify the requirements for strength in terms of tests of standard specimens cured under standard curing conditions for moist curing. Unless otherwise specified, the age at test shall be 28 days.

6.4.1.2 Minimum cement content in bags or pounds per cubic yard or kilograms per cubic metre of concrete (Note 7), and

6.4.1.3 If admixtures are required, the type, name, and dosage range to be used. The cement content shall not be reduced when admixtures are used.

6.4.2 At the request of the purchaser, the manufacturer shall, prior to the actual delivery of the concrete, furnish a statement to the purchaser, giving the dry mass of cement and saturated surface-dry mass of fine and coarse aggregate and quantities, type, and name of admixture (if any) and of water per cubic yard or cubic metre of concrete that will be used in the manufacture of each class of concrete ordered by the purchaser. The manufacturer shall also furnish evidence satisfactory to the purchaser that the materials to be used and proportions selected will produce concrete of the quality specified. Whatever strengths are attained the quantity of cement used shall not be less than the minimum specified.

NOTE 7—Option C can be distinctive and useful only if the designated minimum cement content is at about the same level that would ordinarily be required for the strength, aggregate size, and slump specified. At the same time, it must be an amount that will be sufficient to ensure durability under expected service conditions, as well as satisfactory surface texture and density, in the event specified strength is attained with it. Attention is directed to ACI Standard Practices 211.1 and 211.2 for additional information on mixture proportions.

6.5 The proportions arrived at by Options A, B, or C for each class of concrete and which are approved for use in a project shall be assigned a designation (7CV.PK7, etc.) to facilitate identification of each concrete mixture delivered to the project. This is the designation required in 15.1.7 and supplies information on concrete proportions when they are not given separately on each delivery ticket as outlined in 15.2. However, each delivery of concrete shall be covered by a delivery ticket showing enough information to establish that the mix conforms to the mix designs previously approved for the work.

6.6 The purchaser shall ensure that the manufacturer is provided copies of all reports of tests performed on concrete samples taken to determine compliance with specification requirements. Reports will be provided on a timely basis.

7. Measuring Materials

7.1 Cement, fine and coarse aggregates, water, and admixtures shall be measured by volume. Devices such as counters, calibrated gate openings, or flowmeters shall be available for controlling and determining the quantities of the ingredients discharged. The entire measuring and dispensing mechanism shall produce the specified proportions of each ingredient within the tolerances in 7.8.

NOTE 8—The recommendations of the equipment manufacturer in the operation of the equipment and in calibrating and using the various gages,

TABLE 1 Recommended Total Air Content for Air-Entrained Concrete[A]

Exposure Condition[B,C]	Total Air Content, % Nominal Max Sizes of Aggregate, in. [mm]						
	⅜ [9.5]	½ [12.5]	¾ [19.0]	1 [25.0]	1½ [37.5]	2 [50.0]	3 [75.0]
Mild	4.5	4.0	3.5	3.0	2.5	2.0	1.5
Moderate	6.0	5.5	5.0	4.5	4.5	4.0	3.5
Severe	7.5	7.0	6.0	6.0	5.5	5.0	4.5

[A] For air-entrained concrete, when specified.
[B] For description of exposure conditions, refer to ACI Standard Practice 211.1, Section 6.3.3 with attention to accompanying footnotes.
[C] Unless exposure conditions dictate otherwise, it is permissible to reduce air contents recommended above by up to 1 % for concretes with specified compressive strength, f'_c, of 5000 psi [35 MPa] or above.

revolution counters, speed indicators, or other control devices should be followed.

7.2 All indicating devices that bear on the accuracy of proportioning and mixing of concrete shall be in full view and near enough to be read by the operator while concrete is being produced. The operator shall have convenient access to all controls.

7.3 The proportioning and indicating devices shall be individually checked by following the equipment manufacturer's recommendations as related to each individual concrete batching and mixing unit. Adequate standard volume measures, scales, and weights shall be made available for the checking accuracy of the proportioning mechanism.

7.4 *Yield Check*—Essentially, the volume of concrete discharged from the mixer is checked by first determining the mass of the amount of concrete discharged during some number of revolutions, or as determined by some other output indicator; this is then followed immediately by a determination of the density. The mass of concrete discharged divided by the density is equal to the number of cubic feet or cubic metres mixed and discharged during the chosen interval. The accuracy of the output indicator is thus checked by this expedient. For further guidance and a suggested calibration procedure, refer to ACI 304.6R and VMMB 100-01.

NOTE 9—It is recommended that about 2.5 to 3.0 ft^3 [0.070 to 0.085 m^3] be discharged for this purpose; this amount of concrete will weigh from 350 to 500 lb [160 to 225 kg] and can be discharged into and contained in a 35 or 55-gal [130 to 210-dm^3] drum or other suitable container which in turn can be placed on a scale of adequate capacity. The output of a batcher-mixer unit may be indicated by the number of revolutions, travel of a belt, or changes in gage readings; if so, these figures should be used as a measure of output.

7.5 *Proportioning Check*—Whenever the sources or characteristics of the ingredients are changed, or the characteristics of the mixture are noted to have changed, the purchaser is permitted to require a check of the fine aggregate content and the coarse aggregate content by use of the washout test. Essentially, in the washout test, 1 ft^3 [0.03 m^3] of concrete is washed through a No. 4 [4.75-mm] sieve and through a No. 100 [150-µm] sieve; that retained on the No. 4 sieve is normally considered coarse aggregate whereas that passing the No. 4 and retained on the No. 100 sieve is considered fine aggregate. Corrections to the quantity of aggregates (per cubic foot or cubic metre of concrete) shall be made if the original sieve analysis of each aggregate is available.

7.6 The rate of water supplied the continuous mixer shall be measured by a calibrated flowmeter coordinated with the cement and aggregate feeding mechanism, and with the mixer. The device for the measurement of water shall be capable of delivering to the batch the required quantity. The rate shall be capable of being adjusted in order to control slump at the desired levels and to determine that the water-cement (permitted or required) ratios are being met.

7.7 Liquid admixtures shall be dispensed through a controlled flowmeter.

7.8 Tolerances in proportioning the various ingredients are as follows:

Cement, mass %	0 to +4
Fine Aggregate, mass %	±2
Coarse Aggregate, mass %	±2
Admixtures, mass or volume %	±3
Water, mass or volume %	±1

The tolerances are based on a volume/mass relationship established by calibration of the measuring devices furnished as an integral part of the whole equipment.

NOTE 10—It is noted that to meet these tolerances, attention should be given to:
(*1*) Degree of compaction of the cement,
(*2*) Grading and other physical characteristics of the fine and coarse aggregates,
(*3*) Moisture content and bulking factor of the fine aggregate,
(*4*) Viscosity of the admixture, and
(*5*) Other factors of influence, for example, mechanical condition and weather.

8. Mixing Mechanism

8.1 The continuous mixer shall be an auger-type mixer or any other type suitable for mixing concrete to meet the required consistency and uniformity requirements (see 14.2.3).

8.2 Each batching or mixing unit, or both, shall carry in a prominent place a metal plate or plates on which are plainly marked the gross volume of the unit in terms of mixed concrete, discharge speed, and the mass-calibrated constant of the machine in terms of a revolution counter or other output indicator. The mixer shall produce a thoroughly mixed and uniform concrete.

NOTE 11—Slump and air content tests of samples taken in accordance with 14.2.3 can be made for a quick check of the probable degree of uniformity.

9. Mixing and Delivery

9.1 The batcher-mixer unit shall contain in separate compartments all the necessary ingredients needed for the manufacture of concrete. The unit shall be equipped with calibrated

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:26:11 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

proportioning devices to vary the mix proportions and it shall produce concrete as required by this specification and those of the project.

9.2 *Cold Weather Concrete*—Concrete delivered in cold weather shall have the applicable minimum temperature indicated in the following table. (The purchaser shall inform the producer as to the type of construction for which the concrete is intended.)

	Minimum Concrete Temperature as Placed			
Section Size, in. [mm]	<12 [<300]	12 to 36 [300 to 900]	36 to 72 [900 to 1800]	>72 [>1800]
Temperature, min, °F (°C)	55 [13]	50 [10]	45 [7]	40 [5]

The maximum temperature of concrete produced with heated aggregates, heated water, or both, shall at no time during its production or transportation exceed 90 °F [32 °C].

NOTE 12—When hot water is used rapid stiffening may occur if hot water is brought in direct contact with the cement. Additional information on cold weather concreting is contained in ACI 306R.

9.3 The producer shall deliver the concrete during hot weather at concrete temperatures as low as practicable, subject to the approval of the purchaser.

NOTE 13—In some situations difficulty may be encountered when concrete temperatures approach 90 °F [32 °C]. Additional information may be found in the Bureau of Reclamation Concrete Manual and in ACI 305R.

10. Slump and Air Content

10.1 Slump, air-content, and temperature tests shall be made at the time of placement at the option of the inspector as often as is necessary for control checks. In addition, these tests shall be made, when specified and always when strength specimens are made (11.2).

10.2 If the measured slump, temperature, or air content falls outside the specified limits, a check test shall be made immediately on another portion of the same sample. In the event of a second failure, the concrete shall be considered to have failed the requirements of the specification.

10.3 *Tolerances in Slump*:

10.3.1 Unless other tolerances are included in the project specifications, the following shall apply:

10.3.1.1 When the project specifications for slump are written as a "maximum" or "not to exceed" requirement:

Specified Slump	Tolerance, in. (mm)
3 in. [75 mm] or less	+0–1½ [40]
More than 3 in. [75 mm]	+0–2½ [65]

This option is to be used only if one addition of water is permitted on the job provided such addition does not increase the water-cement ratio above the maximum permitted by the specifications.

10.3.1.2 When the project specifications for slump are *not* written as a "maximum" or "not to exceed" requirement:

Specified Slump	Tolerance, in. (mm)
2 in. [50 mm] and less	± ½ [15]
More than 2 in. [50 mm] through 4 in. [100 mm]	±1 [25]
More than 4 in. [100 mm]	±1½ [40]

10.4 When air-entrained concrete is desired, the purchaser shall specify the total air content of the concrete. See Table 1 for total air content (Note 4).

10.5 The air content of air-entrained concrete when sampled from the transportation unit at the point of discharge shall be within a tolerance of ±1.5 of the specified value.

11. Strength

11.1 When strength is used as a basis for acceptance of the concrete, standard specimens shall be made and cured under standard curing conditions in accordance with the applicable provisions of Practice C31/C31M. The technician performing the strength test shall be certified as an ACI Concrete Laboratory Testing Technician—Grade I or II or by an equivalent written and performance test program.

11.2 One strength test set of two cylinders and the accompanying slump, temperature, and air content tests shall be made for each 25 yd^3 [20 m^3] of concrete or fraction thereof, or whenever significant changes have been made in the proportioning controls. There shall be at least one strength test made for each class of concrete placed in 1 day.

11.3 For each strength test, two standard-size cylinders shall be made (see 14.2.2). The test result shall be the average of the strength of the two specimens except that, if any specimen shows definite evidence other than low strength, of improper sampling, molding, handling, curing, or testing, it shall be discarded and the strength of the remaining cylinder shall then be considered the test result.

11.4 The representative of the purchaser shall ascertain and record the delivery ticket number for the concrete and the exact location in the work where the concrete represented by each strength test was deposited.

11.5 To conform to the requirements of this specification, strength tests representing each class of concrete must meet the following two requirements (Note 14):

11.5.1 The average of any three consecutive strength tests shall be equal to, or greater than, the specified strength, f'_c, and

11.5.2 No individual strength test shall be more than 500 psi [3.5 MPa] below the specified strength, f'_c.

NOTE 14—Due to variations in materials, operations, and testing the average strength necessary to meet these requirements will be substantially higher than the specified strength. The amount higher depends upon the standard deviation of the test results and the accuracy with which that value can be estimated from prior data as explained in ACI 318 and ACI 301. Pertinent data is given in Table 2.

12. Failure to Meet Strength Requirements

12.1 In the event that concrete tested in accordance with the requirements of Section 11 fails to meet the strength requirements of this specification, the manufacturer of the concrete and the purchaser shall confer to determine whether agreement will be reached as to what adjustment, if any, shall be made. If an agreement on a mutually satisfactory adjustment cannot be reached by the manufacturer and the purchaser, a decision shall be made by a panel of three qualified engineers, one of whom shall be designated by the purchaser, one by the manufacturer, and the third chosen by these two members of the panel. The question of responsibility for the cost of such arbitration shall

TABLE 2 Overdesign Necessary to Meet Strength Requirements[A]

Number of Tests[B]	Standard Deviation, psi					
	300	400	500	600	700	Unknown
15	470	620	850	1120	1390	[C]
20	430	580	760	1010	1260	[C]
30 or more	400	530	670	900	1130	[C]
	Standard Deviation, MPa					
	2.0	3.0	4.0	5.0		Unknown
15	3.1	4.7	7.3	10.0		[C]
20	2.9	4.3	6.6	9.1		[C]
30 or more	2.7	4.0	5.8	8.2		[C]

[A] Add the tabulated amounts to the specified strength to obtain the required average strengths.

[B] Number of tests of a concrete mixture used to estimate the standard deviation of a concrete production facility. The mixture used must have a strength within 1000 psi of that specified and be made with similar materials. See ACI 318.

[C] If less than 15 prior tests are available, the overdesign should be 1000 psi [7.0 MPa] for specified strength less than 3000 psi [20 MPa], 1200 psi [8.5 MPa] for specified strengths from 3000 to 5000 psi [20 to 35 MPa] and 1400 psi [10.0 MPa] for specified strengths greater than 5000 psi [35 MPa].

be determined by the panel. Its decision shall be binding, except as modified by a court decision.

13. Test Methods and Practices

13.1 Test the concrete in accordance with the following ASTM methods:

13.1.1 *Compression Test Specimens*—Use standard moist curing in accordance with the applicable provisions of Practice C31/C31M.

13.1.2 *Compression Tests*—Test Method C39/C39M.

13.1.3 *Yield, Unit Weight*—Test Method C138/C138M.

13.1.4 *Air Content*—Test Method C138/C138M, Test Method C173/C173M, or Test Method C231.

13.1.5 *Slump*—Test Method C143/C143M.

13.1.6 *Temperature*—Test Method C1064/C1064M.

13.2 The testing laboratory performing acceptance tests of concrete shall meet the requirements of Practice C1077.

14. Inspection

14.1 *Materials, Batching Facilities, and Mixing Facilities*—The manufacturer shall afford the inspector all reasonable access (without charge) for obtaining necessary samples of materials used in the concrete, and for making necessary checks of the batching and mixing facilities to determine if the concrete is being produced in accordance with this specification. All tests and inspection shall be so conducted as not to interfere unnecessarily with the batching, mixing, and discharge of the concrete to the purchaser.

14.1.1 The volume of plastic and unhardened concrete shall be checked daily on projects requiring more than 50 yd^3 [40 m^3] of concrete per day (see 7.4).

14.1.2 The manufacturer of the concrete shall conduct calibration and mixer efficiency tests at intervals not exceeding 6 months. Data on such tests using materials proposed for use in the project shall be furnished to the purchaser upon request. The amount of various ingredients (cement, fine and coarse aggregate, admixtures, and water) shall be checked as required in 7.5.

14.2 *Fresh Concrete*:

14.2.1 The contractor shall afford the inspector all reasonable access and assistance (without charge) for the procurement of samples of fresh concrete at the time of placement so as to determine conformance of the concrete to this specification.

14.2.2 At any time after at least 2 ft^3 [0.05 m^3] of concrete have been discharged, one sample of concrete shall be taken for the slump test, the air content test, if required, and the strength test. The sample shall be at least 2 ft^3 in volume. Two cylinders for each age of test shall be made. Tests for slump or air content or both shall be started within 5 min of sampling; these tests shall then be completed as expeditiously as possible. Molding of specimens for strength tests shall be started within 15 min of sampling. The time for making these tests and specimens shall be as short as possible.

14.2.3 Samples for determining the uniformity of mixing shall be taken at arbitrarily designated times. After at least 2 ft^3 [0.05 m^3] have been discharged, a sample of at least 4 ft^3 [0.10 m^3] shall be taken followed by another sample being taken no sooner than after 4 min of continuous discharge or 1 yd^3 [0.75 m^3] whichever is smaller. These samples shall be checked for conformance to the criteria set forth in Annex A1.

14.2.4 Tests of concrete required to determine compliance with this specification shall be made by a certified ACI Concrete Field Testing Technician, Grade I or equivalent. Equivalent personnel certification programs shall include both written and performance examinations as outlined in ACI CP-1.

14.3 Laboratory reports of concrete test results used to determine compliance with this specification shall include a statement that all tests performed by the laboratory or its agents were in accordance with the applicable test methods or shall note all known deviations from the prescribed procedures (Note 15). The reports shall also list any part of the test methods not performed by the laboratory.

NOTE 15—Deviation from standard test methods may adversely affect test results.

15. Batch Ticket Information

15.1 The manufacturer of the concrete shall furnish to the purchaser with each increment of discharged concrete, a delivery ticket or a statement of particulars on which is shown the following:

15.1.1 Name of concrete supplier,

15.1.2 Serial number of the delivery ticket or statement,

15.1.3 Date; starting time, and finishing time,

15.1.4 Identification number of batching or mixing equipment, or both,

15.1.5 Name of the purchaser,

15.1.6 Specific designation of the job (name and location),

15.1.7 Specific class or designation of the concrete in conformance with that employed in the job specification, and

15.1.8 Amount of concrete in cubic yards or cubic metres, and reading of the revolution counter or other device that indicates quantity of concrete.

15.2 Additional information designated by the purchaser and required by the job specifications shall be furnished when requested, such as:

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

15.2.1 Type, brand, and amount of cement,

15.2.2 Type, name, and amount of each admixture,

15.2.3 Information necessary to calculate total mixing water added by the producer. Total mixing water includes free water on the aggregates and water batched by the producer from the mixing equipment or other sources,

15.2.4 Maximum size of aggregate,

15.2.5 Mass or volumes of fine and coarse aggregate,

15.2.6 Notation of calibrated settings for flow control of fine and coarse aggregate, added water, and admixtures,

15.2.7 Ingredients certified as being previously approved, and

15.2.8 Signature or initials of the person operating the batching or mixing apparatus.

16.1 ready-mixed concrete; testing

ANNEX

(Mandatory Information)

A1. CONCRETE UNIFORMITY REQUIREMENTS

A1.1 Scope

A1.1.1 This annex includes test procedures and uniformity requirements for use in the evaluation of concrete produced in conformance with Specification C685/C685M by an individual batching-mixing unit, loaded to rated capacity.

A1.2 Significance and Use

A1.2.1 These tests and requirements are used to evaluate loading and operating procedures; verify the accuracy of proportioning and indicating systems; and determine if mixing uniformity has been degraded by excessive wear or by accumulations of hardened concrete, or both (Note A1.1).

NOTE A1.1—The method of loading the batching-mixing unit, proper maintenance, and other factors may have an effect on the ability of the unit to produce uniformly mixed concrete. For this reason, the use of this test method not only measures the efficiency of the mixer, but also the combined effect of the method of loading and operating the unit.

A1.2.2 This annex provides additional procedures and cautions that are necessary in the application of existing test methods and practices when used to determine the uniformity of freshly mixed concrete.

A1.3 Concrete Mixture

A1.3.1 Test a concrete mixture with proportions typical of the anticipated use (Note A1.2).

NOTE A1.2—Recommended test mix parameters are available from the Volumetric Mixer Manufacturers Bureau[7]. Normally, it is not necessary to test all mixtures produced unless they are made with greatly different slump, for instance 1 in. [25 mm] and 6 in. [150 mm]; or greatly different nominal maximum size aggregates such as ⅜ in. [9.5 mm] and 1½ in. [37.5 mm].

A1.4 Testing Apparatus and Materials

A1.4.1 The apparatus and materials shall conform to the requirements of the appropriate referenced ASTM Standards.

A1.4.2 Other special equipment as required by this annex and not specifically described in the referenced ASTM Standards is identified in the subsequent sections.

[7] Available from Volumetric Mixer Manufactures Bureau, 900 Spring St., Silver Spring, MD 20910.

A1.5 Sampling

A1.5.1 Take samples of the concrete discharge at approximately 15 and 85 % of the unit rated capacity by intercepting the full discharge stream (Note A1.3).

NOTE A1.3—Concrete with slumps over about 5 in. [125 mm] may segregate on the mixer blades or in the chute if discharge is stopped and started during the sampling process. For this reason, all samples should be taken without stopping or starting discharge during the sampling procedure.

A1.6 Slump

A1.6.1 Perform two slump tests on each sample in accordance with Test Method C143/C143M. Start testing the slump of each sample within 5 min after it was obtained.

A1.6.2 Calculate the average of the two tests performed on each sample.

A1.7 Fresh Concrete Density (Unit Weight)

A1.7.1 Determine the fresh concrete density of each sample in accordance with Test Method C138/C138M. If applicable, using a concrete sample in a ¼-ft^3 [7-L] air meter container to determine fresh concrete density; then using that same compacted sample to determine air content by Test Method C231; and then further using that sample to determine the coarse aggregate content percent is not prohibited (Note A1.4).

NOTE A1.4—Determination of fresh concrete density in a larger ½-ft^3 [14-L] container may provide a somewhat more accurate determination. The use of a separate sample of concrete for determination of coarse aggregate content may also improve accuracy, as some segregation or loss of coarse aggregate may occur when striking off the air content test sample.

A1.7.2 Calculate the fresh concrete density of the sample as follows:

$$D = (M_c - M_m)/V_m \quad \text{(A1.1)}$$

where:

D = fresh concrete density (unit weight), lb/ft^3 [kg/m^3],
M_c = mass of the measure filled with concrete, lb [kg],
M_m = mass of the measure empty, lb [kg], and
V_m = volume of the measure, ft^3 [m^3].

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:26:11 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

A1.8 Air Content

A1.8.1 Use Test Method C231 or Test Method C173/C173M, as applicable, to determine the air content of the concrete.

A1.9 Air Free Fresh Concrete Density (Air Free Unit Weight)

A1.9.1 Calculate the air free fresh concrete density of each sample as follows:

$$AFFD = (100 * D)/(100 - A) \quad \text{(A1.2)}$$

where:

$AFFD$ = air free fresh concrete density, lb/ft^3 [kg/m^3],
D = fresh concrete density, lb/ft^3 [kg/m^3] as measured in A1.7, and
A = air content, %, as measured in A1.8.

A1.10 Coarse Aggregate Content

A1.10.1 Determine the coarse aggregate content by either the Dry or Wet Method as follows. When the coarse aggregate content is determined from a separate sample of concrete not used for other tests, use a minimum sample mass of 25 lb [10 kg] for concrete made with ¾ in. [19.0 mm] or smaller nominal maximum size coarse aggregate, or minimum mass of 50 lb [20 kg] for concrete made with larger aggregate (Note A1.5).

NOTE A1.5—As noted in A1.7.1, the fresh concrete density and air content sample can be used for determination of coarse aggregate content. When this option is chosen, the amount of coarse aggregate recovered may be as little as 14 lb [6.4 kg], and the precision of the sieve analysis determination may be somewhat less than indicated in Test Method C136.

A1.10.2 Use the mass of the sample as determined in A1.7, or take another portion of the sample in a convenient-sized container and determine the mass of concrete. When concrete contains aggregate larger than 1 in. [25.0 mm] nominal maximum size, use a concrete sample large enough to yield a sample of coarse aggregate for final sieving at least as large as that required by Test Method C136.

A1.10.3 Wash the sample over a No. 4 [4.75 mm] sieve sufficiently to remove the cement and most of the fine aggregate. Determine the coarse aggregate mass using method A1.10.3.1 or A1.10.3.2.

A1.10.3.1 *Dry Method*—Dry the sample and sieve in accordance with Test Method C136. Determine CA_{dry}, the dry mass of coarse aggregate retained on the No. 4 [4.75 mm] sieve.

A1.10.3.2 *Wet Method*—Continue to carefully sieve the washed sample over the No. 4 [4.75 mm] sieve, washing to remove the remainder of the fine aggregate. Determine the mass of the wet sample immersed in water as in Test Method C127. Determine CA_{SSD}, the saturated surface dry mass of the aggregate retained on the No. 4 [4.75 mm] sieve as follows:

$$CA_{SSD} = \frac{C}{\left(1 - \frac{1}{G_{SSD}}\right)} \quad \text{(A1.3)}$$

where:

CA_{SSD} = saturated surface dry mass of the coarse aggregate, lb [kg],
C = immersed mass of the aggregate, lb [kg], and
G_{SSD} = relative density (specific gravity) of the aggregate (SSD).

A1.10.4 Calculate the coarse aggregate content percent by mass, by expressing the mass of coarse aggregate (CA_{dry} or CA_{SSD}) as a percentage of the mass of the original concrete sample.

A1.11 Compressive Strength

A1.11.1 Make and cure a minimum of two cylinders, either 6 by 12 in. [150 by 300 mm] or 4 by 8 in. [100 by 200 mm], from each sample of concrete in accordance with Practice C31/C31M. Cure cylinders as required, except that initial curing shall be by immersion in lime water immediately after molding. Maintain the water temperature between the required 60 to 80 °F [16 to 27 °C] for the initial 24 to 48 h. Finally, cure the cylinders in accordance with Practice C31/C31M until ready for testing.

A1.11.2 Test the cylinders at 7 days in accordance with Test Method C39/C39M. Average the strength of the 7-day tests of cylinders from each sample and express that value as a percentage of the average of all cylinders made from that batch tested at the same age.

A1.11.3 Examine the results of tests of individual cylinders made from the same sample of concrete and exclude the results from that sample if the range of tests exceeds 8.0 % when two cylinders are tested and 9.5 % when three are tested (Note A1.6)

NOTE A1.6—On the average, these ranges should not be exceeded more than roughly 1 time in 20. The values for permissible ranges of individual cylinders are from the precision statement in Test Method C39/C39M. Although the d2s (difference two sigma) values in Test Method C39/C39M are for 6 by 12-in. [150 by 300-mm] cylinders, available data suggest that 4 by 8-in. [100 by 200-mm] cylinder results should be only slightly less precise.

A1.12 Required Uniformity

A1.12.1 Units are required to conform to the minimum requirements of Table A1.1.

A1.13 Report

A1.13.1 Report the following information:
A1.13.1.1 Unit identification and rated capacity.
A1.13.1.2 Description of the unit configuration.
A1.13.1.3 Description of the loading and operating procedures.

TABLE A1.1 Requirements for Within-Batch Uniformity of Concrete[A]

Test	Range of 2 Samples
Air content, %	1.0
Air free fresh concrete density, lb/ft^3[kg/m^3]	1.0 [16]
Slump, in. [mm]	
Average slump 4 in. [100 mm] or less	1.0 [25]
Average slump, greater than 4 in. [100 mm]	1.5 [40]
Coarse aggregate content, percent by mass of concrete	6.0
Seven-day compressive strength, percent of average[B]	7.5

[A] A quick test of the probable uniformity of a batch of concrete is to test for uniformity of the slump and of the air content of air entrained concrete.

[B] Calculated as a percent of the average strength for the two samples taken from the batch. Either two or three cylinders must be tested from each of the two samples from the batch tested. When other requirements are met, tentative approval should be given pending the receipt of 7-day strength test results.

A1.13.1.4 Unit control settings.

A1.13.1.5 Identification of testing agency or agencies including:

(1) Corporate name and address,

(2) Responsible official,

(3) Indication that all testing personnel are certified as required in 14.2.4, and

(4) Indication that all tests were performed in accordance with the referenced test methods as modified herein.

A1.13.1.6 Concrete test data including:

(1) Individual test results for each slump, air content, fresh concrete density, air free fresh concrete density, coarse aggregate content (including method, wet or dry), and 7-day compressive strength (including cylinder size),

(2) Averages of duplicate tests made on the same sample,

(3) Range of results of tests on the two samples, and

(4) Comparison of that range with the maximum permitted in Table A1.1.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C685/C685M–07, that may impact the use of this specification. (Approved February 1, 2010)

(*1*) Revised 4.1 and 4.2 to match the language in C94/C94M.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 688 – 08

Standard Specification for Functional Additions for Use in Hydraulic Cements[1]

This standard is issued under the fixed designation C 688; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers methods to investigate the effectiveness of a material to beneficially change the properties of hydraulic cements when the material is incorporated during manufacture of the cement.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 The effect of additions in cement may markedly change properties other than those they are intended to modify. This specification is designed to test for such changes. Table 1 sets forth values for those properties of cement pastes and mortars that would permit a judgment of the changes effected by an addition. Likewise, Table 2 sets forth similar criteria for concrete. Certain additions may be found effective for more than one purpose as indicated in 3.1.4 and 3.1.5.

3. Terminology

3.1 *Definitions:*

3.1.1 *accelerating addition*—a functional addition that accelerates the setting or early strength, or both, of concrete and mortar.

3.1.2 *retarding addition*—a functional addition that retards the setting of concrete and mortar.

3.1.3 *set-control addition*—a functional addition composed essentially of calcium sulfate in any hydration state from $CaSO_4$ to $CaSO_4 \cdot 2H_2O$.

3.1.4 *water-reducing addition*—a functional addition used to reduce the quantity of mixing water required to produce concrete and mortar of a given consistency.

3.1.5 *water-reducing and accelerating addition*—a functional addition that reduces the quantity of mixing water required to produce concrete of a given consistency and that accelerates the setting or early strength development, or both, of concrete and mortar.

3.1.6 *water-reducing and retarding addition*—a functional addition that reduces the quantity of mixing water required to

TABLE 1 Criteria for Evaluating Neat Cement and Mortar Containing Functional Cement Additions

Tests	Type of Addition					
	Water Reducing	Retarding	Accelerating	Water-Reducing and Retarding	Water-Reducing and Accelerating	Set-Control
Normal consistency, deviation from control, percentage points[A]	−1.0 min	+1.0 max	+1.0 max	−1.0 min	−1.0 mm	±1.0 max
Standard consistency (flow) deviation from control, percentage points[A]	−4.0 min	+2.0 max	+2.0 max	−4.0 min	−4.0 min	±2.0 max
Setting time, (Gillmore) deviation from control, h:min						
Initial						
At least	...	1:00 later[B]		1:00 later[B]		...
Not more than	1:00 earlier nor 1:30 later	3:30 later	1:30 earlier nor 1:30 later	3:30 later	1:30 earlier nor 1:30 later	1:00 earlier nor 1:30 later
Setting time, Vicat Initial[C]						
At least	...	0:50 later[B]	...		...	...
Not more than	0:50 earlier nor 1:15 later	2:50 later	1:15 earlier nor 1:15 later	0:50 later[B] 2:50 later	1:15 earlier nor 1:15 later	0:50 earlier nor 1:15 later
Final						
Not more than	1:00 earlier nor 1:30 later	3:30 later	1:00 earlier nor 1:30 later	3:30 later	1:00 earlier nor 1:30 later	1:00 earlier nor 1:30 later
Compressive strength, min, percent of control:[D]						
1 day in moist air	110	90	125[E]	90	125	[F]
1 day in moist air, 2 days in water	110	90	125[E]	100	125	
1 day in moist air, 6 days in water	110	90	100	110	110	
1 day in moist air, 27 days in water	110	95	95	110	110	
Autoclave Expansion						
max increase in % change in length compared to control	0.10	0.10	0.10	0.10	0.10	0.10
Drying Shrinkage of Mortar						
max % change in length compared to control	0.020	0.020	0.030	0.020	0.020	0.020

[A] The minus sign indicates that the percentage of water required shall be less than that of the control cement by at least the indicated percentage points.
[B] Or 50 % later, whichever is the lesser.
[C] Either Vicat or the Gillmore time of setting method shall be used at the choice of the manufacturer.
[D] The compressive strength of mortar containing the test cement shall be not less than 95 % of that attained at any previous test age. The objective of this limit is to require that the strength of mortar containing the addition under test shall not decrease with age.
[E] In cases where the accelerated set time only is required, the strength can be reduced to 100 % of the control.
[F] The grand average of the 1, 3, 7, and 28-day strengths shall be not less than 95 % of the grand average for the corresponding control cement.

produce concrete and mortar of a given consistency and simultaneously retards the setting of concrete and mortar.

NOTE 1—This section is intended to provide a specification that may be applied to calcium sulfates as defined in Terminology C 219.

NOTE 2—It should be realized that some calcium sulfates, particularly some byproduct calcium sulfates, have produced cements with undesired set behavior after storage.

4. Ordering Information

4.1 The purchaser shall specify the type of functional addition desired.

5. Materials

5.1 *Cements*—The cements used in the evaluation of the addition shall be as described in Section 4.1 of Specification C 465 with the following exceptions:

5.1.1 At least one of the Type I cements shall contain not less than 9 percent tricalcium aluminate (C_3A).

5.1.2 Disregard the last sentence of Section 3.1.6 of Specification C 465 and substitute the following: " Each control cement shall comply with all the requirements in the specification (C 150, C 595, C 845, and C 1157) applicable to that type of cement. The method shall be adequate for the qualitative and quantitative determination of the addition in the finished cement, and shall be fully described in the report of the tests on the addition."

5.2 *Aggregates*—The aggregates used in the evaluation of the addition shall be in accordance with the Aggregates portion of the Materials section of Specification C 465, using proportions specified in Concrete Mixtures section of that specification.

6. *General Requirements* General Requirements

6.1 The cement, mortar, and concrete in which each of the additions is used shall conform to the respective requirements prescribed in Table 1 and Table 2, except that if the test cement fails to meet the requirements of Table 1, but possesses all the requirements listed in Table 2, then the requirements of Table 2 shall govern approval of the addition.

6.2 The trade name, source, and character of the material shall be specified and the means for the quantitative determination of the proposed addition in the finished cement, shall be furnished by the manufacturer or seller of the addition, and the results of such pertinent quantitative analysis shall form a part of the record of tests of the addition.

6.3 At the request of the purchaser of an addition for a specific functional purpose, the manufacturer shall state in writing the content of any substance which is known to or believed to impair other desirable properties of the cement or concrete.

TABLE 2 Criteria for Evaluating Concrete Containing Functional Cement Additions[A]

Tests	Type of Addition				
	Water Reducing	Retarding	Accelerating	Water-Reducing and Retarding	Water-Reducing and Accelerating
Water content, max, percent of control	95	...	...	95	95
Time of setting, (penetration) deviation from control, h:min:					
Initial					
At least	...	1:00 later[B]		1:00 later[B]	
Not more than	1:00 earlier nor	3:30 later	3:30 earlier	3:30 later	3:30 earlier
Final	1:00 later				
Not more than	1:00 earlier nor 1:30 later	3:30 later	...	3:30 later	...
Compressive strength, min, percent of control:[C]					
1 day[D]	110	85	125[E]	100	125
3 days	110	85	125[E]	100	125
7 days	110	90	100	110	110
28 days	110	90	95	110	110
3 months	100	90	95	100	100
1 year	100	90	95	100	100
Flexural strength, min, percent of control:[C]					
1 day[D]	100	85	110	90	110
3 days	100	85	110	100	110
7 days	100	90	100	100	100
28 days	100	90	90	100	100
3 months	100	90	90	100	100
1 year	100	90	90	100	100
Bond strength, percent of control:					
28 days	100	90	100	100	100
Volume change, expressed as change in length, max, increase over control, percentage points:					
28 days	0.010	0.010	0.030	0.010	0.010
3 months	0.010	0.010	0.030	0.010	0.010
1 year	0.010	0.010	0.030	0.010	0.010
Durability factor, min, percent of control[F]	80	80	80	80	80

[A] The values in the table are intended to allow for normal variation in test results. For example, the object of the 90 % compressive strength requirement for a retarding addition is to require a level of performance comparable to that of the reference concrete.

[B] Or 50 % later, whichever is the lesser.

[C] The compressive and flexural strength of the concrete containing the addition under test at any test age shall be not less than 90 % of that attained at any previous test age. The objective of this limit is to require that the compressive or flexural strength of the concrete containing the addition under test shall not decrease with age.

[D] One-day strengths applicable only to Type III cement. One-year strength tests shall be made; however, the addition may be approved after completion of the 3-month strength results, at the discretion of the purchaser.

[E] In cases where the accelerated set time only is required, the strength can be reduced to 100 % of the control.

[F] This requirement is applicable only when the addition is to be used in air-entrained concrete.

6.4 The additions shall be evaluated by comparing cements containing the "test addition" to cements ground from similar clinkers from the same source. Those cements without test additions are referred to in this specification as "control cements."

6.4.1 *Special Provisions for Set-Control Additions Conforming to* 3.1.3:

6.4.1.1 The additions shall be evaluated by comparing cements containing the "test addition" to control cements ground from similar clinkers from the same source and under the same grinding conditions with the mill temperatures being within ± 3 °C (5 °F) of the same value. The control cements shall be produced with calcium sulfate at any hydration state having a past record of satisfactory usage as an addition for portland cement.

6.4.1.2 Each test cement shall contain sufficient test addition $CaSO_4$ to produce a sulfur trioxide (SO_3) content that differs by no more than 0.24 percentage points from that of the control cement. The SO_3 shall be expressed as a percentage of the mass of the cement and reported to the nearest 0.01 %.

6.4.1.3 The test cements containing the additions shall conform to the requirements of 8.1 and Table 1. The cements need not be tested in concrete according to the requirements of 8.2 and Table 2.

6.5 The amount of addition that is incorporated into the cement for evaluation purposes shall be such as to produce the desired effects as listed in Table 1. When these tests show compliance with the requirements of this specification, the addition shall be used only in amounts up to the maximum amount tested in any one of the five cements used in the evaluation. For a cement requiring more than the established amount, a separate compliance test on this one cement can be made which will then establish the new maximum amount which can be used.

www.technobetar.ir

6.6 The cement produced with the functional additions shown in Section 3 shall comply with the specification for the respective cement and the ordinarily determined properties of cement paste, mortar, or concrete made with the cement containing the test addition shall not differ from these same properties of the cement paste, mortar, or concrete made with the control cement as indicated by the standard tests, except as provided in Table 1 and Table 2.

6.7 Generally, the addition rates required for functional purposes are several times greater than those needed for processing purposes and the resultant increase in flowability, or lubricity, from these increased addition rates may cause sufficient reduction in mill retention time to affect significantly the particle size distribution of the treated cement. The test addition may, in instances where the full-scale tests have shown reduced mill retention time to be significant, be determined for acceptance purposes by making supplementary laboratory or pilot batch mill grinds.

6.8 Furthermore, the effect of the addition on the properties of the cement, mortar, or concrete shall be within the limits of Section 8 and Table 1 and Table 2. In the event tests are conducted by making laboratory or pilot batch mill tests, this fact shall be entered in the report as specified in Section 9, and the specific tests shall be indicated.

6.9 After it has been documented once by the test results that a specific trade name and source of an addition have met the requirements of this specification, further tests shall be waived for subsequent shipments of the same product. Each shipment, however, shall be identified as to trade name, source, and date of shipment, and shall be essentially identical to nature and composition to that same trade name product which initially met the requirements of this specification.

7. Sampling

7.1 Sample the cements in accordance with the Sampling Cement section of Specification C 465. The quantity of sample shall be sufficient to make all the evaluation tests prescribed by this method. (A minimum of 300 kg (650 lb) per lot of cement is usually satisfactory.)

8. Test Methods

8.1 *Cements and Mortars*—Test the cements and mortars in accordance with the following ASTM test methods (see Table 1):

8.1.1 *Autoclave Expansion*—Test Method C 151.

8.1.2 *Drying Shrinkage of Mortar*—The length change of air-stored mortar bars made with the test cement shall not be more than 0.020 percentage points greater than that of similar mortar bars made with the control cement cured and tested according to Test Method C 596, except that for accelerators, an increased shrinkage of 0.03 percentage points will be allowed.

8.1.3 *Normal Consistency*—Test Method C 187.

8.1.4 *Standard Consistency (Flow)*—Test Method C 109/C 109M.

8.1.5 *Setting Time*—Test Method C 266.

8.1.5.1 For set-control additions conforming to 3.1.3 repeat the setting time tests 3 months after grinding. Keep cement samples for these tests in sealed metal containers with minimum air contact.

8.1.6 *Compressive Strength*—For functional additions having no water-reducing effects, use Test Method C 109/C 109M. For functional additions having some water-reducing effects, use Test Method C 109/C 109M except that mortars for both the test and the control specimens shall be made to a flow of 110 ± 5. In either case, there shall be six specimens for each condition of test.

8.1.6.1 It is required that cubes for companion cements be made and tested on the same days with storage of specimens side by side in the same section of the moist cabinet during the 24-h curing period. However, in water storage, store control and test specimens in separate tanks. If less than four specimens are left for each period, after discarding faulty cubes, make a retest.

NOTE 3—It is suggested that three batches of nine cubes each be made for each cement, then six cubes be picked at random for each age of test and the three excess cubes held to replace any faulty cubes found.

8.1.7 *False Set*—For set-control additions conforming to 3.1.3, perform false set tests initially and 3 months after grinding in accordance with Test Method C 451. The final penetration in percent shall be no less than 75 % as great as that with the control cement.

8.2 *Concretes*—Test the plastic and hardened concretes in accordance with the following ASTM methods (see Table 2):

8.2.1 *Consistency*—The consistency (slump) of the concrete produced with the test cement shall not differ from that of the control concrete by more than ± 13 mm (± ½ in.), when tested in accordance with Test Method C 143/C 143M, and each shall have a slump of 64 ± 13 mm (2½ ± ½ in.).

8.2.2 *Water Content*—The maximum water content of the test concrete shall be as shown in Table 2 when compared with the control concrete of similar consistency tested as in 8.2.1.

8.2.3 *Time of Setting*—Test Method C 403/C 403M.

8.2.4 *Compressive Strength*—Test Method C 39/C 39M.

8.2.5 *Flexural Strength*—Test Method C 78.

8.2.6 *Bond to Steel*—Test Method C 234.

8.2.7 *Volume Change*—Test Method C 157/C 157M.

8.2.8 *Resistance to Freezing and Thawing (Durability Factor)*—Test Method C 666/C 666M. The air content of both the control and test concrete shall be 6 ± 0.5 % obtained by admixing appropriate quantities of any of the reference air entraining agents listed in the General Requirements of Specification C 226.

8.2.9 *Bleeding*—At the request of the purchaser, test the bleeding characteristics in accordance with Test Method C 232.

9. Report

9.1 The report shall conform to the Report section of Specification C 465, except that comparison of test results shall be made to the requirements prescribed in this specification instead of to the requirements of Specification C 465.

10. Keywords

10.1 additions; functional; hydraulic cement

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C 688 – 00(2005), that may impact the use of this specification. (Approved December 1, 2008)

(*1*) Revised 1.1 and 6.5.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 702 – 98 (Reapproved 2003)

American Association State Highway and Transportation Officials Standard: T 248

Standard Practice for Reducing Samples of Aggregate to Testing Size[1]

This standard is issued under the fixed designation C 702; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers three methods for the reduction of large samples of aggregate to the appropriate size for testing employing techniques that are intended to minimize variations in measured characteristics between the test samples so selected and the large sample.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 125 Terminology Relating to Concrete and Concrete Aggregates[2]

C 128 Test Method for Density, Relative Density (Specific Gravity), and Absorption of Fine Aggregate[2]

D 75 Practice for Sampling Aggregates[3]

3. Terminology

3.1 *Definitions*—The terms used in this practice are defined in Terminology C 125.

4. Significance and Use

4.1 Specifications for aggregates require sampling portions of the material for testing. Other factors being equal, larger samples will tend to be more representative of the total supply. This practice provides procedures for reducing the large sample obtained in the field or produced in the laboratory to a convenient size for conducting a number of tests to describe the material and measure its quality in a manner that the smaller test sample portion is most likely to be a representation of the larger sample, and thus of the total supply. Failure to carefully follow the procedures in this practice could result in providing a nonrepresentative sample to be used in subsequent testing. The individual test methods provide for minimum amount of material to be tested.

4.2 Under certain circumstances, reduction in size of the large sample prior to testing is not recommended. Substantial differences between the selected test samples sometimes cannot be avoided, as for example, in the case of an aggregate having relatively few large size particles in the sample. The laws of chance dictate that these few particles may be unequally distributed among the reduced size test samples. Similarly, if the test sample is being examined for certain contaminants occurring as a few discrete fragments in only small percentages, caution should be used in interpreting results from the reduced size test sample. Chance inclusion or exclusion of only one or two particles in the selected test sample may importantly influence interpretation of the characteristics of the original sample. In these cases, the entire original sample should be tested.

5. Selection of Method

5.1 *Fine Aggregate*—Reduce the size of samples of fine aggregate that are drier than the saturated-surface-dry condition (Note 1) using a mechanical splitter according to Method A. Reduce the size of samples having free moisture on the particle surfaces by quartering according to Method B, or by treating as a miniature stockpile as described in Method C.

5.1.1 If the use of Method B or Method C is desired, and the sample does not have free moisture on the particle surfaces, moisten the sample to obtain free moisture on the particle surfaces, mix thoroughly, and then reduce the sample size.

5.1.2 If use of Method A is desired and the sample has free moisture on the particle surfaces, dry the entire sample to at least the saturated-surface-dry condition, using temperatures that do not exceed those specified for any of the tests contemplated, and then reduce the sample size. Alternatively, if the moist sample is very large, make a preliminary split using a mechanical splitter having chute openings of 38 mm (1½ in.) or more in width to reduce the sample to not less than 5000 g. Dry the portion so obtained, and reduce it to test sample size using Method A.

NOTE 1—The method of determining the saturated-surface-dry condition is described in Test Method C 128. As a quick approximation, if the

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

fine aggregate will retain its shape when molded in the hand, it may be considered to be wetter than saturated-surface-dry.

5.2 *Coarse Aggregates and Mixtures of Coarse and Fine Aggregates*—Reduce the sample using a mechanical splitter in accordance with Method A (preferred method) or by quartering in accordance with Method B. The miniature stockpile Method C is not permitted for coarse aggregates or mixtures of coarse and fine aggregates.

6. Sampling

6.1 Obtain samples of aggregate in the field in accordance with Practice D 75, or as required by individual test methods. When tests for sieve analysis only are contemplated, the size of the field sample listed in Practice D 75 is usually adequate. When additional tests are to be conducted, the user shall be satisfied that the initial size of the field sample is adequate to accomplish all intended tests. Use similar procedures for aggregate produced in the laboratory.

METHOD A—MECHANICAL SPLITTER

7. Apparatus

7.1 *Sample Splitter*—Sample splitters shall have an even number of equal width chutes, but not less than a total of eight for coarse aggregate, or twelve for fine aggregate, which discharge alternately to each side of the splitter. For coarse aggregate and mixed aggregate, the minimum width of the individual chutes shall be approximately 50 % larger than the largest particles in the sample to be split (Note 2). For dry fine aggregate in which the entire sample will pass the 9.5-mm (⅜-in.) seive, a splitter having chutes 12.5 to 20 mm (½ to ¾ in.) wide shall be used. The splitter shall be equipped with two receptacles to hold the two halves of the sample following splitting. It shall also be equipped with a hopper or straight-edged pan which has a width equal to or slightly less than the over-all width of the assembly of chutes, by which the sample may be fed at a controlled rate to the chutes. The splitter and accessory equipment shall be so designed that the sample will flow smoothly without restriction or loss of material (see Fig. 1 and Fig. 2).

NOTE 2—Mechanical splitters are commonly available in sizes adequate for coarse aggregate having the largest particle not over 37.5 mm (1½ in.).

8. Procedure

8.1 Place the original sample in the hopper or pan and uniformly distribute it from edge to edge, so that when it is introduced into the chutes, approximately equal amounts will flow through each chute. Introduce the sample at a rate so as to allow it to flow freely through the chutes and into the receptacles below. Reintroduce the portion of the sample in one of the receptacles into the splitter as many times as necessary to reduce the sample to the size specified for the intended test. Reserve the portion of material collected in the other receptacle for reduction in size for other tests, when required.

METHOD B—QUARTERING

9. Apparatus

9.1 Apparatus shall consist of a straight-edged scoop, shovel, or trowel; a broom or brush; and a canvas blanket approximately 2 by 2.5 m (6 by 8 ft).

10. Procedure

10.1 Use either the procedure described in 10.1.1 or 10.1.2 or a combination of both.

10.1.1 Place the original sample on a hard, clean, level surface where there will be neither loss of material nor the accidental addition of foreign material. Mix the material thoroughly by turning the entire sample over three times. With the last turning, shovel the entire sample into a conical pile by depositing each shovelful on top of the preceding one. Carefully flatten the conical pile to a uniform thickness and diameter by pressing down the apex with a shovel so that each

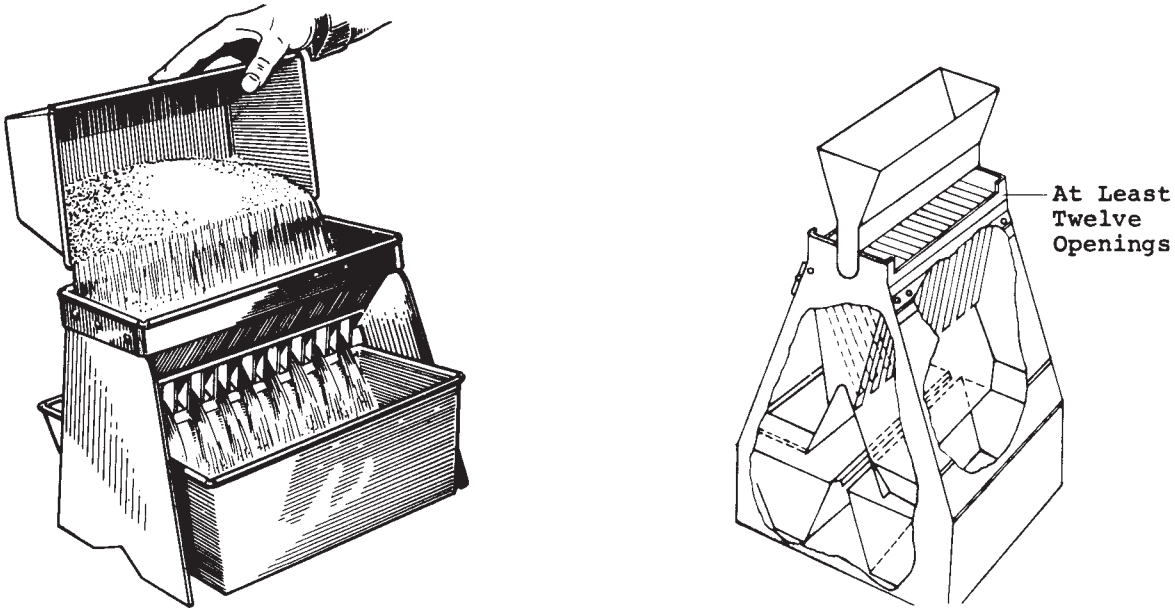
www.technobetar.ir



NOTE— Small Sample Splitters for Fine Aggregate. May be constructed as either closed or open type. Closed type is preferred.

FIG. 2 Sample Splitters (Riffles)

quarter sector of the resulting pile will contain the material originally in it. The diameter should be approximately four to eight times the thickness. Divide the flattened mass into four equal quarters with a shovel or trowel and remove two diagonally opposite quarters, including all fine material, and brush the cleared spaces clean. Successively mix and quarter the remaining material until the sample is reduced to the desired size (Fig. 3).

10.1.2 As an alternative to the procedure described in 10.1.1, when the floor surface is uneven, place the field sample on a canvas blanket and mix with a shovel as described in 10.1.1, or by alternately lifting each corner of the canvas and pulling it over the sample toward the diagonally opposite corner causing the material to be rolled. Flatten the pile as described in 10.1.1. Divide the sample as described in 10.1.1, or if the surface beneath the blanket is uneven, insert a stick or pipe beneath the blanket and under the center of the pile, then lift both ends of the stick, dividing the sample into two equal parts. Remove the stick leaving a fold of the blanket between the divided portions. Insert the stick under the center of the pile at right angles to the first division and again lift both ends of the stick, dividing the sample into four equal parts. Remove two diagonally opposite quarters, being careful to clean the fines from the blanket. Successively mix and quarter the remaining material until the sample is reduced to the desired size (Fig. 4).

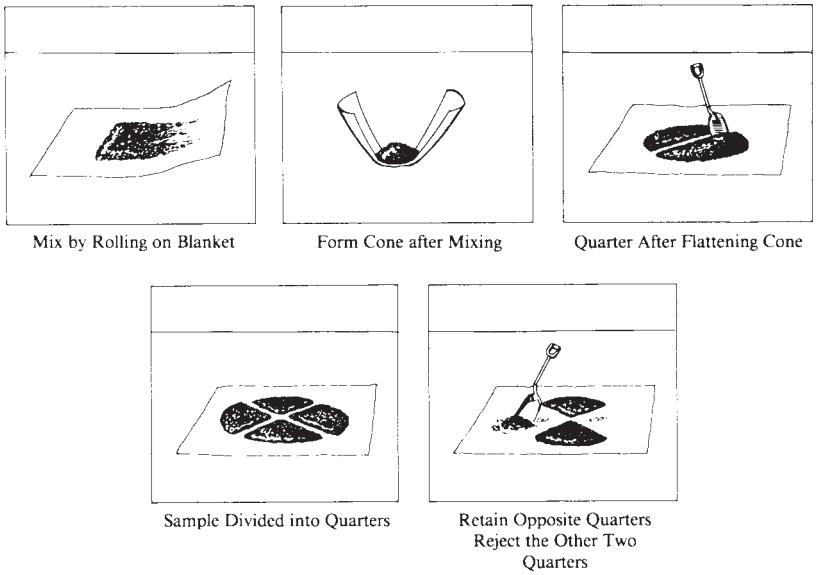

FIG. 4 Quartering on a Canvas Blanket

METHOD C—MINIATURE STOCKPILE SAMPLING (DAMP FINE AGGREGATE ONLY)

11. Apparatus

11.1 Apparatus shall consist of a straight-edged scoop, shovel, or trowel for mixing the aggregate, and either a small sampling thief, small scoop, or spoon for sampling.

12. Procedure

12.1 Place the original sample of damp fine aggregate on a hard clean, level surface where there will be neither loss of material nor the accidental addition of foreign material. Mix the material thoroughly by turning the entire sample over three times. With the last turning, shovel the entire sample into a conical pile by depositing each shovelful on top of the preceding one. If desired, flatten the conical pile to a uniform thickness and diameter by pressing down the apex with a shovel so that each quarter sector of the resulting pile will contain the material originally in it. Obtain a sample for each test by selecting at least five increments of material at random locations from the miniature stockpile, using any of the sampling devices described in 11.1.

13. Keywords

13.1 aggregate; aggregate—coarse; aggregate—fine; field testing—aggregate; sampling—aggregates; sample reduction; specimen preparation

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 706 – 02 (Reapproved 2008)ε1

Standard Specification for Limestone for Animal Feed Use[1]

This standard is issued under the fixed designation C 706; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—A units statement was added editorially as paragraph 1.2 and subsequent paragraphs were renumbered in December 2008.

1. Scope

1.1 This specification covers limestone supplied for use as a mineral supplement in animal feeds.

NOTE 1—The calcium needed for animal nutrition is customarily supplied by limestone. Such limestone must be sufficiently fine to blend with mixed feeds and yet be free from excessive dusting.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 Definitions of terms applying to this specification appear in Terminology C 51.

4. General Requirements

4.1 The product must be suitable for animal feeding.

5. Chemical Requirements

5.1 Limestone, as identified on feed labels, shall conform to the chemical requirements given in Table 1.

6. Physical Requirements

6.1 Sieve analysis and other physical requirements shall be specified by the purchaser.

7. Test Methods

7.1 *Chemical Analysis*—Unless otherwise agreed upon between the purchaser and the manufacturer, the chemical analysis of the limestone shall be conducted in accordance with Test Methods C 25.

7.2 *Particle Size*—Unless otherwise agreed upon between the purchaser and the manufacturer, the sieve analysis of the material shall be determined in accordance with Test Methods C 110.

7.2.1 *Procedure*—If the entire sample is not to be dried, obtain lesser portions by riffling or quartering. Dry at between 115 to 120 °C to a constant mass and cool to room temperature. Obtain a 90 to 120-g dry sample by riffling or quartering. If the material tends to cake, break up the agglomerates with a soft rubber pestle. Quantitatively transfer the weighed sample to an 8-in. diameter standard sieve or set of sieves (for example, Nos. 10, 20, 40, 60, 80, and 100 or other appropriate combination conforming to Specification E 11). Conduct the sieve analysis in accordance with Test Methods C 110.

8. Sampling, Inspection, etc.

8.1 The sampling, inspection, rejection, retesting, packaging, and marking shall be conducted in accordance with Methods C 50.

9. Keywords

9.1 animal; feed; limestone; mineral; supplement

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved Dec. 1, 2008. Published February 2009. Originally approved in 1972. Last previous edition approved in 2002 as C 706 – 02.

TABLE 1 Chemical Requirements

Limestone Classes (See C 51)	Calcium, min, percent (as $CaCO_3$)	Magnesium, max, percent (as $MgCO_3$)	Magnesium, min, percent (as $MgCO_3$)	Moisture, max, percent
High Calcium	95	5	...	0.5
Magnesian	60	35[A]	5	0.5
Dolomitic	49	46[A]	35	0.5
Ground Limestone	82	[B]	[B]	0.5

[A] The high magnesium content of these materials usually limits their use to special-purpose feeds.
[B] As specified by the purchaser.

Designation: C 737 – 08

Standard Specification for Limestone for Dusting of Coal Mines[1]

This standard is issued under the fixed designation C 737; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers limestone suitable for use as dust in coal mines to prevent coal dust explosions.

NOTE 1—Limestone can serve as a source of incombustible material in coal mine operations. Limestone is dusted onto coal exposures in sufficient amount so that not less than 65 % of all loose dust shall be limestone incombustible material. In return air courses the concentration of incombustible materials should be not less than 80 % of the total dust (MSHA 30 CFR 75.403). With such a concentration of limestone incombustible material, dust explosions cannot initiate or be propagated from nearby gas explosions. The limestone must be substantially dry in order to dust satisfactorily.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in inch-pound units are to be regarded as standard. No other units of measurement are included in this standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

3. Chemical Composition

3.1 Limestone shall conform to the following as to chemical composition:

Moisture (at point of manufacture), max, %	0.5
Silica, free and combined, max, %	4.0

4. Physical Properties

4.1 Limestone for this application shall have the following particle size:

Passing a No. 20 (850-μm) sieve, min, %	100
Passing a No. 200 (75-μm) sieve, min, %	70

5. Test Methods

5.1 *Chemical Analysis*—The chemical analysis of the limestone shall be conducted in accordance with Test Methods C 25.

5.2 *Particle Size*—The sieve analysis of limestone shall be conducted in accordance with Test Methods C 110.

6. General Requirements

6.1 Either high calcium or dolomitic limestone may be furnished for this application.

7. Sampling, Inspection, etc.

7.1 The sampling, inspection, rejection, retesting, packaging, and marking shall be conducted in accordance with Methods C 50.

8. Keywords

8.1 coal mines; dolomitic limestone; high calcium limestone; limestone; limestone dust; mine explosions; moisture content; silica content

Designation: C754 – 09a

Standard Specification for Installation of Steel Framing Members to Receive Screw-Attached Gypsum Panel Products[1]

This standard is issued under the fixed designation C754; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers the minimum requirements for the installation of interior nonstructural steel framing and furring members designed to receive screw-attached gypsum panel products. The steel framing and furring members covered in this specification are limited to those complying with Specification C645.

1.2 Details of construction for a specific assembly to achieve the required fire resistance, sound or acoustic rating shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing, sound or acoustic laboratories.

1.3 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

A641/A641M Specification for Zinc–Coated (Galvanized) Carbon Steel Wire

A653/A653M Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process

A1008/A1008M Specification for Steel, Sheet, Cold-Rolled, Carbon, Structural, High-Strength Low-Alloy, High-Strength Low-Alloy with Improved Formability, Solution Hardened, and Bake Hardenable

C11 Terminology Relating to Gypsum and Related Building Materials and Systems

C645 Specification for Nonstructural Steel Framing Members

C840 Specification for Application and Finishing of Gypsum Board

2.2 *ICC-ES Document*[3]

ICC-ES-AC86 Acceptance Criteria for Steel Studs and Gypsum-Board Interior Nonload-Bearing Walls—Complete Construction—AC86—Approved July 1995 (Editorially revised September 2005) (Formerly ICBO AC86 dated July 1995)

3. Terminology

3.1 *Definitions*—Terms shall be as defined in Terminology C11.

3.2 *Descriptions of Terms Specific to This Standard:*

3.2.1 *channel*, *n*—the material described in 4.3 to which furring members are attached.

3.2.2 *cross furring*, *n*—furring member attached perpendicular to main runners or framing members.

3.2.3 *cross furring member*, *n*—a member installed perpendicularly to the main beams designed to receive screw attached gypsum panel products.

3.2.4 *direct furring*, *n*—furring members attached directly to the structural members of the building.

3.2.5 *framing member*, *n*—metal studs, runners (track), and rigid furring channels designed to receive screw attached gypsum panel products.

3.2.6 *furred ceiling*, *n*—a ceiling in which the rigid furring channels and studs are attached directly to the structural members of the building.

3.2.7 *furring*, *v*—preparing a wall or ceiling with framing or furring members to provide a level surface or airspace.

3.2.8 *furring member*, *n*—metal studs, rigid furring channels, or channels used either as direct furring or as cross furring.

3.2.9 *grid suspension system*, *n*—a ceiling system composed of modular interlocking steel components designed to receive screw-attached gypsum panel products.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for the Application of Gypsum and Other Products in Assemblies.

Current edition approved Nov. 1, 2009. Published December 2009. Originally approved in 1974. Last previous edition approved in 2009 as C754 – 09. DOI: 10.1520/C0754-09a.

www.technobetar.ir

3.2.10 *main beam*, *n*—the main support member of a grid suspension system that receives cross furring members.

3.2.11 *main runner*, *n*—the channel or stud that is attached to or suspended from the structural members of the building.

3.2.12 *runner (track)*, *n*—a member designed to receive the ends of metal studs, attached directly to the structural members of the building.

3.2.13 *suspended ceiling*, *n*—a ceiling in which the main runners and cross furring are suspended below the structural members of the building.

4. Materials and Manufacture

4.1 *Studs, Runners, Rigid Furring Channels, and Grid Suspension Systems*—see Specification C645.

4.2 *Tie Wire and Hanger Wire*—Zinc-coated (galvanized) soft-annealed steel, or of a material and size having equivalent corrosion resistance and strength. Wire diameters (uncoated) specified herein correspond with United States steel wire gauge numbers as follows:

Diameter[A]		Wire Gauge
in.	mm	(U.S. Steel Wire Gauge)
0.0348	0.88	No. 20
0.0410	1.04	No. 19
0.0475	1.21	No. 18
0.0540	1.37	No. 17
0.0625	1.59	No. 16
0.0800	2.03	No. 14
0.0915	2.32	No. 13
0.1055	2.68	No. 12
0.1205	3.06	No. 11
0.1350	3.43	No. 10
0.1483	3.77	No. 9
0.1620	4.12	No. 8

[A] Allowable variations in diameter shall be in accordance with tolerances as established in Specification A641/A641M.

4.3 *Channels*—Channels shall be cold-formed from steel with a minimum 33 000 psi (228 MPa) yield strength and 0.0538 in. (1.37 mm) minimum bare steel thickness. Channels shall have a protective coating conforming to Specification A653/A653M–G40 or shall have a protective coating with an equivalent corrosion resistance, and shall have the following minimum weights in lb per 1000 linear ft (kg/m):

Size		Weight		Flange Width	
in.	(mm)	lb/1000 ft	(kg/m)	in.	(mm)
¾	(19)	277	(0.412)	½	(13)
1½	(38)	414	(0.616)	½	(13)
2	(51)	506	(0.753)	½	(13)
2½	(64)	597	(0.888)	½	(13)

4.4 *Grid Suspension System*:

4.4.1 *Main Beam*—Formed from cold-rolled steel "T" sections, indexed with slots to receive ends of cross furring members, and with stamped couplings at each end for the purpose of splicing.

4.4.2 *Cross Furring Members*—Formed from cold-rolled steel, designed to permit screw attachment of gypsum panel products, and formed with an end configuration that permits mechanical interlock with the indexed slots of the main beam.

4.5 *Rod and Flat Hangers*—Formed from steel conforming to Specification A1008/A1008M. When specified, rod and flat hangers shall be protected with zinc coating or another equally rust-inhibiting coating.

5. Installation of Metal Framing

5.1 *Tolerances*:

5.1.1 Spacing of studs and furring members shall be not more than ±⅛ in. (3 mm) from the spacing shown in Tables 1 and 2. Any cumulative error shall be not more than ±⅛ in.

5.2 *Runner (Track) Installation*:

5.2.1 *General*—Runners shall be aligned accurately at the floor and ceiling and securely anchored approximately 2 in. (50 mm) from the runner ends, not more than 24 in. (610 mm) on center. Runners shall be secured with fasteners at partition corners. One runner shall extend to the end of the corner and the other runner shall butt to it and be gapped to allow clearance for the gypsum panel product thickness. Runners shall not be mitered.

5.2.2 *Runners to Concrete Slabs*—Shall be fastened with concrete stub nails, expansion anchors, shielded screws, or power-driven fasteners not exceeding 24 in. (610 mm) on center.

5.2.3 *Runners to Wood*—Shall be fastened with screws providing not less than 1 in. (25 mm) penetration or nails providing 1½ in. (38 mm) penetration into the wood.

5.2.4 *Runners to Suspended Ceilings*—Shall be fastened with "Molly"-type expandable fasteners, toggle bolts, clamps, or screws into channels, splines, "T" runners, or other members.

5.3 *Stud Installation*:

5.3.1 *Stud Height and Spacing Limitations*:

5.3.1.1 Maximum framing spacing determined by gypsum panel product thickness shall be in accordance with Table 1.

5.3.1.2 Stud heights shall be not greater than those shown in Tables 3-5.

5.3.1.3 Studs shall engage both the floor and ceiling runners. The gap between the end of a stud and the web of the top and bottom runner shall be not more than ¼ in. (6 mm).

5.3.1.4 Where conditions require that a partition be constructed with compensation for vertical structural movement, the gap between the end of a stud and the adjacent runner shall be designed by an architect or engineer.

5.3.2 *Location*:

5.3.2.1 Studs shall be positioned vertically and shall be spaced not more than the maximum framing spacing allowed for the finish specified. Studs located adjacent to door and window frames, partition intersections, and corners shall be anchored to runner flanges by screws, or by crimping at each stud and runner flange.

5.3.2.2 At the junction of through and abutting partitions, a stud shall be located not more than 2 in. (50 mm) away from the intersection in the abutting partition from the through partition (see Fig. 1), and not more than 2 in. (50 mm) from partition corners and other construction. A stud shall be located adjacent to all door and borrowed light frames. Studs shall be securely anchored to the jamb anchor clips on each door frame or borrowed light frame by bolt or screw attachment. A header shall be formed over metal door and borrowed light frames with a cut-to-length section of runner placed horizontally with the flanges cut and web bent vertically at each end, and securely attached to the adjacent vertical studs. A cut-to-length stud shall be positioned at the location of vertical joints over

Parallel—parallel to framing members
NA—not applicable
NR—not recommended
oc—on center

[A] Denotes framing spacing for base layer in two-layer application.

TABLE 2 Spans and Spacings of Horizontal Furring Members

Type of Furring	Maximum[A] Spacing c to c,[B] in. (mm)	Maximum Span, ft (mm)
Rigid Furring Channel	24 (610)	4 (1220)
1⅝ in. (41 mm) stud (erected with open side up and against support)	24 (610)	5 (1520)
2½ in. (64 mm) stud (erected with web vertical to support)[C]	24 (610)	6 (1830)
3⅝ in. (92 mm) stud (erected with web vertical to support)[C]	24 (610)	8 (2440)

[A] Consult Table 1 for maximum spacing as determined by gypsum panel product thickness.
[B] c to c—center to center
[C] A6 in. (150 mm) length of same size stud or track shall be nested to form a "box" at each saddle tie.

the header extending to the ceiling runner. Additional cut to length studs required to comply with framing spacing in accordance with Table 1 shall also be added over the header, extending to the ceiling runner.

5.3.2.3 At partition corners, a stud shall be installed so that it forms the outside corner. Following application of a single layer of gypsum panel product to this stud, a second stud shall be installed in the abutting runner and the web shall be screw attached through the gypsum panel product into the flange of the first stud (see Fig. 2). A three-stud conventional corner shall be permitted (see Fig. 3).

5.4 *Chase Wall Partitions*:

5.4.1 A double row of runners and studs as specified in 5.2 and 5.3 shall be installed. Height shall be in accordance with 5.3.1.2.

5.4.2 Where a gypsum panel product is used as bracing between chase walls, a gap of not more than 20 in. (508 mm) between rows of studs shall be permitted.

5.4.3 Horizontal cross braces to opposite studs shall be installed not more than 4 ft (1220 mm) on center vertically. Horizontal cross braces shall be either of the following:

5.4.3.1 Gypsum panel product gussets 12 in. (305 mm) deep attached to the stud webs with three screws.

5.4.3.2 A stud or runner with the web screw attached to the wall stud web with not less than two screws.

5.5 *Rigid Furring Channel Installation, Direct Attachment to Masonry or Concrete*—The furring member shall be attached to masonry or concrete surfaces, either vertically or horizontally. Spacing shall be determined by gypsum panel product thickness in accordance with Table 1. For furring positioned horizontally, the center line of the furring members closest to the floor and ceiling shall be attached not more than 3 in. (76 mm) from the floor and ceiling lines. The furring member shall be secured with fasteners occurring on alternated flanges and spaced 24 in. (610 mm) on center.

5.6 *Resilient Furring Channel Installation to Steel and Wood Members*:

[A] Based on tests conducted with gypsum board attached with screws spaced 12 in. (305 mm) o.c. to framing members.
[B] Maximum stud heights are also applicable to walls sheathed with gypsum board greater than ½ in. (12.7 mm) thick and multiple layers of gypsum board.
[C] Application per Specification C840.
[D] Limiting heights based on ICC-ES "Acceptance Criteria for Steel Studs and Gypsum-Board Interior Nonload-Bearing Walls—Complete Construction—AC86—Approved July 1995 (Editorially revised September 2005)."
[E] Runner flanges need not be fastened to studs except as required by 5.3.2.1.
[F] ICC-ES-AC86 utilized a 0.75 load reduction factor (for strength determination only) to determine the heights as shown in the table.
[G] The *Industry Designator* defines the cold formed steel framing member.
Example: *350S125-18:*
350 designates the member web depth in 100ths of an in., 350 = 3.50 in. (88.9 mm).
S designates the type of member, *S* = stud.
125 designates the member flange width in 100ths of an in., 125 = 1.25 in. (32 mm).
18 designates the member base metal thickness in mils, 18 = .0179 in. (0.455 mm).
[H] Data not available.
[I] Also applicable to 3-⅝ in. (92.1 mm) stud depth, *362S125-18*.

5.6.1 Resilient furring channel shall be installed to wall framing members with the mounting flange of the resilient furring channel down, except at the floor where the attachment flange shall be permitted to be installed with the flange up to accommodate fastening to the framing members (See Fig. 4). In the case of two-legged resilient furring channel only the lower attachment flange shall be attached the the wall framing members.

5.6.2 For wall framing members, the first (lowest) row of resilient furring channel shall be not more than 2 in. (50 mm) off of the floor (as measured from the floor to the center of the face of the resilient channel) and the highest row of resilient furring channel shall be not more than 6 in. (150 mm) from the ceiling (as measured from the ceiling to the center of the face of the resilient channel). For ceiling framing members the first row and the last row of resilient furring channel shall be located not more than 6 in. (150 mm) from the adjacent wall.

5.6.3 The resilient furring channel shall be positioned with the slotted hole(s) directly over the framing member (See Fig. 4). The resilient furring channel shall be attached to the framing member with Type-S × ⅜ in. (10 mm) pan head framing screws using the screw hole provided in the mounting flange.

NOTE 1—If no screw hole is provided or located at the framing member, drill through the mounting flange to attach the resilient furring channel to the member.

5.6.4 Resilient furring channel members shall be spliced either by "nesting" the ends of the resilient furring channel members directly over the framing member and screwing through the mounting flange into the framing members or by butting the resilient furring channel members over the framing member and screwing through the mounting flange into the stud members. A gap of not less than 1/16 in. (2 mm) shall be left between the members. When nesting the ends of the members, an additional screw attaching the mounting flanges of the resilient furring channels to each other at the ends of each of the nested resilient furring channels shall be installed.

[A] Based on tests conducted with gypsum board attached with screws spaced 12 in. (305 mm) o.c. to framing members.
[B] Maximum stud heights are also applicable to walls sheathed with gypsum board greater than ½ in. (12.7 mm) thick and multiple layers of gypsum board.
[C] Application per Specification C840.
[D] Limiting heights based on ICC-ES "Acceptance Criteria for Steel Studs and Gypsum-Board Interior Nonload-Bearing Walls—Complete Construction—AC86—Approved July 1995 (Editorially revised September 2005)."
[E] Runner flanges need not be fastened to studs except as required by 5.3.2.1.
[F] ICC-ES-AC86 utilized a 0.75 load reduction factor (for strength determination only) to determine the heights as shown in the table.
[G] The *Industry Designator* defines the cold formed steel framing member.
Example: *350S125-33:*
350 designates the member web depth in 100ths of an in., 350 = 3.50 in. (88.9 mm).
S designates the type of member, *S* = stud.
125 designates the member flange width in 100ths of an in., 125 = 1.25 in. (32 mm).
33 designates the member base metal thickness in mils, 33 = .0329 in. (0.836 mm).
[H] Data not available.
[I] Also applicable to 3-⅝ in. (92.1 mm) stud depth, *362S125-33*.

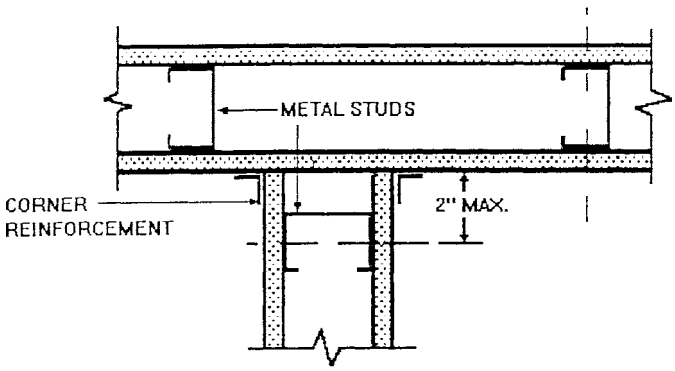

FIG. 1 Abutting Partition Detail

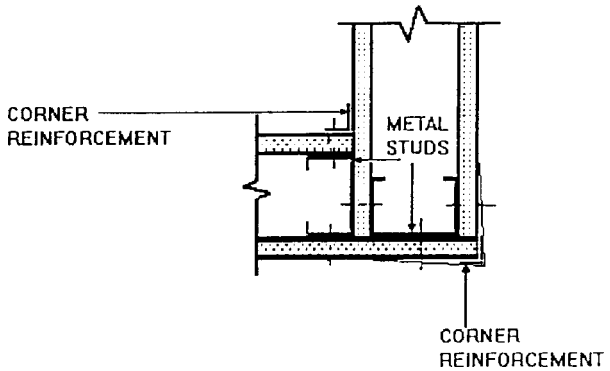

FIG. 2 Partition Corner Detail

resilient furring channels to each other at the ends of the nested resilient furring channels shall be installed.

5.7.5 Gypsum panel products shall be attached to the resilient furring channel using a screw length to ensure that the screw point does not make contact with the framing member.

5.8 *Wall Furring-Bracket System*:

5.8.1 Adjustable wall furring brackets with serrated edges facing upward shall be attached to masonry or concrete walls in the following spacing pattern: 48 in. (1220 mm) on center vertically, 6 in. (152 mm) maximum from floor and ceiling, 36 in. (910 mm) on center horizontally, 4 in. (100 mm) maximum from columns or other abutting construction, and as required above and below windows. Each bracket shall be fastened through the hole nearest to the serrated edges.

5.8.2 Channels ¾ in. (19 mm) shall be laid horizontally on the furring brackets so that the channel flanges engage the

www.technobetar.ir

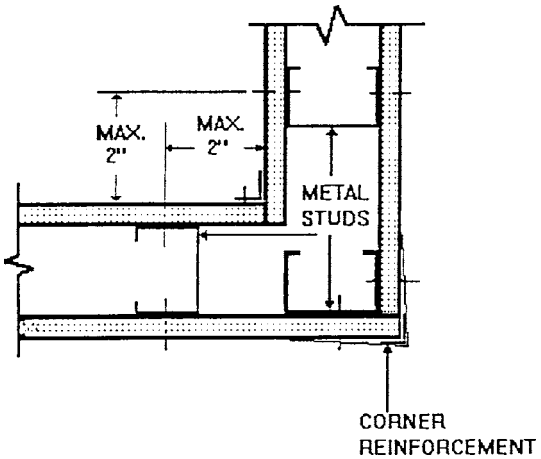

FIG. 3 Partition Corner Detail

serrated edges of the bracket. Each channel shall be plumbed to align with ceiling and base channels. Channels shall be wire-tied to each bracket with a double strand of 16 gauge or a triple strand of 18-gauge tie wire. Each excess bracket length shall be bent down and inward toward the wall.

5.8.3 Rigid furring channels shall be positioned vertically with wing flanges against the channels with spacing determined by gypsum panel product thickness in accordance with Table 1. Each furring channel intersection shall be wire-tied with a double strand of 16-gauge or a triple strand of 18-gauge tie wire.

5.9 *Soffits*—Soffits shall be framed by attaching runners to ceilings and walls as specified in 5.2.1. Runners shall be used for backing of all outside corners. Hangers or spacers (cut-to-length pieces of stud), shall be provided from ceiling runner to outside corner and from outside corner to vertical surface. Where the hanger or spacer length is not more than the maximum framing spacing allowed in Table 1 for the gypsum panel product thickness specified, hangers or spacers shall be located not more than 4 ft (1220 mm) on centers. Where the hanger or spacer length is more than the maximum framing spacing allowed, they become the attachment means and shall be spaced in accordance with Table 1.

6. Suspended and Furred Ceilings

6.1 *Hangers and Inserts for Suspended Ceilings*:

6.1.1 Minimum No. 12-gauge (2.9 mm) galvanized, soft annealed, mild steel wire per Specification A641/A641M shall be used for ceiling areas not more than 16 ft^2 (1.5 m^2) and not more than 6 lb/ft^2 (2.7 kg/m^2).

6.1.2 For ceiling weights greater than 6 lb/ft^2 (2.7 kg/m^2) but not more than 10 lb/ft^2 (4.6 kg/m^2), use Table 6.

6.1.3 Wire hangers shall be saddle-tied around main runners and furring members so as to prevent turning or twisting of the member and to develop the full strength of the hanger with a minimum of three complete wraps around itself within 3 in. (75 mm) (see Fig. 5 and Fig. 6).

6.1.4 Wire for attaching main runners and rigid furring channels directly to concrete beams and joists, to steel beams and joists, and to wood beams and joists shall be per 6.1.1 or 6.1.2.

6.1.5 *Flat Channel Beam Hanger*—For attaching indirect hung grid suspension ceiling systems to 1.5 in. (38 mm) or 2.0 in. (51 mm) cold rolled channel. Flat channel beam hanger shall be formed from steel conforming to Specification A653/A653M and having a minimum width of 1.5 in. (38 mm) and a minimum thickness of 0.048 in. (1.21 mm) (See Fig. 7)

6.2 *Wood Construction*—Hangers for suspended ceilings under wood construction shall be per 6.1.1 or 6.1.2, and shall be attached to supports by any of the following methods.

6.2.1 A hole shall be drilled through the wood member not less than 3 in. (76 mm) above the bottom with the upper end of the wire hanger passed through the hole and twisted three times around itself (see Fig. 8).

6.2.2 Three 12-penny nails shall be driven, on a downward slant, into the sides of the wood member with not less than 1¼ in. (32 mm) penetration and not less than 5 in. (130 mm) from the bottom edges, and not more than 36 in. (910 mm) on center with the upper end of the wire hanger wrapped around the nails and twisted three times around itself (see Fig. 9).

6.2.3 A loop shall be formed on the upper end of the wire hanger and secured to the wood member by not less than four 1½ in. (38 mm), 9-gauge diameter wire staples driven horizontally or on a downward slant into the sides of the wood members, three near the upper end of the loop, and the fourth to fasten the loose end (see Fig. 10).

6.2.4 Where supports for flooring are thicker than 1½ in. (38 mm) and are spaced more than 4 ft (1220 mm) on center, 1½ in. (38 mm) No. 1/0 (0.3065 in.) (7.78 mm) eye screws, or equivalent, spaced not greater than 3 ft (910 mm) on centers shall be screwed into the flooring with the upper end of the hanger inserted through the eye screws and twisted three times around itself.

6.2.5 *Flat Hangers*—Two holes shall be drilled in the upper end of the flat hangers and nailed to the sides of the wood members with 12d penny nails driven through holes and clinched. Nails shall be not less than 3 in. (76 mm) above the bottom edge of the framing member (see Fig. 11).

6.3 *Rigid Furring Channels*—Rigid furring channels applied directly to wood framing shall be applied with screws providing 1-in. (25.4 mm) penetration or as otherwise specified by the manufacturer of the furring channels.

6.4 *Flat Hangers and Inserts*:

6.4.1 *Inserts*—Where 1 by 3⁄16-in. (25 by 4.7-mm) inserts are used, 7⁄16-in. (11-mm) diameter holes shall be punched on the center line at the lower ends of the insert to permit flat hangers to be bolted tightly to the inserts with 3⁄8-in. (10-mm) diameter bolts.

6.4.2 *Hangers*—Lower ends of the flat hangers shall be bolted to the main runners or shall be bent tightly around the members and bolted tightly to the main part of the hanger with 3⁄8-in. (9.5-mm) diameter bolts in a 7⁄16-in. (11-mm) diameter hole (see Fig. 12), or machine screws.

6.4.3 *General*—Holes in both inserts and hangers shall not be nearer to the ends than 3⁄8 in. (10 mm).

6.5 *Main Runners for Suspended Ceilings*—Channels for the various spacings of hangers shall be as specified in Table 7.

6.5.1 Ends and sides of main runners and cross furring shall not come in contact with abutting masonry or reinforced

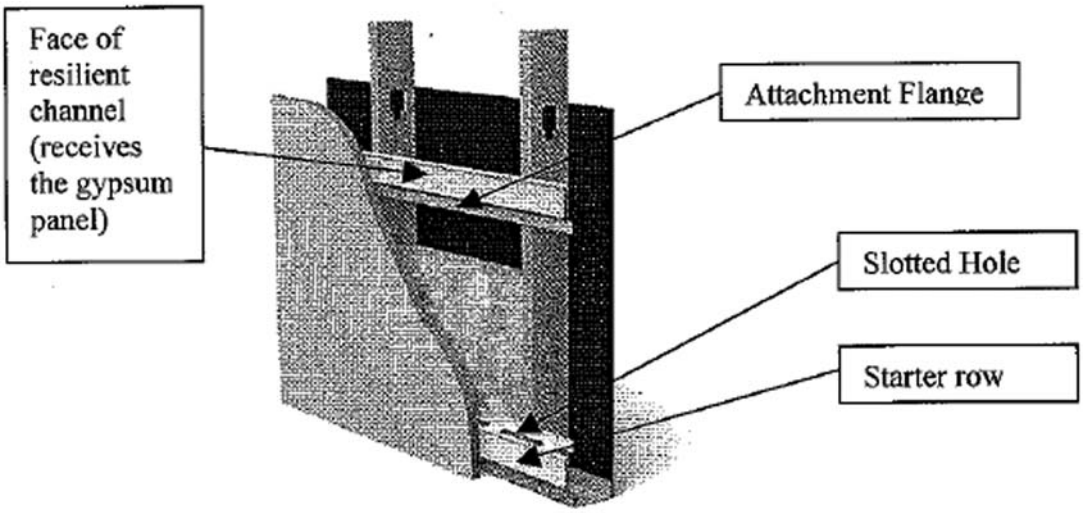

FIG. 4 Resilient Furring Channel

concrete walls or partitions. Clearance of not less than 1 in. (25 mm) from ends and ⅛ in. (3 mm) from sides shall be provided. A channel shall be located within 6 in. (150 mm) of the paralleling walls to support the ends of the cross furring. The ends at walls shall be supported by hangers located not more than 6 in. (150 mm) from such ends.

6.5.2 When main runners and cross furring are spliced, the ends shall be overlapped not less than 12 in. (305 mm) with flanges interlocked and securely fastened near each end of the splice with double loops of No. 16-gauge tie wire, minimum, or with screws.

6.6 *Furring Members for Suspended or Furred Ceilings*:

6.6.1 Furring members shall be spaced in accordance with Table 2 and Table 7.

6.6.2 Furring members shall be securely fastened to main runners and structural supports with special clips, screws, or equivalent attachments. Where required, rigid furring channels shall be saddle-tied to main runners with No. 16-gauge tie wire, a double strand of 18-gauge tie wire, or with screws (see Fig. 13).

6.6.3 When furring members are spliced, the ends shall be overlapped not less than 8 in. (203 mm) and securely fastened near each end of the splice with double loops of No. 16-gauge tie wire or with screws.

6.6.4 Flanges of rigid furring channels shall be interlocked. Ends and sides of furring members shall not come in contact with abutting masonry or reinforced concrete walls or partitions.

6.7 *Grid Suspension System*—Main beams shall be suspended in parallel rows spliced together at their ends.

6.7.1 Hangers for supporting the main beams shall be per 6.1.1 or 6.1.2.

6.7.2 Cross furring members of grid suspension systems shall interlock to the main beams in rows running perpendicular and spaced not to exceed maximums specified in Table 1. Cross furring members along the ceiling perimeter shall be supported by angle or channels attached to the wall.

7. Product Delivery, Identification, and Marking

7.1 All materials shall be delivered in original packages, containers, or bundles bearing the brand name and the name of the manufacturer or the supplier for whom the product is manufactured.

8. Product Storage

8.1 All materials shall be kept dry, preferably by being stored inside a building under a roof. Where necessary to store material outside, it shall be stacked off the ground, properly supported on a level platform, and fully protected from the weather.

9. Keywords

9.1 channel; framing; framing member; furring; grid suspension system; gypsum panel product; hangers; hanger wire; main runners; rigid furring channel; runner; stud; suspended ceiling; tie wire

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C754 – 08, that may impact the use of this specification. (Approved November 15, 2009)

(*1*) Revised 1.2.

(*2*) Added new 5.6, 5.7, and Fig. 4 and renumbered subsequent paragraphs, notes, and figures.

Committee C11 has identified the location of selected changes to this specification since the last issue, C754 – 08, that may impact the use of this specification. (Approved May 15, 2009)

(*1*) Revised Fig. 1.

Committee C11 has identified the location of selected changes to this specification since the last issue, C754 – 07, that may impact the use of this specification. (Approved November 1, 2008)

(*1*) Revised 4.5, 6.1.1, 6.1.2, 6.1.3, 6.1.4, 6.2, and 6.7.1.
(*2*) Added new 6.1.5.
(*3*) Revised the title of Table 6.
(*4*) Added new Fig. 6 and Fig. 7 and renumbered subsequent figures.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 778 – 06

Standard Specification for Standard Sand[1]

This standard is issued under the fixed designation C 778; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This specification covers standard sand for use in the testing of hydraulic cements.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars(Using 2-in. or [50-mm] Cube Specimens)

C 127 Test Method for Density, Relative Density (Specific Gravity), and Absorption of Coarse Aggregate

C 136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C 150 Specification for Portland Cement

C 185 Test Method for Air Content of Hydraulic Cement Mortar

C 595 Specification for Blended Hydraulic Cements

C 702 Practice for Reducing Samples of Aggregate to Testing Size

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *20–30 sand*, *n*—standard sand, predominantly graded to pass a 850-µm (No. 20) sieve and be retained on a 600-µm (No. 30) sieve.

3.1.2 *graded sand*, *n*—standard sand, predominantly graded between the 600-µm (No. 30) sieve and the 150-µm (No. 100) sieve.

3.1.3 *standard sand*, *n*—silica sand, composed almost entirely of naturally rounded grains of nearly pure quartz, used for preparing mortars in the testing of hydraulic cements.

4. Requirements

4.1 Sand shall meet the requirements of Table 1 with respect to grading, source of sand, and absence of undesirable air entraining characteristics.

METHODS OF SAMPLING AND TESTING STANDARD SANDS

5. Apparatus

5.1 *Sieves*—The sieves shall be standard 203-mm (8-in.) diameter, full-height, wire-cloth sieves, conforming to the requirements of Specification E 11, and of the following sizes:

1.18-mm (No. 16)	425-µm (No. 40)
850-µm (No. 20)	300-µm (No. 50)
600-µm (No. 30)	150-µm (No. 100)

5.2 *Sample Splitter*—The sample splitter, receptacles, and feeder pan or hopper shall conform to the general design requirements listed in Method A, apparatus section of Practice C 702, except that the device shall have no fewer than eight chutes having a maximum opening no greater than 13 mm, and

[1] This specification is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.95 on Coordination of Standards.

Current edition approved May 15, 2006. Published May 2006. Originally approved in 1974. Last previous edition approved in 2002 as C 778 – 02.

TABLE 1 Standard Sand Requirements

Characteristics	20-30 Sand	Graded Sand
Grading, percent passing sieve:		
1.18 mm (No. 16)	100	100
850 µm (No. 20)	85 to 100	
600 µm (No. 30)	0 to 5	96 to 100
425 µm (No. 40)		65 to 75
300 µm (No. 50)		20 to 30
150 µm (No. 100)		0 to 4
Difference in air content of mortars made with washed and unwashed sand, max, % air[A]	2.0	1.5[B]
Source of sand	Ottawa, IL or LeSuer, MN	Ottawa, IL

[A] This determination is needed when contamination of sand is suspected as discussed in 8.1.

[B] Compressive strength of Test Method C 109/C 109M mortar made with Specification C 150 or C 595 cement will be reduced approximately 4 % for each percent of air in the compacted cube. However, as many as three batches of washed and three of unwashed sand may be needed to reliably detect a difference in strength of 7 % between washed and unwashed sand mortars.

a minimum opening at least three times the diameter of the largest particle of sand in a sample to be split.

5.3 *Reference Masses and Devices for Determining Mass*—Reference masses and devices for determining mass shall conform to the requirements of Specification C 1005 as appropriate for the size of the sample the mass of which is to be determined.

6. Sampling

6.1 Sample each lot or shipment and test for the grading requirements in Table 1. Determine air entraining characteristics only when contamination of sand is suspected. Sample the shipment in accordance to the procedure listed in 9.1.

6.2 *Procedure*—Using *Method A–Mechanical Splitter* procedure described in Practice C 702, reduce the entire contents of a bag of standard sand to a testing size of approximately 100 g.

7. Sieve Analysis

7.1 *Sieving*—Sieve the sand by hand or mechanically as described in Test Method C 136.

7.2 *Reporting*—Report the results of the sieve analysis as total percentage passing each sieve.

8. Tests for Air-Entraining Potential of Sand

8.1 Small amounts of some surfactants or other contaminants will produce air voids in mortars made with 20–30 sand, graded sands or both. When contamination is suspected, test the sands in accordance with the procedures described in this section to determine the effect on air content or strength (see Note 1).

NOTE 1—It may be desirable to wash these sands routinely to avoid potential problems. Additionally, the washing procedure outlined in 8.1.1 will tend to minimize segregation of sand that may occur when the sand is handled in a dry state.

8.1.1 Obtain a sample of at least 2800 g from a full bag of sand. Place the remainder of the sand from the bag in a concrete mixer of the drum type. Add sufficient water to cover the sand and mix for 2 min. Decant the water over a 75 µm sieve and drain for 2 min. Repeat the washing and decanting procedure four times. Tilt the mixer and drain the sand for 20 min or longer. Determine the mass of damp sand and place it in approximately batch-sized quantities in separate containers. Dry the sand to constant mass in an oven at 110 °C. Cool and adjust the quantity of dry sand to the amount required for a test. Prepare two batches of each of "washed" and as "as received" sand for test following the procedures in Test Method C 185 for 20–30 sand or Test Method C 109/C 109M for graded sand.

8.1.2 Tests for air-entraining potential of a standard sand shall be made on a single day by a single operator.

8.2 *20–30 Sand*—Prepare two batches of mortar with washed sand and two with "as received" sand in accordance with Test Method C 185. Compare the average air content for washed and unwashed sand mortars for compliance with limit in Table 1.

8.3 *Graded Sand*—Prepare two batches of mortar with washed sand and two with "as received" sand in accordance with Test Method C 109/C 109M. When Test Method C 109/C 109M mortar cubes are removed from the molds, determine the density of a group of at least three cubes from each batch by determining the mass of the cubes both in air and immersed in water. Follow procedures outlined in Test Method C 127 for bulk specific gravity (SSD). Determine the mass of the cubes to at least the nearest gram. Calculate the apparent air content as follows:

$$\text{apparent air content} = ((D_t - D_m)/D_t) \times 100 \quad (1)$$

where:

D_m = the measured density (bulk specific gravity (SSD)), and

D_t = the theoretical density of air-free mortar, g/cm^3.

Note that D_t is calculated as the total mass of the ingredients in a batch of mortar divided by the sum of the absolute volumes of the cement, sand, and water used in the batch. Average the apparent air content of the two batches made with washed sand and compare that average with the similar average for "as received" sand mortar to determine compliance with the limit in Table 1.

9. Rejection

9.1 *Standard Sand*—Reject a bag of standard sand if the contents fail to meet one or more of the requirements of this specification. Sample a shipment of standard sand by selecting every 15th bag by consecutive number beginning with the 5th bag of the shipment. Count bags missing from the sequence as if they were there. Accept a shipment of standard sand if the contents of the selected bags meet the requirements of this specification. If any of the selected bags fail to meet one or more of the requirements of this specification, resample the shipment by selecting every 15th bag by consecutive number beginning with the 10th bag of the shipment. Accept a shipment of standard sand if the contents of the selected bags on the resampling meet the requirements of this specification. If any of the selected bags in the resampling fail to meet one or more of the requirements of this specification, and the rejected bag is within a 15-bag sequence of a bag rejected in the first selection of bags, reject the entire sequence of bags between accepted tests. Reject the entire shipment if half of the number

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

of bags tested fail to meet the requirements of this specification, or if the shipment consists of five bags or less if one randomly selected bag fails the specification.

9.2 Table 2 shows for both sampling and resampling in Column 2 the number of bags to be tested based on the total number of consecutive bags in the shipment. Column 3 shows the identification of the bag to be selected for test based on the consecutive number of the bags.

TABLE 2 Sampling and Resampling of Standard Sand

Total No. of Consecutive Bags in Shipment	No. of Bags to Test	Test in Consecutive No., the Following Bags
Sampling:		
less than 5	1	random
5 to 19	1	5th
20 to 34	2	5th and 20th
35 to 49	3	5th, 20th, and 35th
50 to 64	4	5th, 20th, 35th, and 50th
Resampling:		
less than 5	none	reject shipment
5 to 19	1	10th
20 to 34	2	10th and 25th
35 to 49	3	10th, 25th, and 40th
50 to 64	4	10th, 25th, 40th, and 55th

NOTE 2—For example, if, in a shipment of 30 bags, on first sampling, the 20th bag fails the specification, and on resampling, the 25th bag fails the specification, the entire shipment is rejected. If the shipment were 100 bags and on first sampling only the 20th bag fails, and on resampling only the 25th bag fails, only bags Nos. 11 to 34 would be rejected.

10. Packaging and Package Marking

10.1 *Packaging*—Standard sands shall be delivered in bags with impervious liners made of material that will not contaminate the sand.

10.2 *Marking*—Each bag shall be plainly marked as follows: ASTM C 778 20-30 Sand or ASTM C 778 Graded Sand as the case may be. The source of the sand and the mass of the sand contained therein shall be plainly indicated on each bag.

11. Keywords

11.1 20-30 sand; graded sand; hydraulic cement testing sand; standard sand

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C 778 – 02, that may impact the use of this specification. (Approved May 15, 2006)

(*1*) Revised 5.2.
(*2*) Added new 6.1.
(*3*) Revised 9.1 and Note 2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 779/C 779M – 05

Standard Test Method for Abrasion Resistance of Horizontal Concrete Surfaces[1]

This standard is issued under the fixed designation C 779/C 779M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers three procedures for determining the relative abrasion resistance of horizontal concrete surfaces. The procedures differ in the type and degree of abrasive force they impart, and are intended for use in determining variations in surface properties of concrete affected by mixture proportions, finishing, and surface treatment. They are not intended to provide a quantitative measurement of the length of service that may be expected from a specific surface.

1.2 The values stated in SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of each other.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

NOTE 1—Other procedures are available for measuring the abrasion resistance of concrete surfaces in addition to the three procedures contained in this test method. Consideration should be given to Test Methods C 944 and C 418. The test method most closely representing service conditions should be used.

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 418 Test Method for Abrasion Resistance of Concrete by Sandblasting

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 944 Test Method for Abrasion Resistance of Concrete or Mortar Surfaces by the Rotating-Cutter Method

3. Significance and Use

3.1 The three test methods provide simulated abrasion conditions, which can be used to evaluate the effects on abrasion resistance of concrete, concrete materials, and curing or finishing procedures. They may also be used for quality acceptance of products and surface exposed to wear. They are not intended to provide a quantitative measurement of length of service.

3.2 The equipment used by each of these procedures is portable and thus suitable for either laboratory or field testing. The three procedures determine the relative wear of concrete surfaces as follows:

3.2.1 *Procedure A*—The revolving-disk machine operates by sliding and scuffing of steel disks in conjunction with abrasive grit.

3.2.2 *Procedure B*—The dressing-wheel machine operates by impact and sliding friction of steel dressing wheels.

3.2.3 *Procedure C*—The ball-bearing machine operates by high-contact stresses, impact, and sliding friction from steel balls.

NOTE 2—Diagrams of three machines meeting these specifications are shown in Fig. 1, Fig. 2, and Fig. 3.[4]

PROCEDURE A—REVOLVING DISKS

4. Apparatus

4.1 The function of the apparatus is dependent upon the abrasive action of the flat faces of three 60-mm (2⅜-in.) diameter, cold-rolled steel revolving disks, each attached to motor-driven vertical shafts which also revolve about a vertical axis. The inside diameter of the resulting circular and abraded track shall be approximately 150 mm (6 in.) and the outside diameter 275 mm (11 in.). Crossed slots 90° to each other and cut 5 mm (3⁄16 in.) deep and 6 mm (¼ in.) wide are located symmetrically in the abrasive flat faces.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.62 on Abrasion Testing of Concrete.

Current edition approved Dec. 15, 2005. Published January 2006. Originally approved in 1974. Last previous edition approved in 2000 as C 779 – 00.

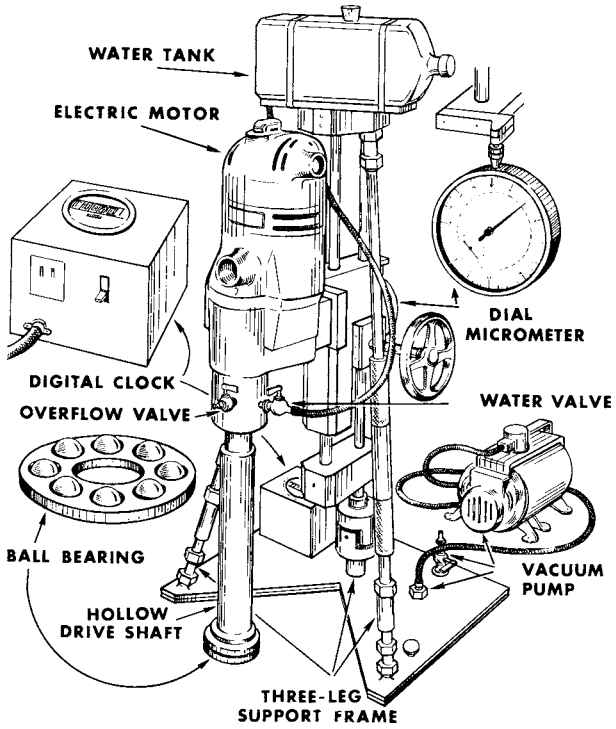

FIG. 3 Ball Bearing Abrasion Test Machine

4.2 The disks are free floating inasmuch as they are self-supporting and are driven transversely along a circular path at 12 rev/min (12 rpm) while being individually turned on their own axis at 280 rev/min (280 rpm). Cups attached at the top of the shaft of each disk shall be loaded with lead shot to produce a uniform total load of 22 N (5 lbf) on each abrading disk face.

4.3 The abrasive grit shall consist of 250 µ [No. 60] silicon carbide. This is fed from a storage cup mounted on the revolving circular plate through a 3-mm (⅛-in.) orifice passing through the plate. The flow of abrasive shall be controlled to a rate of 4 to 6 g/min by an adjusting needle located in the orifice. The abrasive falls at the midwidth of the circular abraded track, and midway between two of the disks.

4.4 The micrometer bridge consists of a machine-finished 25-mm (1-in.) rectangular steel bar of at least 300-mm (12-in.), clear span supported by a tripod and drilled along its centerline with ten 3-mm (⅛-in.) diameter holes spaced 6-mm (¼ in.) on center. The measuring instrument is a depth micrometre with a needle having an effective depth range of 25 to 50 mm (1 to 2 in.) and graduated to an accuracy of at least 0.025 mm (0.001 in.).

5. Test Specimen

5.1 For laboratory test purposes, the machine is designed to accommodate approximately 300 by 300-mm (12 by 12-in.) test specimens. The apparatus is equipped with an adjusting handle linked by a sprocket and chain-drive assembly to the four 25-mm (1-in.) diameter posts which support the entire rotating abrasion element. This feature permits the abrasion of test panels up to approximately 100-mm (4-in.) in thickness. A zero adjustment in the height of the abrasion assembly also permits the use of the apparatus as a portable device for measuring the abrasion resistance on the surfaces in place as well as on test specimens.

6. Procedure

6.1 Prior to the test period, precondition the sample to remove curing compound and surface irregularities by running the abrasion machine for 5 min, after which the initial measurements shall be taken. Obtain initial measurements to an accuracy of at least 0.025 mm (0.001 in.) of the test area by taking two series of 20 measurements each. Place the micrometer bridge so that the line of the second series of readings bisects at right angles to the first series of measurements. In making measurements subsequent to the abrasion period, take care that the micrometer bridge is placed in precisely the same position in which the reference measurements were obtained. To ensure this, outline the ends of the positioned micrometer bridge on the surface prior to making the initial measurements.

6.2 A test period of 30 min generally produces significant wear on most concrete surfaces, but it is recommended to extend the test period to 60 min, if information on the longtime abrasion resistance is desired.

6.3 In using the device as a portable apparatus, take care in the selection of the areas to be tested. Although the base of the apparatus is equipped with rubber pads, not only to prevent the apparatus from creeping during the abrasion operation but also to minimize the effect of slight variations in the level of the test areas. Select test areas with a minimum of variation in level so as to eliminate the creeping effect.

6.4 Take measurements of depth wear with a micrometer bridge as described in 4.4 to an accuracy of at least 0.025 mm (0.001 in.). Prior to each set of measurements, clean the specimen surface carefully by removing loose particles.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:58 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.5 Make three tests on surfaces representative of the concrete to be evaluated. When wear of the disks reduces the depth of the slots to less than 1.5 mm (1/16 in.), they shall be replaced. New disk faces shall be subjected to a break-in period of at least 15 min.

7. Interpretation of Results

7.1 The comparison of measurements of average depth of wear of representative surfaces at 30 and 60-min exposure to abrasion will indicate the relative abrasion resistance of these surfaces.

8. Report

8.1 Report the depth of wear of each surface tested as well as the average obtained on replicate surfaces.

8.2 Record mixture proportions (including cement content and water-cement ratio), specific gravities, grading of fine and coarse aggregates, Los Angeles abrasion test results, type and amount of material added to freshly placed concrete surface, type and extent of troweling, curing details, and age of concrete when tested.

PROCEDURE B—DRESSING WHEELS

9. Apparatus

9.1 The function of the apparatus is dependent upon the abrasive action of three sets of steel dressing wheels riding in a circular path over a horizontal concrete surface. The dressing wheels in each of the three sets of wheels turn freely on a horizontal axle at the bottom of a free-floating, weighted, vertical steel shaft.

9.2 Each of the three sets of seven dressing wheels are spaced so that each set cuts approximately a 40-mm (1½-in.) wide path. The machine produces a circular abrasion path of about 140-mm (5½-in.) inside diameter and 220-mm (8½-in.) outside diameter.

9.3 The apparatus shall consist of a motor-driven spider arrangement turning at 56 rev/min (56 rpm). The motor shall be mounted on a horizontal plate supported by four screw jacks allowing the motor to be raised and lowered. The spider shall be hung from the vertical motor shaft. The three vertical shafts shall be mounted in the spider arrangement so that they rotate with the spider and are free to move up and down in independent thrust-bearing sockets.

9.4 The three shafts shall be fitted with a yoke inside, upon which a series of seven dressing wheels are placed on a horizontal axle. The mass of each complete dressing wheel assembly as it bears on the concrete surface shall be 7.5 kg (16.5 lb).

9.5 The dressing wheels shall have an outside diameter of 60 mm (2⅜ in.) and a thickness of 3 mm (⅛ in.) and shall be provided with 18 flattened points, each having dimensions of 3.0 by 2.0-mm (0.125 by 0.075 in.). The dressing wheels shall be assembled on the shaft alternated with steel washers. The total width of seven dressing wheels and eight washers shall be approximately 40 mm (1½ in.). The dressing wheels must be loose enough to turn freely and independently.

9.6 The measuring instrument shall be a dial micrometer, reading to an accuracy of at least 0.025 mm (0.001 in.) with a range of at least 10 mm (0.4 in.). The contact end of the micrometer spindle shall have a spherical surface of 9.5-mm (⅜-in.) diameter. A jig located on the underside of the spider holds the micrometre magnetically in the approximate center of the path of the dressing wheels.

10. Test Specimen

10.1 Place a sample approximately 300 by 300 by 100-mm (12 by 12 by 4-in.) thick into the machine and lock it in place with vises provided. Do not remove the sample until the test is completed. Test three identical samples.

11. Procedure

11.1 Position the abrasion apparatus over surface to be tested. Rubber pads on the bottom of machine will hold the machine in place. Turn the screw crank until the full weight of each dressing-wheel shaft is resting on the concrete surface. Lower the spider as far as possible without exerting any pressure from the spider itself onto these three shafts. Allow a spacing of 15 mm (0.5 in.) for vertical travel of the dressing wheels. Lock the screw crank to prevent any change in vertical movement of the spider during testing.

11.2 Take an initial measurement to the nearest 0.025 mm (0.001 in.) on the test area with the dial micrometer in place while revolving the spider two revolutions by hand. Record this initial reading as a reference reading and then remove the micrometer. Start the machine and let it run for 30 min, brush off the loose material, insert the dial micrometer, and record the average reading again. If the readings are not reasonably uniform, record several readings taken around the circumference of the abraded surface from which the average reading may be computed. The difference between the reference reading and the 30-min reading is indicative of the depth of wear.

11.3 Make three tests on surfaces representative of the concrete to be evaluated. After every third test, install new dressing wheels.

11.4 A test period of 30 min generally produces significant wear on most concrete surfaces, but it is recommended to extend the period to 60 min, if simulation of more severe abrasion is desired. Take depth-of-wear readings at 15-min intervals to the nearest 0.025 mm (0.001 in.) to obtain a time versus wear curve.

12. Interpretation of Results

12.1 The comparison of measurements of average depth of wear of representative surfaces at 30 and 60-min exposure to abrasion will indicate the relative abrasion resistance of these surfaces.

12.2 A comparison of curves will indicate whether the resistance to abrasion is primarily at the surface or at a greater depth.

13. Report

13.1 Plot the time versus depth of wear of tests performed for 30 and 60-min durations on three representative surface locations or specimens and determine the average line.

13.2 Record the mixture proportions including cement content and water-cement ratio, specific gravities, grading of fine

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:58 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

and coarse aggregates, Los Angeles abrasion test results, type and amount of material added to freshly placed concrete surface, type and extent of troweling, curing details, and age of concrete when tested.

PROCEDURE C—BALL BEARINGS

14. Apparatus

14.1 The function of the apparatus is dependent upon the abrasive action of a rapidly rotating ball bearing under load on a wet concrete test surface. Water is used to flush out loose particles from the test path, bringing the ball bearing in contact with sand and stone particles still bonded to the concrete surface, thus providing impact as well as sliding friction.

14.2 The apparatus shall consist of a motordriven, hollow, vertical shaft resting on and turning ball bearings which rest on the concrete surface. As the ball bearings cut into the concrete surface, depth-of-wear readings can be taken continuously without stopping the test.

14.3 A digital clock shall be electrically connected to the drive motor so that both the drive motor and the clock can be started simultaneously. The clock shall read in seconds up to 9999 s.

14.4 The abrasion tool shall be composed of eight 18-mm ($^{23}/_{32}$-in.) diameter steel balls equally spaced in a retainer ring. The diameter of the ball circle shall be 60 mm (2½ in.). The abrasion tool shall be given a breaking-in period of 300 s. The abrasion tool shall be discarded when the diameter of the steel ball has been reduced to 17.8 mm (0.7 in.).

NOTE 3—During this period the steel balls will become slightly textured, leaving an apparent larger diameter.

14.5 The hollow vertical drive shaft shall be provided with a flanged bearing plate at its lower end, grooved to match the ball circle of the abrasion tool, and a centered 3-mm (⅛-in.) diameter orifice to permit a constant flow of water. The drive shaft shall be further provided with an adjustment of plumbness to the test surface. The total load on the ball bearing shall be 120 N (27 lbf) including the weight of drive motor, hollow drive shaft, and contained water. The motor shall be capable of revolving the drive shaft at 1000 rpm/min (1000 rpm) under load.

14.6 The dial indicator shall have a travel of 15 mm (½ in.) and to an accuracy of at least 0.025 mm (0.001 in.).

14.7 A 4-L (1-gal) plastic tank mounted on the motor base supplies water which flows by gravity through the hollow drive shaft and orifice in the flange plate onto the concrete surface.

14.8 The machine base shall be provided with a vacuum hold-down device having three support points.

15. Test Specimen

15.1 When tests are run on concrete specimens rather than on a concrete slab in place, mount the samples securely so as to have a rigidity approximating that of a slab in place. This can be achieved by using bonding agents or a vacuum to hold the test sample to the horizontal surface upon which the machine is mounted.

15.2 Use test samples 300 by 300 by 100-mm (12 by 12 by 4-in.) thick. The rate of wear on this size sample has been found to be about 90 % of the rate of wear of a concrete slab in place. The size of the test specimen will affect the rate of wear measured by this test method.

16. Procedure

16.1 Mount the machine firmly and securely on a concrete surface by use of a vacuum hold-down device.

16.2 Place a sheet of paper between the test surface and the ball bearings under the load of the motor. Revolve the drive shaft several times by hand. A complete circular mark formed on the paper indicates the drive shaft is normal to the surface. If a crescent is formed, adjust the plumbness of the drive shaft and repeat the procedure until a circle is obtained.

16.3 Open the two valves at the base of the drive motor; one to allow water to fill the hollow drive shaft, the other to determine that the hollow shaft is filled. Then close the overflow valve. Fill the water tank to the prescribed mark to assure a standard initial head.

16.4 Bring the dial gage clamped to the supporting shaft to bear on the sliding bracket of the motor and drive shaft. Reset the digital clock to zero.

16.5 Take the reference dial micrometer reading immediately following the slight jump of the dial, just after the motor is started.

16.6 Take dial micrometer readings to an accuracy of at least 0.025 mm (0.001 in.) of the depth of abrasion at least every 50 s for a total period of 1200 s, or until a maximum depth of 3.0 mm (0.1225 in.) is reached. Take an average reading of the pulsating micrometer dial.

16.7 Take three tests on surfaces representative of the concrete to be evaluated.

17. Interpretation of Results

17.1 Determine the depth of wear for each interval of the test. The comparison of curves showing a plot of depth of wear versus time for each series of concrete surfaces tested will indicate the relative abrasion resistance of these surfaces.

17.2 A material that is uniform in abrasion resistance will have a curve approximating a half-parabola inclined toward the time axis. A comparison of curves will indicate whether the resistance to abrasion is primarily at the surface or at greater depth.

17.3 When comparing test results of concrete surfaces of a wide range in abrasion resistance, establish the time required to reach a particular depth.

18. Report

18.1 Plot the time versus depth of wear of tests performed on three representative concrete surfaces and determine the average line.

18.2 Record mixture proportions including cement factor and water-cement ratio, specific gravities, and grading of fine and coarse aggregates, Los Angeles abrasion test results, type and amount of material added to freshly placed concrete surface, type and extent of troweling, curing details, and age of concrete when tested.

TABLE 1 Within-Laboratory Precision for Single Operator

Procedure	Coefficient of Variation, Percent of Mean[A]	Acceptable Range of Two Results, Percent of Mean[A]
A Revolving disk	5.51	15.6
B Dressing wheel	11.69	33.1
C Ball bearing	17.74	50.2

[A] These numbers represent respectively the 1s % and d2s % limits as described in Practice C 670, in the section on Alternative Form of the Precision Statement.

19. Precision and Bias

19.1 *Precision*[5]—Criteria for judging the acceptability of abrasion resistance test results obtained by this method[6] are given as follows:

NOTE 4—The figures given in Table 1 column 2 are the coefficients of variation that have been found to be appropriate for the materials and conditions of test as determined with inch-pound units and equipment as described in column 1.

19.2 *Bias*—Since there is no acceptable reference material suitable for determining bias for the procedure in this test method, no statement on bias is being made.

20. Keywords

20.1 abrasion; concrete; impact; surface treatments; wear

[5] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1015 .

[6] The precision of this test method has been found to depend primarily on the procedure used and not on the depth and period of abrasion and the age of concrete after casting.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C786/C786M – 10

Standard Test Method for Fineness of Hydraulic Cement and Raw Materials by the 300-µm (No. 50), 150-µm (No. 100), and 75-µm (No. 200) Sieves by Wet Methods[1]

This standard is issued under the fixed designation C786/C786M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers wet sieving techniques for determination of fineness of hydraulic cement and raw materials by means of the 300-µm (No. 50), the 150-µm (No. 100), and the 75-µm (No. 200) sieves.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard. Values in SI units [or inch-pound units] shall be obtained by measurement in SI units [or inch-pound units] or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10 of measurements made in other units. Values are stated in SI units when inch-pound units are not used in practice.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C114 Test Methods for Chemical Analysis of Hydraulic Cement

C184 Test Method for Fineness of Hydraulic Cement by the 150-µm (No. 100) and 75-µm (No. 200) Sieves[3]

C430 Test Method for Fineness of Hydraulic Cement by the 45-µm (No. 325) Sieve

E11 Specification for Woven Wire Test Sieve Cloth and Test Sieves

IEEE/ASTM SI 10 American National Standard for Use of the International System of Units (SI): The Modern Metric System

3. Apparatus

3.1 *Wet Test Sieves*—Standard 300-µm (No. 50), 150-µm (No. 100), or 75-µm (No. 200) sieve cloth conforming to the requirements of Specification E11, for standard sieves shall be woven from AISI Type 304 wire. The cloth shall be mounted in the frame without distortion, looseness, or wrinkling. Sieve frames are designated as 76.2 or 101.6-mm [3 or 4-in.] diameter type, as follows:

	Sieves	
	76 mm [3-in.] mm [in.]	102 mm [4-in.] mm [in.]
Diameter of frame	76 ± 6 [3.0 ± 0.25]	102 ± 6 [4.0 ± 0.25]
Depth of sieve from top of frame	83 ± 6 [3.25 ± 0.25]	108 ± 6 [4.25 ± 0.25]
Overall height	102 ± 6 [4.0 ± 0.25]	127 ± 6 [5.0 ± 0.25]

3.1.1 For a sieve fabricated by soldering the cloth to the frame, the joint shall be made smooth to prevent material from lodging in the joints between the sieve cloth and the frame. Two-piece sieves shall clamp tightly on the cloth to prevent particles from lodging in the joints between the sieve cloth and the frame, and shall have legs of sufficient length, 19-mm [0.75-in.] minimum, to allow air circulation beneath the sieve cloth.

3.2 *Spray Nozzle*—conforming to the requirements of Test Method C430. Nozzles having an alternative design are acceptable if the sieve test results agree with those performed using a nozzle conforming to Test Method C430.

3.3 *Pressure Gage*—conforming to the requirements of Test Method C430.

3.4 *Balance*—analytical, accurate to within 0.005 g.

3.5 *Weights*—The weights used in fineness determinations shall conform to the requirements of Test Methods C114.

3.6 *Brush*—A nylon or pure bristle brush will be required for use in cleaning the sieves. A 13-mm [0.5-in.] diameter round-style brush with a 229-mm [9-in.] handle is a convenient

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.25 on Fineness.

Current edition approved Feb. 1, 2010. Published March 2010. Originally approved in 1974. Last previous edition approved in 2003 as C786 – 96(2003). DOI: 10.1520/C0786_C0786M-10.

www.technobetar.ir

size. (**Warning—**Do not use brass or steel-bristle brushes for cleaning sieves due to the possibility that the stiff bristle will part the wire weave, thereby altering the size of the openings and rendering the sieve useless. A 13-mm [½-in.] hog bristle stencil brush is also satisfactory for brushing sieves.)

3.7 *Dry Test Sieves*—The standard samples for calibrating the wet test sieves must be standardized on 203-mm [8-in.] diameter sieves meeting the requirements of Test Method C184. The 300-µm (No. 50) sieve shall meet the same requirements.

3.8 *NBS SRM No. 1004*—Glass Bead Standard.

4. Dry Sieve Standardization

4.1 *Correction Factors*:

4.1.1 Correction of the residues obtained on the 203-mm [8-in.] diameter 300-µm (No. 50) and 150-µm (No. 100) dry testing sieves is not required.

4.1.2 Where applicable, a correction factor for a 75-µm (No. 200) sieve shall be determined using the instructions given in Annex A1. A correction factor should be determined when accuracy is desired in order to compare results between laboratories.

4.2 *Standard Samples*—Each laboratory must prepare its own standard samples for wet-sieve tests for each of the sieve sizes used. Select standard samples at a level of fineness in the same range as that used in routine work. After the selected material is reserved, uniformly mix the gross sample by placing it on a sheet of rubber, oil cloth, or heavy wrapping paper, depending on the sample size, and raising first one corner of the sheet and then the other so as to roll the sample over and over at least 100 times. Temporarily seal the prepared standard material in airtight containers during the standardization procedure prior to sealing small portions as standard samples in vials. Using the 203-mm [8-in.] diameter sieves from 3.7, perform the dry sieving tests, following the procedure of Test Method C184. Repeat the test three times and use the average of the amounts passing, expressed as percent, as the standard value of the sample. Use this standard sample to calibrate the wet sieves. Place the entire sample in airtight vials as soon as possible to prevent changes due to humidity. Vials shall be prepared in denominations such as to contain approximately 50 g for standardizing the 300-µm (No. 50); 25 g for the 150-µm (No. 100); or 10 g for the 75-µm (No. 200) sieve.

5. Wet Sieve Calibration

5.1 Weigh the contents of the applicable size standard sample vial for the desired sieve determination on a balance of appropriate sensitivity to the nearest 0.01 g. Record the weight and transfer the sample quantitatively to a clean dry wet test 300-µm (No. 50), 150-µm (No. 100), or 75-µm (No. 200) sieve and proceed as directed in Section 6. The sieve correction factor is the difference between the test residue obtained and the residue value indicated by the standardization tests of Section 4, expressed as a percentage of the test residue. This factor is expressed as follows:

$$C = \frac{(Rs \times Wt/100) - Rt}{Rt} \times 100 \quad (1)$$

where:

C = sieve correction factor (which may be either plus or minus), %,
R_t = test residue from sample retained on sieve, g,
R_s = standard residue retained on sieve, %, and
W_t = weight of test sample, g.

5.1.1 Example of Determination of Wet Sieve Calibration:

% Residue on 150-µm (No. 100) sieve for standard sample, R_s = 5.40%
Residue from test sample, R_t = 1.25 g
Weight of sample, W_t = 25.5 g

$$\text{Correction factor, } C, \% = \frac{(5.40 \times 25.5/100) - 1.25}{1.25} \times 100 = \pm 10.2 \quad (2)$$

NOTE 1—The sieve correction is specified as a factor to be multiplied by the residue obtained, and therefore the amount to be added to or subtracted from the test residue in any given instance is proportional to the amount of the residue.

6. Procedure for Wet Sieving

6.1 Weigh the sample to the nearest 0.01 g using approximately 50 g for a 300-µm (No. 50), 25 g for a 150-µm (No. 100), or 10 g for a 75-µm (No. 200) determination. Record the weight and transfer the sample quantitatively to a clean dry sieve. Wet the sample thoroughly with a gentle stream of water. Remove the sieve from under the nozzle and adjust the pressure on the spray nozzle to 69 ± 4 kPa [10 ± 0.5 psi]. Return the sieve to its position under the nozzle and wash for 1½ min, moving the sieve in the spray with a circular motion in a horizontal plane at the rate of one motion per second. Every portion of the screen should be sprayed during each circular motion of the sieve. Hold the sieve so that the bottom of the spray nozzle extends 13 mm [0.5 in.] below the top of the sieve frame. Immediately after removing the sieve from the spray, rinse once with about 50 cm^3 of distilled or deionized water using caution not to lose any of the residue. Gently blot the lower surface of the screen cloth with a damp, clean cloth. Dry the sieve and residue in an oven or over a hot plate (see Note 2), supporting the sieve in such a manner that air may pass freely beneath it. Cool the sieve; then brush the residue from the sieve, and weigh on a balance to the nearest 0.01 g (see Note 3).

NOTE 2—Care should be taken when heating the sieve, so that any solder that may have been used in assembling the sieve does not soften.

NOTE 3—Prior to each use, dip the sieve in dilute acetic acid (1+6) or dilute HCl (1+10) and immediately rinse it with distilled or deionized water to remove particles lodged in the meshes. Recalibrate the sieve after 25 determinations.

7. Calculation

7.1 Calculate the fineness of the material as follows:

$$R_c = (R_t/W) \times (100 + C) \quad (3)$$

$$F = 100 - R_c \quad (4)$$

where:

F = fineness expressed as the corrected percentage of sample passing the sieve,
R_c = corrected residue, %,
W = weight of sample used for test, g,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:55 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

R_t = residue from the sample retained on the sieve, g, and
C = sieve correction factor (determined in accordance with Section 5, which may be either plus or minus), %.

7.1.1 Example for 150-µm (No. 100) Sieve Determination:

Sieve correction factor, C	= ±10.2 %
Exact weight of sample used for test, W	= 25.10 g
Residue from sample retained on sieve, R_t	= 1.42 g
Corrected residue,	
$R_c = (1.42/25.10) \times (100 + 10.2)$	= 6.2 %
$F = 100 - 6.2$	= 93.8 %

8. Precision and Bias

8.1 No precision data are available due to the limited use of this method. Therefore, users are advised to develop their own laboratory precision.

8.2 Since there is no accepted reference material suitable for determining any bias that may be associated with this test method, no statement on bias is being made.

9. Keywords

9.1 fineness; hydraulic cement and raw materials; sieve

ANNEX

(Mandatory Information)

A1. DRY SIEVE CORRECTION FACTORS

A1.1 300-µm (No. 50) and 150-µm (No. 100) 203-mm [8-in.] Diameter Sieves

A1.1.1 The particle size distribution curve of cement at the 300-µm (No. 50) and 150-µm (No. 100) is level in this region, and therefore it is felt that no sieve correction is necessary.

A1.2 75-µm (No. 200) 203-mm [8-in.] Diameter Sieve

A1.2.1 A75-µm (No. 200) sieve may or may not need to be standardized, depending on the accuracy required. For internal laboratory use where changes in fineness are of more importance than the absolute value, it is not necessary to standardize the dry sieve. The sieve cloth, as a minimum, should conform to Specification E11. A correction factor should be established where accuracy is desired in order to compare results between laboratories.

A1.2.2 To determine the percentage of test material passing through a nominal 75-µm (No. 200) sieve, two additional sieves are needed: a 90-µm (No. 170) and a 63-µm (No. 230) sieve. Using NBS SRM No 1004 (No. 140-No. 400 sieve), Glass Bead Standard, determine the effective openings of each of the three sieves.

NOTE A1.1—NBS SRM No. 1004 tends to blind the screen during use and the beads lodged in the meshes are difficult to remove. Tapping the frame of the sieve and gentle brushing of the cloth from the underside will aid in recovering all the beads and keep the bead loss down to approximately 50 mg.

A1.2.3 Select a test material. It is important that the sample for calibration be of the same typical fineness as the range in which the sieve is to be used. The use of the same test material selected for the 75-µm (No. 200) dry sieve calibration is encouraged (see 4.2). Determine the percent residue of the test material on each of the three sieves, following the procedure of Test Method C184. Plot the average percent residues *versus* the effective opening. The percent residue at the nominal opening of the No. 200 sieve can be read off the plot and the difference between the actual obtained residue and the nominal residue at 75 µm may be used algebraically as a sieve correction factor for that sieve, only in the same general fineness area.

A1.3 Example—Determination Of Sieve Correction factor for 75-µm (No. 200) Sieve

A1.3.1 Using the SRM 1004, the following was determined:

(*a*) Effective opening of nominal sieves being corrected:

75-µm (No. 200)	72 µm
90-µm (No. 170)	90 µm
63-µm (No. 230)	65 µm

(*b*) Test sample residue, % (to be plotted on graph paper):

at 90 µm	1.1 %
at 72 µm	2.3 %
at 65 µm	2.8 %

(*c*) From the above plot:

$$\text{Residue at } 75-\mu\text{m} = 2.1\% \qquad \text{(A1.1)}$$

A1.3.2 Since the sieve is woven too tightly and retains more than it should if it were a 75-µm opening, the correction, C, to be applied to the residue in percent is –0.2%.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C786 – 96(2003), that may impact the use of this test method. (Approved February 1, 2010)

(*1*) Revised the standard as a dual-units test method.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 796 – 04

Standard Test Method for Foaming Agents for Use in Producing Cellular Concrete Using Preformed Foam[1]

This standard is issued under the fixed designation C 796; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This test method furnishes a way of measuring, in the laboratory, the performance of a foaming chemical to be used in producing foam (air cells) for making cellular concrete.

1.2 This test method includes the following:

1.2.1 Manufacture of laboratory quantities of cellular concrete.

1.2.2 Determination of the air content of the freshly prepared cellular concrete and of the hardened concrete after handling in conventional machinery.

1.2.3 Determination of the following properties of the hardened concrete: compressive strength, tensile splitting strength, density, and water absorption. It may not be necessary to study all of the above properties in all cases, depending on the proposed use of the material.

1.3 The values stated in inch-pound units are to be regarded as the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.5 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 88 Test Method for Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate

C 150 Specification for Portland Cement

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 495 Test Method for Compressive Strength of Lightweight Insulating Concrete

C 496/C 496M Test Method for Splitting Tensile Strength of Cylindrical Concrete Specimens

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 802 Practice for Conducting an Interlaboratory Test Program to Determine the Precision of Test Methods for Construction Materials

C 869 Specification for Foaming Agents Used in Making Preformed Foam for Cellular Concrete

3. Terminology

3.1 *Definitions:*

3.1.1 *cellular concrete*—a lightweight product consisting of portland cement, cement-silica, cement-pozzolan, lime-pozzolan, or lime-silica pastes, or pastes containing blends of these ingredients and having a homogeneous void or cell structure, attained with gas-forming chemicals or foaming agents (for cellular concretes containing binder ingredients other than, or in addition to portland cement, autoclave curing is usually employed).[3] In cellular concrete the density control is achieved by substituting macroscopic air cells for all or part of the fine aggregate. Normal-weight coarse aggregate is usually not used but lightweight aggregates, both fine and coarse, are often utilized in cellular concrete.

3.2 *Symbols:*

D_{ex1} = experimental density of the concrete before pumping, lb/ft^3(kg/m^3)

D_{ex2} = experimental density of the concrete after pumping, lb/ft^3(kg/m^3)

D_{th} = theoretical density of the plastic mix based on absolute volume, lb/ft^3(kg/m ^{3})

D_d = design density of the text mixture, lb/ft^3(kg/m^3)

SGC = specific gravity of cement = 3.15

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

Current edition approved Nov. 1, 2004. Published November 2004. Originally approved in 1974. Last previous edition approved in 1997 as C 796 – 97.

T = time required to overfill the container, min
T_1 = time required to generate 1 ft^3(1 m^3) of foam, min
V = volume of foam container, ft^3(m^3)
V_a = volume of air required in the test batch, ft^3(m^3)
V_c = volume of test specimen (cylinder), ft^3(m^3)
V_f = volume of foam in the test batch, ft^3(m^3)
V_w = volume of water absorbed by test specimen in 24 h, ft^3(m^3)
W_1 = net weight of foam in overfilled container before striking off, lb (kg)
W_2 = net weight of foam in container after striking off, lb (kg)
W_c = weight of cement in the test batch, lb (kg)
W_f = weight of foam in the test batch, lb (kg)
W_{TW} = total weight of water in the test batch, including weight of foam, lb (kg)
W_{uf} = density of foam, lb/ft^3(kg/m^3)
W_w = weight of water added to test batch at mixer, lb (kg)

4. Summary of Test Method

4.1 This test method includes the following:

4.1.1 Manufacture of laboratory quantities of cellular concrete.

4.1.2 Determination of the air content of freshly prepared cellular concrete and of hardened concrete after handling in conventional machinery.

4.1.3 Determination of the following properties of hardened concrete: compressive strength, tensile splitting strength, density, and water absorption. It may not be necessary to study all of the above properties in all cases, depending on the proposed use of the material.

5. Significance and Use

5.1 This test method is used to develop data for comparison or compliance with the requirements of Specification C 869.

6. Apparatus

6.1 *Mixer*—The mixer shall be a power-driven paddle-type mixer with a capacity of at least 4 ft^3(0.12 m^3), an operating speed of 40 to 50 r/min (4.2 to 5.2 rad/s), and equipped with rubber wiper blades.

6.2 *Foam Generator*—The foam generator shall be a laboratory-sized generator approved by the manufacturer of the foam being used and shall be similar to the type used in the field.

6.3 *Pump*—The pump shall be an open or closed throat-type pump and shall be run at 260 to 630 r/min (27.2 to 66.0 rad/s). The pump shall be equipped with a 4.5-ft^3(0.13-m^3)" feed" reservoir and 50 ft (15 m) of open-end 1-in. (25-mm) inside diameter rubber hose on the pump discharge, the exit end of the hose being at the same height as the pump.

6.4 *Curing Cabinet*—The curing cabinet shall be as described in Specification C 511.

6.5 *Molds*—The cylindrical molds for compression test specimens shall be as described in the Apparatus section of Test Method C 495. The molds for all other test specimens shall conform to the cylinder molds in the Apparatus section of Practice C 192/C 192M.

6.6 *Strike-Off Plate for Molds*—A ¼-in. (6-mm) thick, flat steel plate at least 8 in. (200 mm) longer and 2 in. (50 mm) wider than the diameter of the mold.

6.7 *Scales*—Scales and weights shall be accurate to within 0.1 % of the weight of the material being measured.

6.8 *Compression Machines*—Compression testing machines used for compressive strength tests and tensile-splitting strength tests shall conform to the requirements of Test Methods C 495 and C 496/C 496M, respectively.

6.9 *Drying Oven*—The drying oven shall be as described in Test Method C 88.

6.10 *Compressed Air*—A source of compressed air capable of maintaining pressures in the range of 60 to 100 psi (0.4 to 0.7 MPa) to ±1 psi (±0.007 MPa).

6.11 *Weighing Container for Concrete*— A machined-steel container of 0.5 ft^3(0.014 m^3) volume with a flat smooth rim.

6.12 *Strike-Off Plate for Weighing Container*—A ¼-in. (6-mm) thick, flat steel plate, at least 8 in. (200 mm) longer and 2 in. (50 mm) wider than the diameter of the rim of the weighing container.

6.13 *Stop Watch*—A stop watch graduated in seconds and minutes.

6.14 *Calipers*—Calipers to span 3, 6, and 12 in. (76, 152, and 305 mm).

6.15 *Foam Weighing Container*—A lightweight vessel of approximately 2 ft^3(0.06 m^3) capacity, with a smooth rim for striking off.

6.16 *Strike-Off Plate for Foam Weighing Container*—A ¼-in. (6-mm) thick, flat steel plate at least 8 in. (200 mm) longer and 2 in. (50 mm) wider than the diameter of the rim of the container.

6.17 *Small Tools*—Small tools such as a rubber-headed hammer and a trowel shall be provided.

7. Materials and Proportions

7.1 *Cement*—The cement used shall be Type I or Type III portland cement meeting the requirements of Specification C 150.

7.2 *Water-Cement Ratio*—The water requirement will vary with the type and source of cement. For the purpose of these tests, w/c = 0.58 for Type I cement and w/c = 0.64 for Type III cement shall be used. However, if a particular cement or foaming agent used with these values of w/c does not produce a satisfactory mix, a trial mix or mixes may be made using a different water-cement ratio.

7.3 *Batch Quantities*—The cement quantity shall be sufficient to allow molding all the test specimens from one test batch. The mixture water-cement ratio determined from 7.2 shall be used to make the test batch.

7.3.1 The foaming solution in the foam shall be considered as part of the total mixing water. Foam volume shall be adjusted for the batch to produce a density after pumping of 40 ± 3 lb/ft^3(641 ± 48 kg/m^3).

8. Procedure

8.1 Make an aqueous solution of the foaming agent in the dilution specified by the manufacturer. If the dilution is not specified, preliminary tests are necessary to determine the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:52 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

required dilution. A suggested starting point for such tests is 40 parts water to 1 part foaming agent, by volume.

8.2 Charge the foam generator with the amount of foaming solution suggested by the manufacturer of the generator.

8.3 Connect the generator with the source of compressed air, adjusting the pressure to that recommended by the manufacturer of the foaming agent being tested.

8.4 Using the stop watch, calibrate the generator as follows. Weigh the empty foam container and determine its volume. Overfill the container with foam, measuring the time required using a stop watch then weigh. Strike off the excess foam, holding the strike-off plate in a horizontal position (plane of the plate horizontal) and moving it across the top of the container with a sawing action. Again weigh. Calculate the time required per cubic foot (or cubic metre) of foam using the following equation:

$$T_1 = (T \times W_2)/(W_1 \times V) \quad (1)$$

8.4.1 Calculate also the unit weight of the foam as follows:

$$W_{uf} = W_2/V \quad (2)$$

8.4.2 Calculate the length of time required to generate the required volume of foam, $V_f\ T_1$, as follows:

$$V_fT_1 = 62.4\ V_aT_1/(62.4 - W_{uf})\ (V_fT_1 = 1000\ V_aT_1/(1000 - W_{uf})) \quad (3)$$

8.4.3 Calculate the weight, W_f, of the required volume of foam, V_fW_{uf}.

NOTE 1—The weight of the foam will usually range from 2 to 4 lb/ft^3 (32 to 64 kg/m^3) depending on the foam chemical used. Adjust the unit weight of foam, W_{uf}, to the manufacturer's recommendation if the foam generator is adjustable.

8.4.3.1 If Type I cement is used, weigh out 58.0 – W_f lb (26.31 – W_f kg) of water, W_w, and 100.0 lb (45.36 kg) of Type I cement.

8.4.3.2 If Type III cement is used, weigh out 64.0 – W_f lb (29.03 – W_f kg) of water, W_w, and 100.0 lb (45.36 kg) of Type III cement.

8.5 Wet the mixer with water and drain. Add the water, W_w, and start the mixer. Gradually add the cement (over a period of ½ min). With a trowel, break up any lumps of undispersed cement. Mix for 5 min.

8.6 While still mixing, add V_f ft^3(m^3) of foam. The required foam time is V_fT_1. Mix for 2 min after all the foam has been added. Discharge the mixer into the pump feed reservoir. Immediately, proceed to 8.7.

8.7 *Weighing*—Fill a tared weighing container with a representative sample of the concrete in the reservoir. Before taking the sample, carefully mix the concrete in the reservoir to assure better uniformity without entrapping large air bubbles in the mix. Use a paddle of proper size to reach the bottom of the reservoir. Use a scoop to transfer the concrete to the container and tap the sides of the container briskly with the rubber hammer during the filling operation. Overfill the container and strike off the excess concrete, holding the strike-off plate in a horizontal position (plane of plate horizontal) and moving it across the top of the container with a sawing motion. Wipe the surface of the container free of spilled concrete with a cloth. Weigh the full container. Calculate the density of the concrete and record as the density before pumping (D_{ex1}).

8.7.1 Pump the batch of concrete through the 50-ft (15-m) hose, discharging it into a sampling basin. From the sampling basin, take a second density sample as in 8.7, weigh, and record as the density after pumping ($D_{ex\ 2}$).

8.8 *Molding*—Immediately, fill the cylinder molds with concrete from the sampling basin. Tap the sides of the mold with the rubber hammer while the mold is being filled. The minimum number of specimens required is four cylinders, 3 by 6 in. (76 by 152 mm) and ten cylinders 6 by 12 in. (152 by 305 mm).

8.8.1 As soon as possible after casting, strike off the top surface of each specimen and cover the specimen with a plastic bag to prevent evaporation, without marring the surface.

8.9 *Removal from Molds and Curing*— Follow the applicable requirements of the Test Specimen section of Test Method C 495 with the following exception: continue air drying from day 25 to day 28 in place of oven drying the specimens. Do not oven dry specimens that are to be load-tested.

8.10 *Compressive Strength*—Test four 3 by 6-in. (76 by 152-mm) cylinders for compressive strength in accordance with Test Method C 495.

8.11 *Tensile Splitting Strength*—Test four 6 by 12-in. (152 by 305-mm) cylinders for tensile splitting strength at age 28 days in accordance with Test Method C 496/C 496M, for lightweight concrete.

8.12 *Oven-Dry Weight*—Determine the oven-dry density in accordance with the section on Oven-Dry Weight of Test Method C 495. Use three 6 by 12-in. (152 by 305-mm) cylinders from 7.9 at age 28 days.

8.13 *Water Absorption*:

8.13.1 Take three 6 by 12-in. (152 by 305-mm) specimens from 8.9 at age 28 days. Take the dimensions with calipers as described in the Test Specimen Section of Test Method C 495.

8.13.2 Submerge the specimens 6 in. (150 mm) below the water surface. Maintain the water temperature at 73.5 ± 3.5 °F (23.0 ± 2.0 °C). Remove from water, allow excess water to run off (30 s) and weigh. This is the wet weight of the specimen.

9. Calculation

9.1 *Air Content*:

9.1.1 Determine the experimental density of the freshly mixed concrete at the mixer, D_{ex1}, and at the pump discharge (end of hose), D_{ex2}, by dividing the net weights of the samples from 8.7 and 8.7.1 by the volume of the container. Record to the nearest 0.5 lb/ft^3(8 kg/m ^{3}).

9.1.2 Determine the experimental density of the specimens from 8.12 before and after drying from the weights and volumes of the specimens. Use three 6 by 12-in. (152 by 305-mm) cylinders. Record to the nearest 0.5 lb/ft^3(8 kg/m^3).

9.1.3 Determine the air content of the freshly mixed concrete from the experimental densities, before and after pumping, and the theoretical density, D_{th}, based on the absolute volume. Record the air content to the nearest 1 %. Calculate the theoretical density in lb/ft^3(kg/m^3) as follows:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:52 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Inch-Pound Units:

$$D_{th} = (W_w + W_c + W_f)/[(W_w/62.4) + (W_c/(SGC \times 62.4)) + (W_f/62.4)] \quad (4)$$

SI Equivalents:

$$D_{th} = (W_w + W_c + W_f)/[(W_w/1000) + (W_c/(SGC \times 1000)) + (W_f/1000)] \quad (5)$$

9.1.3.1 Calculate the air content before pumping or the percent of air at the mixer as follows:

$$\text{Air content before pumping} = 100\,[1 - (D_{ex1}/D_{th})] \quad (6)$$

9.1.3.2 Calculate the air content after pumping, or the percent of air at end of hose as follows:

$$\text{Air content after pumping} = 100\,[1 - (D_{ex2}/D_{th})] \quad (7)$$

NOTE 2—Using the prescribed procedure and assuming the specific gravity of cement is 3.15 and that the total water used is 58.0 lb (26.31 kg) for Type I cement, the theoretical density is 109.9 lb/ft^3(1761 kg/m ^{3}). Similarly, for Type III cement the total water is 64.0 lb (29.03 kg) and the theoretical density is 106.9 lb/ft^3(1712 kg/m ^{3}).

9.1.4 Calculate the loss of air during pumping as the difference between the air content before and after pumping. Record to the nearest 1 %.

$$\text{Loss of air, \% by volume} = 100\,[(D_{ex2} - D_{ex1})/D_{th}] \quad (8)$$

9.1.5 Calculate the design density (D_d) of the test mixture in lb/ft^3(kg/m ^{3}) as follows:

Inch-Pound Units:

$$D_d = (W_w + W_c + W_f)/[(W_w/62.4) + (W_c/SGC \times 62.4) + V_f] \quad (9)$$

SI Equivalents:

$$D_d = (W_w + W_c + W_f)/[(W_w/1000) + (W_c/SGC \times 1000) + V_f] \quad (10)$$

9.2 *Water Absorption*:

9.2.1 Find the average weight of water absorbed by the cylinders by subtracting the average dry weight of cylinders (see 8.12) from the average wet weight of cylinders (see 8.13). Record to the nearest 0.1 lb (or 0.05 kg).

9.2.2 Find the average volume of water absorbed by dividing the average weight of water absorbed by the density of water in lb/ft ^{3}(kg/m^3). Determine the water absorption using the following equation:

$$\text{absorption, \% by volume} = (V_w/V_c) \times 100 \quad (11)$$

Record absorption to the nearest 0.5 %.

10. Report

10.1 Using the degrees of precision specified in Section 9, report the following:

10.1.1 Identification of chemical tested, including manufacturer's name, brand, and lot number,

10.1.2 Water to cement ratio and type of cement used,

10.1.3 Air content before and after pumping,

10.1.4 Oven-dry density,

10.1.5 Water absorption, % by volume,

10.1.6 Compressive strength,

10.1.7 Loss of air during pumping, %,

10.1.8 Tensile splitting strength, and

10.1.9 Difference between design density and experimental densities before and after pumping.

11. Precision and Bias

11.1 *Precision*[4]

11.1.1 Data used to develop the precision statement were obtained using the inch-pound version of this test method. The precision indices shown in parenthesis are exact conversions of the values in inch-pound units. Data were obtained from three laboratories for one material.

11.1.2 *Single-Operator Precision*—The single-operator standard deviations are listed in the third column of Table 1.

TABLE 1 Single Operator Precision

Test	Avg. of Laboratory Averages	Standard Deviation (1s)	Acceptable Range of Two Results (d2s)
Compressive Strength, psi (MPa)	427 (2.9)	61 (0.4)	171 (1.2)
Splitting Tensile Strength, psi (MPa)	46 (0.3)	9 (0.06)	24 (0.2)
Density, lb/ft^3 (kg/m^3)	31.3 (501)	1.7 (27)	4.8 (77)
Absorption, %	17.8	0.6	1.8

Therefore, results of two properly conducted tests by the same operator are not expected to differ by more than the values shown in the fourth column of Table 1.

11.1.3 *Multilaboratory Precision*—The multilaboratory standard deviations are listed in the third column of Table 2. Therefore, results of two properly conducted tests on the same material by two different laboratories are not expected to differ by more than the values shown in the fourth column of Table 2.

11.1.4 The numbers of laboratories and materials used in the interlaboratory study do not meet the minimum requirements for determining precision prescribed in Practice C 802. This precision statement is provisional. Within five years, additional data that meets the requirements of Practice C 802 will be obtained and processed.

11.2 *Bias*

11.2.1 Since there is no accepted reference material for determining the bias of this test method, no statement on bias is made.

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR:C09–1027.

TABLE 2 Multilaboratory Precision

Test	Avg. of Laboratory Averages	Standard Deviation (1s)	Acceptable Range of Two Results (d2s)
Compressive Strength, psi (MPa)	427 (2.9)	68 (0.5)	190 (1.3)
Splitting Tensile Strength, psi (MPa)	46 (0.3)	8.6 (0.06)	24 (0.2)
Density, lb/ft^3 (kg/m^3)	31.3 (501)	2.0 (32)	5.6 (90)
Absorption, %	17.8	0.6	1.8

APPENDIX

(Nonmandatory Information)

X1. DERIVATION OF FORMULA FOR FOAM VOLUME

X1.1 The formula for foam volume required for the test batch may be derived as follows:

X1.1.1 Knowing the wet density, 40 lb/ft^3 (641 kg/m^3), calculate the volume of air required as follows:

Inch-Pound Units:

$$\text{Wet density, } 40 \text{ lb/ft}^3 = (W_{TW} + W_c)/[(W_{TW}/62.4) + (W_c/(3.15 \times 62.4)) + V_a] \quad \text{(X1.1)}$$

SI Equivalents:

$$\text{Wet density, } 641 \text{ kg/m}^3 = (W_{TW} + W_c)/[(W_{TW}/1000) + (W_c/(3.15 \times 1000)) + V_a] \quad \text{(X1.2)}$$

X1.1.2 Solving for the volume of air required in cubic feet (or cubic metres):

Inch-Pound Units:

$$V_a = (0.359\ W_{TW} + 0.7965\ W_c)/40 \text{ ft}^3 \quad \text{(X1.3)}$$

SI Equivalents:

$$V_a = (0.359\ W_{TW} + 0.7965\ W_c)/641 \text{ m}^3 \quad \text{(X1.4)}$$

X1.2 The air volumes required for the test batches are as follows:

Type of Cement	V_a, ft^3(m^3)
Type I	2.51 (0.071)
Type III	2.57 (0.073)

X1.3 Treating the diluted foam chemical as water (sp gr = 1) the following relationships between air volume and foam volume may be stated:

$$V_f = V_a + (W_f/62.4)/\text{ft}^3 \quad \text{or} \quad V_f = V_a + (W_f/1000)/\text{m}^3 \quad \text{(X1.5)}$$

X1.4 If W_{uf} is the unit weight of foam, then $W_f = W_{u\,f} \times V_f$ and the equation in X1.3 may be stated in the following manner:

$$V_f - (W_{uf}V_f/62.4) = V_a \text{ ft}^3 \quad \text{or} \quad V_f - (W_{uf}V_f/1000) = V_a\text{m}^3 \quad \text{(X1.6)}$$

$$V_f = V_a/[1 - (W_{uf}/62.4)]/\text{ft}^3 \quad \text{or}$$
$$V_f = V_a/[1 - (W_{uf}/1000)]/\text{m}^3, \quad \text{and} \quad \text{(X1.7)}$$

$$V_f = 62.4\ V_a/(62.4 - W_{uf})/\text{ft}^3 \quad \text{or} \quad V_f = 1000\ V_a/(1000 - W_{uf})/\text{m}^3 \quad \text{(X1.8)}$$

Designation: C802 – 09a

Standard Practice for Conducting an Interlaboratory Test Program to Determine the Precision of Test Methods for Construction Materials[1]

This standard is issued under the fixed designation C802; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice describes techniques for planning, conducting, and analyzing the results of an interlaboratory study of a test method. It is designed to be used in conjunction with Practice C670. Thus, the procedures recommended in this practice have the limited purpose of providing reliable information on which precision statements of the type described in Practice C670 can be based. It is not appropriate for use in programs whose purpose is to develop a test method or to assess the relative merits of two or more test methods.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C109/C109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C136 Test Method for Sieve Analysis of Fine and Coarse Aggregates

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C1067 Practice for Conducting A Ruggedness or Screening Program for Test Methods for Construction Materials

E105 Practice for Probability Sampling Of Materials

E177 Practice for Use of the Terms Precision and Bias in ASTM Test Methods

E178 Practice for Dealing With Outlying Observations

3. Significance and Use

3.1 Certain criteria need to be met before undertaking an interlaboratory study to determine the precision of a test method. It is not necessary that all of the following conditions described be completely fulfilled in every case; however, if some conditions are not met or are met incompletely, the program will become more complicated and require more work and expense, or may result in impaired information. The recommendations outlined in this section are intended to ensure that the test method is free of technical difficulties to the greatest extent possible before an expensive and time-consuming interlaboratory study is undertaken.

3.1.1 The first requirement is the existence of a valid and well-written test method that has been developed in one competent laboratory (or by cooperative work in a small number of laboratories), and has been subjected to a screening procedure, or to ruggedness testing as described in Practice C1067. As a result of the screening procedure and some experience with the test method in the sponsoring laboratory and one or two others, a written version of the test method has been developed (but not necessarily published as a standard method) that describes the test procedure in terms that can easily be followed in any properly equipped laboratory. Conditions that affect the test results should be identified and the proper degree of control of those conditions should be specified in the description of the test procedure (see Note 1).

NOTE 1—The desired degree of control of conditions that affect test results may not always be practically achievable, and tolerances in the test method should recognize this fact. Variations in test results due to variations in such conditions contribute to the total variation which determines the precision of the test method. If the resulting variation is so great that uncertainties in average values obtained by the test method are unacceptably high, then the test method itself is at fault, and efforts should be made to improve it or to replace it by a better one. An expensive and time-consuming interlaboratory study should not be undertaken on such a test method.

3.1.2 Any apparatus required for performing the test should be appropriately designed and available at reasonable cost.

3.1.3 Personnel in participating laboratories should have enough experience with the test method so that they are competent to run the test. The importance of this requirement will vary with the complexity of the method and the degree to which it departs from familiar procedures.

3.1.4 Preliminary knowledge should exist about how changes in materials and conditions affect the test results. There should be a reasonable degree of certainty that the

www.technobetar.ir

within-laboratory variances are the same in different laboratories, and that troublesome interactions do not exist. These conditions are investigated in the analysis of the data of an interlaboratory study, and are discussed further in 8.2.2, 8.2.3, and Appendix X1.

3.1.5 Facilities and procedures for procurement, preparation, and distribution of samples must be available and should be as simple and free of difficulties as practicable.

3.1.6 Selection of samples must be done by a randomization process, and one person who is familiar with randomization procedures should be responsible for seeing that the procedure is carried out. Refer to Recommended Practice E105.

3.1.7 Adequate numbers of participating laboratories, operators, and materials must be available. Requirements in these areas are specified in Sections 4 and 5.

3.1.8 The entire interlaboratory test program should be developed from the beginning with the help and advice of persons familiar with statistical procedures and with the materials involved (see Note 2). The same persons who design the experiment should also carry out, or at least have control over, the process of analysis of the data.

NOTE 2—It may not always be possible to obtain people who are familiar with the materials involved who have a sufficient knowledge of the proper statistical techniques and their proper use. In this case, the committee should obtain the services of a competent statistician who has experience in practical work with data from materials testing, and provide him with an opportunity for learning something about the particular materials and test method involved. Planners of an interlaboratory study should also be warned to avoid the pitfall of assuming that the use of statistical analysis software programs necessarily results in special expertise in the handling of data or the interpretation of results.

3.2 It is important to bear in mind that estimates of the precision of a test method are always based on a particular set of data obtained at a particular time and they need to be kept up-to-date. As materials, apparatus, and conditions change, and operators change or gain more experience, the characteristic precision of the results obtained may change, especially if the test method is new. In some cases, it may even be desirable to conduct more tests at a later date (though not necessarily a repetition of the complete interlaboratory study) in order to provide a check on estimates previously obtained and either verify them or introduce revisions.

4. Laboratories

4.1 The problem of obtaining competent participating laboratories for an interlaboratory study is often one of the most difficult ones connected with the process. The number of laboratories available is seldom as extensive as one would like, and if the test method is new, complicated, or expensive and time-consuming to run, the problem is further complicated. The problem usually becomes one of finding and obtaining the cooperation of enough qualified laboratories to obtain meaningful estimates of precision, rather than that of selection among a group of available laboratories. If there is great difficulty in obtaining a sufficient number of competent and willing laboratories, then the possibility exists that the test method should not be subjected to a formal interlaboratory study.

4.2 For the purposes of programs using this recommended practice, it is recommended that at least ten participating laboratories be included **(1, 2).**[3] In cases where it is impossible to obtain ten laboratories, the effect of an increased number may be obtained by repeating the program with the same group of laboratories six months later. Usually, results obtained from the same laboratory after a time lapse of approximately six months display most of the characteristics of results from a different laboratory, especially if a different operator and apparatus can be used. If this procedure is followed, it is necessary to be sure that the same materials are used, and that their characteristics have not changed in the interim.

4.3 In general, it is recommended that any laboratory that is considered qualified to run the test in routine testing situations should be permitted and encouraged to participate. "Qualified" implies proper laboratory facilities and testing equipment, competent operators familiar with the test method, a reputation for reliable testing work, and sufficient time and interest to do a good job. It does not mean, however, that only a select group of laboratories that are considered to be those best qualified for the interlaboratory study should be picked. Precision estimates for inclusion in a test method must be obtained under conditions and through the efforts of laboratories and personnel that are representative of the situations in which the test method will be used in practice **(3).** If a laboratory has all the other requirements, but its personnel has had insufficient experience with the method, the operators in that laboratory should be given an opportunity to familiarize themselves with the method and to practice its application before the interlaboratory study starts.

5. Materials

5.1 The number and type of materials to be included in an interlaboratory study will depend on the following:

5.1.1 The range of the values of the property being measured on a given material and how the precision varies over that range,

5.1.2 The number of different materials to which the test method is to be applied,

5.1.3 The difficulty and expense involved in obtaining, processing, and distributing samples,

5.1.4 The difficulty of, length of time required for, and expense of performing the tests, and

5.1.5 The uncertainty of prior information on any of these points. For example, if it is already known that the precision is relatively constant or proportional to the average level over the range of values of interest, a smaller number of materials will be needed than if it is known that the precision changes erratically at different levels. A preliminary pilot or screening program may help to settle some of these questions, and may often result in the saving of considerable time and expense in the full interlaboratory study **(4).**

5.2 In general, a minimum of three materials should be considered acceptable.

[3] The boldface numbers in parentheses refer to the list of references at the end of this practice.

www.technobetar.ir

6. Estimates of Precision

6.1 In accordance with Recommended Practice C670, the procedure described in this practice is designed to provide two basic estimates of the precision of a test method: (*a*) single-operator precision, and (*b*) multilaboratory precision. If other estimates of precision are desired, other references should be consulted (see Practice E177) **(5).**

6.2 *Single-operator precision* provides an estimate of the difference that may be expected between duplicate measurements made on the same material in the same laboratory by the same operator using the same apparatus within a time span of a few days.

6.3 *Multilaboratory precision* provides an estimate of the difference that may be expected between measurements made on the same material in two different laboratories.

7. Collection of Data

7.1 In order to minimize the problems concerned with analysis of data, a definite form and instructions for obtaining and recording the data should be developed and distributed to all participating laboratories.

7.2 *Directions to Laboratories*—The directions to the laboratories should deal mainly with reporting of data. No special instructions for performing the tests that differ from those given in the description of the test method should be included. The laboratories should be cautioned to conduct tests and report results exactly as specified in the test method, with the one exception as noted in 7.2.2.

7.2.1 *Averaging Test Results*—Laboratories should particularly be cautioned against practices such as running a number of tests and selecting the "best" ones or reporting the average of several determinations, except as such averaging is specified in the test method. For example, Test Method C109/C109M specifies three or more test specimens, and requires that the strength of all acceptable test specimens made from the same sample and tested at the same period shall be averaged and reported. In this case, the directions for the interlaboratory test should specify the number of determinations to be obtained and reported. Whenever a test result is defined, either in the test method or in the instructions to laboratories participating in an interlaboratory test program, as the average of a particular number of determinations, the individual determinations should be reported, in addition to the averages. When two or more measurements are averaged to obtain a test result, the data from the interlaboratory test program may be used to develop an estimate of the precision of these individual measurements. See 3.3.3 of Practice C670.

7.2.2 *Rounding of Data*:

7.2.2.1 Generally, laboratories should be required to report all figures obtained in making the measurements, rather than rounding the results before recording them. In some cases, this may result in recording of more digits than is customary or even more than the test method calls for in the section on Reporting (see X1.3.1). This is necessary because the variation from which information about the precision of the test method comes is contained in the least significant digits, which are often discarded in reporting the results of routine testing **(6).** For example, Method C136 calls for reporting of percentages to the nearest whole number. This is adequate for the usual reporting purposes, but for purposes of determining precision, at least one decimal place is needed. It is better to require the reporting of too many decimal places than too few, since a decision about rounding all data can be made when the analysis is done. If too few places are reported, however, valuable information may be irretrievably lost, and the result might well be the impairment of the entire program.

7.2.2.2 In cases where a test result is the result of a calculation based on two or more measured quantities, the basic measurements should be used in the calculations without any rounding. The planners of the interlaboratory program will then have to determine how many places need to be reported in order to retain the essential information for determining variability. Sometimes it is advisable to ask the laboratories to report the basic quantities measured instead of, or in addition to, the final calculated result. This enables the final result to be checked, or changes in decisions about the test results to be made, when the data are analyzed. This procedure is especially appropriate if the results are to be analyzed by computer, and the program can be utilized to perform the basic calculations and analyze the calculated results.

7.3 *The Data Sheet*—This practice is based on the following assumptions: p laboratories each have made n replicate measurements on each of q materials (see Ref **7**). Table 1 and Table 2 are sample data sheets for an individual laboratory and for a summary of data for the entire program for a program with: p = ten laboratories, n = four replicates, (test results on each material in each laboratory), and, q = five materials. These data sheets suggest the forms to be used when an individual measurement constitutes the basic test result. In cases where individual measurements are averaged or otherwise subjected to calculation to produce a test result, the form of the individual laboratory sheet may be altered or a secondary sheet provided to permit recording of the fundamental measurements and the test results.

7.4 *Number of Replicates*:

7.4.1 The number of replicate determinations to be made on each material in each laboratory depends largely on the number of laboratories participating, on the homogeneity of the material, and on the expense, difficulty, and time involved in

increasing the number of determinations. It should be recognized that in order to obtain the necessary information to write a meaningful precision statement, it is often necessary to use more replicates in the interlaboratory study than is required for routine use of the test method. An increase in the number of replicates improves the estimates of within-laboratory precision but has no effect on between-laboratory precision (**8**)**.** It is recommended that, for 10 to 15 participating laboratories, at least three replicates should be required. In cases where it is not possible to obtain 10 participating laboratories, the number of replicates, n, should be equal to or greater than $(30/p) + 1$. For more than 15 laboratories, the number of replicates may be reduced to two. (If 30 is not a multiple of p, $30/p$ is rounded to the next higher integer.) This will give an adequate estimate of within-laboratory precision, but information about between-laboratory precision is not as good as desired with fewer than 10 laboratories.

7.4.2 The variation among replicate measurements is supposed to be representative of the irreducible error variance characteristic of the test method. In some cases, it is possible to take supposedly replicate measurements in such a manner that there is little or no opportunity for chance variation, and the measurements are in effect simply repetitions of the same measurement. For example, in making a chemical analysis by atomic absorption or some other kind of automatic measuring device, laboratories have been known to take three readings of the meter on the same sample in quick succession. The three readings so taken were almost identical, but were still reported as replicate readings. In cases such as this, three separate readings with different portions of the sample should be tested possibly on different days, with the same operator and apparatus in order to provide meaningful replicate measurements.

7.5 *Outliers*—In general, the practice of discarding individual test results that appear to differ by suspiciously large

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

amounts from the others, should be avoided unless there is clear evidence that there was some physical reason to consider the result faulty. It is recommended that no purely statistical criterion be used for the purpose. In particular, laboratories should be asked to report all results in their proper place and include notes describing the conditions surrounding those results that are suspected of being faulty. Sometimes if a test really went wrong, a laboratory should discard the results and repeat the test. Tests should not be repeated, however, just because the results don't look good. Further discussion of the problems of outliers is given in Appendix X2, Practice E178, and in Refs (**9** and **10**).

7.6 *Missing Data*—Sometimes individual items of data are missing from the summary because they were discarded, failed to be supplied by a laboratory, or for other reasons. In general, if the number of missing data items from all laboratories constitutes no more than 1 % of the total number of items, the analysis may be conducted as though the missing items were present. For example, if one result out of four replicates on a given material from a given laboratory is missing, the three remaining results should be added and then divided by 3 to get the average, $\bar{x}_i$. The within-laboratory variance, s_i^2, should also be calculated using 3 for the number of results. From then on, both results should be used as though they were based on four measurements. If the number of missing results exceeds 1 % of the total, some of the tests should be repeated in order to obtain proper measurements for the missing values. Missing values handled in this way must be individual values distributed throughout the mass of data, and should not be concentrated as a group in one laboratory-material cell. If the latter occurs, the laboratory should provide another group of measurements on the material in question. Analysis-of-variance procedures exist for the analysis of such unbalanced sets of data. The advice of a statistical consultant should be obtained when such practices are used.

8. Analysis of Data

8.1 The procedure described herein is simplified, and statistical terms are avoided to the greatest extent possible in order to make the recommended practice easily usable by persons with little statistical background. This exposes the recommended practice to the danger that, although the technique recommended is widely applicable to many situations using many kinds of data, it may be used mechanically in situations in which it is not applicable by persons who are not familiar with the statistical background of the recommended procedures. For this reason, it is recommended to seek the advice of a person who is familiar with the statistical procedures before undertaking analysis of an interlaboratory study by this or any other published procedure. An example of the procedure is given in Appendix X1. For further description of the method, see Ref (**5**).

8.2 *Between-Laboratory and Within-Laboratory Analysis for Each Material*—The first step in the analysis is to obtain estimates of between-laboratory and within-laboratory variances for each material. This may be done by using the form shown in Table 3. Table 3 is set up as an example, using material A in ten laboratories with four replicate test results per laboratory to correspond with the sample summary data sheet in Table 2. Similar tables should be set up for each material in the study. The subscript i is used to designate a particular laboratory in the analysis and goes from 1 to p, the total number of laboratories. Capital letter subscripts, A, B, etc., are used to designate quantities calculated for the different materials. The averages, $\bar{x}_i$, and variances, s_i^2, in the last two columns are the within-laboratory averages and variances for the given material, and are calculated from the n replicate test results for each of the p laboratories as follows:

$\bar{x}_i$ = $\Sigma\, x_i/n$ = sum of n replicate test results for laboratory i divided by n.

s_i^2 = $(\Sigma\, x_i^2 - n\,\bar{x}_i^2)/(n-1)$ = sum of squares of n replicate test results for laboratory i less n times the square of the average for laboratory i, divided by one less than the number of replicate test results.

NOTE 3—The results of the calculations described here may be subject to a rounding error if the numbers involved are large. See Appendix X1 and Note X1.1 for an example of this and a discussion of how to deal with this problem.

www.technobetar.ir

From the p individual within-laboratory averages and variances, four quantities for the given material; namely, the overall average, pooled within-laboratory variance, variance of laboratory averages, and between-laboratory component of variance, are calculated and entered on Table 3 as follows:

$\bar{x}_A$ = $\Sigma\, \bar{x}_i/p$ = sum of p averages for the laboratories divided by p

s_A^2 (pooled) = $\Sigma s_i^2/p$ = average of within-laboratory variances (see Note 4).

$s_{\bar{x}_A}^2$ = $[\Sigma\, \bar{x}_i^2 - p\,(\bar{x}_A)^2]/(p - 1)$ = sum of squares of p within-laboratory averages less p times the overall average squared, divided by $p - 1$.

$s_{L_A}^2$ = $s_{\bar{x}_A}^2 - [s_A^2\,(\text{pooled})/n]$ = the variance of laboratory averages less $1/n$ times the pooled variance.

A sample work sheet showing exactly how these calculations are made appears in Appendix X1.

NOTE 4—The method of pooling variances used here applied only when all the individual variances being pooled are based on the same number of measurements. In general, a pooled estimate of a variance is not obtained by averaging individual variances.

8.2.1 Before proceeding with the analysis, it is necessary to investigate agreement of the data with the following two assumptions: (*a*) the variances are the same in different laboratories (homogeneity of variance), and (*b*) the results show the same pattern of change from one material to another in different laboratories (lack of interactions). These two aspects of the analysis are discussed in 8.2.2 and 8.2.3.

8.2.2 *Investigation of Agreement of Variances*—This method is based on the assumption that the within-laboratory variances in different laboratories (of which the s_i^2 in Table 3 and its variations, are estimates) are the same. This does not mean that the s_i^2 have to be very close together, since an individual variance can be about four times the average variance (for $p = 10$ and $n = 4$) when all the calculated variances are really estimates of the same variance. In order to check for agreement among variances, it is helpful to plot the individual variances against the laboratories, draw a horizontal line across the plot at the level of the average variance, and examine the lowest and highest individual variances. A variance that is very low compared to the others may indicate that the laboratory is not permitting the normal causes for variation between results to show up, while a high variance indicates the lack of proper control of the testing process.

8.2.2.1 Table 4 gives approximate values (upper 5 % level) for the ratio of the largest variance to the sum of the variances that should not be exceeded (**11**).

8.2.2.2 The case of a small variance is not usually as troublesome as that of a variance that is too large. However, when one laboratory performs its tests in such a way that the normal causes of variation do not affect the results, an unrealistically low variance may occur. If no significantly high variance is present, as judged by the criterion given above, the following method may be used to examine a suspiciously low variance. The statistic used is the ratio of highest to lowest variance in the group. Table 5 gives the approximate values (upper 5 % level) for this ratio that should not be exceeded (**12**).

TABLE 4 Approximate Values (Upper 5 % Level) for the Ratio of the Largest Variance to the Sum of the Variances

30	0.2929	0.1980	0.1593	0.1377	0.1237

[A] Values obtained by graphic interpolation.

8.2.2.3 Often the data from one laboratory may indicate a high or low variance compared to the others, and elimination of that laboratory from the analysis results in a set of data with similar variances for the remaining laboratories (see Appendix X1). If all the variances are erratic, however, the test method is in trouble. Efforts to develop precision statements from the data should be suspended and further study of the test method should be undertaken to determine the causes for such erratic behavior. The advice of a statistical consultant should be obtained whenever there is doubt about eliminating a high or low variance.

8.2.3 *Interactions*—A common problem with test results obtained from an interlaboratory study is the presence of interactions between laboratories and materials. This means that the pattern of change of the results obtained on a given group of materials in one laboratory differs from the pattern obtained in another laboratory. In extreme cases, different laboratories may even fail to rate materials in the same order. The accepted statistical technique for finding significant interactions is an analysis of variance. A reasonably reliable method for checking to see if troublesome interactions may exist, however, is to make a plot of the averages obtained on the

TABLE 5 Approximate Values (Upper 5 % Level) for the Ratio of Highest to Lowest Variance

No. of Laboratories	No. of Replicates				
	2	3	4	5	6
5	[A]	202	51	25	16

www.technobetar.ir

materials by each laboratory (see X1.3.5). These plots should show similar patterns of change from material to material for all laboratories. One laboratory may show a noticeably different pattern from the others and may be eliminated. However, if the patterns vary for more than one or two of the laboratories, the test method needs to be reinvestigated, and the causes of the interactions discovered and eliminated. The advice of a statistical consultant should be obtained.

8.3 *Within-Laboratory and Between-Laboratory Variances*—After the analysis described in 8.2 has been completed for all materials and investigations for homogeneity of variance and for interactions have been completed, the quantities indicated are assembled in Table 6. The averages in Column 2 are the overall averages for each material, which are arranged in increasing order of the magnitude of the average. The components of variance in Columns 3 and 4 are the pooled within-laboratory variance and the component of between-laboratory variance, respectively, for each material. The variances in Columns 5 and 6 are the pooled within-laboratory variances (same as Column 3) and the sum of the two components of variance (Column 3 plus Column 4), respectively (see Note 5).

NOTE 5—These within-laboratory and between-laboratory variances apply to single determinations in a laboratory, even though the data from which they are derived involve replicate measurements in a laboratory. Thus, precision statements based on these variances will apply to comparisons between two single measurements within a laboratory or between laboratories, respectively.

8.4 *Estimates of Precision*—The reason for listing the materials in increasing order of magnitude in Table 6 is to permit examination of the precision and how it varies with the level of the property measured, and thus to make a decision about the proper form of the precision statement. For this purpose, the quantities listed in Table 7 are calculated and entered as shown, still in increasing order of magnitude of the average. Column 2 in Table 7 is the same as Column 2 in Table 6. Columns 3 and 4 contain the square roots of the numbers in Columns 5 and 6 of Table 6. Columns 5 and 6 of Table 7 contain the corresponding coefficients of variation, expressed as percents, that is, the within-laboratory or between-laboratory standard deviation, respectively, divided by the corresponding average and multiplied by 100.

8.4.1 *Determination of Form of Precision Statement*—The appropriate form of a precision statement depends on the relationship between the average level of the property measured for the different materials and the within-laboratory and between-laboratory standard deviations. There are three main forms of the relationship that cover most of the cases which are pertinent to ASTM test methods: (*a*) cases in which the standard deviation is relatively constant over the range of materials; (*b*) cases in which the standard deviation has an approximately linear relationship with the average level and the coefficient of variation is relatively constant; and (*c*) cases where the materials fall into two or more distinct groups within which condition (*a*) or (*b*) holds approximately, and for each of which a characteristic precision can be determined. In most cases, the determination of which of these alternatives applies, or whether some more complicated situation exists can be determined for practical purposes by plotting the standard deviations and coefficients of variation against the average level. Two separate graphs, one for the two standard deviations and one for the two coefficients of variation, are usually adequate (see Note 6). If more sophisticated techniques are desired, they may be found in other references **(5, 13).** The appropriate measures of precision described in 8.4.2-8.4.5 become the indexes of precision as described in Practice C670.

NOTE 6—Usually, the same case should be applicable to both between-laboratory and within-laboratory precision. Sometimes, however, one of the two types of measures of precision is dependent on the level and the other is not. In situations like this, it may be possible to select a suitable compromise in order to have the two precision statements in the same form. The advice of a statistical consultant should be obtained.

8.4.2 *Constant Standard Deviation*—In this case the pooled within-laboratory standard deviation over all materials becomes the single-operator standard deviation or one-sigma limit (1s) and the pooled between-laboratory standard deviation becomes the multilaboratory standard deviation or one-sigma limit (1s) as described in Sections 3 and 4 of Practice C670. The pooled standard deviations are derived by adding Columns 5 and 6 of Table 6 for within-laboratory and between-laboratory estimates, respectively, dividing each of the two totals by q, and taking the square roots.

8.4.3 *Constant Coefficient of Variation*—In this case the average within-laboratory coefficient of variation becomes the single-operator, one-sigma limit in percent (1s %) and the average between-laboratory coefficient of variation becomes the multilaboratory one-sigma limit in percent (1s %) as described in 3.1.3 of Practice C670. Since it is not possible to pool coefficients of variation in the same manner as variances and standard deviations, the simple arithmetic averages of Columns 5 and 6 in Table 7 are used.

8.4.4 *Separate Groups with Constant Standard Deviation or Coefficient of Variation (see Note 7)*—In this case the single-operator and multilaboratory one-sigma limits or one-sigma limits in percent are calculated separately for each group in the same manner as described in 8.4.2 or 8.4.3 above. For each

group, the range of average values over which the index of precision applies is supplied with the estimates. Refer to 6.2.2.2 and 6.2.2.3 of Practice C670.

NOTE 7—Situations of the type described in 8.4.4 and 8.4.5 are often indications that something is wrong with the experimental situation or the test method. If the standard deviation and coefficient of variation are so erratic that it is difficult to write an applicable precision statement without giving separate indexes of precision for each material tested in the interlaboratory program, this is very possibly an indication that the test method itself may be subject to erratic variations and may need to be restudied and revised. Also interactions or non-normal distributions may exist in the data. See X1.3.4 and X1.3.5 and Ref. **(8).** In cases of erratic precision, a precision statement in the test method may really be more misleading than helpful to persons trying to use or interpret the results of the test method. It may actually provide invalid information about what should be expected when the test method is used.

8.4.5 *Irregular or Nonlinear Relationship Between Standard Deviation, Coefficient of Variation, and Average Level (see* Note 7*)*—One way of dealing with situations that do not apply to 8.4.2-8.4.4 is to use the largest estimate of the standard deviation or coefficient of variation (whichever comes closest to being constant) and to use the abbreviation" max" after the indexes of precision (see section 6.2.2.1 of Practice C670). This practice should be discouraged because the resulting indexes of precision are certain to be more lenient than they should be. The maximum limit applies strictly to the level at which the maximum standard deviation or coefficient of variation occurred. Tests done at other levels, for which lower precision limits apply, will be judged on the basis of a wider tolerance than they should be. Also, as pointed out in 8.2.2, individual estimates of variance can vary widely from each other yet still be estimates of the same underlying variance, and it may often be that the pooled or averaged estimates are still the most appropriate ones to use, even if upon superficial examination, the individual variances appear to scatter rather wildly. It is again emphasized that the advice of a statistical consultant is needed here.

8.4.5.1 Cases where the standard deviation or coefficient of variation is a nonlinear function of the average level are dealt with in Ref. **(5).** Very often the amount of data, especially the number of laboratories and materials, is insufficient to establish the form of such a relationship beyond question, and estimates of precision based on one of the cases already described will serve. In addition, the difficulty of writing a precision statement based on a nonlinear relation, that can be easily understood and applied by the user of a test method indicates that such statements should be avoided if possible.

APPENDIXES

(Nonmandatory Information)

X1. EXAMPLE OF ANALYSIS OF DATA FROM AN INTERLABORATORY STUDY

X1.1 *Introduction*—The following example is based on data from an interlaboratory study of tests of expansive cements conducted by ASTM Subcommittee C01.12 on Blended Cements.

X1.2 *Characteristics of the Study and Data*—The major test program was preceded by preliminary tests in three of the participating laboratories, each using a different kind of cement and the test procedures to be used in the major test program. The purpose of the preliminary tests was to determine whether there were any glaring deficiencies connected with the test procedures, and to alter the procedures, if necessary, before undertaking the major test program. This is the screening procedure referred to in 3.1.1 (see Note X1.1).

X1.2.1 In the main test program, eleven laboratories tested five cements for several properties, including restrained and unrestrained expansion of mortar, compressive strength at several ages of unrestrained and restrained modified 2-in. (50.8-mm) cubes, time of setting, false set, and restrained expansion and compressive strength of concrete.

X1.2.2 The data used in this analysis are the 3-day unrestrained compressive strengths of the 2-in. (50.8-mm) mortar cubes. In each laboratory, three rounds of mortar specimens were made with four of the cements, with three cube specimens per round. Four rounds were made with the fifth cement, but in this analysis only the data from the first three rounds reported were used. The average of the three cubes from a single round was used as an individual test result. Thus, the data used

www.technobetar.ir

constitute a study with p = 11 laboratories; q = five materials; and n = three replicates (each an average of three specimens). Certain minor adjustments were made in the data in order to present a better illustration of the technique of analyzing the results of an interlaboratory study, but the data are essentially as reported by the laboratories.

X1.3 *Analysis of Data:*

NOTE X1.1—Since the discussion and tables following constitute directions for manipulating the numbers only, and what is of interest is the process of analysis itself, rather than the analyzed data, it is not deemed appropriate to include metric equivalents, and in the tables, no units at all are given. Units in both systems, however, are given in the finished precision statements, which are examples of what would be published as a result of the analysis. For those who are interested in converting the numbers, however, the following information is given:

(*1*) All the numbers given are in psi or $(psi)^2$.

(*2*) For individual values, averages, and sums of individual values,

$$psi \times 6.9 = kPa \text{ and}$$

$$psi \times 0.0069 = MPa.$$

(*3*) For sums of squares, variances, etc.

$$(psi)^2 \times 47.54 = (kPa)^2$$

X1.3.1 *Step 1: Assembling the Data*—Table X1.1 shows the data sheet for one laboratory for all the tests. The individual cube values and averages for each round are given. In this laboratory, the individual results are given to the nearest 25 psi, which is the case with most of the compressive strength data from the study. Some of the laboratories, however, gave results of individual cube strengths to the nearest 1 psi. The testing machines used in testing 2-in. cubes generally are graduated to 50-lb intervals and can be estimated to half a graduation. The total load is divided by four to get pounds per square inch. Some laboratories give individual results to the nearest 25 psi and some to the nearest 50 psi. Others round the result of the division to the nearest 1 psi, which gives different results in the final digit depending on whether or not half divisions on the dial are estimated and how the results of the division are rounded. In addition, different methods were used in averaging the three individual cube measurements to get a test result.

	Avg.	2908	3950	2683	1980	2100

X1.3.1.1 In setting up the instructions for an interlaboratory study, directions for handling details such as this should be spelled out, so that the laboratories use the same procedure. In the analysis presented here, the individual cube results were used as reported, and the averages of the three were recalculated and rounded to the nearest 1 psi in cases where the averages given by the laboratories had been rounded to the nearest 10 psi.

X1.3.1.2 Table X1.2 is a Summary Data Sheet for all laboratories and all materials. The individual entries are the averages of the three cubes per round. The arithmetic labor of an analysis such as this can often be reduced by coding the data, that is, by subtracting a constant from all the numbers. This treatment has no effect on the variances and standard deviations that form the essential parts of the estimates of precision. Averages are reduced by the amount of the constant subtracted and can be restored by merely adding it again. The practice is helpful in avoiding difficulties that sometimes arise from squaring and summing the squares of large numbers when

www.technobetar.ir

a calculator that carries a limited number of digits is used. The data were not coded for the analysis given in this example, but they could have been. For Material A, with Laboratory 2 excluded (see X1.3.3.1), the subtraction of 2550 (or any number in the range 2526 to 2567) would have reduced all the data to three-digit numbers. The most appropriate number would have been different for the different materials.

X1.3.2 *Step 2: Processing for Outliers*—The criterion given by Dixon and Massey **(10)** was used to examine the sets of three cubes per round and of three rounds per material in a laboratory for outliers. The only cases that exceeded the critical value of 0.988 were cases in which two of the figures were identical, in which case any difference of the third measurement, however small, results in a calculated statistic of 1.00, and the method breaks down. Thus, no outliers were eliminated.

X1.3.3 *Step 3: Between and Within Analysis for All Materials*—Tables X1.3-X1.7 (see Table 3) show the results of the between and within analysis for the various materials tested. The data given under headings a, b, and c are the replicate measurements for the given material for each laboratory, taken from the Summary Data Sheet. The $\bar{x}_i$ and s_i^2 are obtained as described in 8.2.

X1.3.3.1 These tables show two values of $\bar{x}$ and s^2(pooled) for each material, one pair calculated with Laboratory 2 included, and one without Laboratory 2. This is done because it quickly became evident, as discussed further below, that the results of Laboratory 2 differed radically from those of the other ten laboratories. Laboratory 2 had a variance from 4 to 10 times as large as the second highest variance for four of the five materials. It also had the lowest average in four out of the five cases, by quite a large margin. The components of variance used in the analysis, therefore, were those calculated with Laboratory 2 excluded. The final analysis, thus, was based on p = 10 laboratories, q = five materials, and n = three replicates.

TABLE X1.3 Between and Within Analysis for Material A[A,B]

Laboratory	Data			Average $\bar{x}_i$	Within-Laboratory Variance s_i^2
	a	b	c		
1	2858	2867	2908	2878	718
2	1813	2388	2625	2275	174 356
3	3083	3033	3158	3091	3958
4	2783	2692	2817	2764	4177

[A] p = 11 laboratories
n = 3 replicate test results
$\bar{x}_C$ (with Lab. 2) = 2709
s_C^2 (pooled, with Lab. 2) = 28 951
$\bar{x}_C$ (without Lab. 2) = 2762
s_C^2 (pooled, without Lab. 2) = 16 685
$s_{\bar{x}_C}^2$ = 36 592
$s_{L_C}^2$ = 31 031
The ratio of the high variance to the sum of variances = 0.4759, the ratio of the high variance to the low variance (with Lab. 2) = 171, and the ratio of the high variance to the low variance (without Lab. 2) = 56.

X1.3.3.2 Table X1.10 is a work sheet showing in detail how the calculations were done for Material A, with Laboratory 2 excluded. Rows 1 through 3 are the individual measurements from the columns headed a, b, and c in Table 3. Row 4 contains the sums of the three replicate measurements, and Row 5 contains the individual averages entered under $\bar{x}_i$ in Table 3. Row 6 contains the sums of the squares of the three replicate measurements for each laboratory. Row 7 contains the quantities obtained by squaring the averages in Row 5 and multiplying by 3 (the number of replicates) (see Note X1.2). Row 8 gives the differences between the values in Rows 6 and 7 and corresponds to the numerator in the equation for s_i^2 (see 8.2). Row 9 contains the s_i^2 obtained by dividing Row 8 by $n - 1$, in this case, 2. The column headed Sum contains the sums of the $\bar{x}_i$ and the s_i^2 in Rows 5 and 9, respectively. The column

The ratio of the high variance to the sum of the variances = 0.7616, the ratio of the high variance to the low variance (with Lab. 2) = 2555, and the ratio of the high variance to the low variance (without Lab. 2) = 240.

TABLE X1.8 Averages, Components of Variance, and Variances for All Materials

Material	Average	Components of Variance		Variances[A]	
		W/L	B/L	W/L	B/L
D	1932.68	6775.5	22 672.5	6775.5	29 448.0
E	2168.28	5035.5	29 554.8	5035.5	34 590.3
C	2761.73	16 685.4	31 030.6	16 685.4	47 716.0
A	3047.84	10 355.0	35 114.0	10 355.0	45 469.0
B	3869.69	18 401.9	29 030.6	18 401.9	47 432.5

[A] Based on one measurement on each material in each laboratory.

headed Average contains the two sums divided by 10, the number of laboratories. These two figures are x_A and s_A^2, respectively. The four figures in the last column headed Sum of Squares are (*a*) the sum of the squares of the values in Row 5; (*b*) 10 times the square of the average x_i, 3048; (*c*) the difference between (*a*) and (*b*); and (*d*) the number (*c*) divided by 9, or one less than the number of laboratories.

TABLE X1.9 Averages, Standard Deviations, and Coefficients of Variation for All Materials

Material	Average	Standard Deviations		Coefficients of Variation	
		W/L	B/L	W/L	B/L
D	1932.68	82.314	171.604	4.3	8.9
E	2168.28	70.961	185.985	3.3	8.6
C	2761.73	129.172	218.440	4.7	7.9
A	3047.84	101.759	213.235	3.3	7.0
B	3869.69	135.654	217.790	3.5	5.6

NOTE X1.2—It will be noted that the quantities obtained by squaring the $\bar{x}_i$'s in Row 5 and multiplying by 3 do not agree in all cases with those given in Row 7. This is due to the rounding error involved in calculating the averages. All the $\bar{x}_i$'s are given to the nearest unit. In the two cases (Laboratories 4 and 6) where Σx_i is an exact multiple of 3 and there is no rounding error, 3 $\bar{x}_i^2$ in Row 7 agrees with the quantity obtained by using the $\bar{x}_i$ from Row 5. The quantities in Row 5 in Table X1.10 were obtained by retaining all 10 digits that resulted from the division of Σx_i by 3 and squaring this result, not by squaring the rounded $\bar{x}_i$'s. This will usually take care of the rounding error. Another method of avoiding the effects of rounding error is to use the formula $(\Sigma x_i)^2/n$ in place of $n\bar{x}_i^2$. In the example, square the Σx_i in Row 4 and divide by 3 to get the quantities for Row 7.

The sum and average in the two columns to the right of column 11 were obtained by summing the rounded $\bar{x}_i$'s, but in this case the rounding error tends to be averaged out over the ten laboratories. Rounding error could be avoided entirely here also, by (*a*) using the full ten or more digits provided by the calculator to get the sum of the $\bar{x}_i$'s or (*b*) by summing the 10 Σ $\bar{x}_i$'s and then dividing by 30 (which is pn) to get $\bar{x}_A$, the average $\bar{x}$.

X1.3.4 *Step 4: Investigation for Homogeneity of Variance*—Figs. X1.1-X1.5 are plots of the individual within-laboratory variances for each laboratory for the five different materials. The drastic departure of the variances of Laboratory 2 is clearly demonstrated by these plots. The average within-laboratory variances, s_x^2 (pooled), both with and without Laboratory 2 are also shown on the plots, except for Material B, for which the average variance with Laboratory 2 included was off the diagram. Use of the criterion for the highest variance given in 8.2 confirmed that the variances for Laboratory 2 were too extreme in four of the five cases and, therefore, Laboratory 2 was eliminated in those four cases. Since more than one half of the cases for Laboratory 2 were involved, an alternative judgement could have been to eliminate Laboratory 2 from the analysis in all five cases. Use of the criterion for the lowest variance revealed one out of five cases for Laboratory 9 where the elimination of a low variance was indicated. In that case, Laboratory 9 was eliminated from the analysis. Since less than one-half of the cases for Laboratory 9 were involved, an alternative judgement could have been to allow Laboratory 9 in all five cases to remain in the analysis.

X1.3.5 *Step 5: Investigation for Interactions*—Average strength was plotted against material designation arranged in increasing order of average strength for the materials for each of the laboratories. These plots for the first three laboratories are shown on Fig. X1.6. Laboratories 1 and 3 show very similar patterns, but the plot for Laboratory 2 again indicates that the results from this laboratory really do not fit the pattern. The drop in strength between Materials D and E was the only

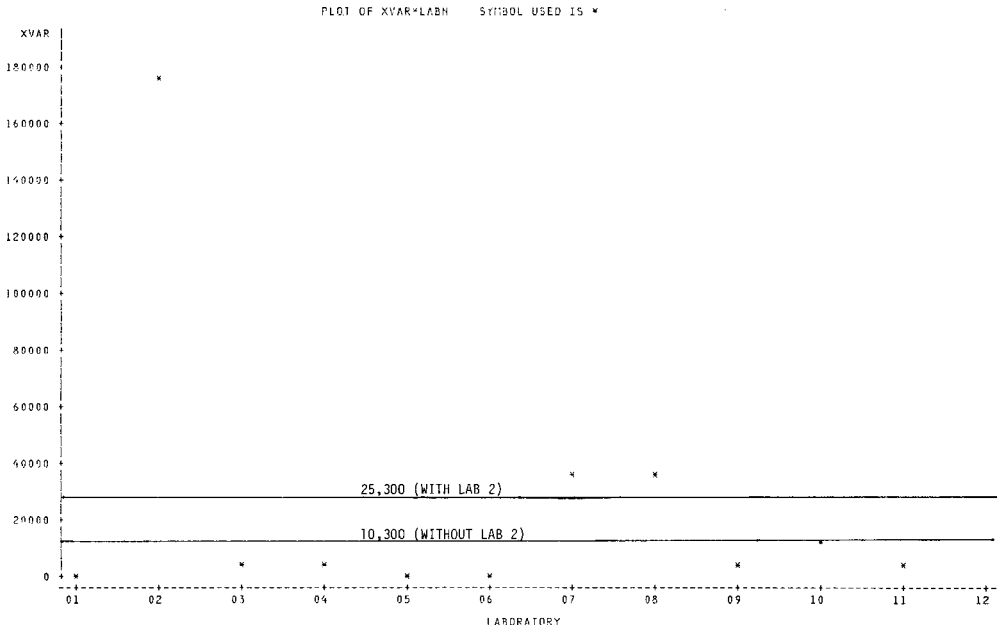

FIG. X1.1 Variance Versus Laboratory For Material A

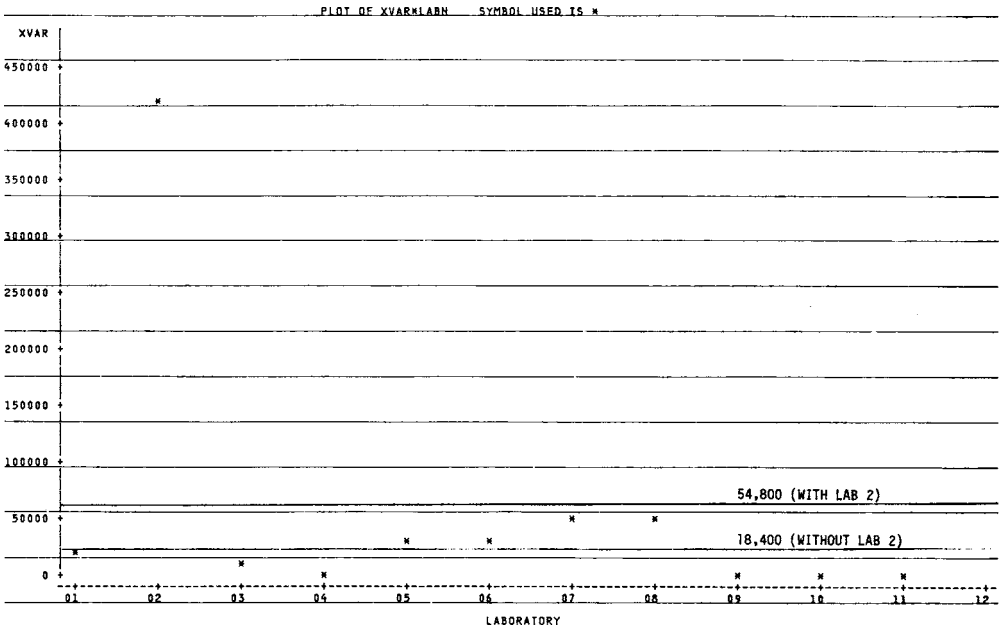

FIG. X1.2 Variance Versus Laboratory for Material B

case where a reversal of the order of two materials occurred. All of the other eight laboratories showed results with a similar pattern to those of Laboratories 1 and 3. It was, therefore concluded that, with partial (or total) the elimination of Laboratory 2, no serious interactions remained.

X1.3.6 *Step 6: Development of the Estimates of Precision*—Table X1.8 and Table X1.9, show the components of variance, variances, standard deviations, and coefficients of variation, developed in accordance with Practice C670. The variances given in Table X1.8 are for individual determinations in each laboratory, even though three replicates were used in the analysis.

X1.3.7 *Step 7: Determination of the Form of the Precision Statements*—Fig. X1.7 and Fig. X1.8, respectively, show plots of the standard deviation versus average and coefficient of variation versus average. Each plot shows between-laboratory and within-laboratory results separately. Fig. X1.7 indicates that the standard deviation tends to increase with increasing level of strength, both within and between laboratories. Examination of the curves also indicates the possibility that two levels of standard deviation might exist, one for the two lower strength cements, D and E, and another for the three higher ones. With only the information from the five materials given, it is difficult to determine which one of these situations really

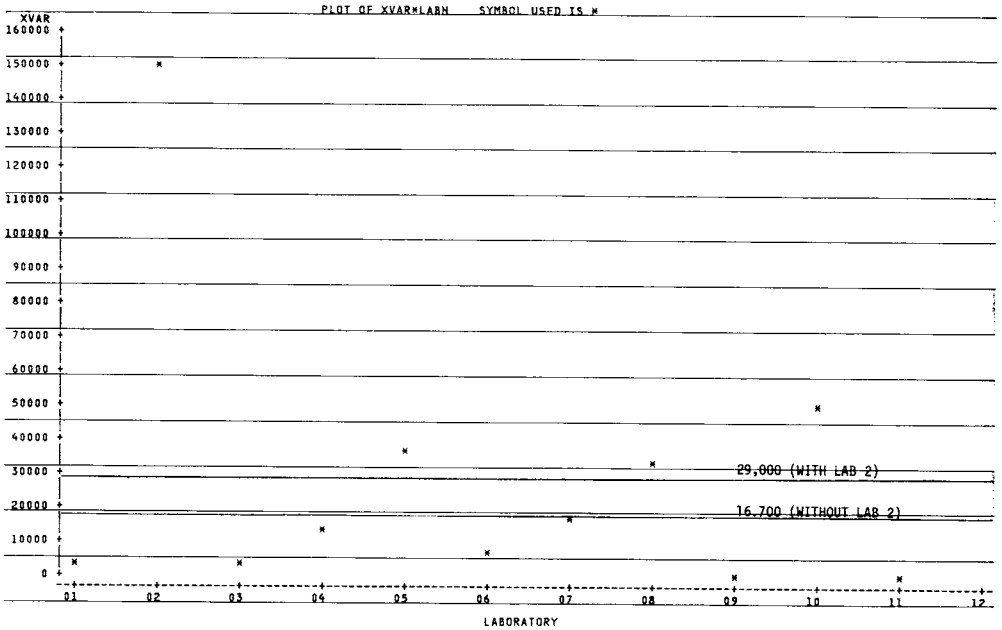

FIG. X1.3 Variance Versus Laboratory for Material C

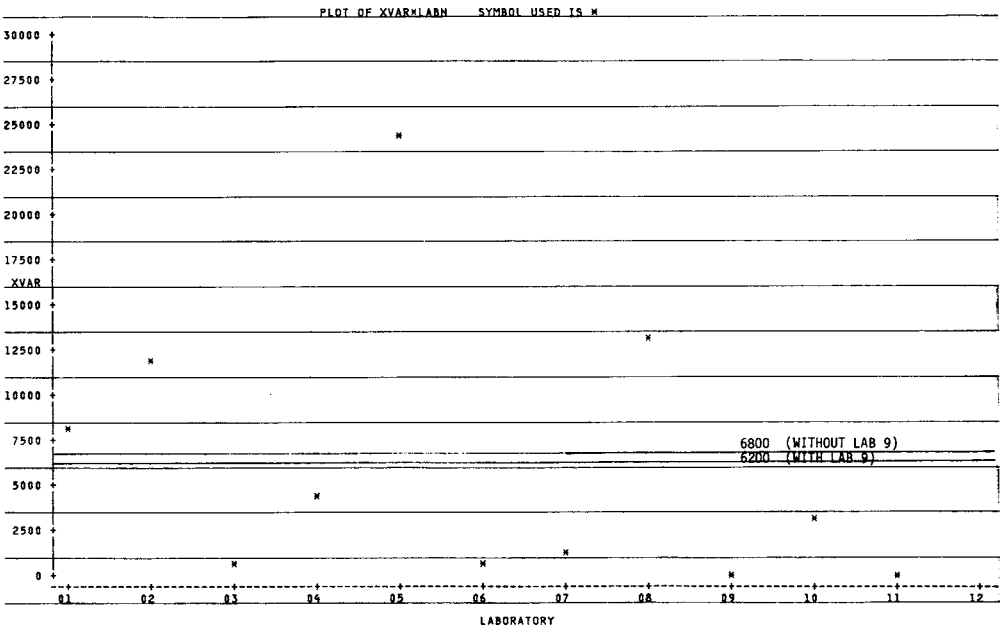

FIG. X1.4 Variance Versus Laboratory for Material D

exists. Fig. X1.8 indicates that the between-laboratory coefficient of variation tends to decrease with increasing level, although the coefficients for the two lower materials were the same. The within laboratory coefficients appear to be about the same for all levels.

X1.3.7.1 References (**14-18**) give information on the relationship between the variability and strength of concrete. References (**15-17**) report that standard deviation is relatively constant above 3000 psi (20.7 MPa) and coefficient of variation is constant below that level. The results of this analysis are compatible with this conclusion if the transition is lower, say about 2500 psi (17.2 MPa). Note that these results are on small mortar cubes instead of large concrete specimens, and are tested at 3 days instead of 28 days as is usual in concrete testing. The precision statements that follow are thus based on the assumption of constant coefficients of variation of 3.8 and 8.8 %, respectively, for within-laboratory and between-laboratory results for average strengths below 2500 psi (17.2 MPa), and on constant standard deviations of 125 and 215 psi (0.862 and 1.48 MPa), respectively, for within-laboratory and between-laboratory results for average strengths above 2500 psi. Maximum allowable ranges for three cubes from the same batch, for three test results, each consisting of an average of three cubes and for the difference between averages of three test results in different laboratories are also given (see Practice C670).

www.technobetar.ir

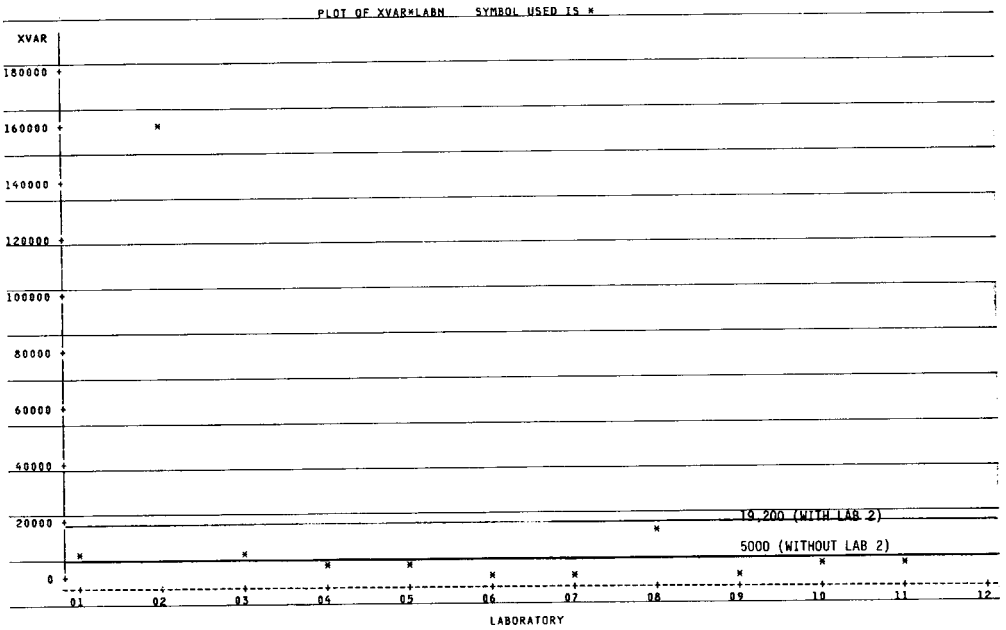

FIG. X1.5 Variance Versus Laboratory for Material E

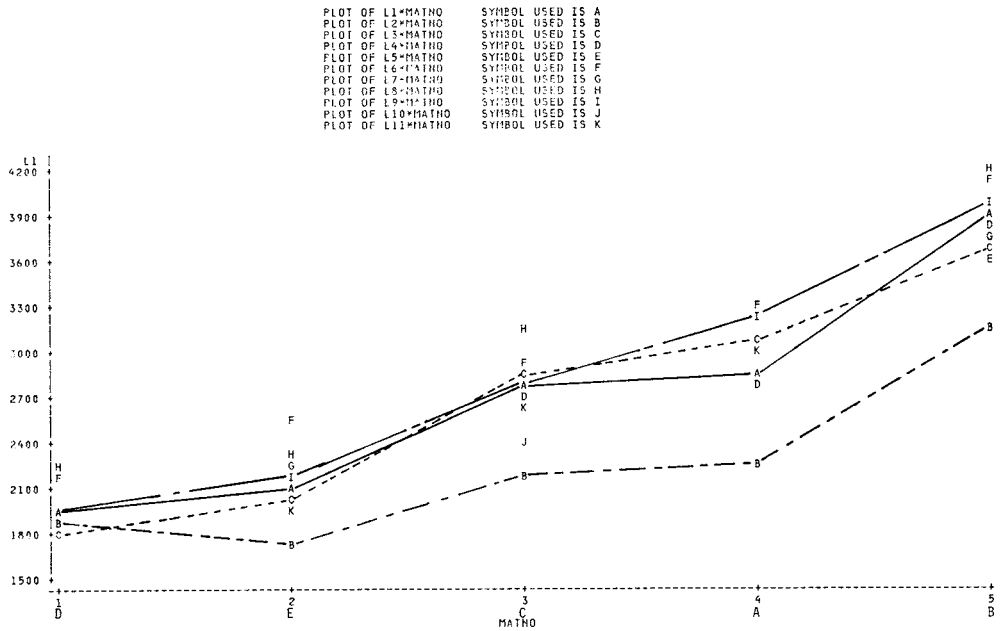

FIG. X1.6 Average Strength Versus Material

X1.3.8 *Step 8: Writing the Precision Statements*—The precision statements based on the data as described in X1.3.7.1 are as follows:

Single-Operator Precision (Average Strength Below 2500 psi (17.2 MPa))—The single-operator coefficient of variation of a single test result for average strengths below 2500 psi (a test result is defined in this method as the average of three separate measurements) has been found to be 3.8 %.[A] Therefore, results of two properly conducted tests by the same operator (each consisting of the average of three cubes from the same batch of mortar) should not differ by more than 10.8 %[A] of the average of the two results. The range of three test results obtained by the same operator should not exceed 12.5 % of the average of the three.[B]

Multilaboratory Precision (Average Strength Below 2500 psi (17.2 MPa))—The multilaboratory coefficient of variation of a single test result for average strengths below 2500 psi (a test result is defined in this method, as the average of three separate measurements) has been found to be 8.8 %.[A] Therefore, results of two properly conducted tests in different laboratories on the same cement should not differ by more than 24.9 % of their average.[A]

www.technobetar.ir

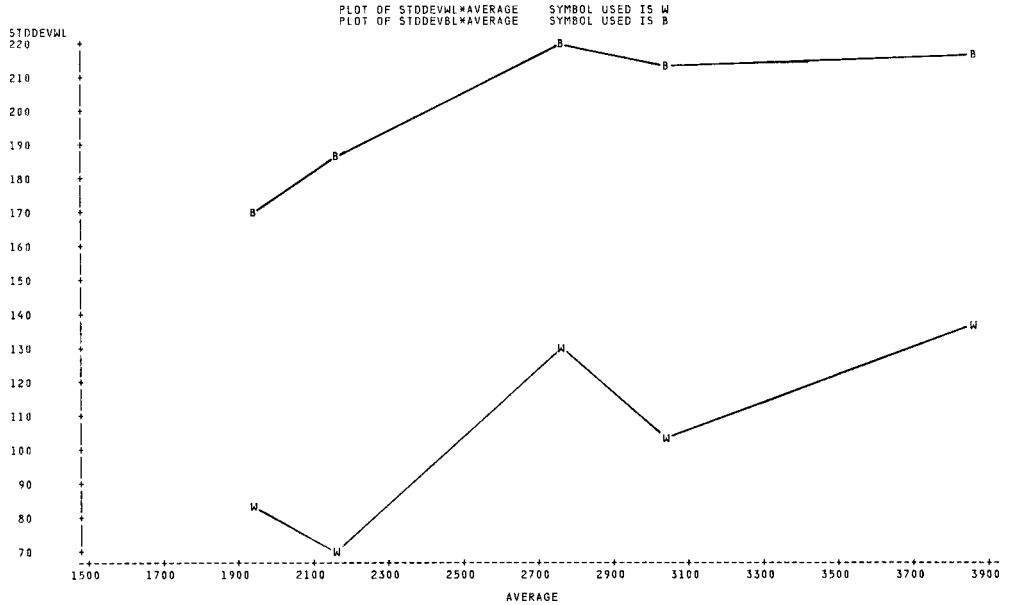

FIG. X1.7 Standard Deviation Versus Average

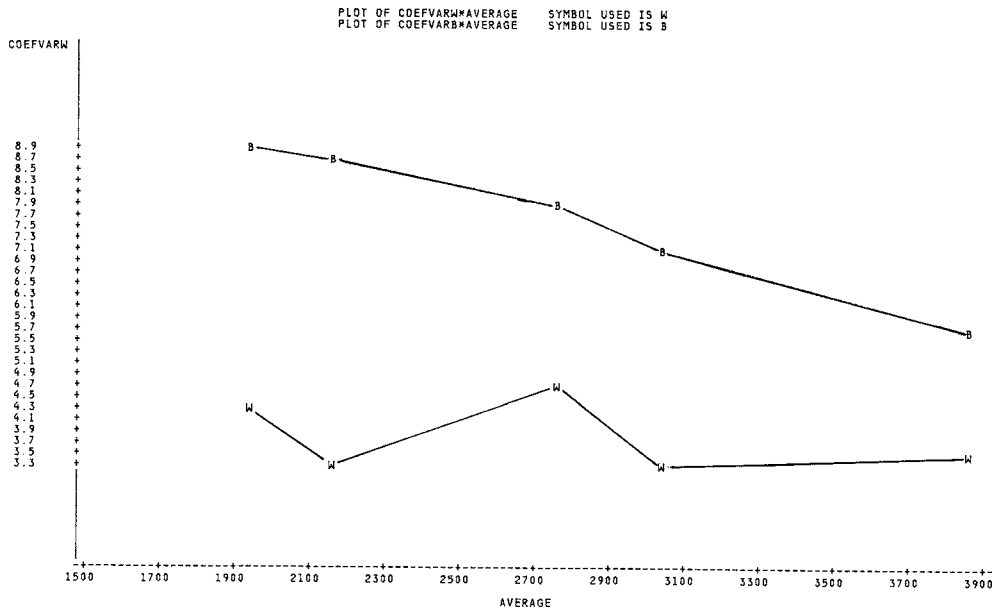

FIG. X1.8 Coefficient of Variation Versus Average

Single-Operator Precision (Average Strength Above 2500 psi (17.2 MPa))—The single-operator standard deviation of a single test result for average strengths above 2500 psi (a test result is in this method, as the average of three separate measurements) has been found to be 125 psi (0.862 MPa). Therefore, results of two properly conducted tests by the same operator (each consisting of the average of three cubes from the same batch of mortar) should not differ by more than 355 psi (2.45 MPa).[A] The range of the three test results obtained by the same operator should not exceed 410 psi (2.83 MPa).[B]

Multilaboratory Precision (Average Strength Above 2500 psi (17.2 MPa))—The multilaboratory standard deviation of a single test result for average strengths above 2500 psi (a test result is defined in this method, as the average of three separate measurements) has been found to be 215 psi (1.48 MPa).[A] Therefore, results of two properly conducted tests in different laboratories on the same cement should not differ by more than 610 psi (4.21 MPa).[A]

[A] These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C670.

[B] Calculated as described in Practice C670.

X1.3.8.1 The figures in the above example are obtained as follows:

(1) The (1s) and (1s %) figures are the standard deviations and coefficients of variation, respectively, as given in X1.3.7.

(2) The (d2s) and (d2s %) figures are the (1s) and (1s %) figures multiplied by 2.83 (that is, $2\sqrt{2}$).

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:49 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

(3) The maximum allowable ranges for three test results are the (1s) and (1s %) figures for single-operator precision multiplied by 3.3, the multiplier for ranges of 3 as described in Practice C670.

X2. OUTLIERS

X2.1 The objective of the process of screening for outliers is to retain all data that legitimately belong in the population of results characteristic of the test method, and to eliminate only those that differ so drastically that their inclusion distorts the realistic picture of that population (**9**). The procedure used should be a conservative one. The error of discarding results that should not be discarded tends to be more common than that of retaining results that should not be retained. For example, criteria that call for discarding results that would be expected 5 % of the time are often used. An interlaboratory program that includes ten laboratories, five materials and four replicates produces 200 measurements. On the average, such programs should produce ten results in the 5 % rejection range. Rejection of these results as outliers could cause the final estimates of precision to be much smaller than they ought to be.

X2.2 If it is considered desirable to apply statistical techniques for the rejection of outliers, the criteria and technique to be used should be selected and applied by the organizing committee on the advice of the statistical consultant, and not by the individual laboratories. Also the significance level of the test used should be no greater than 1.0 %. Approved methods are described in Refs (**10** and **13**).

Designation: C 803/C 803M – 03

Standard Test Method for Penetration Resistance of Hardened Concrete[1]

This standard is issued under the fixed designation C 803/C 803M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope *

1.1 This test method covers the determination of the resistance of hardened concrete to penetration by either a steel probe or pin.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific hazard statements, see Section 7.

2. Referenced Documents

2.1 *ASTM Standards:*

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials[2]

C 125 Terminology Relating to Concrete and Concrete Aggregates[2]

2.2 *ANSI Standard:*

A10.3 Safety Requirements for Powder Actuated Fastening Systems[3]

3. Terminology

3.1 *Definitions:*

3.2 For definitions of terms used in this test method, refer to Terminology C 125.

4. Summary of Test Method

4.1 A driver delivers a known amount of energy to either a steel probe or pin. The penetration resistance of the concrete is determined by measuring either the exposed lengths of probes that have been driven into the concrete or by measuring the depth of the holes created by the penetration of the pins into the concrete.

5. Significance and Use

5.1 This test method is applicable to assess the uniformity of concrete and to delineate zones of poor quality or deteriorated concrete in structures.

5.2 This test method is applicable to estimate in-place strength, provided that a relationship has been experimentally established between penetration resistance and concrete strength. Such a relationship must be established for a given test apparatus (see also 9.1.5), using similar concrete materials and mixture proportions as in the structure. Use the procedures and statistical methods in ACI 228.1R for developing and using the strength relationship.[4]

NOTE 1— Since penetration results may be affected by the nature of the formed surfaces (for example, wooden forms versus steel forms), correlation testing should be performed on specimens with formed surfaces similar to those to be used during construction. Additional information on the factors affecting penetration test results and summaries of past research are available.[4,5]

5.3 Steel probes are driven with a high-energy, powder-actuated driver, and probes may penetrate some aggregate particles. Probe penetration resistance is affected by concrete strength as well as the nature of the coarse aggregate. Steel pins are smaller in size than probes and are driven by a low energy, spring-actuated driver. Pins are intended to penetrate the mortar fraction only; therefore, a test in which a pin strikes a coarse aggregate particle is disregarded.

5.4 This test method results in surface damage to the concrete, which may require repair in exposed architectural finishes.

---

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.64 on Nondestructive and In-Place Testing.

Current edition approved Jan. 10, 2003. Published April 2003. Originally approved in 1975. Last previous edition approved in 1997 as C 803/C 803M-97ε1.

6. Apparatus [6]

6.1 *Resistance Testing With Probes*:

6.1.1 *Driver Unit*—The driver unit shall be capable of driving the probe into the concrete with an accurately controlled amount of energy so that the probe will remain firmly embedded. The driver unit shall incorporate features to prevent firing when not properly placed in the positioning device on the concrete surface.

NOTE 2—A powder-actuated device conforming to ANSI A10.3 has been used successfully.

6.1.1.1 For a specified energy loading, the variation of the velocity of standard probes propelled by the standard driving unit shall not have a coefficient of variation greater than 3 % for any ten tests made by accepted ballistic methods.

NOTE 3—A conventional counter chronograph and appropriate ballistic screens may be used to measure velocity at 2 m [6.5 ft] from the end of the driving unit.

6.1.2 *Probe*— The probe shall be a hardened alloy-steel rod plated for corrosion protection, with a blunt conical end that can be inserted into the driver unit and driven into the concrete surface so that it remains firmly embedded and the length of the projecting portion can be measured. The hardness shall be between Rockwell 44 HRC and 48 HRC. The exposed end of the probe shall be threaded to accommodate accessories designed to facilitate measurement and withdrawal.

NOTE 4—If probes are to be removed from the concrete, a device, consisting of a nut that can be screwed onto the end of the probe by a wrench and spacers that can be slipped over the probe for the nut to bear against, will serve to withdraw the probes.

6.1.2.1 The length of probes shall be uniform within ± 0.5 %.

6.1.3 *Measurement Equipment*:

6.1.3.1 *Measuring Instrument*—A measuring instrument, such as a caliper, depth gage, or other measuring device, and associated equipment, shall be used to measure the exposed length of a probe to the nearest 0.5 mm [0.025 in.].

6.1.3.2 The measuring equipment shall include a reference base plate or other device that is supported on the concrete surface at three equally spaced points at least 50 mm [2 in.] from the probe to be measured.

NOTE 5—In order to hold the reference base plate against the surface of the concrete when measurements in the horizontal direction or in the bottom of an overhead concrete surface are being made, a plate retainer consisting of a spring and a nut that can be screwed onto the threaded end of the probe may be used.

NOTE 6—A probe-measuring cap that can be screwed onto the threaded end of the probe has been used to facilitate measuring exposed length and to compensate for the height of the reference base plate.

6.1.4 *Positioning Device*—A device to be placed on the surface of the concrete for positioning and guiding the probe and driver unit during firing will be used.

NOTE 7—This may be a single-positioning device or a triangular device with holes at the three corners that permits the firing of three probes in a triangular pattern in accordance with 7.1.1.

6.2 *Resistance Testing with Pins*:

6.2.1 *Driver Unit*—The driver shall be a device capable of driving a pin into the concrete with an accurately controlled amount of energy. The pin will be forced into the concrete, creating a hole so that the depth of penetration can be measured.

NOTE 8—A spring-actuated driver unit with a spring stiffness of 49.7 kN/m [284 lb/in.] has been successfully used to test concrete with strength in the range of 3 to 28 MPa [450 to 4000 psi].

6.2.2 The spring-actuated driver requires regular verification of the amount of energy transferred to the pin. Servicing is required whenever there is reason to question its proper operation.

NOTE 9—The amount of energy transferred to the pin can be verified using calibration blocks supplied by the manufacturer. Pins are driven into the blocks using the spring-actuated driver, and the measured penetration is compared to manufacturer's specifications. If the penetration does not meet the manufacturer's specification, the driver unit should be serviced.

6.2.3 *Pin*—The pin shall be a hardened alloy-steel drill rod, heat treated to Rockwell hardness 62 to 66 HRC, with one end sharpened and the other end blunt. The dimensions of the pins shall be uniform within ±2.0 %. Each pin shall be used only once and then discarded.

NOTE 10—A pin with approximate length of 30 mm [1.2 in.], a diameter of 3.6 mm [0.14 in.] and a tip machined at an angle of 22.5 degrees with its longitudinal axis, has been used successfully in the driver unit described in Note 8.

6.2.4 *Measuring Equipment*:

6.2.4.1 *Measuring Instrument*—A depth gage with a reference plate shall be used to measure the depth of penetration of the pin tip into the concrete to the nearest 0.001 in. [0.025 mm].

6.2.4.2 The measuring rod of the depth gage shall have a diameter and a tip angle that are less than that of the pin.

6.2.4.3 The test equipment shall include an air blower to clean the small hole created by a pin before measurement of the depth of penetration.

7. Hazards

7.1 *Resistance Testing With Probes*:

7.1.1 Exercise care in the operation of the driver unit to prevent unexpected or inadvertent discharge of a probe.

7.1.2 Wear safety goggles, hearing protection, and other appropriate protective equipment when driving probes into concrete.

7.1.3 The driving unit, if powder actuated, shall conform to the applicable requirements of ANSI A10.3.

7.1.4 If reinforcing bars or other metal embedments in the concrete are suspected to have cover depths shallower than the anticipated probe penetration, select test positions so that probes will not strike such embedded items (Note 11).

NOTE 11—The location of reinforcement may be established using reinforcement locators or metal detectors. Follow the manufacturer's instructions for proper operation of such devices.

7.2 *Resistance Testing with Pins*:

7.2.1 Use care in the operation of the spring actuated driver to prevent injury from the inadvertent firing of the pin.

[6] Apparatus to conduct these tests is available commercially.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:46 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.2.2 Personnel should wear safety goggles and other appropriate protective equipment when performing the test.

8. Sampling

8.1 *Resistance Testing With Probes*:

8.1.1 The concrete to be tested must have reached a sufficient degree of resistance to penetration so that the probe will not penetrate more than one half the thickness of the concrete member and will remain firmly embedded. No probe shall be located less than 175 mm [7 in.] from any other probe, nor less than 100 mm [4 in.] from the edge of a concrete surface.

8.1.2 A minimum of three firmly embedded test probes in a given test area shall constitute one test. If the range of three valid probe penetration measurements exceeds the value in the third column of Table 1, make a fourth measurement and discard the measurement with the greatest deviation from the average. If the three remaining measurements still do not meet the limit given in Table 1, select a different test area and obtain three new measurements.

NOTE 12—The number of tests to be taken depends on the intended use of the results. Refer to ACI 228.1R[4] for recommendations.

8.2 *Resistance Testing with Pins*:

8.2.1 The concrete to be tested must have reached a sufficient degree of resistance to penetration so that the pin does not penetrate to a depth greater than the exposed length of the pin when inserted into the hammer of the driver.

NOTE 13—For the driver unit described in Note 8, the exposed length is 7.6 mm [0.30 in.].

8.2.2 No pin penetration shall be located less than 50 mm [2 in.] or more than 150 mm [6 in.] from any other pin penetration, nor less than 50 mm [2 in.] from the edge of a concrete surface.

8.2.3 The average depth of penetration measured for six pins driven into the concrete in a given test area shall constitute one test. See Note 12.

8.2.4 Discard a reading when the pin obviously hit a coarse aggregate or an entrapped air void, and perform a new test. If the range of six valid pin penetration measurements exceeds the value in the third column of Table 2, make a seventh measurement and discard the measurement with the greatest deviation from the average. If the six remaining measurements still do not meet the limit given in Table 2, select a different test area and obtain six new measurements.

9. Procedure

9.1 *Resistance Testing With Probes*:

9.1.1 Concrete surfaces to be tested that are coarser than burlap dragged finishes shall be ground over an area larger than that covered by the positioning device and reference base plate.

9.1.2 Place the positioning device on the surface of the concrete at the location to be tested. Mount a probe in the driver unit, position the driver in the positioning device, and fire the probe into the concrete. Follow the safety directions supplied with the apparatus.

9.1.3 Remove the positioning device and tap the probe on the exposed end with a small hammer to ensure that it has not rebounded and to confirm that it is firmly embedded. Reject loose probes.

9.1.4 Place the reference base plate over the probe and position it so that it bears firmly on the surface of the concrete without rocking or other movement. If the surface of the concrete has been raised around the base of the probe, remove the crushed concrete to allow the reference base plate to lie flat. If necessary, install plate retainers and probe-measuring caps. Measure the distance from the reference base plate to the end of the probe, or to the upper surface of the measuring cap, to the nearest 0.5 mm [0.025 in.]. Verify that requirements of 8.1.2 are met. If a probe is more than 10 degrees from perpendicular with respect to the surface of the concrete, discard that probe and embed another. Determine the average exposed probe length.

NOTE 14—Mechanical and electronic devices are available to facilitate determining the average exposed length of the probes.

9.1.5 When tests are to be made on concrete having a density of approximately 2000 kg/m^3 [125 lb/ft^3] or less, and on all concrete with strengths less than 17 MPa [2500 psi], decrease the amount of energy delivered to the probe by the driver or use a larger-diameter probe, or both. Decrease the

TABLE 1 Precision[A] for Resistance Testing with Probes

Maximum Size of Aggregate	(1s) Limit[B], mm [in.]	Maximum Range of Three Individual[C] Measurements, mm [in.]	(d2s) Limit[D] Maximum Difference Between Two Tests (Each test calculated as the average of three measurements), mm [in.]
No. 4 (Mortar)	2.0 [0.08]	6.6 [0.26]	3.3 [0.13]
25 mm [1-in.]	2.5 [0.10]	8.4 [0.33]	4.1 [0.16]
50 mm [2 in.]	3.6 [0.14]	11.7 [0.46]	5.6 [0.22]

[A] These values represent indexes of precision as described in Practice C 670.
[B] These values are the single-operator standard deviations for tests made on concrete with the maximum size aggregate shown in Column 1.
[C] These values are the maximum allowable ranges for groups of three individual measurements made close together, either as individual measurements or by using the triangular positioning device.
[D] A difference larger than the values given indicates a high probability that there is a statistically significant difference in the concrete in the two areas represented by the two groups of three measurements each.

TABLE 2 Precision[A] for Resistance Testing with Pins

Material	(1s) Limit[B], mm [in.]	Maximum Range of Six Individual[C] Measurements, mm [in.]	(d2s) Limit[D] Maximum Difference Between Two Tests (Each test calculated as the average of six measurements), mm [in.]
Concrete 3–28 MPa [450–4000 psi]	0.4 [0.016]	1.6 [0.064]	0.5 [0.018]

[A] These values represent indexes of precision as described in Practice C 670.
[B] These values are the single-operator standard deviations for tests on concrete shown in Column 1.
[C] This value is the maximum allowable range for groups of six individual measurements made in a 300 mm [12 in.] diameter region.
[D] A difference larger than the values given indicates a high probability that there is a statistically significant difference in the concrete in the two areas represented by the two groups of six measurements each.

www.technobetar.ir

delivered energy by positioning the probe further down the barrel of the driver unit, as recommended by the manufacturer. Do not use the low-power setting if the probes are not firmly embedded in the concrete. Separate strength relationships must be developed for different probe sizes and power level settings.

NOTE 15—Probes of 79.4-mm [3.125-in.] overall length and 7.9-mm [0.312-in.] diameter, with the penetrating end diameter reduced to 6.4 mm [0.250 in.] for approximately 14.3 mm [0.562 in.] in length, have been found satisfactory for testing concrete having a density of 2000 kg/m^3 [125 lb/ft ^{3}] or greater. A7.9-mm [0.312-in.] diameter and 79.4-mm [3.125-in.] length probe should be used with concrete having a density of less than 2000 kg/m^3 [125 lb/ft^3]. A change in section or shoulder has been found to be helpful in preventing rebound after setting.

9.2 *Resistance Testing with Pins*:

9.2.1 Concrete surfaces to be tested which are heavily textured, soft, or consist of loose mortar shall be ground flat with an abrasive stone consisting of medium grain texture silicon carbide or equivalent material. The area to be ground for each pin penetration measurement shall be at least as large as the bearing area of the driver. The area shall be sufficiently flat if there is no visible gap between the surface and a pin laid sideways on the surface.

9.2.2 Insert a new pin into the spring-actuated driver unit.

9.2.3 Load the spring-actuated driver unit by compressing the spring until the trigger mechanism engages.

9.2.4 Place the driver unit firmly against the perpendicular to the surface of the concrete to be tested. Pull the trigger to release the spring and drive the pin into the concrete surface. Remove the unit including the pin.

9.2.5 Clean the pin hole using the air blower device.

9.2.6 Insert the depth gage into the pin hole and measure the depth of penetration to the nearest 0.02 mm [0.001 in.].

10. Report

10.1 For probe or pin tests, report the following information:

10.1.1 Identification of the location tested in the concrete construction and the type of concrete member tested,

10.1.2 Description of concrete mixture including type of coarse aggregate,

10.1.3 Description of surface finish and, if required, the surface preparation used prior to testing.

10.1.4 Approximate locations of test areas, and

10.1.5 Date and time of testing.

10.2 For probe tests, report the following information:

10.2.1 Driver unit identification number and energy level used in testing,

10.2.2 Dimensions of probes,

10.2.3 Approximate thickness of member tested,

10.2.4 The exposed lengths of the probes and the average exposed length in each test area, and

10.2.5 Description of unusual conditions, including tests rejected for data analysis.

10.3 For pin tests, report the following information:

10.3.1 Driver unit identification number,

10.3.2 Approximate thickness of member tested,

10.3.3 The penetration depths of the pins and the average penetration depth in each test area, and

10.3.4 Description of unusual conditions, including tests rejected for data analysis.

11. Precision and Bias

11.1 *Precision*—The data used to develop the precision statements were obtained using apparatus and measurements in inch-pound units. The precision indexes given in Table 1 and Table 2 are conversions of the inch-pound values given in parentheses.

11.2 *Resistance Testing With Probes*:

11.2.1 The indexes of precision given in Table 1 apply to measurements obtained by a single operator using the same instrument on the same concrete, that is, concrete made with the same materials, procedures, equipment, and curing conditions.

11.3 *Resistance Testing with Pins*:

11.3.1 The single-specimen, single-operator, driver, day precision is 0.4 mm [0.016 in.] (1s) as defined in Practice C 670.

11.3.2 The indexes of precision given in Table 2 apply to measurements obtained by a single operator using the same instrument on the same concrete, that is, concrete made with the same materials, procedures, equipment, and curing conditions.

11.4 *Bias*—This test method has no bias because penetration resistance is defined in terms of this test method.

12. Keywords

12.1 concrete strength; concrete uniformity; in-place strength; in-place test; penetration resistance

C 803/C 803M – 03

SUMMARY OF CHANGES

Committee C09 has identified that the following changes to this test method have been incorporated since the last issue (C 803/C 803M-97$^{\epsilon 1}$):

(1) Nonmandatory language in various sections has been replaced with mandatory language.
(2) A Terminology section has been added.
(3) The procedure in 9.1.4 has been clarified and a new requirement was added to deal with probes that are not driven perpendicular to the concrete surface.
(4) In 9.2.1, the area to be ground is revised to accommodate different bearing areas of the driver.
(5) Various editorial improvements.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 805/C 805M – 08

Standard Test Method for Rebound Number of Hardened Concrete[1]

This standard is issued under the fixed designation C 805/C 805M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope*

1.1 This test method covers the determination of a rebound number of hardened concrete using a spring-driven steel hammer.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

E 18 Test Methods for Rockwell Hardness of Metallic Materials

3. Terminology

3.1 *Definitions:*

3.1.1 For definitions of terms used in this test method, refer to Terminology C 125.

4. Summary of Test Method

4.1 A steel hammer impacts, with a predetermined amount of energy, a steel plunger in contact with a surface of concrete, and the distance that the hammer rebounds is measured.

5. Significance and Use

5.1 This test method is applicable to assess the in-place uniformity of concrete, to delineate regions in a structure of poorer quality or deteriorated concrete, and to estimate in-place strength.

5.2 Relationships between rebound number and concrete strength that are provided by instrument manufacturers shall be used only to provide indications of relative concrete strength at different locations in a structure. To use this test method to estimate strength, it is necessary to establish a relationship between strength and rebound number for a given concrete mixture and given apparatus. Establish the relationship by correlating rebound numbers measured on the structure with the strengths of cores taken from corresponding locations. At least two replicate cores shall be taken from at least six locations with different rebound numbers. Select test locations so that a wide range of rebound numbers in the structure is obtained. Obtain, moisture condition, and test cores in accordance with Test Method C 42/C 42M.

NOTE 1—See ACI 228.1R[3] for additional information on developing the relationship and on using the relationship to estimate in-place strength.

5.3 For a given concrete mixture, the rebound number is affected by factors such as moisture content of the test surface, the method used to obtain the test surface (type of form material or type of finishing), vertical distance from the bottom of a concrete placement, and the depth of carbonation. These factors need to be considered in interpreting rebound numbers.

5.4 Different hammers of the same nominal design may give rebound numbers differing from 1 to 3 units. Therefore, tests should be made with the same hammer in order to compare results. If more than one hammer is to be used, perform tests on

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.64 on Nondestructive and In-Place Testing.

Current edition approved Aug. 1, 2008. Published September 2008. Originally approved in 1975. Last previous edition approved in 2002 as C 805 – 02.

www.technobetar.ir

a range of typical concrete surfaces so as to determine the magnitude of the differences to be expected.

5.5 This test method is not suitable as the basis for acceptance or rejection of concrete.

6. Apparatus

6.1 *Rebound Hammer*, consisting of a spring-loaded steel hammer that when released strikes a steel plunger in contact with the concrete surface. The spring-loaded hammer must travel with a consistent and reproducible velocity. The rebound distance of the steel hammer from the steel plunger is measured on a linear scale attached to the frame of the instrument.

NOTE 2—Several types and sizes of rebound hammers are commercially available to accommodate testing of various sizes and types of concrete construction.

6.2 *Abrasive Stone*, consisting of medium-grain texture silicon carbide or equivalent material.

6.3 *Test Anvil*, approximately 150-mm [6-in.] diameter by 150-mm [6-in.] high cylinder made of tool steel with an impact area hardened to 66 ± 2 HRC as measured by Test Methods E 18. An instrument guide is provided to center the rebound hammer over the impact area and keep the instrument perpendicular to the surface.

6.4 *Verification*—Rebound hammers shall be serviced and verified annually and whenever there is reason to question their proper operation. Verify the functional operation of a rebound hammer using the test anvil described in 6.3. During verification, support the test anvil on a bare concrete floor or slab. The manufacturer shall report the rebound number to be obtained by a properly operating instrument when tested on an anvil of specified hardness.

NOTE 3—Typically, a rebound hammer will result in a rebound number of 80 ± 2 when tested on the anvil described in 6.3. The test anvil needs to be supported on a rigid base to obtain reliable rebound numbers. Verification on the test anvil does not guarantee that the hammer will yield repeatable data at other points on the scale. The hammer can be verified at lower rebound numbers by using blocks of polished stone having uniform hardness. Some users compare several hammers on concrete or stone surfaces encompassing the usual range of rebound numbers encountered in the field.

7. Test Area and Interferences

7.1 *Selection of Test Surface*—Concrete members to be tested shall be at least 100 mm [4 in.] thick and fixed within a structure. Smaller specimens must be rigidly supported. Avoid areas exhibiting honeycombing, scaling, or high porosity. Do not compare test results if the form material against which the concrete was placed is not similar (see Note 4). Troweled surfaces generally exhibit higher rebound numbers than screeded or formed finishes. If possible, test structural slabs from the underside to avoid finished surfaces.

7.2 *Preparation of Test Surface*—A test area shall be at least 150 mm [6 in.] in diameter. Heavily textured, soft, or surfaces with loose mortar shall be ground flat with the abrasive stone described in 6.2. Smooth-formed or troweled surfaces do not have to be ground prior to testing (see Note 4). Do not compare results from ground and unground surfaces. Remove free surface water, if present, before testing.

NOTE 4—Where formed surfaces were ground, increases in rebound number of 2.1 for plywood formed surfaces and 0.4 for high-density plywood formed surfaces have been noted.[4] Dry concrete surfaces give higher rebound numbers than wet surfaces. The presence of surface carbonation can also result in higher rebound numbers.[5] In cases of a thick layer of carbonated concrete, it may be necessary to remove the carbonated layer in the test area, using a power grinder, to obtain rebound numbers that are representative of the interior concrete. Data are not available on the relationship between rebound number and thickness of carbonated concrete. The user should exercise professional judgment when testing carbonated concrete.

7.3 Do not test frozen concrete.

NOTE 5—Moist concrete at 0 °C [32 °F] or less may exhibit high rebound values. Concrete should be tested only after it has thawed. The temperatures of the rebound hammer itself may affect the rebound number. Rebound hammers at -18 °C [0 °F] may exhibit rebound numbers reduced by as much as 2 or 3 units[6].

7.4 For readings to be compared, the direction of impact, horizontal, downward, upward, or at another angle, must be the same or established correction factors shall be applied to the readings.

7.5 Do not conduct tests directly over reinforcing bars with cover less than 20 mm [0.75 in.].

NOTE 6—The location of reinforcement may be established using reinforcement locators or metal detectors. Follow the manufacturer's instructions for proper operation of such devices.

8. Procedure

8.1 Hold the instrument firmly so that the plunger is perpendicular to the test surface. Gradually push the instrument toward the test surface until the hammer impacts. After impact, maintain pressure on the instrument and, if necessary, depress the button on the side of the instrument to lock the plunger in its retracted position. Read the rebound number on the scale to the nearest whole number and record the rebound number. Take ten readings from each test area. No two impact tests shall be closer together than 25 mm [1 in.]. Examine the impression made on the surface after impact, and if the impact crushes or breaks through a near-surface air void disregard the reading and take another reading.

9. Calculation

9.1 Discard readings differing from the average of 10 readings by more than 6 units and determine the average of the remaining readings. If more than 2 readings differ from the average by 6 units, discard the entire set of readings and determine rebound numbers at 10 new locations within the test area.

10. Report

10.1 Report the following information, if known, for each test area.

10.1.1 General information:

10.1.1.1 Date of testing,

[4] Gaynor, R. D., "In-Place Strength of Concrete—A Comparison of Two Test Systems," and "Appendix to Series 193," National Ready Mixed Concrete Assn., TIL No. 272, November 1969.

[5] Zoldners, N. G., "Calibration and Use of Impact Test Hammer," *Proceedings* , American Concrete Institute, Vol 54, August 1957, pp. 161–165.

[6] National Ready Mixed Concrete Assn., TIL No. 260, April 1968.

www.technobetar.ir

10.1.1.2 Air temperature and time of testing,
10.1.1.3 Age of concrete, and
10.1.1.4 Identification of test location in the concrete construction and the size of member tested.
10.1.2 Information about the concrete:
10.1.2.1 Mixture identification and type of coarse aggregate, and
10.1.2.2 Specified strength of concrete.
10.1.3 Description of test area:
10.1.3.1 Surface characteristics (trowelled, screeded. formed),
10.1.3.2 If applicable, type of form material used for test area,
10.1.3.3 If surface was ground and depth of grinding,
10.1.3.4 If applicable, curing conditions, and
10.1.3.5 Surface moisture condition (wet or dry).
10.1.4 Hammer information:
10.1.4.1 Hammer identification or serial number, and
10.1.4.2 Date of hammer verification.
10.1.5 Rebound number data:
10.1.5.1 Orientation of hammer during test,
10.1.5.2 On vertical surfaces (walls, columns, deep beams), relative elevation of test region,
10.1.5.3 Individual rebound numbers,
10.1.5.4 Remarks regarding discarded readings,
10.1.5.5 Average rebound number, and
10.1.5.6 If applicable, description of unusual conditions that may affect test readings.

11. Precision and Bias

11.1 *Precision*—The single-specimen, single-operator, machine, day standard deviation is 2.5 units (1s) as defined in Practice C 670. Therefore, the range of ten readings should not exceed 12.

11.2 *Bias*—The bias of this test method cannot be evaluated since the rebound number can only be determined in terms of this test method.

12. Keywords

12.1 concrete; in-place strength; nondestructive testing; rebound hammer; rebound number

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 805 – 02, that may impact the use of this test method. (Approved August 1, 2008)

(*1*) The standard was revised as a combined units designation.
(*2*) Revised 5.2 by requiring a correlation to be developed only by using cores.
(*3*) Revised 5.3 by adding information on the effect of elevation in a concrete placement.
(*4*) Revised 5.5 to clarify that the method is not suitable to accept or reject concrete.
(*5*) Revised 7.2 by adding a provision to remove free water before testing. Revised Note 4 by deleting the sentence referring to wetting of the surface.
(*6*) Revised Section 10 Report to provide more logical groupings of the information to be reported and to acknowledge that all the information may not be known.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 806 – 04

Standard Test Method for Restrained Expansion of Expansive Cement Mortar[1]

This standard is issued under the fixed designation C 806; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of length changes of expansive cement mortar, while under restraint, due to the development of internal forces resulting from hydration of the cement.

1.2 The values stated in non-SI units are to be regarded as the standard. When both the inch-pound units and the SI units are present, the non-SI units are to be regarded as the standard. The values in SI units are approximate, are listed for information only, and will likely provide different values than the inch-pound units.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cement mixtures are caustic and may cause burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:* [3]

3. Terminology

3.1 Definitions of terms used in this test method are given in Terminology C 219.

4. Apparatus

4.1 *Molds*—The molds for casting test specimens, when used in conjunction with the restraining cage described in 4.2, shall provide for forming either 2 by 2 by 10-in. prisms having a 10-in. gage length, or 50 by 50 by 250-mm prisms having a 250-mm gage length. The molds shall otherwise conform to the requirements of Practice C 490, except that the gage stud holder, gage studs, and spacer screws described in that specification will not be used.

4.2 *Restraining Cage*, consisting of a threaded steel rod with steel end plates held in place by nuts as shown in Fig. 1. The rod shall be provided with cap nuts for prevention of corrosion. The rod shall conform to Specification A 307 Grade A except, it shall support 1180-lbf (5249 N) proof load when tested in accordance with Method 1 of Test Methods F 606.

4.3 *Length Comparator*—The length comparator for measuring length shall conform to and be used in accordance with the requirements of Practice C 490. If the terminals of the comparator are fitted with collars, they shall be such that the cap nuts on the ends of the threaded rod of the specimen do not rest on the collar during measuring.

4.4 *Tamper*—The tamper shall be made of nonabsorptive, nonabrasive material such as medium-hard rubber or seasoned oak wood, rendered nonabsorptive by immersion for 15 min in paraffin at approximately 392 °F (200 °C), and shall have a cross section of about ½ by 1 in. (13 by 25 mm) and convenient length of about 6 in. (150 mm). The tamping face of the tamper shall be flat and at right angles to the length of the tamper.

4.5 *Apparatus for Demolding Specimens*—Apparatus similar to that described in the Apparatus section of Test Method C 157, may be found useful for demolding specimens.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.13 on Special Cements.

FIG. 1 Restraining Cage

4.6 *Weights and Weighing Devices*—Scales used shall comply with Specification C 1005.

NOTE 1—Generally defined, the sensibility reciprocal is the change in load required to change the position of rest of the indicating element or elements of a nonautomatic-indicating scale a definite amount at any load.

4.7 *Glass Graduates*, of suitable capacities (preferably large enough to measure the mixing water in a single operation) shall be made to deliver the indicated volume at 68 °F (20 °C). The permissible variation shall be ±2 mL. These graduates shall be subdivided to at least 5 mL, except that the graduation lines may be omitted for the lowest 10 mL for a 250-mL graduate and the lowest 25 mL for a 500-mL graduate. The main graduation lines shall be circles and shall be numbered. The least graduations shall extend at least one seventh of the way around, and intermediate graduations shall extend at least one fifth of the way around.

4.8 *Mixer, Bowl, and Paddle*—The mixer shall be an electrically driven mechanical mixer of the type equipped with paddle and mixing bowl, as specified in the Apparatus section of Practice C 305.

4.9 *Trowel*—The trowel shall have a steel blade 4 to 6 in. (102 to 152 mm) in length, with straight edges.

5. Temperature and Humidity

5.1 The temperature of the air in the vicinity of the mixing operation, the dry materials, mixing water, molds, base plates, mixing bowl, moist closet or moist room, and storage water shall not vary from 73.4 °F (23 °C) by more than ±3 °F (±1.7 °C).

5.2 The relative humidity of the laboratory shall be not less than 50 %. The moist closet or moist room shall provide a relative humidity of not less that 95 %.

6. Graded Standard Sand

6.1 Sand used shall comply with the graded sand requirement of Specification C 778.

Passing Sieve	Percentage Retained
No. 100 (150-µm)	98 ± 2
No. 50 (300-µm)	72 ± 5
No. 30 (600-µm)	2 ± 2
No. 16 (1.18-mm)	none

NOTE 2—*Segregation of Graded Sand*—The graded standard sand should be handled in such a manner as to prevent segregation, since variations in the grading of the sand cause variations in the consistency of the mortar. In emptying sacks of sand into bins or in scooping sand out of bins or sacks, care should be exercised to prevent the formation of mounds of sand or craters in the sand, down the slopes of which the coarser particles will roll. Bins should be of sufficient size to permit these precautions. Devices for drawing the sand from bins by gravity should not be used.

7. Test Specimen

7.1 The test specimen shall be a 2 by 2 by 10-in. prism having a 10-in. gage length, or a 50 by 50 by 250-mm prism

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:20:41 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

having a 250-mm gage length. At least two specimens shall be prepared for each test.

8. Preparation and Assembly of Specimen Molds and Restraining Cage

8.1 Install the cap nuts firmly in place on the ends of the restraining rods and measure the restraining rods for length while they are at a temperature of 73.4 ± 1 °F (23.0 ± 0.5 °C).

8.2 The edges of the end plates of the restraining cage that contact the sides and bottom of the mold shall be thinly covered with a heavy mineral oil or light cup grease such as petrolatum. After assembly of the molds, place a restraining cage in each compartment. Seal the contact lines between the outer sides and base plate of the molds with paraffin or micro-crystalline wax. Thinly cover the interior faces of the molds with mineral oil and remove any oil or grease from the restraining cage rod and end plates.

9. Proportioning and Mixing of Mortars

9.1 Proportion the standard mortar by using one part of cement to 2.75 parts of graded standard sand by mass. Mix 800 g of cement, 2200 g of graded standard sand, and 400 mL of water to produce a batch sufficient for two test specimens.

9.2 Mix in accordance with the procedure for mixing mortars given in Practice C 305. Upon completion of mixing, shake the mixing paddle into the mixing bowl to remove excess mortar.

10. Molding Specimens

10.1 Start molding specimens immediately after completion of mixing. Place the mortar in the mold in two layers with the first layer just covering the restraining rod and the second layer slightly overfilling the mold. Compact each layer by tamping. Work the mortar into the corners, around the restraining rod, without striking the rod, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, strike-off the mortar flush with the top of the mold, and smooth the surface with a few strokes of the trowel.

11. Curing of Specimens

11.1 Immediately after completion of molding, cover the specimens with a polyethylene sheet, or other suitable material for preventing loss or gain of moisture, at the surface of the specimens. The cover should make contact with the surface of the mortar. Place the specimens in the moist room or moist cabinet.

11.2 Remove the specimens from the molds at an age of 6 ± ¼ h after the addition of water to the cement during the mixing operation (Note 3). Particular care must be exercised in this operation in order not to damage the specimens because of their low strength at this age. It is preferable to use the demolding devices referred to in 4.5 for freeing specimens from the base and side plates.

NOTE 3—At this time comparator readings may be made. Although these readings may differ slightly from the initial reading made on the restraining rod prior to molding the specimen, it can serve as a check on the initial reading which should be used as the basis for calculating the length change.

11.3 Cure the specimens in lime-saturated water at 73.4± 3.0 °F (23.0 ± 1.7 °C) until they have reached an age of 7 days ± 1 h, including the period in the molds, except that the temperature of the curing water shall be 73.4 ± 1 °F (23.0 ± 0.5 °C) for at least the last 15 min. At the end of this period, remove the specimens from the water one at a time, wipe with a damp cloth, and immediately make comparator readings with the cap nuts in place.

11.4 Return the specimens to curing in lime-saturated water at 73.4 ± 3.0 °F (23.0 ± 1.7 °C) until they have reached an age of 28 days including the period in the molds. At the end of the curing period, make comparator readings immediately after the specimens have been subjected to about 15 min of storage in water at 73.4 ± 1.0 °F (23.0± 0.5 °C) and in the same manner as described in 11.3.

12. Calculation

12.1 Calculate the expansion or shrinkage at any age as follows:

$$E_x = \frac{L_x - L_i}{10\,(250)} \times 100 \qquad (1)$$

where:

E_x = expansion at x age, %,
L_x = comparator reading of specimen at x age – reference bar comparator reading, in. (mm), and
L_i = initial comparator reading of restraining rod – reference bar comparator reading, in. (mm).

13. Report

13.1 Report the following information:

13.1.1 Number of specimens for each condition and date molded,

13.1.2 Source and identification of cement.

13.1.3 Age of specimen for each observation for length change,

13.1.4 Length-change data, expressed as linear expansion or contraction based on the length of the specimen at time of molding shall be reported as percent change dimension to the nearest 0.001 %, and

13.1.5 Any other pertinent information.

14. Precision and Bias [4]

14.1 *Precision*:

14.1.1 *Within Batch Precision*—The standard deviation of two bars made from the same batch and tested together was found to be 0.00276 %. Therefore two bars made from the same batch should not differ from each other by more than 0.008 % length change.[5]

14.1.2 *Single Operator Precision*—The single operator standard deviation has been found to be 0.0038 at seven and twenty eight days age, based on the average of two bars. Therefore the results of two properly conducted tests by the

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C01-1001.

[5] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

www.technobetar.ir

same operator on the same material should not differ by more than 0.011 % length change.[5]

14.1.3 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 0.0093 at seven and twenty eight days age, based on the average of two bars. Therefore the results of two properly conducted tests on the same material in two different laboratories should not differ by more than 0.026 % length change.[5]

14.2 *Bias*—A bias statement cannot be prepared due to the fact that absolute standards are not available.

15. Keywords

15.1 cement mortar; expansive cement; restrained expansion

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 806 – 04

Standard Test Method for Restrained Expansion of Expansive Cement Mortar[1]

This standard is issued under the fixed designation C 806; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of length changes of expansive cement mortar, while under restraint, due to the development of internal forces resulting from hydration of the cement.

1.2 The values stated in non-SI units are to be regarded as the standard. When both the inch-pound units and the SI units are present, the non-SI units are to be regarded as the standard. The values in SI units are approximate, are listed for information only, and will likely provide different values than the inch-pound units.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cement mixtures are caustic and may cause burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:* [3]

A 307 Specification for Carbon Steel Bolts and Studs, 60 000 PSI Tensile Strength

C 157 Test Method for Length Change of Hardened-Hydraulic-Cement, Mortar, and Concrete

C 219 Terminology Relating to Hydraulic Cement

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 778 Specification for Standard Sand

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

F 606 Test Methods for Determining the Mechanical Properties of Externally and Internally Threaded Fasteners, Washers, and Rivets

3. Terminology

3.1 Definitions of terms used in this test method are given in Terminology C 219.

4. Apparatus

4.1 *Molds*—The molds for casting test specimens, when used in conjunction with the restraining cage described in 4.2, shall provide for forming either 2 by 2 by 10-in. prisms having a 10-in. gage length, or 50 by 50 by 250-mm prisms having a 250-mm gage length. The molds shall otherwise conform to the requirements of Practice C 490, except that the gage stud holder, gage studs, and spacer screws described in that specification will not be used.

4.2 *Restraining Cage*, consisting of a threaded steel rod with steel end plates held in place by nuts as shown in Fig. 1. The rod shall be provided with cap nuts for prevention of corrosion. The rod shall conform to Specification A 307 Grade A except, it shall support 1180-lbf (5249 N) proof load when tested in accordance with Method 1 of Test Methods F 606.

4.3 *Length Comparator*—The length comparator for measuring length shall conform to and be used in accordance with the requirements of Practice C 490. If the terminals of the comparator are fitted with collars, they shall be such that the cap nuts on the ends of the threaded rod of the specimen do not rest on the collar during measuring.

4.4 *Tamper*—The tamper shall be made of nonabsorptive, nonabrasive material such as medium-hard rubber or seasoned oak wood, rendered nonabsorptive by immersion for 15 min in paraffin at approximately 392 °F (200 °C), and shall have a cross section of about ½ by 1 in. (13 by 25 mm) and convenient length of about 6 in. (150 mm). The tamping face of the tamper shall be flat and at right angles to the length of the tamper.

4.5 *Apparatus for Demolding Specimens*—Apparatus similar to that described in the Apparatus section of Test Method C 157, may be found useful for demolding specimens.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.13 on Special Cements.

Current edition approved July 1, 2004. Published July 2004. Originally approved in 1975. Last previous edition approved in 1995 as C 806 – 95.
