D 1037 Test Methods for Evaluating Properties of Wood-Base Fiber and Particle Panel Materials

E 84 Test Method for Surface Burning Characteristics of Building Materials

E 96/E 96M Test Methods for Water Vapor Transmission of Materials

E 119 Test Methods for Fire Tests of Building Construction and Materials

3. Terminology

3.1 *Definitions*—Definitions of terms shall be in accordance with Terminology C 11.

3.1.1 *nominal thickness*, *n*—the manufacturer-stated fractional value of thickness of the gypsum panel product expressed in decimal value to the nearest one-thousandth (0.001) of an inch.

4. Materials and Manufacture

4.1 Fiber-reinforced gypsum panels shall consist essentially of gypsum with fibers dispersed throughout.

4.1.1 *Gypsum*—Specification C 22/C 22M.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Sept. 15, 2007. Published October 2007. Originally approved in 1994. Last previous edition approved in 2007 as C 1278/C 1278M – 07.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

4.1.2 *Fibers*—Cellulose, derived from paper, paperboard stock, wood, or other organic material.

4.2 The back surface of foil-backed fiber-reinforced gypsum panels shall in addition be covered with aluminum foil.

4.3 Water-resistant fiber-reinforced gypsum panels shall be treated with a material that imparts water resistance throughout.

4.4 Fiber-reinforced gypsum panels, type X (special fire-resistant) designates fiber-reinforced gypsum panels complying with this specification that provide not less than 1-h fire resistance rating for panels ⅝-in. [15.9-mm] thick or ¾-h fire resistance rating for panels ½-in. [12.7-mm] thick, applied parallel with and on each side of load bearing 2 by 4 wood studs spaced 16 in. [406 mm] on center with 6d coated nails, 1⅞-in. [48-mm] long, 0.0915-in. [2.3-mm] diameter shank, ¼-in. [6.4-mm] diameter heads, spaced 7 in. [178 mm] on center with fiber-reinforced gypsum panel joints staggered 16 in. [406 mm] on each side of the partition and tested in accordance with Test Methods E 119.

NOTE 1—Consult producers for independent test data on assembly details and fire resistance ratings for other types of construction. See fire test reports or listings from recognized fire testing laboratories for assembly particulars, materials, and ratings.

4.5 Fiber-reinforced gypsum panels shall have a flame spread index of not more than 25 when tested in accordance with Test Method E 84.

4.6 *Physical Properties, Dimensions, and Tolerances of Gypsum Panel*:

4.6.1 Specimens shall be taken from samples obtained in accordance with Specification C 1264.

4.6.1.1 Specimens shall be tested in accordance with Test Methods C 473.

4.6.2 *Core, End, and Edge Hardness*—The specimens shall have an average hardness of not less than 20 lbf [90 N] when tested in accordance with Method B.

4.6.3 *Edges and Ends*—The edges and ends shall be straight.

4.6.4 *Length*—The nominal length shall be from 6 to 24 ft [1830 to 7320 mm], with a tolerance of ± ¼ in. [6 mm] from the specified length.

4.6.5 *Tapered Edge Depth*—The average thickness of the edge of recessed or tapered edge shall be not less than 0.020 in. [0.51 mm] but not more than 0.090 in. [2.29 mm] less than the average thickness of the fiber-reinforced gypsum panel.

5. Interior Fiber-Reinforced Gypsum Panels

5.1 *Physical Properties of Interior Fiber-Reinforced Gypsum Panels*:

5.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
½ [12.7]	110 [490]
⅝ [15.9]	155 [690]

5.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch, [mm]
½ [12.7]	3 [10]
⅝ [15.9]	2 [6]

5.1.3 *Nail Pull Resistance*—The specimens shall have an average nail pull resistance of not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
½ [12.7]	120 [535]
⅝ [15.9]	145 [645]

5.2 *Dimensions and Tolerances of Interior Fiber-Reinforced Gypsum Panel*:

5.2.1 Specimens shall be taken from samples in accordance with Specification C 1264.

5.2.1.1 Specimens shall be tested in accordance with Test Methods C 473.

5.2.2 *Thickness*—The thickness shall be ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances of ± 0.015 in. [± 0.40 mm], and with a local tolerance of ± 0.030 in. [± 0.80 mm].

5.2.3 *Width*—The width shall be up to 54 in. [1370 mm], with a tolerance of 3⁄32 in. [3 mm] under the specified width.

5.2.4 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the panel.

5.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

5.4 *Foil-Backed Fiber-Reinforced Gypsum Panels*:

5.4.1 Foil-backed fiber-reinforced gypsum panels shall meet all of the requirements for fiber-reinforced gypsum panels. In addition, aluminum foil shall be bonded to the back surface.

5.4.2 When tested in accordance with Test Methods E 96/E 96M, the permeance of foil-backed fiber-reinforced gypsum panels shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the panel and 0 % relative humidity on the foil-covered back side of the panel.

6. Water-Resistant Fiber-Reinforced Gypsum Backing Panels

6.1 *Physical Properties of Water-Resistant Fiber-Reinforced Gypsum Backing Panels*:

6.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
½ [12.7]	110 [490]
⅝ [15.9]	155 [690]

6.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch, [mm]
½ [12.7]	3 [10]
⅝ [15.9]	2 [6]

6.1.3 *Nail Pull Resistance*—The specimens shall have an average nail pull resistance of not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
½ [12.7]	120 [535]
⅝ [15.9]	145 [645]

6.1.4 *Water Resistance*—The specimens shall have an average water absorption of not more than 5 weight percentage after 2-h immersion.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:48:51 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.1.5 *Surface Water Absorption*—The specimens shall have an average face surface water absorption of not more than 1.6 g after two hours of elapsed time.

6.2 *Dimensions and Tolerances of Water-Resistant Fiber-Reinforced Gypsum Backing Panel*:

6.2.1 Specimens shall be taken from samples obtained in accordance with Specification C 1264.

6.2.1.1 Specimens shall be tested in accordance with Test Methods C 473.

6.2.2 *Thickness*—The nominal thickness shall be ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances of ± 1/64 in. [± 0.4 mm], and with a local tolerance of ± 1/32 in. [± 0.8 mm].

6.2.3 *Width*—The width shall be up to 54 in. [1370 mm], with a tolerance of 3/32 in. [3 mm] under the specified width.

6.2.4 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the panel.

6.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

7. Exterior Fiber-Reinforced Gypsum Soffit Panels

7.1 *Physical Properties of Exterior Fiber-Reinforced Gypsum Soffit Panels*:

7.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
½ [12.7]	110 [490]
⅝ [15.9]	155 [690]

7.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch, [mm]
½ [12.7]	3 [10]
⅝ [15.9]	2 [6]

7.1.3 *Nail Pull Resistance*—The specimens shall have an average nail pull resistance of not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
½ [12.7]	120 [535]
⅝ [15.9]	145 [645]

7.2 *Dimensions and Tolerances of Exterior Fiber-Reinforced Gypsum Soffit Panel*:

7.2.1 Specimens shall be taken from samples obtained in accordance with Specification C 1264.

7.2.1.1 Specimens shall be tested in accordance with Test Methods C 473.

7.2.2 *Thickness*—The nominal thickness shall be ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances in the thickness of ± 1/64 in. [± 0.4 mm], and with a local tolerance of ± 1/32 in. [± 0.8 mm].

7.2.3 *Width*—The width shall be up to 54 in. [1370 mm], with a tolerance of 3/32 in. [3 mm] under the specified width.

7.2.4 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the panel.

7.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

8. Water-Resistant Exterior Fiber-Reinforced Gypsum Sheathing Panels

8.1 *Physical Properties of Water-Resistant Exterior Fiber-Reinforced Gypsum Sheathing Panels*:

8.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
½ [12.7]	110 [490]
⅝ [15.9]	155 [690]

8.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch, [mm]
½ [12.7]	3 [10]
⅝ [15.9]	2 [6]

8.1.3 *Nail Pull Resistance*—The specimens shall have an average nail pull resistance of not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
½ [12.7]	120 [535]
⅝ [15.9]	145 [645]

8.1.4 *Water Resistance of Water-Resistant Exterior Fiber-Reinforced Gypsum Sheathing Panel*—The specimens shall have an average water absorption of not more than 10 weight percentage after 2-h immersion.

8.2 *Dimensions and Tolerances of Water-Resistant Exterior Fiber-Reinforced Gypsum Sheathing Panels*:

8.2.1 Specimens shall be taken from samples obtained in accordance with Specification C 1264.

8.2.1.1 Specimens shall be tested in accordance with Test Methods C 473.

8.2.2 *Thickness*—The nominal thickness shall be from ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances of ± 1/32 in. [± 0.8 mm], and with a local tolerance of ± 1/16 in. [± 1.6 mm].

8.2.3 *Width*—The nominal width shall be 24 or 48 in. [610 or 1220 mm], with a tolerance of ⅛ in. [3.2 mm] under the specified width.

8.2.4 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the panel.

8.3 *Edges*—The edges shall be either square or V-tongue and groove.

9. Interior Fiber-Reinforced Gypsum Underlayment Panels

9.1 *Physical Properties of Interior Fiber-Reinforced Gypsum Underlayment Panels*:

9.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
¼ [6.4]	40 [175]
⅜ [9.5]	70 [310]
½ [12.7]	110 [490]

9.1.2 *Nail Pull resistance*—The specimens shall have an average nail pull resistance of not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
¼ [6.4]	70 [310]
⅜ [9.5]	90 [400]
½ [12.7]	120 [535]

9.2 *Dimensions and Tolerances of Interior Fiber-Reinforced Gypsum Underlayment Panels*:

9.2.1 Specifications shall be taken from samples in accordance with Specification C 1264.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:48:51 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.2.2 *Thickness*—The nominal thickness shall be ¼ , ⅜ , or ½ in. [6.4, 9.5, or 12.7 mm] with tolerance of ± 0.015 in. [± 0.4 mm], and with a local tolerance of ± 0.030 in. [± 0.8 mm].

9.2.3 *End Squareness* —Corners shall be square with a tolerance of ± 0.125 in. [± 3 mm] in the full width of the panel.

9.3 *Edges*—Edges shall be square.

9.4 *Water Absorption*

9.4.1 Specimens shall be tested in accordance with Test Methods C 473.

9.4.2 Water absorption shall not exceed 10 %.

9.5 *Thickness Swelling*

9.5.1 Specimens shall be tested in accordance with Thickness Swelling in Test Methods D 1037.

9.5.2 The specimens shall have an average thickness swelling of no more than the following:

Thickness, in. [mm]	Method A and B
¼ [6.4]	1 %
⅜ [9.5]	1 %
½ [12.7]	1 %

10. Fiber-Reinforced Gypsum Roof Board Panels

10.1 *Physical Properties of Fiber-Reinforced Gypsum Roof Board Panels*:

10.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
¼ [6.4]	40 [175]
⅜ [9.5]	70 [310]
½ [12.7]	110 [490]
⅝ [15.9]	155 [690]

10.1.2 *Nail Pull resistance*—The specimens shall have an average nail pull resistance of not less than the following:

Thickness, in. [mm]	Method B, lbf [N]
¼ [6.4]	70 [310]
⅜ [9.5]	90 [400]
½ [12.7]	120 [535]
⅝ [15.9]	145 [645]

10.2 *Dimensions and Tolerances of Fiber-Reinforced Gypsum Roof Deck Cover Board Panels*:

10.2.1 Specifications shall be taken from samples in accordance with Specification C 1264.

10.2.2 *Thickness*—The nominal thickness shall be ¼ , ⅜ , ½ , ⅝ in. [6.4, 9.5, 12.7, 15.9 mm] with tolerance of ± 0.030 in. [± 0.4 mm], and with a local tolerance of ± 0.015 in. [± 0.8 mm].

10.2.3 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the panel.

10.3 *Edges*—Edges shall be square.

10.4 *Water Absorption*

10.4.1 Specimens shall be tested in accordance with Test Methods C 473.

10.4.2 Water absorption shall not exceed 10 %.

11. Finish and Appearance

11.1 The surfaces of the fiber-reinforced gypsum panels shall be true and free from imperfections that would render the panels unfit for use with or without decoration.

12. Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage

12.1 Shall be in accordance with Specification C 1264.

13. Keywords

13.1 ceiling; fiber-reinforced gypsum panels; foil-backed; FRGP; gypsum; gypsum panel products; partition; sheathing; soffit; type X; wall; water-resistant

APPENDIXES

(Nonmandatory Information)

This Appendix gives general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this specification.

The definition of type X as given in 4.4 and the alternate definition given in this appendix, are intended only as a test to define the gypsum board as meeting the requirements of type X. These tests do not indicate a preferred application, nor do they limit the use of the product in other fire-rated assemblies.

All gypsum panel products for which type X is defined, except gypsum lath and gypsum shaftliner board, use the same test for type X products, therefore the type X designation indicates a consistent level of fire resistance.

X1. ALTERNATE DEFINITION FOR TYPE X

X1.1 Fiber-reinforced gypsum panels, type X (special fire-resistant) designates fiber-reinforced gypsum panels providing a greater fire resistance than regular fiber-reinforced gypsum panels of the same thickness. Type X (special fire-resistant) fiber-reinforced gypsum panels, when tested in accordance with Test Methods E 119, shall provide the following minimum fire resistance ratings for the assemblies described:

X1.1.1 One hour for a ⅝-in. [15.9-mm] thickness applied to a partition in a single layer application on each side of 3⅝-in. [92-mm] deep non-loadbearing galvanized steel studs complying with Specification C 645 spaced 24 in. [610 mm] on center. The ⅝-in. [15.9-mm] thick fiber-reinforced gypsum panels 48-in. [1220-mm] wide shall be attached using 1-in. [25-mm] long drywall screws spaced 8 in. [203 mm] on center along the edges and ends, and 12 in. [305 mm] along intermediate studs. All joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly, and

X1.1.2 Two hours for a ½-in. [12.7-mm] thickness applied to a partition in a double layer application on each side of 2½-in. [64-mm] deep non-loadbearing galvanized steel studs complying with Specification C 645 spaced 24 in. [610 mm] on center. The base layer 48-in. [1220-mm] wide shall be attached using 1-in. [25-mm] long drywall screws spaced 12 in. [305 mm] on center along panel edges, ends and along intermediate studs. Joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly. The face layer 48-in. [1220-mm] wide shall be attached using 1⅝-in. [41-mm] long drywall screws spaced 12 in. [305 mm] along panel edges, ends and along intermediate studs. Joints shall be oriented parallel to and located over studs, offset 24 in. [610 mm] from the base layer joints, and staggered on opposite sides of the assembly.

X2. INSTALLATION RECOMMENDATIONS

X2.1 Installation guidelines for Interior Fiber-Reinforced Gypsum Underlayment Panels are outlined in manufacturer literature. For more information on best installation practice contact Tile Council of North America.

X2.2 Installation guidelines for Fiber-Reinforced Gypsum Roof Board Panels may be obtained by contacting National Roofing Council of America.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1278/C 1278M – 07, that may impact the use of this specification. (Approved September 15, 2007)

(*1*) Definitions and specifications were revised or added under existing Sections 1 and 2, and new Sections 9, 10, and Appendix X2 (subsequent sections were renumbered) to add Interior Fiber-Reinforced Gypsum Underlayment Panels and Fiber-Reinforced Gypsum Roof Board Panels to this specification.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1278/C 1278M – 06, that may impact the use of this specification. (Approved August 1, 2007)

(*1*) Revised Sections 5 and 8 to remove ¼ in., 5⁄16 in., and ⅜ in. Interior Fiber-Reinforced Gypsum Panels and ⅜ in. Water-Resistant Exterior Fiber-Reinforced Gypsum Panels from this specification.

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1278/C 1278M – 03$^{\epsilon 1}$, that may impact the use of this specification. (Approved November 1, 2006)

(*1*) Added new 3.1.1.

(*2*) Revised 5.2.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1280 – 09

Standard Specification for Application of Gypsum Sheathing[1]

This standard is issued under the fixed designation C 1280; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the minimum requirements for and methods of application of gypsum sheathing for use as a substrate for exterior wall cladding.

1.2 Details of construction for a specific assembly to achieve the required fire resistance shall be obtained from reports of fire-resistance tests, engineering evaluations, or listings from recognized fire testing laboratories.

1.2.1 This specification shall govern where it is more stringent (size or thickness of framing and size and spacing of fasteners) than the fire-rated construction.

1.3 Where sound control is required for a gypsum sheathing assembly, the details of construction shall be in accordance with the acoustical test report of an assembly that has met the required acoustical value(s).

1.3.1 This specification shall govern where it is more stringent (size or thickness of framing and size and spacing of fasteners) than the sound-rated construction.

1.4 Where resistance to racking loads or shear is required for a gypsum sheathing assembly, the details of construction shall be in accordance with the racking or shear test report of an assembly that has met the required racking or shear value(s).

1.4.1 This specification shall govern where it is more stringent (size or thickness of framing and size and spacing of fasteners) than the racking or shear-tested construction.

1.5 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.6 The text of this standard references footnotes which provide explanatory material. These footnotes shall not be considered as requirements of the standard.

1.7 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 954 Specification for Steel Drill Screws for the Application of Gypsum Panel Products or Metal Plaster Bases to Steel Studs from 0.033 in. (0.84 mm) to 0.112 in. (2.84 mm) in Thickness

C 955 Specification for Load-Bearing (Transverse and Axial) Steel Studs, Runners (Tracks), and Bracing or Bridging for Screw Application of Gypsum Panel Products and Metal Plaster Bases

C 1002 Specification for Steel Self-Piercing Tapping Screws for the Application of Gypsum Panel Products or Metal Plaster Bases to Wood Studs or Steel Studs

C 1007 Specification for Installation of Load Bearing (Transverse and Axial) Steel Studs and Related Accessories

C 1063 Specification for Installation of Lathing and Furring to Receive Interior and Exterior Portland Cement-Based Plaster

C 1396/C 1396M Specification for Gypsum Board

2.2 *U.S. Department of Commerce Publication:*

PS20 American Softwood Lumber Standard[3]

3. Terminology

3.1 *Definitions:* Definitions shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *exterior cladding*, *n*—a permanent material or system that impedes the transmission of environmental elements to the sheathing.

3.2.2 *fastener*, *n*—nails, staples, or screws used for application of the sheathing.

3.2.3 *framing member*, *n*—studs, headers, bracing, and blocking that serve to receive the sheathing.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for the Application of Gypsum and Other Products in Assemblies.

Current edition approved May 1, 2009. Published May 2009. Originally approved in 1994. Last previous edition approved in 2007 as C 1280 – 07.

3.2.4 *horizontal application*, *n*—a synonym for *perpendicular application.*

3.2.5 *parallel application*, *n*—gypsum sheathing applied with the edges parallel to the framing members; a synonym for *vertical application.*

3.2.6 *perpendicular application*, *n*—gypsum sheathing applied with the edges at right angles to the framing members; a synonym for *horizontal application.*

3.2.7 *require*, *v*—to mandate by a force outside this specification, such as a building code, project specification, contract, or purchase order.

3.2.8 *specified*, *adj*—pertaining to a mandatory requirement of this specification or a referenced requirement.

3.2.9 *specify*, *v*—to mandate by an obligation of this standard or a referenced document.

3.2.10 *vertical application*, *n*—synonym for *parallel application.*

3.2.11 *weather resistive barrier*, *n*—a temporarily exposed protective membrane that is intended to impede the penetration of environmental elements until the installation of a permanent exterior cladding.

4. Exposure After Installation

4.1 Gypsum sheathing board is a substrate that shall be covered by an exterior cladding or other weather-resistive barrier and is not intended for long-term exposure. It shall not be exposed to the elements for more than 30 days after it has been installed. Gypsum sheathing shall be covered with a weather-resistive barrier within 30 days if the exposure time will be more than 30 days.

NOTE 1—Some building codes require an additional weather-resistive barrier. The exterior face paper of the sheathing shall be dry prior to application of the additional weather-resistive barrier.

5. Materials and Manufacture

5.1 *Gypsum Sheathing*—Specification C 1396/C 1396M.

5.1.1 *Type X (Special Fire-Resistant) Gypsum Sheathing*—Gypsum sheathing that provides a greater degree of fire resistance than regular gypsum sheathing as defined in Specification C 1396/C 1396M.

5.2 *Fasteners*—Fasteners shall be as described in 5.2.1 through 5.2.3. The fastener length shall be not less than that specified in Table 1.

5.2.1 *Nails*—Nails shall be not less than 12-gauge galvanized, 7⁄16-in. (11.1-mm) diameter head.

5.2.2 *Screws*:

TABLE 1 Minimum Fastener Lengths

Framing Type	Fastener Type	Sheathing Thickness, in. (mm)	Minimum Fastener Length, in. (mm)
Wood	nails	½ (12.7)	1½ (38)
		⅝ (15.9)	1¾ (45)
	screws	½ (12.7)	1¼ (32)
		⅝ (15.9)	1¼ (32)
	staples	½ (12.7)	1½ (38)
		⅝ (15.9)	1¾ (45)
Steel	screws	½ (12.7)	1 (25)
		⅝ (15.9)	1¼ (32)

5.2.2.1 Screws for fastening gypsum sheathing to wood framing members, and to steel framing members less than 0.033 in. (0.84 mm) in thickness, shall meet the requirements of Specification C 1002.

5.2.2.2 Screws for fastening gypsum sheathing to steel framing members from 0.033 to 0.112 in. (0.84 to 2.84 mm) in thickness shall meet the requirements of Specification C 954.

5.2.2.3 Trim-head screws shall not be permitted for the attachment of gypsum sheathing.

5.2.2.4 Screws for fastening self-furred metal lath over gypsum sheathing as described in 8.2.7 shall be as specified in Specification C 1063.

5.2.3 *Staples*—Staples shall be of galvanized steel, not less than 16-gauge, 7⁄16-in. (11.1-mm) wide crown outside measurement. Legs shall have divergent points.

5.3 *Framing Members*:

5.3.1 *Wood Framing*—Wood framing members shall conform to PS20.

5.3.2 *Steel Framing*—Load-bearing steel framing shall meet the requirements of Specification C 955.

6. Substrate, Surface Preparation

6.1 The maximum spacing for framing members for gypsum sheathing shall be not more than 24 in. (610 mm) on center on walls.

6.1.1 Wood framing shall be straight and true, attached securely following accepted engineering practices and as required for the intended design. The surfaces to which abutting edges or ends of gypsum sheathing are to be attached shall be not less than 1½-in. (38-mm) wide. The bearing surface shall be not less than ¾ in. (19 mm) for internal corners or angles.

6.1.2 Load-bearing metal framing members shall be of the proper size and design for their intended use and shall be installed in accordance with Specification C 1007.

7. Framing Alignment

7.1 Framing members shall be installed so that the surface will be in an even plane, unless otherwise specified, after the gypsum sheathing has been applied.

8. Cutting and Application of Gypsum Sheathing

8.1 *Cutting Gypsum Sheathing*:

8.1.1 The gypsum sheathing shall be cut by scoring and breaking or by sawing, working from the face side. The face paper shall be cut with a sharp knife or other suitable tool when cutting by scoring. The gypsum sheathing shall be broken by snapping the gypsum sheathing in the reverse direction or by cutting the back paper with a knife or suitable tool.

8.1.2 The cut edges and ends of gypsum sheathing shall be trimmed to obtain neat fitting joints when installed.

8.1.3 Holes for pipes, fixtures, or other small openings shall be scored on the face paper before removing the cutout with a saw or special tool designed for this purpose.

8.1.4 Where gypsum sheathing meets projecting surfaces, the gypsum sheathing shall be scribed and cut neatly.

8.2 *Application of Gypsum Sheathing*:

8.2.1 Gypsum sheathing shall be fitted snugly around all window and door openings.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:49:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.2.1.1 Sheathing joints shall be offset a minimum of 4 in. (100 mm) from the edge of any opening.

8.2.1.2 Gypsum sheathing shall be flashed at openings so that water intrusion will not contact the sheathing.

8.2.2 All vertical end and edge joints shall abut over the centers of framing members and shall be offset a minimum of one framing space between adjacent rows of gypsum sheathing.

8.2.3 *Control Joints*:

8.2.3.1 Control joints shall be provided in wall runs exceeding 30 ft (9100 mm) in length. The distance between control joints shall be not more than 30 ft (9100 mm).

8.2.3.2 Control joints shall be installed in walls wherever there is a building construction joint or where required.

8.2.3.3 The location of the control joints shall be as required by either the building design or the exterior cladding specified.

8.2.3.4 Control joints, other accessories, and metal plaster base shall be fastened through gypsum sheathing to framing members.

8.2.4 Gypsum sheathing, 4-ft (1220-mm) wide, shall be applied either parallel or perpendicular to framing members.

8.2.4.1 Square edge gypsum sheathing applied perpendicular to framing members shall be covered with a weather-resistive barrier, or horizontal joints shall be sealed.

8.2.5 Tongue and groove gypsum sheathing shall be applied with the long dimension perpendicular to framing members, with the grooved edges down, interlocking the tongue of the panel below without forcing.

8.2.6 Fasteners shall be spaced not more than 8 in. (203 mm) on center along vertical ends or edges and intermediate supports. The length of fasteners shall be as indicated in Table 1.

8.2.6.1 Fasteners shall be located not less than ⅜ in. (9.5 mm) from the ends and edges of the gypsum sheathing.

8.2.6.2 Gypsum sheathing shall be held tight against the framing when driving fasteners.

8.2.6.3 Fasteners shall be driven so that the heads are at or slightly below the surface of the gypsum sheathing without breaking the face paper or fracturing the core.

8.2.6.4 Screws shall be driven without stripping the framing member around the screw shank.

8.2.6.5 Staples shall be driven with the crown parallel to the framing member.

8.2.7 *Application of Gypsum Sheathing Under Self-Furred Metal Lath*—Where fire resistance or shear resistance is not required, and when metal lath and portland cement plaster are to be applied as the exterior cladding over gypsum sheathing installed over framing members spaced not more than 16 in. (406 mm) on center, and the metal lath shall be installed in accordance with Specification C 1063 within 24 h after the gypsum sheathing, the gypsum sheathing shall be permitted to be applied as specified in 8.2.7.1 and 8.2.7.2, and fastening of the gypsum sheathing shall be completed with the attachment of the self-furred metal lath.

8.2.7.1 For 2-ft (610-mm) wide sheathing installed in accordance with 8.2.5, vertical ends of gypsum sheathing shall be fastened in accordance with 8.2.6. Gypsum sheathing shall be fastened in place at each intermediate stud with a minimum of two fasteners per board spaced not more than 2 in. (50 mm) from opposite edges.

8.2.7.2 For 4-ft (1220-mm) wide sheathing installed in accordance with 8.2.4, vertical ends or edges of gypsum sheathing shall be fastened in accordance with 8.2.6. Gypsum sheathing shall be fastened in place at each intermediate stud with fasteners spaced not more than 24 in. (610 mm) on center.

9. Keywords

9.1 exterior walls; gypsum; sheathing

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C 1280 – 04, that may impact the use of this specification. (Approved May 1, 2009)

(*1*) Added new paragraphs 5.2.2.3 and 5.2.2.4.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1293 – 08b

Standard Test Method for Determination of Length Change of Concrete Due to Alkali-Silica Reaction[1]

This standard is issued under the fixed designation C 1293; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the susceptibility of an aggregate or combination of an aggregate with pozzolan or slag for participation in expansive alkali-silica reaction by measurement of length change of concrete prisms.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

1.3 The values stated in SI units are to be regarded as the standard. No other units of measurement are included in this standard. When combined standards are cited, the selection of measurement system is at the user's discretion subject to the requirements of the referenced standard.

to Demonstrate the Effectiveness of Supplementary Cementing Materials and Lithium-Based Admixtures to Prevent Alkali-Silica Reaction in Concrete

3. Terminology

3.1 Terminology used in this standard is as given in Terminology C 125 or Descriptive Nomenclature C 294.

4. Significance and Use

4.1 Alkali-silica reaction is a chemical interaction between some siliceous constituents of concrete aggregates and hydroxyl ions (**1**).[5] The concentration of hydroxyl ion within the concrete is predominantly controlled by the concentration of sodium and potassium (**2**).

4.2 This test method is intended to evaluate the potential of an aggregate or combination of an aggregate with pozzolan or slag to expand deleteriously due to any form of alkali-silica reactivity (**3**,**4**).

4.3 When testing an aggregate with pozzolan or slag, the results are used to establish minimum amounts of the specific pozzolan or slag needed to prevent deleterious expansion. Pozzolan or slag from a specific source can be tested individually or in combination with pozzolan or slag from other sources.

4.4 When selecting a sample or deciding on the number of samples for test, it is important to recognize the variability in lithology of material from a given source, whether a deposit of sand, gravel, or a rock formation of any origin. For specific advice, see Guide C 295.

4.5 This test method is intended for evaluating the behavior of aggregates in portland cement concrete with an alkali (alkali metal oxide) content of 5.25 kg/m^3 or in concrete containing pozzolan or slag with an alkali content proportionally reduced from 5.25 kg/m^3 Na_2O equivalent by the amount of pozzolan or slag replacing portland cement. This test method assesses the potential for deleterious expansion of concrete caused by alkali-silica reaction, of either coarse or fine aggregates, from tests performed under prescribed laboratory curing conditions that will probably differ from field conditions. Thus, actual field performance will not be duplicated due to differences in concrete alkali content, wetting and drying, temperature, other factors, or combinations of these (**5**).

4.6 Results of tests conducted on an aggregate as described herein should form a part of the basis for a decision as to whether precautions should be taken against excessive expansion due to alkali-silica reaction. Results of tests conducted on combinations of an aggregate with pozzolans or slag should form a part of the basis for a decision as to whether the specific pozzolan or slag, when used in the amount tested, was effective in preventing excessive expansion. These decisions should be made before a particular aggregate is used in concrete construction. Criteria to determine the potential deleteriousness of expansions measured in this test are given in Appendix X1.

4.7 When the expansions in this test method are greater than the limit shown in X1.2, the aggregate or combination of aggregate with the tested amount of pozzolan or slag is potentially alkali-reactive. Supplemental information should be developed to confirm that the expansion is actually due to alkali-silica reaction. Petrographic examination of the concrete prisms should be conducted after the test using Practice C 856 to confirm that known reactive constituents are present and to identify the products of alkali-silica reactivity. Confirmation of alkali-silica reaction is also derived from the results of the test methods this procedure supplements (see Appendix X1).

4.8 If the supplemental tests show that a given aggregate is potentially deleteriously reactive, additional studies may be appropriate to evaluate preventive measures in order to allow safe use of the aggregate. Preventive measures are mentioned in the Appendix to Specification C 33.

4.9 This test method does not address the general suitability of pozzolans or slag for use in concrete. These materials should comply with Specification C 618, Specification C 989, or Specification C 1240.

5. Apparatus

5.1 The molds, the associated items for molding test specimens, and the length comparator for measuring length change shall conform to the applicable requirements of Test Method C 157/C 157M and Practice C 490, and the molds shall have nominal 75-mm square cross sections.

5.2 The storage container options required to maintain the prisms at a high relative humidity are described in 5.2.1.

5.2.1 *Recommended Container*—The recommended containers are 19 to 22-L polyethylene pails with airtight lids and approximate dimensions of 250- to 270-mm diameter at bottom, 290 to 310 mm at top, by 355 to 480 mm high. Prevent significant loss of enclosed moisture due to evaporation with airtight lid seal. Place a perforated rack in the bottom of the storage container so that the prisms are 30 to 40 mm above the bottom. Fill the container with water to a depth of 20 ± 5 mm above the bottom. A significant moisture loss is defined as a loss greater than 3 % of the original amount of water placed at the bottom of the pail. Place a wick of absorbent material around the inside wall of the container from the top so that the bottom of the wick extends into the water (See Note 1).

5.2.2 *Alternative Containers*—Alternative storage containers may be used. Confirm the efficiency of the alternative storage container with an alkali-reactive aggregate of known expansion characteristics.[6] The expansion efficiency is confirmed when expansions at one year obtained using the alternative container are within 10 % of those obtained using the recommended container. Alternative storage containers must contain the required depth of water. When reporting results, note the use of an alternative container, if one is used, together with documentation proving compliance with the above.

[5] The boldface numbers in parentheses refer to the list of references at the end of this test method.

[6] The sole source of supply of non-reactive aggregates and alkali-silica reactive aggregates of known expansion characteristics **(6)** known to the committee at this time is The Petrographer, Engineering Materials Office, Ministry of Transportation, 1201 Wilson Ave., Downsview, Ontario, Canada, M3M1J8.. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee [1], which you may attend.

www.technobetar.ir

NOTE 1—Polypropylene geotextile fabric or blotting paper are suitable materials for use as the wick.

5.3 The storage environment necessary to maintain the 38.0 °C reaction accelerating storage temperature consistently and homogeneously is described in 5.3.1.

5.3.1 *Recommended Environment*—The recommended storage environment is a sealed space insulated so as to minimize heat loss. Provide a fan for air circulation so the maximum variation in temperature measured within 250 mm of the top and bottom of the space does not exceed 2.0 °C. Provide an insulated entry door with adequate seals so as to minimize heat loss. Racks for storing containers within the space are not to be closer than 30 mm to the sides of the enclosure and are to be perforated so as to provide air flow. Provide an automatically controlled heat source to maintain the temperature at 38.0 ± 2.0 °C (see Note 2). Record the ambient temperature and its variation within the space to ensure compliance.

NOTE 2—It has been found to be good practice to monitor the efficiency of the storage environment by placing thermocouples inside dummy concrete specimens inside a dummy container within the storage area. The storage room described in Test Method C 227 generally will be satisfactory.

5.3.2 *Alternative Storage Environment*—Use of an alternative storage environment is permitted. Confirm the efficiency of the alternative storage container with an alkali-reactive aggregate of known expansion characteristics.[6] The expansion efficiency is confirmed when expansions at one year obtained using the alternative storage environment are within 10 % of those obtained using the recommended environment. When reporting the results, note the use of an alternative storage environment, if one is utilized, together with documentation proving compliance with the above.

6. Reagents

6.1 *Sodium Hydroxide (NaOH)*—USP or technical grade may be used. (**Warning**—Before using NaOH, review: (*1*) the safety precautions for using NaOH; (*2*) first aid for burns; and (*3*) the emergency response to spills as described in the manufacturers Material Safety Data Sheet or other reliable safety literature. NaOH can cause severe burns and injury to unprotected skin and eyes. Always use suitable personal protective equipment including: full-face shields, rubber aprons, and gloves impervious to NaOH (Check periodically for pinholes.).)

6.2 *Water*:

6.2.1 Use potable tap water for mixing and storage.

7. Materials

7.1 *Cement*—Use a cement meeting the requirements for a Type I Portland cement as specified in Specification C 150. The cement must have a total alkali content of 0.9 ± 0.1 % Na_2O equivalent (Na_2O equivalent is calculated as percent Na_2O + 0.658 × percent K_2O). Determine the total alkali content of the cement either by analysis or by obtaining a mill run certificate from the cement manufacturer. Add NaOH to the concrete mixing water so as to increase the alkali content of the mixture, expressed as Na_2O equivalent, to 1.25 % by mass of cement (see Note 3).

NOTE 3—The value of 1.25 % Na_2O equivalent by mass of cement has been chosen to accelerate the process of expansion rather than to reproduce field conditions. At the 420 kg/m^3 cement content, this corresponds to an alkali level of 5.25 kg/m^3 .

7.2 *Aggregates*:

7.2.1 To evaluate the reactivity of a coarse aggregate, use a nonreactive fine aggregate. A nonreactive fine aggregate is defined as an aggregate that develops an expansion in the accelerated mortar bar, (see Test Method C 1260) of less than 0.10 % at 14 days (see X1.6 for interpretation of expansion data). Use a fine aggregate meeting Specification C 33 with a fineness modulus of 2.7 ± 0.2.

7.2.2 To evaluate the reactivity of a fine aggregate, use a nonreactive coarse aggregate. Prepare the nonreactive coarse aggregate according to 7.2.3.[6] A nonreactive coarse aggregate is defined as an aggregate that develops an expansion in the accelerated mortar bar (see Test Method C 1260) of less than 0.10 % at 14 days (see X1.6 for interpretation of expansion data). Use a coarse aggregate meeting Specification C 33. Test the fine aggregate using the grading as delivered to the laboratory.

7.2.3 Sieve the coarse aggregate and recombine in accordance with the requirements in Table 1. Select the Table 1 grading based on the as-received grading of the sample. Coarse aggregate fractions larger than 19.0-mm sieve are not to be tested as such. When petrographic examination using Guide C 295 reveals that the material making up the size fraction larger than the 19.0-mm sieve is of such a composition and lithology that no difference should be expected compared with the smaller size material, then no further attention need be paid to the larger sizes. If petrographic examination suggests the larger size material to have a different reactivity, the material should be studied for its effect in concrete according to one of the other alternative procedures described herein:

7.2.3.1 *Proportional Testing*—Crush material larger than the 19.0-mm sieve to pass the 19.0-mm sieve. The crushing operation shall be performed in a manner that minimizes production of material passing the 4.75-mm sieve. Grade this crushed material per the Table 1 grading, and add to the original mass of graded aggregate produced in 7.2.3 such that the ratio of crushed, graded, oversize aggregate to total graded aggregate equals the ratio of material retained on the 19.0-mm sieve to the total material retained above the 4.75-mm sieve (See Note 4).

NOTE 4—For example, if the material retained on the 19-mm sieve formed 25 % of the total material retained above the 4.75-mm sieve, then the mass of crushed and returned oversize material shall form 25 % of the total graded aggregate.

7.2.3.2 *Separated Size Testing*—Crush material larger than the 19.0-mm sieve to pass the 19.0-mm sieve, grade that material as per Table 1 and test in concrete as a separate aggregate.

TABLE 1 Grading Requirement

Sieve Size		Mass Fraction	
Passing	Retained	Coarse	Intermediate
19.0-mm	12.5-mm	⅓	. . .
12.5-mm	9.5-mm	⅓	½
9.5-mm	4.75-mm	⅓	½

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.3 *Concrete Mixture Proportions*—Proportion the concrete mixture to the following requirements:

7.3.1 *Cementitious Materials Content*—420 ± 10 kg/m.[3]

7.3.1.1 When evaluating the susceptibility of an aggregate to expansive alkali-silica reaction, use cement as 100 % of the cementitious material.

7.3.1.2 When evaluating combinations of aggregate with pozzolan or slag, replace cement with the desired amount of pozzolan or slag on a percent by mass basis.

7.3.2 *Coarse Aggregate Content*—Use a dry mass of coarse aggregate per unit volume of concrete equal to 0.70 ± 0.02 of its dry-rodded bulk density as determined by Test Method C 29/C 29M for all classes of aggregates (for example, low density, normal, and high density).

7.3.3 *Water-Cementitious Materials Ratio (w/cm)*—Maintain *w/cm* in the range of 0.42 to 0.45 by mass. Adjust the *w/cm* within this range to give sufficient workability to permit satisfactory compaction of the concrete in the molds. If necessary to obtain sufficient workability within the specified *w/cm* range, use of a high-range water reducer (HRWR), meeting the requirements of Specification C 494/C 494M Type F is permitted. If, within the specified *w/cm* range, specimens representative of the concrete mixture cannot be fabricated due to excessive bleeding or segregation, the use of a viscosity-modifying admixture (VMA) is permitted. Report the *w/cm* ratio used and the amount, if any, of HRWR or VMA.

7.3.4 *Admixture (NaOH)*—Dissolve in the mixing water and add as required to bring the alkali content of the concrete mixture, expressed as Na_2O_e = % Na_2O + 0.658× % K_2O, up to 1.25 % by mass of cement (see Note 5). Use no other admixture in the concrete except as permitted in the section on *Water-Cementitious Materials Ratio*.

NOTE 5—Example calculations for determining the amount of NaOH to be added to the mixing water to increase the alkali content of the cement from 0.90 % to 1.25 %:

Example A (Cement Only)	
Cementitious materials content of 1 m^3 concrete	= 420 kg
Cement content of concrete	= 420 kg
Amount of alkali in the concrete	= 420 kg × 0.90 % = 3.78 kg
Specified amount of alkali in concrete	= 420 kg × 1.25 % = 5.25 kg
Amount of alkali to be added to concrete	= 5.25 kg – 3.78 kg = 1.47 kg

The difference (1.47 kg) is the amount of alkali, expressed as Na_2O equivalent, to be added to the mix water. Factor to convert Na_2O to NaOH: since

$$(Na_2O + H_2O \rightarrow 2\ NaOH)$$

Compound	Molecular Weight
Na_2O	61.98
NaOH	39.997

Conversion factor:

$$2 \times 39.997/61.98 = 1.291; \quad (1)$$

Amount of NaOH required in Example A:

$$1.47 \times 1.291 = 1.898\ kg/m^3 \quad (2)$$

Example B (20 % of cement is replaced by pozzolan)	
Cementitious materials content of 1 m^3 concrete	= 420 kg
Cement content of concrete (20 % by mass pozzolan)	= 420 kg × 0.8 = 336 kg
Amount of alkali in the concrete	= 336 kg × 0.90 % = 3.02 kg
Specified amount of alkali in concrete	= 336 kg × 1.25 % = 4.20 kg
Amount of alkali to be added to concrete	= 4.20 kg – 3.02 kg = 1.18 kg

The difference (1.18 kg) is the amount of alkali, expressed as Na_2O equivalent, to be added to the mix water.

Amount of NaOH required for Example B:

$$1.18 \times 1.291 = 1.523\ kg/m^3 \quad (3)$$

8. Sampling

8.1 Obtain the aggregate sample in accordance with Practice D 75 and reduce it to test portion size in accordance with Practice C 702.

9. Specimen Preparation

9.1 *Mixing Concrete*:

9.1.1 *General*—Mix concrete in accordance with the standard practice for making and curing concrete test specimens in the laboratory as described in Practice C 192/C 192M.

9.1.2 *Slump*—Measure the slump of each batch of concrete immediately after mixing in accordance with Test Method C 143/C 143M.

9.1.3 *Yield, and Air Content*—Determine the yield, and air content of each batch of concrete in accordance with Test Method C 138/C 138M. Concrete used for slump, yield, and air content tests may be returned to the mixing pan and remixed into the batch.

9.2 Prepare three specimens of the type required for concrete in Test Method C 157/C 157M from one batch of concrete (see Note 6).

NOTE 6—It has been found useful to cast an additional (4th) prism that can be removed from the test and used for petrographic examination at any time.

9.3 *Initial Conditioning*—Cure, store, and remove molds in accordance with Test Method C 157/C 157M.

10. Procedure

10.1 *Initial Comparator Reading*—Follow the procedure of Test Method C 157/C 157M, except do not place in saturated lime water. Make initial length reading at the time of removal from the mold at an age of 23.5 ± 0.5 h. Thereafter, keep the specimens at 38.0 ± 2 °C in storage containers in accordance with 5.2.

10.2 *Subsequent Comparator Readings*—Stand the specimen on end. Specimens shall not be in contact with water in the reservoir within the storage container. Seal the container and place container in a 38.0 ± 2 °C storage environment. At no time should the storage container be in contact with the walls or floor of the 38.0 ± 2 °C storage environment and there shall be an adequate flow of air around the container.

10.2.1 When the specimens are 7 days old, take a comparator reading after removal of the container and contents from the storage environment according to 10.2.2. Subsequent readings are required at the ages of 28 and 56 days, as well as 3, 6, 9, and 12 months when testing an aggregate for susceptibility to

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:49:39 EDT 2010

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

expansive alkali-silica reaction and additionally at 18 and 24 months when testing combinations of aggregates with pozzolans or slag. Additional readings beyond those required for the specific application are suggested at 6-month intervals.

10.2.2 Remove the containers holding the prisms from the 38.0 ± 2.0 °C temperature environment and place in a moist cabinet or moist room that is in compliance with Specification C 511 for a period 16 ± 4 h before reading.

10.3 Fabricate all specimens placed in a given storage container at the same time so that all specimens in that container are due for comparator reading at the same time.

10.4 Identify the specimens so as to place the specimens in the comparator with the same end up. After the comparator reading of the prism, replace the specimen in the storage container but invert the upper end as compared with the previous storage period. In this way the prisms are not stored through two consecutive storage periods with the same ends up.

11. Calculation

11.1 Calculate the change in length between the initial comparator reading of the specimen and the comparator reading at each time interval to the nearest 0.001 % of the effective gage length and record as the length change of the prism for that period. Calculate the average length change in percentage for the group of prisms at the age.

11.2 Data from at least three bars must be available at any age to constitute a valid test at that age.

12. Report

12.1 Report the following information:

12.1.1 Type and source of coarse and fine aggregates, and the coarse aggregate grading used,

12.1.2 Type and source of portland cement,

12.1.3 The alkali content of the cement as percent potassium oxide (K_2O), sodium oxide (Na_2O), and calculated percent NaO_e,

12.1.4 Type, source, and amount (percent by mass of cementitious material) of any pozzolan or slag used,

12.1.5 The amount, if any, of high-range water reducer or viscosity-modifying admixture used,

12.1.6 Concrete mixture proportions based on SSD aggregates, and corrected for yield,

12.1.7 The amount of sodium hydroxide (NaOH) added to the mixing water, expressed as percent sodium oxide (Na_2O) equivalent by mass of the cement,

12.1.8 The w/cm based on saturated, surface dry (SSD) aggregates,

12.1.9 The slump, with mass yield and air content of the concrete batched,

12.1.10 The average length change in percent at each reading of the prisms along with the individual length change in percentage for each prism,

12.1.11 Any significant features revealed by examination of the concrete prisms either during the test or at the end of the test (for example, cracks, gel formation, or peripheral reaction rims on aggregate particles), and

12.1.12 Type of storage container and 38.0 ± 2.0 °C storage environment used to store the concrete prisms if they differ from those specified in 5.2.1 and 5.3.1.

13. Precision and Bias

13.1 *Multi-Laboratory Precision*:

13.1.1 *Average Expansion Less Than 0.014 %*—The multi-laboratory standard deviation of a single test result (mean of measurements of three prisms) for average expansion less than 0.014 % has been found to be 0.0032 % (CSA A23.2-14A).[4] Therefore, results of two properly conducted tests in different laboratories on the same aggregate should not differ by more than 0.009 %, nineteen times out of twenty.

13.1.2 *Average Expansion Greater Than 0.014 %*—The multi-laboratory coefficient of variation of a single test result (mean of measurements of three prisms) for average expansion greater than 0.014 % has been found to be 23 % (CSA A23.2-14A).[4] Therefore, results of two properly conducted tests in different laboratories on the same aggregate should not differ from each other by more than 65 % of their average, nineteen times out of twenty.

13.2 *Within-Laboratory Precision*:

13.2.1 *Average Expansion Less Than 0.02 %*—For average expansions of less than 0.02 %, the multi-specimen, within-laboratory standard deviation has been found to be 0.0025 % (CSA A23.2-14A). Therefore, the range (difference between highest and lowest) of the three individual prism measurements used in calculating an average test result should not exceed 0.008 %, nineteen times out of twenty.

13.2.2 *Average Expansion Greater Than 0.02 %*—For average expansions of more than 0.02 %, the multi-specimen, within-laboratory coefficient of variation has been found to be 12 % (CSA A23.2-14A). Therefore, the range (difference between highest and lowest) of the three individual prism measurements used in calculating an average test result should not exceed 40 % of the average, nineteen times out of twenty.

13.3 *Bias*—Since there is no accepted reference material for determining the bias of this test method, no statement is being made.

14. Keywords

14.1 aggregate; alkali-silica reactivity; concrete; length change; pozzolan; slag

APPENDIX

(Nonmandatory Information)

X1. Interpretation of Results

X1.1 The question of whether or not criteria based on the results obtained using this test method should be used for acceptance of materials for use as concrete aggregate will be dealt with, if deemed appropriate, in Specification C 33.

X1.2 Work has been reported from which it may be inferred that an aggregate might reasonably be classified as potentially deleteriously reactive if the average expansion of three concrete specimens is equal to or greater than 0.04 % at one year (**7**) (CSA A23.2-27A-00 Table 1).

X1.3 It is reasonable to conclude that the amount of pozzolan or slag used in combination with an aggregate is at least the minimum needed to prevent excessive expansion in field concrete if the average expansion is less than 0.04 % at two years (CSA A23.2-28A-02).

X1.4 A history of satisfactory field performance in concrete is the best method of evaluating the potential for an aggregate to cause premature deterioration of concrete due to alkali-silica reaction. When field performance of an aggregate in concrete is to be accepted, the following conditions should be met (**8**):

X1.4.1 The cement content and alkali content of the cement should be the same or higher in the field concrete than is proposed in the new structure.

X1.4.2 The concrete examined should be at least 10 years old.

X1.4.3 The exposure conditions of the field concrete should be at least as severe as those in the proposed structure.

X1.5 This test method supplements the results of other test methods. The results of the other test methods are usually reported before the results of this test method are available. Standards that this test method supplements include: Test Method C 227, Guide C 295, Test Method C 289, and Test Method C 1260. It is recommended that the relevant procedure(s) be performed concurrently with this test method and any discrepancies between the results explained. Care should be exercised in the interpretation of these other test method results (**9-14**).

X1.6 The use of this test method should especially be considered when other test methods may be inadequate. Some examples of such problems are as follows: The potential reactivity of various varieties of quartz may not be accurately determined by Test Method C 227 since the test method may produce a false-negative result (**3**). False-negative results are possible with a number of aggregates such as slow-late expanding argillaceous greywackes, strained quartz and microcrystalline quartz associated with strained quartz (**3,4,13**). False-negative results are also possible due to storage conditions (**9**), reactive aggregate levels far above or below pessimum (**3**) or insufficient alkali to accelerate the test (**3**). The potential reactivity of various varieties of quartz may not be accurately determined by Test Method C 1260 since the test method may produce a false-positive result with a number of marginally reactive aggregates (**13**). Test Method C 1260 may also give a false-negative result with aggregates suspected of containing deleterious strained quartz (**14**).

X1.7 If the data generated with other test methods and supplemented with information from this test method judge an aggregate to be "not potentially deleteriously alkali-silica reactive," no restrictions are usually required with the use of that aggregate in order to protect against expansion due to alkali-silica reaction (**7**) (see Note X1.1).

X1.8 Additional interlaboratory testing data is provided in Ref (**15**).

NOTE X1.1—In critical structures such as those used for nuclear containment or large dams, where slight expansions cannot be tolerated, a lower expansion limit may be required.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1293 – 08a, that may impact the use of this test method. (Approved December 1, 2008)

(*1*) Revised 1.3.
(*2*) Revised 7.2.3, 12.1.1, and Table 1.
(*3*) Deleted old 12.1.13.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1293 – 08, that may impact the use of this test method. (Approved February 1, 2008)

(*1*) Revised 1.3, 5.1, 7.2.3, and 7.2.3.1.
(*2*) Added new 12.1.13 and Note 4.
(*3*) Revised Table 1.
(*4*) Removed all informational inch-pound units throughout to conform to ASTM Form and Style.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1293 – 06, that may impact the use of this test method. (Approved January 15, 2008)

(*1*) Revised 7.3.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1301 – 95 (Reapproved 2009)ε1

Standard Test Method for Major and Trace Elements in Limestone and Lime by Inductively Coupled Plasma-Atomic Emission Spectroscopy (ICP) and Atomic Absorption (AA)[1]

This standard is issued under the fixed designation C 1301; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—A units statement was added editorially as new paragraph 1.3 and subsequent paragraphs were renumbered in June 2009.

1. Scope

1.1 The following test method covers the use of inductively coupled plasma-atomic emission spectroscopy (ICP) and atomic absorption spectroscopy (AA) in the analysis of major and trace elements in limestone and lime (calcined limestone).

1.2 Table 1 lists some of the elements that can be analyzed by this test method and the preferred wavelengths. Also see U.S. EPA Methods 200.7 and 200.9.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

TABLE 1 Elements and Some Suggested Wavelengths[A]

Major Elements	ICP Wavelength, nm	AA Wavelength, nm
Calcium	317.933 (315.887)[B]	422.7
Magnesium	279.079 (285.213)	285.2
Silicon	251.611 (288.160)	251.6
Aluminum	308.215 (309.271)	309.3
Iron	259.940	248.3
Manganese	257.610	279.5
Sodium	588.995 (589.59)	589.0
Potassium	766.491	766.5
Phosphorus	214.914 (213.618)	...[C]
Strontium	421.552	460.7
Trace Elements	**ICP Wavelength, nm**	**AA Wavelength, nm**
Antimony	206.833	217.6
Arsenic	193.696	193.7
Barium	455.403 (493.409)	553.6
Beryllium	313.042	234.9
Boron	249.773	249.8
Cadmium	226.502 (228.80)	228.8
Chromium	267.716 (205.552)	357.9
Cobalt	228.616	240.7 (242.5)
Copper	324.754	324.8
Lead	220.353	217.0 (283.3)
Molybdenum	202.030 (203.844)	313.3
Nickel	231.604 (221.647)	232.0
Selenium	196.090	196.0
Silver	328.068	328.1
Sulfur	180.731 (180.669)	...[C]
Thallium	190.864	276.8
Tin	189.989	235.5 (286.3)
Vanadium	292.402	318.4
Zinc	213.856 (202.551)	213.9

[A] The suggested wavelengths may vary for your particular instrument.
[B] Numbers in parentheses are alternate wavelengths.
[C] Not recommended or not used.

[1] This test method is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.05 on Chemical Tests

Current edition approved June 1, 2009. Published September 2009. Originally approved in 1995. Last previous edition approved in 2001 as C 1301 – 95(2001).

3. Terminology

3.1 *Definitions*—Definitions for terms used in this test method can be found in Terminologies C 51 and E 135.

3.2 *Additional Definitions:*

3.2.1 *total recoverable*, *n*—trace element concentration in an unfiltered sample after heating in acid.

3.2.2 *total digestion*, *n*—complete digestion of a sample, including silica and silicate minerals, using the fusion-flux method.

4. Summary of Test Method

4.1 A sample, digested by either fusion or acid, is atomized and passed into an excitation medium (a plasma in the case of ICP; a flame in the case of AA). The resulting ions are analyzed by atomic spectroscopy. Elemental concentrations are determined by graphically relating the emission/absorption at specific wavelengths for an unknown sample to analytical curves made from reference standards of known composition.

5. Significance and Use

5.1 The presence and concentration of elements in lime and limestone is important in determining product quality and its suitability for various uses. This test method provides a means of measuring the major and trace element concentration in lime and limestone.

6. Interferences

6.1 *Chemical*—Chemical interferences, most common in AA, arise from the formation of molecular compounds that cause absorbances at the wavelength of interest. This molecular band spectral overlap can be minimized by buffering the sample with matrix modifiers (a Lanthanum additive, for example), using standard additions techniques, matrix matching or by careful selection of operating conditions (for example, using a hotter nitrous oxide/acetylene flame, selecting an alternate wavelength).

6.2 *Physical*—Physical interferences are the result of the inconsistencies in the introduction of the sample into the instrument, namely the transport and atomization/nebulization of the sample. These inconsistencies are a function of changing viscosity and surface tension, and are found primarily in samples of high-dissolved solids or high-acid concentrations. Physical interferences can be reduced by diluting the sample and by the use of a peristaltic pump.

6.3 *Spectral*—Spectral interference, most common in ICP, consists of overlapping and unresolved peaks. Computer software, along with the analysis of the suspected interfering element, can compensate for this effect. Using an alternate wavelength is also a solution. Another spectral interference is caused by background, both stray light and continuous spectrum (continuous argon spectrum, for example). Background correction adjacent to the analyte line will correct background spectral interference.

7. Apparatus

7.1 *Spectrometer*.

7.1.1 *Inductively Coupled Plasma Emission Spectrometer (ICP)*—Either a scanning sequential or multi-element simultaneous type ICP, with resolution appropriate for the elements to be analyzed. The optical path may be in air, vacuum or an inert gas. A detailed description of an ICP is given in Practice E 1479.

7.1.2 *Atomic Absorption Spectrometer (AA)*—An atomic absorption spectrometer consisting of single or double beam optics, a monochromator, photomultiplier detector, adjustable slits, a wavelength range from 190 to 800 nm, and provisions for interfacing with either a strip chart recorder or a computer. A simultaneous background correction system is also recommended. A detailed description of an AA is given in Practice E 863.

7.1.2.1 *Hollow Cathode Lamps*—Single hollow cathode lamps, one for each element. Multi-element hollow cathode lamps can be used but spectral interferences are possible.

8. Reagents

8.1 *Purity of Reagents*—Reagents should conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society as a minimum when such specifications are available.[6] The high sensitivity of both the ICP and AA may require reagents of high purity. It is recommended that the reagents be of sufficiently high purity so as not to lessen the accuracy of the determination.

8.2 *Purity of Water*—At minimum, water should conform to Type II of Specification D 1193.

8.3 *Stock Solutions*—Standard stock solutions may be purchased or prepared from high purity metals or metal salts (Method 6010, SW-846; EPA Methods 200.7 and 200.9). Salts should be dried at 105°C for 1 h, unless otherwise specified.

8.4 *Multi-element Calibration Standards*—ICP calibration is most often performed using multi-element calibration standards prepared from single element stock solutions. Prior to preparing the mixed standards, each stock solution should be analyzed separately to determine possible spectral interference or the presence of impurities. Standards are combined in such a way that they are chemically compatible (no precipitation occurs) and do not cause spectral interferences. An example of multi-element combinations is given in EPA Method 200.7.

8.5 *Interference Check Sample*—Interference check samples are made from single element stock solutions at a concentration level equal to that of the samples to be analyzed.

8.6 *Calibration Blank*—A calibration blank is prepared at the same acid strength as that of the samples to be analyzed; usually 5 or 10 %. To prepare a 10 % nitric acid calibration blank, add one volume of nitric acid to nine volumes of water. This same blank can be used as the rinse solution for flushing the system between standards and samples.

8.7 *Reagent Blank*—The reagent blank contains all the reagents in the same concentrations (including nitric acid) as the samples to be analyzed. The reagent blank is carried through the same processes as a sample for analysis.

[6] *Reagent Chemicals, American Chemical Society Specifications,* American Chemical Society, Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see *Analar Standards for Laboratory Chemicals,* BDH Ltd., Poole, Dorset, U.K., and the *United States Pharmacopeia and National Formulary,* U.S. Pharmacopeial Convention, Inc. (USPC), Rockville, MD.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.8 *Nitric Acid*—High purity nitric acid is recommended.

8.9 *Lithium Tetraborate (Li2B4O7) Powder or Lithium Metaborate (LiBO2)) Powder.*

8.10 *Non-Wetting Agent*—Saturated solution of Hydrogen Bromide (HBr), Potassium Bromide (KBr) or Potassium Iodide (KI) as a non-wetting agent to prevent the flux from sticking to the crucible.

8.11 *Lanthanum Chloride (LaCl3) Powder*—Lanthanum is added to samples for AA analysis as a releasing agent (for Calcium) and ionization suppressant (for Aluminum). When added to the sample solution, Lanthanum will preferentially react with potential interferents and "release" the analyte. In addition, the Lanthanum will preferentially ionize relative to Aluminum, aiding in the number of ground state Aluminum atoms. A typical Lanthanum additive is prepared by dissolving 175 g LaCl3 in 1 L of water (equivalent to 100 g/L Lanthanum).

9. Preparation of Apparatus

9.1 Prepare and operate the spectrometer in accordance with the manufacturer's instructions. The present method assumes that good operating procedures are followed. Design differences between spectrometers make it impractical to specify the required steps in detail here.

10. Calibration and Standardization

10.1 Allow a warm-up time of at least 30 min. Operate the spectrometer according to the operation manual for the instrument.

10.2 Calibrate the instrument by aspirating the blank and standards. A 10 % by volume HNO_3 rinse solution is aspirated for a minimum of 60 s between each standard. Most new systems are controlled by computer. The computer will establish the slope, intercept and correlation coefficients for each element. Some suggested wavelengths are given in Table 1 and EPA Methods 200.2, 200.7, and 200.9.

10.3 A peristaltic pump is recommended for aspirating standards and samples. The peristaltic pump will reduce physical interferences caused by changes in specimen viscosity and concentration (transport processes).

11. Sample Preparation

11.1 *Major Elements*—Samples for major element analysis are prepared for total digestion using lithium tetraborate or lithium metaborate as a flux. Major elements include Calcium, Magnesium, Silicon, Aluminum, Iron, Manganese, Sodium and Potassium. Trace elements such as Lead, Arsenic, Selenium and Antimony will partially volatilize using this fusion method and it is therefore not recommended for trace element analysis.

11.1.1 Take a representative minus 100 mesh sample split and dry at 105°C for 2 h.

11.1.2 Weigh 0.25 g of dried sample in a graphite or platinum crucible. Then weigh 1.00 g of lithium metaborate in the crucible. Add a few drops of non-wetting agent if needed. Mix the sample and lithium metaborate (the flux) well. Cover the mixed sample-lithium metaborate with an additional 0.50 g of lithium metaborate. This will give a total sample-flux ratio of 1:6.

11.1.3 Place a lid (optional) on the crucible prepared in 11.1.2 and place in a muffle furnace at 1000°C for 30 min. Gently agitate the molten contents of the crucible at least once during the 30° min heating.

11.1.4 Add 12.5 mL of concentrated nitric acid and 40 mL of water to a clean 250 mL wide-mouth plastic bottle.

11.1.5 When the 30 min heating in 11.1.3 is complete, quickly pour molten contents of the crucible into the plastic bottle described in 11.1.4. The water will bubble and sizzle. Quickly put the lid on the plastic bottle and shake. To aid in digestion place the bottle in a warm ultrasonic bath.

11.1.6 The contents of the plastic bottle can either be quantitatively transferred to a 250 mL volumetric flask and diluted to volume or diluted to volume by weight (that is, 1 mL = 1 g) in the same 250 mL plastic bottle it was digested in. Keep in mind, however, that the standards need to be made in the same manner as the samples. Add 10 mL Lanthanum additive to samples for AA analysis (10 mL addition is part of the dilution to volume). Filtering is not necessary.

11.2 *Trace Elements*—Samples for trace element analysis are prepared using hydrochloric acid (1:5 or 1+4) and nitric acid (1:2 or 1+1). The trace elements concentrations determined by this method are termed "total recoverable" (that is, components not digested in hot acid are not recovered). Trace elements include, but are not limited to, Antimony, Arsenic, Barium, Beryllium, Boron, Cadmium, Chromium, Cobalt, Copper, Lead, Molybdenum, Nickel, Selenium, Silver, Strontium, Thallium, Tin, Vanadium, and Zinc.

11.2.1 Take a representative minus 100 mesh sample split and dry at 105°C for 2 h.

11.2.2 Weigh 1.00 g of dried sample and transfer to a clean beaker.

11.2.3 Add 10 mL of dilute hydrochloric acid (see 11.2) and 4 mL of dilute nitric acid (see 11.2). In the case of limestone, add the acids slowly so that the powdered sample will not splatter on the sides of the beaker during it's effervescent reaction with the acid. Cover the sample (a ribbed watch glass is best) and place on a hot plate. Heat at approximately 85°C for 30 min. Boiling should be kept to a minimum. After 30 min allow the sample to cool. Then quantitatively transfer the liquid and any undissolved residue to a 100 mL volumetric flask. Dilute to volume.

12. Procedure

12.1 Aspirate the specimens prepared in Section 11 into the AA or ICP using the same conditions used during calibration.

12.2 Analyze the instrument check standards, blanks and internal control samples at a 10 % or better frequency. The results on the instrument check standards are to be within 10 %, and the internal control specimens should fall within established limits of deviation. If the results exceed these limits, investigate the cause and take corrective action.

12.3 It is recommended that 10 % of the samples analyzed be duplicates. Process duplicates through the same dissolution and analysis procedures as any other sample. The results should fall within established limits of deviation. If the results exceed these limits, investigate the cause and take corrective action. The applicability of duplicate analysis data as a

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

measure of analytical and sampling reproducibility assumes specimen homogeneity.

12.4 Analyze an interference check specimen at the beginning and the end of each specimen run or a minimum of twice per 8 h work shift, whichever is more frequent. This check specimen should contain, in relatively high concentration, those elements which are expected to be present at significant levels in the samples and which are known interfering species. All other elements should be present at relatively low levels in order to assess the quality of interference corrections.

12.5 Use the background and interference corrected data to calculate the concentration of each element. This calculation, including the dilution factor, is performed by the computer.

13. Precision and Bias

13.1 Participation in a round robin is anticipated.

14. Keywords

14.1 atomic absorption; atomic emission spectroscopy; digestion; dissolution; inductively coupled plasma; lime; limestone; spectrometer; trace elements

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1315 – 08

Standard Specification for Liquid Membrane-Forming Compounds Having Special Properties for Curing and Sealing Concrete[1]

This standard is issued under the fixed designation C 1315; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification provides requirements for membrane-forming liquids suitable for use as curing compounds and sealers on freshly placed concrete and as sealers on hardened concrete. These membranes have special properties, such as, alkali resistance, acid resistance, adhesion-promoting qualities, and resistance to degradation by UV light.

NOTE 1—For liquid membrane-forming curing compounds specified primarily by their ability to retain water in newly placed concrete (and by drying time, and for white pigmented products, reflectance), see Specification C 309.

1.2 The values stated in SI units are to be regarded as the standard. (Inch pound units are shown in parentheses).

1.3 The following precautionary caveat pertains only to the test methods portion, Section 8, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 This is a performance specification. The allowable composition of products covered by this specification is limited by various local, regional, and national regulations. Issues related to air quality (solvent emission), worker exposure, and other hazards are not addressed here. It is the responsibility of the producers and users of these materials to comply with pertinent regulations.

Warning—Some VOC exempt solvents used to meet the regulations are extremely flammable with low auto ignition temperatures and rapid evaporation rates. Consult the manufacturer's product information sheet for important application and safety information.

www.technobetar.ir

3.1.2 *Type II*—White pigmented.

3.2 The curing compound shall conform to one of the following classes:

3.2.1 *Class A* curing compounds conform to the requirements of 6.4.1, and are essentially non-yellowing,

3.2.2 *Class B* curing compounds conform to the requirements of 6.4.2, where moderate yellowing is not prohibited, and

3.2.3 *Class C* curing compounds are not restricted with regard to yellowing or darkening, and are for use where the color changes are acceptable.

NOTE 2—Polymer materials known to satisfy the durability requirements of this document include, but are not limited to, chlorinated rubbers, styrene-acrylate and styrene-butadiene copolymers. These polymers have demonstrated their durability by their ability to adhere to concrete and not be affected by the alkalies from cement.

NOTE 3—Pigmented colors other than white, or other special attributes, are beyond the scope of this specification and are subject to negotiation between the purchaser and the supplier.

4. Ordering Information

4.1 The purchaser shall include the following information in the purchase order when applicable:

4.1.1 Type and class of liquid membrane-forming compound to be furnished,

4.1.2 Rate of application to be used to determine conformance to this specification,

4.1.2.1 For Type I compounds if not specified, the liquid membrane-forming material shall be applied by uniform spraying at a rate of 7.4 m^2/L (300 ft^2/gal) for testing purposes.

4.1.2.2 For Type II compounds, if not specified, the liquid membrane-forming material shall be applied by uniform spraying at a rate of 5.0 m^2/L (200 ft^2/gal) for testing purposes.

NOTE 4—The application rate used for testing may or may not be the same as the rate used for field application. Many agencies use the same rate for field application on relatively smooth surfaces as the rate used for testing, while requiring a substantially greater application rate on deeply textured surfaces.

4.1.3 The intended method of application (for example: spraying, brushing, or by roller). If not specified, materials shall be of a sprayable consistency.

5. General Requirements

5.1 Type I liquid membrane-forming compound shall be clear or translucent and have a minimum of 25 % solids by mass when tested in accordance with 8.5.

5.2 Type II liquid membrane-forming compound shall consist of finely divided white pigment and vehicle integrally ready mixed for immediate use as is and have a minimum of 25 % vehicle solids by mass when tested in accordance with 8.6. The membrane-forming compound shall present a uniform white appearance when applied uniformly to a new concrete surface at the specified rate of application.

NOTE 5—Although this is a performance specification, a minimum vehicle solids content is specified in order to provide an approximately 0.025 mm (1 mil) thick dry film at the specified rate of application. This film thickness is considered necessary to achieve the desired characteristics.

5.3 Liquid membrane-forming compounds shall be of such a consistency that they can be readily applied by spraying, or by brushing or rolling, to form a uniform coating at temperatures above 4 °C (40 °F).

NOTE 6—For uniform application in the field on vertical concrete surfaces, the specified rate of application may be achieved by two coats, each applied at one half the normal rate with approximately 1 h drying time between coats or in accordance with manufacturer's recommendations.

5.4 Liquid membrane-forming compounds shall adhere to freshly-placed concrete that has stiffened or set sufficiently to resist marring during application. Liquid membrane-forming compounds shall also adhere to damp or dry, hardened concrete surfaces. In every case, the compound shall form a continuous film after application at the specified rate.

5.5 Liquid membrane-forming compounds shall not react deleteriously with concrete. Deleterious reactions are detected by scratching the surface of a mortar specimen used for the water-retention test with a knife or screwdriver, not less than 72 h after application, and comparing with the surface hardness similarly determined on a similar specimen that has been moist cured for one half the time. Any softening of the treated surface shall be considered sufficient cause for rejection of the compound.

5.5.1 Testing for deleterious reactions is not needed on a routine basis. However, it must be done when testing compounds of a new or unknown composition.

5.6 Liquid membrane-forming compounds shall be storable for at least 6 months without deterioration. Compounds of the water emulsion type shall not be exposed to freezing. Type II liquid membrane-forming compounds shall be capable of being mixed to a uniform consistency by stirring or agitation. When tested for long term settling, as is stated in 8.4, the compound shall have a rating of not less than 4.

6. Specific Characteristics

6.1 *Water Retention*—Liquid membrane-forming compounds, when tested in accordance with 8.1 shall restrict the loss of water to not more than 0.40 kg/m^2 in 72 h.

6.2 *Reflectance*—Type II liquid membrane-forming compounds, when tested in accordance with 8.2 shall exhibit a daylight reflectance of not less than 65 %. Reflectance properties are only for white pigmented materials.

6.3 *Drying Time*—Liquid membrane-forming compounds, when tested in accordance with 8.3 shall dry to touch in not more than 4 h.

6.4 *Ultraviolet Light (UV) Degradation-Yellowing*— When tested in accordance with 8.7.6, compounds shall be durable and remain as a complete film, free of blisters, peeling, or flaking on the surface of the mortar panel.

6.4.1 Class A Type I or Type II compounds shall have a color equal to or lighter than Gardner Color Standard No. 1 when tested in accordance with 8.7.6.

6.4.2 Class B Type I or Type II compounds shall have a color equal to or lighter than Gardner Color Standard No. 3 when tested in accordance with 8.7.6.

6.4.3 Class C shall not be tested for yellowing.

6.5 *Acid and Alkali Resistance*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:33:05 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.5.1 The cured membrane, when tested in accordance with 8.7.7 for 48 h, shall not pin-hole, blister or disintegrate.

6.6 *Adhesion*—This requirement is to assure that the product being specified does not reduce the bonding effectiveness of adhesives commonly used to adhere flooring materials such as ceramic tile, resilient tile, wood flooring and carpet to concrete.

6.6.1 When tested in accordance with 8.8, surfaces coated with the membrane-forming compound shall pass the performance requirement of 8.8.5.

7. Sampling

7.1 Samples shall be taken either at the plant or warehouse prior to delivery, or at the point of delivery, at the option of the purchaser. If sampling is done prior to shipment, the inspector representing the purchaser shall have free access to the materials being sampled and shall be afforded all reasonable facilities for inspection and sampling.

7.2 Thoroughly shake or stir liquid membrane-forming compounds before taking a sample. Take one sample for each lot, batch, or other unit of production in a shipment. If the liquid membrane-forming compound is in mixing tanks or vats, one third of the sample shall represent the material coming from the tank at the beginning of the filling operation, one third shall represent the material coming at the middle of the filling operation, and one third shall represent the material coming at the end of the filling operation. If the liquid membrane-forming compound to be sampled is in containers, obtain a sample by taking a portion out of a number of containers equal in number to the next integer larger than the cube root of the total number of containers in the lot.

7.3 Seal all of the filled containers represented by the sample to prevent leakage, substitution or dilution. The sampling agency shall mark each container represented by the sample with a suitable identification mark for later identification and correlation.

8. Test Methods

8.1 *Water Retention Test*—Perform as per Test Method C 156. Unless otherwise specified by the manufacturer, use an application rate of 7.4 m^2/L (300 ft^2/gal) for Type I compounds and 5.0 m^2/L (200 ft^2/gal) for Type II compounds.

8.2 *Reflectance Test*—Using Test Method E 1347, determine the daylight reflectance of Type II membrane-forming compound on a mortar specimen after completion of the water retention test.

8.3 *Drying Time Test*:

8.3.1 *Scope*—This test method is used to determine the length of time for a liquid membrane-forming curing compound to dry to the touch.

8.3.2 *Significance and Use*—The ability of a liquid membrane-forming compound to dry in a suitable length of time enables the user the ability to perform other tasks on the concrete, such as sawing joints, and the like without lifting the membrane from the concrete by tracking.

8.3.3 *Procedure*—Apply the membrane-forming compound to a fresh mortar specimen at the specified rate of application and expose it to air at 23 ± 2 °C (73 ± 4 °F), 50 ± 10 % relative humidity and at an air velocity of approximately 180 m/min (600 ft/min) horizontally across the surface of the test specimen. Test the film with a finger using moderate pressure. Consider the film to be dry when the soft tacky condition no longer exists and the film feels firm.

8.3.4 *Precision and Bias*—The precision of the procedure for measuring the drying time of liquid membrane-forming compounds is being determined. The test method has no bias because there is not any acceptable reference material.

8.4 *Long Term Settling Test*—Use Test Method D 1309 for routine testing. In the case of dispute, use Test Method D 869.

8.5 *Solids Test (Type I)*—Test in accordance with Test Method D 2369.

8.6 *Vehicle Solids Test (Type II)*— Determine total nonvolatile content in accordance with Test Method D 2369, and pigment solids in accordance with Test Method D 2371 for solvent-borne products or Test Method D 3723 for water-borne products. Calculate percent vehicle solids as percent total solids minus percent pigment solids.

NOTE 7—This procedure is not satisfactory for water-borne products containing organic colorants or filler, or pigments which dehydrate or decompose below 230 °C (450 °F).

8.7 *UV Degradation, Yellowing, Acid, and Alkali Resistance*:

8.7.1 *Scope*—This procedure is used to evaluate the resistance of the membrane to the effects of UV radiation, acid, and alkali.

8.7.2 *Significance and Use*—Curing membranes are exposed to water and alkali in concrete and frequently are subjected to ultraviolet light, any or all of which can degrade some polymers. These tests are used to evaluate durable membranes. Polymers used in formulations to comply with these requirements are alkali and acid resistant and adhere well to concrete surfaces. As such, they are suitable for use under many latex and alkyd base paints and do not interfere with the adhesion of most resilient floor coverings, parquet wood floors, carpets or carpet tiles. The compounds are also suitable for sealing and protecting exterior concrete surfaces against the intrusion of water and some chemicals.

8.7.3 *Materials*—Five mortar panels, prepared as directed in Practice D 1734, 5 % aqueous sodium hydroxide by mass, 10 % aqueous hydrochloric acid by mass, and watch glasses.

8.7.4 *Equipment*—as described in Practice G 154, with UV-A 340 light source.

8.7.5 *Preparation of Specimens*—Coat five mortar panels at the rate of 7.4 m^2/L (300 ft^2/gal) and allow to dry for at least 24 h.

8.7.6 *Yellowing Resistance*:

8.7.6.1 Expose three of the panels for 336 h (2 weeks) in accordance with Practice G 154 with a test cycle consisting of alternating periods of 8 h UV radiation at 60 °C (140 °F) and 4 h condensation at 50 °C (122 °F).

8.7.6.2 *Interpretation of Results*—Compare the panels after the test period to the color of the Gardner Color Standards of Test Method D 1544. Report the results as lighter, the same, or darker than the designated color. Also report if the membrane was damaged or destroyed during the test.

8.7.7 *Alkali and Acid Resistance*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:33:05 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.7.7.1 *Procedure*—Test the cured membrane on two panels as directed in Test Method D 1308 using the covered spot test method and 5 % aqueous sodium hydroxide solution on one panel and 10 % aqueous hydrochloric acid solution on the other panel.

8.7.7.2 *Interpretation of Results*—Report whether the membranes pinhole, disintegrate, blister or discolor.

8.7.7.3 *Precision and Bias*—No information is presented about the precision or bias of this test method since the result is non-quantitative.

8.8 *Adhesion*:

8.8.1 *Scope*—This test is used to determine if the membrane formed by the product being tested is compatible with tile adhesives of the types listed in 8.8.3.3 or other types as agreed upon between supplier and purchaser.

8.8.2 *Significance and Use*—Durable curing and sealing membranes are used to promote surface strength and prevent dusting of concrete. The subsequent adhesion of topcoats such as tile adhesives is sometimes affected positively or adversely by the membrane. This test method evaluates the bonding between the membrane and an adhesive.

8.8.3 *Apparatus*:

8.8.3.1 *Mortar Panels*—Three mortar panels for each adhesive to be tested, prepared according to Practice D 1734[4] (the test is run in triplicate).

8.8.3.2 *Test Apparatus* as described in Annex A2 of Test Method D 4541 with a 40-mm (1 9⁄16-in.) loading fixture (available from the manufacturer). (See Note 8.)

NOTE 8—The usual apparatus employs a 20-mm loading fixture. The 40-mm fixture permits measurements in the low range of forces required.

8.8.3.3 *Adhesives*—Ceramic tile adhesive shall meet the requirements of ANSI A136.1–1992. Adhesives for other systems shall be of a type recommended for the installation of materials of interest over concrete. No product specifications are currently in force for these other adhesives.

8.8.4 *Procedure*—For each adhesive to be tested, coat three mortar panels with the membrane-forming curing compound under test at the specified application rate and allow to dry 72 h at 23 ± 2 °C (73.5 ± 3.5 °F) 50 ± 10 % relative humidity. Apply the adhesive on each panel at the rate specified by the manufacturer to a 40-mm (1 9⁄16-in.) diameter area, affix the loading fixture, allow the adhesive to cure in accordance with the manufacturer's instructions, and determine the pull-off strength in accordance with Test Method D 4541. (See Note 9.)

NOTE 9—Pull-off strength results obtained using devices other than specified in Annex A2 of Test Method D 4541 may be different because the results depend on parameters of the specific test instrument.

8.8.5 *Interpretation of Results*—This test is a pass/fail determination. If the measured pull-off strength is greater than 0.50 MPa (70 psi) in at least two thirds of the trials, the membrane passes.

8.8.5.1 If the measured pull-off strength is less than 0.50 MPa (70 psi), examine the failure surface to determine if failure occurred in the adhesive/membrane bond or at other interfaces. Estimate the percent of adhesive and cohesive failure in accordance to their respective areas and locations within the test system.

8.8.5.2 The test system is described as consisting of: substrate (A, the mortar specimen); the coating under test (B, a C 1315 liquid membrane-forming curing compound); the adhesive (Y, e.g. tile or carpet adhesive); and the pull-off fixture (Z).

8.8.5.3 Designate cohesive failures by the layers within which they occur as A, B, or Y, and the percent of each.

8.8.5.4 Designate adhesive failures by the interfaces at which they occur as A/B, B/Y, or Y/Z, and the percent of each.

8.8.5.5 A result that is very different from most of the results, caused by a mistake in recording or calculating, or by circumstances involved in preparation of the test specimens, shall be dropped from the analysis of the test. Valid reasons for dropping results include misalignment of the apparatus, improper application of the adhesive, voids or inclusions in the adhesive and sliding or twisting the fixture during the cure of the adhesive.

8.8.5.6 Disregard any test where failure in the adhesive (Y), failure of the bond (Y/Z), or both represents more than 50 % of the area. If all tests result in failure of the adhesive (Y or YZ) at less than 0.50 MPa (70 psi) repeat the evaluation using a different adhesive. (See Note 10.)

NOTE 10—To avoid results of this type, an adhesive can be tested between two pull-off fixtures to establish its inherent pull-off strength prior to running the material evaluation.

8.8.5.7 If more than 20 % of the failure occurs in B, A/B and B/Y at less than 0.50 MPa (70 psi), the membrane is suspect and the trial fails.

8.8.6 *Precision and Bias*—Precision is being determined. The test method for measuring adhesion has no bias because the value of adhesion is defined only in terms of this test method.

9. Packaging and Package Marking

9.1 The liquid membrane-forming compound shall be delivered in the manufacturer's original, clean, and sealed containers. The manufacturer shall ensure that material in all containers is representative of the compound produced. Each container shall be marked with:

9.1.1 The name of the manufacturer,

9.1.2 The trade name of the compound,

9.1.3 The ASTM designation and type of compound,

9.1.4 The nominal percentage of nonvolatile material (Note 11), and

9.1.5 The manufacturer's lot or batch designation.

NOTE 11—The listing of the nominal percentage of nonvolatile materials by the manufacturer, and the reporting of this information on the identification accompanying the sample, will enable the testing agency to determine whether the compound in the containers was adequately stirred and the sample is reasonably representative of the membrane-forming compound produced. Type II membrane-forming compounds are especially prone to separation due to settling of the pigment.

[4] The sole commercial source of supply of the mortar panels known to the committee at this time is Masonry Test Block Company, 6389 Lawndale, Saginaw, MI 48004. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee [1], which you may attend.

10. Keywords

10.1 acid resistance; adhesion promoting; alkali resistance; curing compounds; liquid membrane-forming compounds; sealers; yellowing resistance

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1315 – 07, that may impact the use of this specification. (Approved March 1, 2008)

(*1*) Revised paragraph 8.1.

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1315 – 06, that may impact the use of this specification. (Approved June 1, 2007)

(*1*) Added new paragraph 1.4.

(*2*) Deleted old paragraphs 5.7 and 8.7, and old Footnote 4.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1318 – 95 (Reapproved 2009)ε1

Standard Test Method for Determination of Total Neutralizing Capability and Dissolved Calcium and Magnesium Oxide in Lime for Flue Gas Desulfurization (FGD)[1]

This standard is issued under the fixed designation C 1318; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—A units statement was added editorially as new paragraph 1.4 and subsequent paragraphs were renumbered in June 2009.

1. Scope

1.1 This test method covers analysis of magnesian, dolomitic and high-calcium limes for total neutralizing capability and dissolved major oxides. Dissolved calcium and magnesium are the major species that neutralize acid under the conditions of the test.

1.2 The test conditions are chosen to measure the acid-neutralizing capacity of both calcium hydroxide and magnesium hydroxide contained in slaked lime. By controlling the neutralization pH at 6, magnesium hydroxide and magnesium oxide are titrated in addition to calcium hydroxide fraction.

1.3 This test method also determines the fraction of Mg ions present in the lime that will dissolve under lime flue gas desulfurization (FGD) conditions. Because the Mg^{++} ion alters FGD performance, it is important to know its concentration.

1.4 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

3. Terminology

3.1 *Definitions*—Unless otherwise specified, for definitions of terms used in these test methods refer to Terminology C 51.

4. Summary of Test Method

4.1 Lime is slaked by boiling and is reacted with acid at a pH and residence time similar to those found in full-scale FGD reaction tanks.

4.2 A sample of lime is titrated with 1N hydrochloric acid, maintaining a pH of 6 for 30 min. After 30 min, the acid consumption is recorded. The total neutralizing capacity is calculated from the acid consumption and reported as CaO. Dissolved magnesium is determined by atomic absorption spectrometry or by EDTA titration and reported as percent dissolved Magnesium Oxide (as MgO).

5. Significance and Use

5.1 There are existing lime-based flue gas desulfurization units in operation that require a method to measure the oxides available for sulfur dioxide absorption. Dissolved magnesium oxide varies among limes depending on the limestone sources and calcination conditions.

6. Interferences

6.1 Any substance reacting with acid under the conditions of the test will contribute to the total oxide and dissolved oxide values.

[1] This test method is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.05 on Chemical Tests.

Current edition approved June 1, 2009. Published September 2009. Originally approved in 1995. Last previous edition approved in 2001 as C 1318 – 95(2001).

www.technobetar.ir

6.2 Magnesium in forms other than MgO, which dissolve under test conditions, may affect the dissolved MgO and total oxide value.

7. Apparatus

7.1 *Digital Readout pH Meter*, with combination electrode readable to 0.01 pH units, or an autotitrator with an automatic temperature compensator capable of titrating to a preset endpoint (Note 1).

NOTE 1—Use of an automatic titrator is recommended.

7.2 *Stirrers and Stir Bars*.

7.3 *Atomic Absorption Spectrometer*, if not using EDTA titration.

7.4 *Filtering Funnel*, Type AE glass fiber paper, volumetric flasks (size as needed), 500 mL volumetric flasks, and various Class A pipettes.

8. Reagents

8.1 *1.0 Normal Hydrochloric Acid*, standardize using procedures in Test Methods C 25, Section 28.

8.2 *Distilled Water*, CO_2 free.

8.3 *Calcium and Magnesium Standard Solutions* (commercially available or use methods in Test Methods C 25, Section 31).

8.4 *EDTA Standard Solution* (0.4 %), standardize according to Test Methods C 25, Section 31.5, Standardization of EDTA.

9. Sample Preparation

9.1 The sampling and grinding of any lime sample shall be carried out as rapidly as possible, so that the absorption of moisture and carbon dioxide is held to a minimum.

9.2 The sample as received at the laboratory shall be thoroughly mixed and a representative sample with minimum weight of 100 g shall be taken and pulverized to pass a No. 50 mesh sieve for analysis.

9.3 The prepared sample shall be stored in a tightly capped container.

10. Procedure

10.1 *Slaking of Lime Sample*:

10.1.1 Weigh rapidly 1.402 g of the finely pulverized sample and brush carefully into a 250 mL Erlenmeyer flask containing about 50 mL of CO_2 free water and immediately stopper the flask.

10.1.2 Remove the stopper. Swirl the flask, place on a hot plate and boil actively 1 min for complete slaking. Remove from the hot plate, stopper the flask loosely and place in a cold-water bath to cool to room temperature.

10.2 *Titration of Sample*:

10.2.1 Set the pH electrode, burette tip, and temperature sensing device in place, while maintaining agitation.

10.2.2 Begin the titration by adding standard 1.0 normal hydrochloric acid solution. Titrate to and maintain a pH of 6 within 0.4 pH units for 30 min (Note 2). Time begins from initial addition of acid.

NOTE 2—When doing a manual titration, the increment of acid addition may require the use of partial drops (suspend a small amount of titrant on the buret tip and wash into the titration flask with CO_2 free distilled water) to avoid exceeding the 0.4 unit limit of pH 6.

10.2.3 Record the amount of acid consumed after 30 min.

10.2.4 Filter the solution and rinse the flask thoroughly with CO_2 free distilled water.

10.2.5 Carefully transfer the solution to an appropriately sized volumetric flask, add approximately 10 mL of 1:1 hydrochloric acid, and dilute to volume.

10.3 *Determination of Dissolved Oxides*:

10.3.1 *Atomic Absorption*:

10.3.1.1 From the diluted solution make the required dilutions and determine the dissolved magnesium by standard atomic absorption spectroscopy techniques.

10.3.1.2 Calculate the dissolved magnesium as MgO according to 11.2.

10.3.2 *EDTA Titration*:

10.3.2.1 From the diluted solution pipette 20 mL of sample into a 500 mL Erlenmeyer flask and dilute with CO_2 free distilled water to an approximate volume of 100 mL.

10.3.2.2 Determine the total dissolved calcium according to Test Methods C 25, Paragraph 31.6.4. Record mL of EDTA required for titration.

10.3.2.3 Repeat 10.3.2 and determine the total dissolved oxides according to Test Methods C 25, Paragraph 31.6.5. Record mL of EDTA required for this titration.

11. Calculation of Results

11.1 *Percent Total Neutralizing Capability (TNC)*:

$$\%\ TNC\ (\text{as CaO}) = \frac{A \times B \times C_1}{W} \quad (1)$$

where:

A = mL HCl used in 10.2.3,
B = normality HCl,
C_1 = chemical factor = 2.804 (mequi of CaO/10), and
W = sample weight, g.

11.2 *Atomic Absorption*:

11.2.1 *Dilution Factor*:

$$\text{Dilution factor} = \text{Initial Volume (see 10.2.5)/Pipette volume for final dilution} \quad (2)$$

11.2.2 *Percent Dissolved Magnesium*:

$$\%\ \text{Dissolved Mg++ (as MgO)} = \frac{A \times B \times C_2 \times D}{W \times 1000} \quad (3)$$

where:

A = concentration of magnesium from AA, ppm Mg^{++},
B = dilution factor,
C_2 = chemical factor = 1.658 (MgO/Mg^{++}),
D = final dilution volume, mL, and
W = sample weight, g.

11.3 *EDTA Titration*:

11.3.1 *Dilution Factor*:

$$\text{Dilution factor} = \text{Initial Volume (see 10.2.5)/titration volume (20 mL)} \quad (4)$$

11.3.2 *Percent Dissolved Calcium*:

$$\%\ \text{Dissolved Ca++ (as CaO)} = \frac{A \times B \times C_3 \times D}{W \times 10} \quad (5)$$

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:33:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

where:
A = mL of EDTA standard solution used,
B = dilution factor,
C_3 = chemical factor = 1.399 (CaO/Ca^{++}),
D = EDTA titer, mg Ca^{++}/mL EDTA, and
W = sample weight, g.

11.3.3 *Percent Total Dissolved Oxides (TDO)*:

$$\%\ TDO\ (\text{as CaO}) = \frac{A \times B \times C_3 \times D}{W \times 10} \quad (6)$$

where:
A = mL of EDTA standard solution used,
B = dilution factor,
C_3 = chemical factor = 1.399 (CaO/Ca^{++}),
D = EDTA titer, mg Ca^{++}/mL EDTA, and
W = sample weight, g.

11.3.4 *Percent Dissolved Magnesium*:

$$\%\ \text{Dissolved Mg++ (as MgO)} = (A - B) \times C_4 \quad (7)$$

where:
A = % total dissolved oxides,
B = % dissolved calcium, and
C_4 = chemical factor = 0.7188 (MgO/CaO).

12. Precision and Bias

12.1 The precision and bias of this test method have not been determined.

12.2 When sufficient data has been obtained and analyzed, a statement of precision will be provided.

12.3 The user is cautioned to verify by the use of reference materials, if available, that the bias of the test method is adequate for the contemplated use.

13. Keywords

13.1 dissolved calcium; dissolved magnesium; flue gas desulfurization (FGD); lime; pH determination; total neutralizing capability

Designation: C 1328 – 05

Standard Specification for Plastic (Stucco) Cement[1]

This standard is issued under the fixed designation C 1328; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers two types of plastic cement for use in portland cement-based plasters for exterior (stucco) and interior application.

1.2 The values stated in SI units are to be regarded as the standard. Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units.

1.3 The text of this standard refers to notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 The following safety hazards caveat pertains only to Sections 14 and 15. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

C 1506 Test Method for Water Retention of Hydraulic Cement-Based Mortars and Plasters

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI) (the Modernized Metric System)

3. Terminology

3.1 *Definitions*—Terms used in this specification are defined in Terminology C 219 and Specification C 926.

3.2 *Definition of Term Specific to This Standard:*

3.2.1 *plastic cement*—a hydraulic cement, primarily used in portland cement-based plastering construction, consisting of a mixture of portland or blended hydraulic cement and plasticizing materials (such as limestone or hydrated or hydraulic lime), together with other materials introduced to enhance one or more properties such as setting time, workability, water retention, and durability.

3.2.1.1 *Discussion*—The term "plastic" does not refer to the inclusion of one or more organic components in the cement. The cement is predominantly inorganic in chemical composition. The term "plastic" refers to the ability of the cement to impart to the plaster a high degree of workability, and for the

[1] This specification is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.11 on Masonry Cement.

Current edition approved September 15, 2005. Published October 2005. Originally approved in 1996. Last previous edition approved in 2003 as C 1328 – 03a.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

plaster to remain workable or plastic for a period of time so that, after initial application and floating on the wall, it can be reworked to obtain both densification and desired texture.

4. Physical Properties

4.1 Plastic cement shall conform to the applicable requirements prescribed in Table 1.

5. Sampling

5.1 At the option of the purchaser, the cement shall be sampled and tested to verify compliance with this specification, sampling and testing shall be performed in accordance with Practice C 183.

5.2 Practice C 183 is not designed for manufacturing quality control and is not required for manufacturer's certification.

6. Temperature and Humidity

6.1 The temperature and relative humidity of the air in the vicinity of the mixing slab and dry materials, molds, base plates, and mixing bowl shall conform to the requirements of Test Method C 109/C 109M.

6.2 The moist cabinet or moist room shall conform to the requirements of Specification C 511.

7. Fineness

7.1 Determine the residue on the 45-μm (No. 325) sieve in accordance with Test Method C 430.

8. Normal Consistency

8.1 Determine normal consistency by the Vicat apparatus in accordance with Test Method C 187.

9. Autoclave Expansion

9.1 Determine the autoclave expansion in accordance with Test Method C 151. After molding, store the bars in the moist cabinet or room for 48 h ± 30 min before removal from the molds for measurement and testing in the autoclave. Calculate the difference in length of the test specimen before and after autoclaving to the nearest 0.01 % of the effective gage length, and report as the autoclave expansion of the plastic cement.

10. Time of Setting

10.1 Determine the time of setting by the Gillmore needle method in accordance with Test Method C 266.

11. Density

11.1 Determine the density of the plastic cement in accordance with Test Method C 188, using kerosine as the liquid. Use the density so determined in the calculation of the air content of the plaster.

12. Blended Sand

12.1 The sand shall be a blend of equal parts by weight of graded standard sand and standard 20–30 sand conforming to Specification C 778.

13. Preparation of Plaster

13.1 *Proportions for Plaster*—Plaster for air entrainment, compressive strength, and water retention tests shall be proportioned to contain 1620 g of sand and a mass of cement, in grams, as indicated in Table 2. The sand shall consist of 810 g of graded standard sand and 810 g of 20–30 standard sand (Note 1). The quantity of water, measured in millilitres, shall be such as to produce a flow of 110 ± 5, as determined by Test Method C 109/C 109M.

NOTE 1—Historically, field-mixed plaster has been proportioned by volume measured in increments or fractions of 1 ft^3. The comparable whole SI-unit volume to 1 ft^3 is 28 L. The specified plaster proportions approximate the 1:3 nominal proportions by volume, commonly specified for construction, on the basis of the following assumed mass and volume relationships:

The mass of dry sand in 28 L of loose damp sand is 36 k.
28 L of Type S Plastic (Stucco) cement has a mass of 35 kg.
28 L of Type M Plastic (Stucco) cement has a mass of 42 kg.

For example, the amount of cement needed to provide a 1:3 volume proportion of cement to sand using a Type S Plastic (Stucco) cement is:

TABLE 1 Physical Requirements

Plastic Cement Type	S	M
Fineness, residue on a 45-μm (No. 325) sieve, max,%	24	24
Autoclave expansion, max, %	1.0	1.0
Time of setting, Gillmore method:		
Initial set, minutes, not less than	90	90
Initial set, minutes, not more than	1000	1000
Compressive strength (average of three cubes):		
The compressive strength of mortar cubes, composed of 1 part cement and 3 parts blended sand (half graded standard sand and half standard 20–30 sand) by volume, prepared and tested in accordance with this specification, shall be equal to or higher than the values specified for the ages indicated below:		
7 days, MPa (psi)	9.0 (1300)	12.4 (1800)
28 days, MPa (psi)	14.5 (2100)	20.0 (2900)
Air content of mortar:		
Min, volume%	8	8
Max, volume %	20	20
Water retention value, min, %, of original flow	70	70

www.technobetar.ir

TABLE 2 Cement in Laboratory Batch of Plastic

Plastic (Stucco) Cement Type	Mass of Cement, g
S	525
M	630

$$A = 1620 \times (C/B) = 1620 \times (35/108) = 525 \quad (1)$$

where:

A = number of grams of cement to be used in the mortar with 1620 g of sand,
B = $3 \times 36 = 108$ kg, the mass of dry sand in 84 (or 3×28) L of loose damp sand, and
C = mass of Type S Plastic (Stucco) cement per 28 L.

13.2 *Mixing of Plasters*—Mix the plaster in accordance with Practice C 305.

13.3 *Determination of Flow*—Determine the flow in accordance with Test Method C 109/C 109M.

14. Air Entrainment

14.1 *Procedure*—If the plaster has the correct flow, use a separate portion of the plaster for the determination of entrained air. Determine the mass of 400 mL of plaster in accordance with Test Method C 185.

14.2 *Calculation*—Calculate the air content of the plaster, and report it to the nearest 1 % as follows:

$$D = (W_1 + W_2 + V_w)/[(W_1/S_1) + (W_2/S_2) + V_w] \quad (2)$$

$$A = 100 - (W_m/4D)$$

where:

D = density of air-free plaster, g/cm^3,
W_1 = mass of cement, g,
W_2 = mass of sand, g,
V_w = mL-g of water used,
S_1 = density of cement, g/cm^3,
S_2 = density of standard sand, 2.65 g/cm^3,
A = volume percent of entrained air, and
W_m = mass of 400 mL of plaster, g.

15. Compressive Strength

15.1 *Test Specimens*:

15.1.1 *Molding*—Immediately after determining the flow and mass of 400 mL of plaster, return all of the plaster to the mixing bowl and remix for 15 s at the medium speed. Then mold the test specimens in accordance with Test Method C 109/C 109M, except that the elapsed time for mixing plaster, determining flow, determining air entrainment, and starting the molding of cubes shall be within 8 min.

15.1.2 *Storage*—Immediately after molding, store all test specimens in the molds on plane plates in a moist cabinet or moist room for 48 to 52 h in such a manner that the upper surfaces shall be exposed to the moist air. Then remove the cubes from the molds, and place them in the moist cabinet or moist room for 5 days in such a manner as to allow free circulation of air around at least five faces of the specimens. At the age of 7 days, immerse the cubes for the 28-day tests in saturated lime water in storage tanks of noncorrodible materials.

15.2 *Procedure*:

15.2.1 Test the cube specimens immediately after their removal from the moist cabinet or moist room for 7-day specimens, and immediately after their removal from storage water for all other specimens. If more than one specimen at a time is removed from the moist cabinet or moist room for 7-day tests, cover these cubes with a damp cloth until the time of testing.

15.2.2 The remainder of the testing procedure shall conform to Test Method C 109/C 109M.

16. Water Retention

16.1 Water retention shall be determined in accordance with the procedures in Test Method C 1506, except wherever the term "mortar" is used, read "plaster."

17. Storage

17.1 The cement shall be stored in such a manner as to permit easy access for the proper inspection and identification of each shipment, and in a suitable weathertight building that will protect the cement from dampness and minimize warehouse set.

18. Inspection

18.1 Adequate facilities shall be provided to the purchaser for the necessary inspection and sampling.

18.2 All packages shall be in good condition at the time of inspection.

19. Rejection

19.1 At the option of the purchaser, the cement shall be rejected if it fails to meet any of the requirements of this specification.

19.2 At the option of the purchaser, packages more than 2 % below the mass marked thereon shall be rejected. At the option of the purchaser, the entire shipment represented shall be rejected if the average mass of packages in any shipment as shown by weighing 50 packages taken at random is less than that marked on the packages.

19.3 At the option of the purchaser, cement remaining in storage prior to shipment for a period greater than six months after testing shall be retested and, at the option of the purchaser, shall be rejected if it fails to meet any of the requirements of this specification.

20. Manufacturer's Certification

20.1 Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at the time of shipment stating the results of the tests made on samples of the material taken during production or transfer and certifying that the applicable requirements of this specification have been met.

21. Packaging and Package Marking

21.1 When plastic cement is delivered in packages, the brand, name of the manufacturer, net mass of the package in kg (see Note 2) shall be indicated plainly thereon. Similar information shall be provided in the shipping documents accompanying the shipment of plastic cement in bulk.

NOTE 2—To facilitate the change to SI units, a standard SI package size

Designation: C 1329 – 05

Standard Specification for Mortar Cement[1]

This standard is issued under the fixed designation C 1329; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers three types of mortar cement for use where mortar for masonry is required.

1.2 The values stated in SI units are to be regarded as the standard. Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units.

1.3 The text of this standard refers to notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 The following safety hazards caveat pertains only to Section 16. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C 778 Specification for Standard Sand

C 1357 Test Methods for Evaluating Masonry Bond Strength

C 1506 Test Method for Water Retention of Hydraulic Cement-Based Mortars and Plasters

IEEE/ASTM SI 10 Standard for Use of the International System of Units (SI): The Modern Metric System

3. Terminology

3.1 *Definitions*—Terms used in this specification are defined in Terminology C 219.

3.2 *Definition of Term Specific to This Standard:*

3.2.1 *mortar cement*—a hydraulic cement, primarily used in masonry construction, consisting of a mixture of portland or blended hydraulic cement and plasticizing materials (such as

[1] This specification is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.11 on Masonry Cement.

Current edition approved September 15, 2005. Published October 2005. Originally approved in 1996. Last previous edition approved in 2004 as C 1329 – 04.

[2] *Annual Book of ASTM Standards*, Vol 04.01. See the section on Safety Precautions in the Manual of Cement Testing.

[3] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

limestone or hydrated or hydraulic lime), together with other materials introduced to enhance one or more properties such as setting time, workability, water retention, and durability.

3.2.1.1 *Discussion*—Mortar cement is similar to masonry cement in use and function (See Specification C 91). However, this specification requires lower air contents and includes a flexural bond strength requirement.

4. Classification

4.1 Mortar cements are classified as Type N, S, or M, according to the physical requirements prescribed in Table 1.

5. Physical Properties

5.1 Mortar cement shall conform to the applicable requirements prescribed in Table 1 for its classification.

6. Sampling

6.1 At the option of the purchaser, the cement shall be sampled and tested to verify compliance with this specification, sampling and testing shall be performed in accordance with Practice C 183.

6.2 Practice C 183 is not designed for manufacturing quality control and is not required for manufacturer's certification.

7. Temperature and Humidity

7.1 The temperature and relative humidity of the air in the vicinity of the mixing slab and dry materials, molds, base plates, and mixing bowl shall conform to the requirements of Test Method C 109/C 109M.

7.2 The moist cabinet or moist room shall conform to the requirements of Specification C 511.

8. Fineness

8.1 Determine the residue on the 45-μm (No. 325) sieve in accordance with Test Method C 430.

9. Normal Consistency

9.1 Determine the normal consistency by the Vicat apparatus in accordance with Test Method C 187.

10. Autoclave Expansion

10.1 Determine the autoclave expansion in accordance with Test Method C 151. After molding, store the bars in the moist cabinet or room for 48 h ± 30 min before removal from the molds for measurement and testing in the autoclave. Calculate the difference in length of the test specimen before and after autoclaving to the nearest 0.01 % of the effective gage length, and report as the autoclave expansion of the mortar cement.

11. Time of Setting

11.1 Determine the time of setting by the Gillmore needle method in accordance with Test Method C 266.

12. Density

12.1 Determine the density of the mortar cement in accordance with Test Method C 188, using kerosine as the liquid. Use the density so determined in the calculation of the air content of the mortars.

13. Blended Sand

13.1 The sand shall be a blend of equal parts by weight of graded standard sand and 20–30 standard sand conforming to Specification C 778.

14. Preparation of Mortar

14.1 *Proportions for Mortar*—Mortar for air entrainment, compressive strength, and water retention tests shall be proportioned to contain 1620 g of sand and a mass of cement, in grams, as indicated in Table 2. The sand shall consist of 810 g of graded standard sand and 810 g of 20-30 standard sand (Note 1). The quantity of water, measured in millilitres, shall be such as to produce a flow of 110 ± 5 as determined by Test Method C 109/C 109M.

NOTE 1—Historically, field-mixed mortar has been proportioned by volume measured in increments or fractions of 1 ft^3. The comparable whole SI-unit volume to 1 ft^3 is 28 L. The specified mortar proportions approximate the 1:3 nominal proportions by volume, commonly specified for construction, on the basis of the following assumed mass and volume relationships:

The mass of dry sand in 28 L of loose damp sand is 36 kg.
28 L of Type N mortar cement has a mass of 32 kg.
28 L of Type S mortar cement has a mass of 34 kg.
28 L of Type M mortar cement has a mass of 36 kg.

For example, the amount of cement needed to provide a 1:3 volume proportion of cement to sand using a Type N mortar cement is calculated as follows:

TABLE 1 Physical Requirements

Mortar Cement Type	N	S	M
Fineness, residue on a 45-μm (No. 325) sieve, max, %	24	24	24
Autoclave expansion, max, %	1.0	1.0	1.0
Time of setting, Gillmore method:			
Initial set, minutes, not less than	120	90	90
Initial set, minutes, not more than	1000	1000	1000
Compressive strength (average of three cubes):			
The compressive strength of mortar cubes, composed of 1 part cement and 3 parts blended sand (half graded standard sand and half standard 20–30 sand) by volume, prepared and tested in accordance with this specification, shall be equal to or higher than the values specified for the ages indicated below:			
7 days, MPa (psi)	3.5 (500)	9.0 (1300)	12.4 (1800)
28 days, MPa (psi)	6.2 (900)	14.5 (2100)	20.0 (2900)
Flexural bond strength			
28 days, min, MPa (psi)	0.5 (70)	0.7 (100)	0.8 (115)
Air content of mortar:			
Min, volume %	8	8	8
Max, volume %	17	15	15
Water retention value, min, %, of original flow	70	70	70

www.technobetar.ir

TABLE 2 Cement in Laboratory Batch of Mortar

Mortar Cement Type	Mass of Cement, g
N	480
S	510
M	540

$$A = 1620 \times (C/B) = 1620 \times (32/108) = 480 \quad (1)$$

where:

A = number of grams of cement to be used in the mortar with 1620 g of sand,
B = 3 × 36 = 108 kg, the mass of dry sand in 84 (or 3 × 28) L of loose damp sand, and
C = mass of Type N mortar cement per 28 L.

14.2 *Mixing of Mortars*—Mix the mortar in accordance with Practice C 305.

14.3 *Determination of Flow*—Determine the flow in accordance with Test Method C 109/C 109M.

15. Air Entrainment

15.1 *Procedure*—If the mortar has the correct flow, use a separate portion of the mortar for the determination of entrained air. Determine the mass of 400 mL of mortar in accordance with Test Method C 185.

15.2 *Calculation*—Calculate the air content of the mortar, and report it to the nearest 1 % as follows:

$$D = (W_1 + W_2 + V_w)/[(W_1/S_1) + (W_2/S_2) + V_w]A = 100 - (W_m/4D) \quad (2)$$

where:

D = density of air-free mortar, g/cm^3,
W_1 = mass of cement, g,
W_2 = mass of sand, g,
V_w = mL-g of water used,
S_1 = density of cement, g/cm^3,
S_2 = density of standard sand, 2.65 g/cm^3,
A = volume percent of entrained air, and
W_m = mass of 400 mL of mortar, g.

16. Compressive Strength

16.1 *Test Specimens*:

16.1.1 *Molding*—Immediately after determining the flow and mass of 400 mL of mortar, return all of the mortar to the mixing bowl and remix for 15 s at the medium speed. Then mold the test specimens in accordance with Test Method C 109/C 109M, except that the elapsed time for mixing mortar, determining flow, determining air entrainment, and starting the molding of cubes shall be within 8 min.

16.1.2 *Storage*—Immediately after molding, store all test specimens in the molds on plane plates in a moist cabinet or moist room for 48 to 52 h in such a manner that the upper surfaces shall be exposed to the moist air. Then remove the cubes from the molds, and place them in the moist cabinet or moist room for 5 days in such a manner as to allow free circulation of air around at least five faces of the specimens. At the age of 7 days, immerse the cubes for the 28-day tests in saturated lime water in storage tanks of noncorrodible materials.

16.2 *Procedure*:

16.2.1 Test the cube specimens immediately after their removal from the moist cabinet or moist room for 7-day specimens, and immediately after their removal from storage water for all other specimens. If more than one specimen at a time is removed from the moist cabinet or moist room for 7-day tests, cover these cubes with a damp cloth until the time of testing.

16.2.2 The remainder of the testing procedure shall conform to Test Method C 109/C 109M.

17. Water Retention

17.1 Water retention shall be determined in accordance with the procedures in Test Method C 1506.

18. Flexural Bond Strength

18.1 Flexural bond strength shall be determined in accordance with the test method for laboratory prepared specimens of Test Methods C 1357, except sand shall be a blend of equal mass of graded and standard 20-30 sand conforming to Specification C 778 and mortar shall be proportioned to contain mass of cement in kg equal to 0.20 times the net mass in kg printed on the bag and 22.0 kg of sand. The flexural bond strength of mortar cement shall be determined as the average gross area flexural bond strength of 30 joints minus 1.28 times the standard deviation of the sample.

19. Storage

19.1 The cement shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weathertight building that will protect the cement from dampness and minimize warehouse set.

20. Inspection

20.1 Adequate facilities shall be provided to the purchaser for the necessary inspection and sampling.

20.2 All packages shall be in good condition at the time of inspection.

21. Rejection

21.1 At the option of the purchaser, the cement shall be rejected if it fails to meet any of the requirements of this specification.

21.2 At the option of the purchaser, packages more than 2 % below the mass marked thereon shall be rejected. At the option of the purchaser, the entire shipment shall be rejected if the average mass of packages in any shipment, as shown by weighing 50 packages taken at random, is less than that marked on the packages.

21.3 At the option of the purchaser, cement remaining in storage prior to shipment for a period greater than six months after testing shall be retested and, at the option of the purchaser, shall be rejected if it fails to meet any of the requirements of this specification.

22. Manufacturer's Certification

22.1 Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at the time of

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:33:11 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

shipment stating the results of the tests made on samples of the material taken during production or transfer and certifying that the applicable requirements of this specification have been met.

23. Packaging and Package Marking

23.1 When mortar cement is delivered in packages, the brand, name of the manufacturer, type of mortar cement, and net mass of the package in kilograms (Note 2) shall be indicated plainly thereon. Similar information shall be provided in the shipping documents accompanying the shipment of mortar cement in bulk.

NOTE 2—To facilitate the change to SI units, a standard metric package size of 32 kg for Type N, 34 kg for Type S, and 36 kg for Type M will provide convenient mass increments reasonably similar to the traditional 70–, 75–, and 80–lb packages.

24. Keywords

24.1 flexural bond strength; masonry; mortar; mortar cement

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. Designation: C 1355/C 1355M – 96 (Reapproved 2006)

Standard Specification for Glass Fiber Reinforced Gypsum Composites[1]

This standard is issued under the fixed designation C 1355/C 1355M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers glass fiber reinforced gypsum (GRG) composites having minimum properties and quality suitable to allow the production of GRG parts for non-loading bearing, thin section, ornamental shapes for architectural embellishment of interior building construction.

1.2 The values stated in either inch-pound units or SI (metric) are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be independent of the other. Values from the two systems shall not be combined.

1.3 The text of this standard references footnotes which provide explanatory material. These footnotes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 472 Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete

C 473 Test Methods for Physical Testing of Gypsum Panel Products

C 947 Test Method for Flexural Properties of Thin-Section Glass-Fiber-Reinforced Concrete (Using Simple Beam With Third-Point Loading)

D 256 Test Methods for Determining the Izod Pendulum Impact Resistance of Plastics

D 578 Specification for Glass Fiber Strands

D 696 Test Method for Coefficient of Linear Thermal Expansion of Plastics Between -30°C and 30°C with a Vitreous Silica Dilatometer

D 2583 Test Method for Indentation Hardness of Rigid Plastics by Means of a Barcol Impressor

E 84 Test Method for Surface Burning Characteristics of Building Materials

E 136 Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C

3. Terminology

3.1 *Definitions:* Definitions of terms shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *GRG composite*, *n*—a thin section laminate made from the combination of alpha gypsum cement, glass fiber, additives and water.

3.2.2 *GRG part*, *n*—an individual molded component used as architectural embellishment.

4. Materials and Manufacture

4.1 *Materials*:

4.1.1 *Alpha Gypsum Cement*—Alpha-calcium sulfate hemihydrate-plaster which is noncombustible, has a low water demand, neutral (pH) or low alkalinity, and a purity of not less than 90 % by weight of $CaSO_4 \cdot 2H_2O$.

4.1.2 *"E" Glass Fiber*—Chopped glass fiber strands or continuous strand mats of calcia-alumina silicate glasses conforming to Specification D 578.

4.1.3 *Water*—Potable water.

4.1.4 *Additives*—In accordance with the alpha gypsum cement manufacturer's specifications.

4.2 *Manufacturer's Certification of Raw Materials*:

4.2.1 *Alpha Gypsum Cement*—Each lot of alpha gypsum cement shall be certified to be in compliance with 4.1 and 5.1.

4.2.2 *Glass Fiber Reinforcement*—Each lot of glass fiber reinforcement shall be certified to be in compliance with Specification D 578.

4.3 *Composite Preparation*:

4.3.1 Prepare a flat, rectangular composite of sufficient size to obtain specimens required in 5.2. The composite prepared shall be the same formula as the intended GRG part.

5. Mechanical Properties

5.1 *Neat Alpha Gypsum Cement*:

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved May 1, 2006. Published May 2006. Originally approved in 1996. Last previous addition approved in 2001 as C 1355/C 1355M – 96(2001).

www.technobetar.ir

5.1.1 Normal Consistency shall be not more than 30 when tested in accordance with Test Methods C 472.

5.1.2 Compressive Strength shall be not less than 6000 psi (41.4 MPa) when tested in accordance with Test Methods C 472.

5.1.3 Hardness shall be not less than 33 Barcol when tested in accordance with Test Method D 2583.

5.2 *Composite*:

5.2.1 *Specimen Preparation*

5.2.1.1 *Flexural Strength*—Average Flexural Yield (FY) shall be not less than 1200 psi (8.3 MPa) and an average Flexural Ultimate (FU) shall be not less than 2500 psi (17.2 MPa) when tested in accordance with Test Method C 947, using a crosshead speed of 0.08 in./min (2 mm/min). Specimens shall be conditioned to a constant weight in accordance with Test Methods C 473.

5.2.1.2 *Impact Resistance*—Average impact resistance shall be not less than 3 ft-lb (4 j) when tested in accordance with Test Methods D 256, Test Method A (Izod-unnotched method).

5.2.1.3 *Hardness*—Average hardness shall be not less than 50 Barcol when tested in accordance with Test Methods D 2583. Specimens shall be conditioned according to Test Methods C 473.

5.2.1.4 *Coefficient of Linear Thermal Expansion*—Coefficient of linear thermal expansion shall be not more than 11.1 $\times$ 10^{-6} in./in. °F (20.0 $\times$ 10^{-6} mm/mm °C) when tested in accordance with Test Method D 696.

5.2.1.5 *Humidified Deflection*—Average humidified deflection shall be not more than ⅛ in. (3 mm) when tested on a 3⁄16 in. specimen (5 mm) in accordance with Test Methods C 473.

5.2.1.6 *Surface Burning Characteristics*—Flame spread index shall be 0 and smoke developed index shall be less than 10 when tested in accordance with Test Method E 84.

5.2.1.7 *Behavior at 750 °C*—Shall pass all criteria when tested in accordance with Test Method E 136.

5.2.1.8 *Nail Pull Resistance*—Shall be not less than 110 lbf (489 N) when tested on a 3⁄16 in. specimen (5 mm) in accordance with Test Methods C 473 (Method B).

6. Samples Taken at the Point of Manufacture

6.1 When specified by the purchase agreement, samples of the GRG composite shall be taken at the place of manufacture and tested for compliance with 5.2.

7. Number of Tests and Retests

7.1 The number of tests and type of tests to be performed shall be part of the purchase agreement. Data from prior tests showing compliance with Section 5 are permitted to be supplied by the producer showing compliance with the specified requirements.

8. Inspection

8.1 Inspection of the GRG composite shall be agreed upon between the purchaser and the producer or the supplier as part of the purchase agreement.

9. Rejection and Rehearing

9.1 GRG composite that fails to conform to the requirements of this specification shall be reported to the producer or the supplier promptly and in writing. In case of dissatisfaction with the results of the test, the producer or supplier, shall be permitted to make a claim for a hearing to retest.

10. Certification

10.1 When specified in the purchase agreement, a producer's or supplier's report certifying that the GRG composite is in compliance with this specification, shall be furnished at the time of shipment.

11. Quality Assurance

11.1 Testing for compliance with this specification is required whenever glass fiber reinforced gypsum formulae are initially established.

11.2 Additional testing for compliance with this specification is required whenever constituent materials are added or deleted.

11.3 Each producer's test specimens shall be representative of actual production procedures and materials.

12. Keywords

12.1 alpha gypsum cement; glass fiber reinforced gypsum; glass fiber reinforced gypsum composite; GRG; GRG composite

Designation: C 1356 – 07

Standard Test Method for Quantitative Determination of Phases in Portland Cement Clinker by Microscopical Point-Count Procedure[1]

This standard is issued under the fixed designation C 1356; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers a systematic procedure for measuring the percentage volume of the phases in portland cement clinker by microscopy.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in SI units are to be regarded as the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 150 Specification for Portland Cement

C 219 Terminology Relating to Hydraulic Cement

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

D 75 Practice for Sampling Aggregates

D 3665 Practice for Random Sampling of Construction Materials

3. Terminology

3.1 *Definitions:*

3.1.1 *clinker phase*, *n*—a physically and chemically distinct optically identifiable portion of the clinker sample, including both principal phases (alite, belite, aluminate, and ferrite), minor phases (for example, free lime, periclase, and alkali sulfates), and voids.

3.1.1.1 *Discussion*—Voids, though not a phase in the sense of being a crystalline compound, are a distinct, identifiable portion of a clinker microstructure.

3.1.2 *voids*, *n*—isolated or interconnected open areas in the clinker, also called pores.

3.2 *Principal Clinker Phases:*[3]

3.2.1 *alite*, *n*—crystalline tricalcium silicate (C_3S), modified in composition and crystal structure by incorporation of foreign ions; the crystals are pseudo-hexagonal with well-defined faces, though less regular shapes commonly occur.

3.2.2 *aluminate*, *n*—tricalcium aluminate (C_3A) modified in composition and crystal structure by incorporation of a substantial proportion of foreign ions; aluminate forms cubic crystals when relatively pure, and forms identifiable elongated crystals commonly called "alkali aluminate" when in solid solution with significant amounts of potassium or sodium, or both.

3.2.3 *belite*, *n*—crystalline dicalcium silicate (C_2S), modified in composition and crystal structure by incorporation of foreign ions; belite usually occurs as rounded crystals marked by striations formed by cross sections of lamellae, and may occur as single crystals or in clusters.

3.2.4 *ferrite*, *n*—a solid solution of approximate composition tetracalcium aluminoferrite (C_4AF) modified in composition by variation in the Al/Fe ratio and by substantial incorporation of foreign ions; ferrite is characterized by high reflectivity in polished sections and is normally the only strongly colored compound among the principal clinker phases.

3.2.4.1 *Discussion*—Aluminate and ferrite form most of the interstitial material between the silicate crystals and, under certain conditions of cooling, may not be easily identifiable or resolved by ordinary light microscopy.

3.3 *Minor Clinker Phases:*

3.3.1 *alkali sulfates*, *n*—sodium sulfate, potassium sulfate, and double sulfates such as calcium langbeinite (K_2SO_4–$2CaSO_4$).

3.3.2 *free lime*, *n*—calcium oxide (C) found mostly as round crystals.

3.3.3 *periclase*, *n*—crystalline form of free magnesium oxide (M), that has not been taken up in solid solution with other phases.

3.4 For definitions of other terms relating to hydraulic cements, refer to Terminology C 219.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.23 on Compositional Analysis.

Current edition approved June 1, 2007. Published July 2007. Originally approved in 1996. Last previous edition approved in 2001 as C 1356 – 96(2001).

4. Summary of Test Method

4.1 The test method consists of the preparation and microscopical examination of a specimen produced by encapsulating clinker in a mounting medium and sectioning the specimen so as to expose the interior of particles for visual examination. Polishing the section surface and treating it with etchants to highlight specific phases complete the preparation. During microscopical examination phases are identified and their proportions determined by a point-count procedure. In this procedure, the specimen is moved in uniform increments on a microscope stage, and phases falling under the cross hairs of the eyepiece are identified and counted (**1-5**).

5. Significance and Use

5.1 This test method provides a relatively simple and reliable microscopical means of measuring the phase abundance of portland cement clinker (Note 1). Microscopical point counting provides a direct measure of the clinker phase composition in contrast to the calculated Bogue phase composition (Note 2).

NOTE 1—This test method utilizes a reflected light microscope. Related methods such as transmitted light microscopy, scanning electron microscopy, and automated imaging techniques may also be used for clinker analysis but are not presently included in this test method.

NOTE 2—This test method allows direct determination of the proportion of each individual phase in portland-cement clinker. This test method is intended to provide an alternative to the indirect estimation of phase proportion using the equations in Specification C 150 (footnote C in Table number 1 and footnote B in Table number 2).

5.2 This test method assumes the operator is qualified to operate a reflected light microscope and the required accessories, is able to correctly prepare polished sections and use necessary etchants, and is able to correctly identify the constituent phases.

5.3 This test method may be used as part of a quality control program in cement manufacturing as well as a troubleshooting tool. Microscopic characterization of clinker phases may also aid in correlating cement properties and cement performance in concrete, to the extent that properties and performance are a function of phase composition.

6. Apparatus

6.1 Reflected light microscope.

6.2 Mechanical stage with stepping increments ranging from 0.05 to 2.0 mm (to enable analysis of clinkers of different average crystal sizes) and vernier scales graduated in both X and Y directions.

6.3 Microscope objectives of magnification 5×, 10×, 20×, and 40× or other magnifications suitable for the task.

NOTE 3—The use of reflected light with oil immersion is optional. It is highly recommended for study of finely crystalline aluminate and ferrite which typically form the ground mass in which the silicates occur. Reflected light objective lenses with magnification up to 100× designed for use in oil-immersion are required.

6.4 Assorted eyepieces (5×, 10×, 20×) which when combined with the objectives described in 6.3 will provide magnifications up to 800×.

6.5 Eyepiece reticles (graticulae) with a linear grid pattern containing 9, 16, or 25 intersections.

6.6 Eyepiece micrometer for measuring dimensions of the object under investigation and calibrated for each magnification.

6.7 Stage micrometer for the calibration of the eyepiece micrometer.

6.8 Light source that provides uniform and consistent illumination of the field and light of constant intensity.

6.9 Counting (tallying) device capable of recording up to ten categories of data.

6.10 Crushing device capable of reducing sample particle size to between 1 and 4 mm.

6.11 Riffle sample splitter to reduce sample from initial volume to approximately 100 g.

6.12 Wire cloth sieves with openings suitable for sieving the entire clinker sample to broadly define the model size class, and sieves with 1-mm and 4-mm square openings to concentrate particles of recommended size for specimen preparation.

6.13 Vacuum impregnation device to force epoxy into clinker voids. (Vacuum bell jar or desiccator connected to a vacuum pump.)

6.14 Curing oven, hot plate, slide warmer, or ultraviolet light may be used to accelerate the epoxy hardening.

6.15 Thin, diamond-rimmed wafering saw for sectioning the encapsulated clinker.

6.16 Glass grinding (lapping) plates (300 mm × 300 mm × 5 mm) required only if the mechanical system is not equipped to handle the final grinding with alumina powder.

6.17 Ultrasonic cleaning device (optional) to clean the sample prior to, between, and after polishing steps.

7. Reagents and Materials

7.1 Consumable grinding (lapping) and polishing supplies. After the encapsulated specimen has been cut with the saw, all or most of the following grinding and polishing steps are required: 120-, 320-, and 600-grit silicon carbide grinding papers or equivalent and 5 μm, 0.3μ m, and 0.05 μm alumina polishing powders or their equivalent. Diamond grinding discs, silicon carbide paper, or polishing cloths and alumina polishing powder may be used. Various types of polishing cloths may be used to produce a nearly flat clinker surface or a relief surface to aid in identification of periclase (**1**).[4]

7.2 Sample cups (with volumes ranging from 10 to 20 mL) to contain epoxy-clinker mix during hardening.

7.3 Epoxy resin and hardener for encapsulation of the clinker. Low viscosity resin will facilitate penetration into clinker voids. When hardened it should have an abrasive resistance close to that of the clinker to minimize relief during polishing. It should be resistant to substances used for washing and etching.

7.4 Isopropyl alcohol (2-propanol) for washing the specimen and for use in the ultrasonic cleaner. Propylene glycol is suitable as a lubricant for the saw blade.

7.5 Immersion oil with an index of refraction of 1.51 if reflected light immersion-oil technique is used.

[4] The boldface numbers in parentheses refer to the list of references at the end of this standard.

7.6 Etching material to highlight different phases for counting. (See Appendix X3.)

8. Sampling

8.1 Take samples of portland-cement clinker in accordance with the applicable provisions of Practices D 75 and D 3665 so as to be representative of the quantity of material with which testing is concerned (see Appendix X1).

8.2 Sieve the initial sample to obtain clinker particles representing approximately 70 % of the clinker particle size distribution, centered about the mode. This particle size interval represents a size range of approximately two standard deviations, one on each side of the mode, and is herein defined as the "bulk mode" (M_b), the combined material between the extremes of the particle size distribution. State the sieve sizes used. If either extreme of the particle size distribution is to be studied, the selected portion shall be identified as non-modal, and the percentages retained or passing standard sieves shall be stated. The recommended size fraction for microscopical analysis is 2 to 4 mm. Therefore, that portion of the initial clinker sample representing the bulk mode shall be crushed, sieved, and riffled to provide approximately 100 g. Whole clinkers may be encapsulated to study the phase distribution within clinker nodules.

9. Preparation of Sample Specimen

9.1 Polished sections shall be polished to a fineness such that grinding pits and scratches have been eliminated (see Appendix X1).

9.2 Etching of the clinker surface may be used to facilitate identification of clinker phases **(1)**; additional information may be found in the Appendix X1.

10. Counting Procedure

10.1 Choose the microscope magnification such that adjacent reticle grid points do not fall on the same crystal, except for a few unusually large crystals. Magnification from 200× to 500× will accommodate most clinkers. Reticles with multiple grid points are recommended. Single crosshair reticles are not suitable.

10.2 Choose the stepping interval such that an entirely different field of view is observed after each step.

10.3 Attach a mechanical stage to the microscope. The mechanical stage may be an electrically driven specimen carriage connected to an automatic electronic counter or a simple hand-operated carriage and counter. Place a small amount of soft modeling clay on a standard, petrographic glass slide (27 mm × 46 mm) and level the sample thereon. Either use a commercial leveling device or use a small spirit level to adjust the mount while pressing it firmly into the clay. A tissue paper between the polished section and the leveling device or spirit level prevents surface scratches. Place the glass slide with attached clay and leveled mount on the mechanical stage. Check the accuracy of leveling by observing the focus at several points on the polished surface. Move to a starting point (the initial field of view from which data will be taken) at the edge of the mount and record the position in the X-Y coordinate system, using the graduated scales on the mechanical stage.

10.4 Use a tally sheet or a counting device to record the phases as required. The observer should not keep a mental tally of any data because of possible bias. Identify and record each phase under the grid intersections. In some cases, the aluminate and ferrite quantities may be combined and labeled "matrix". Move the mechanical stage a distance of one stepping interval in the chosen X or Y direction to bring another field into view. The phases under the grid points are identified, counted, and the mechanical stage advanced one stepping interval to an adjacent field of view. This procedure is continued until a range of 3000-4000 points are recorded.

At the clinker periphery, some of the reticle points may fall on the encapsulating epoxy that surrounds the clinker particle. Count only points within the clinker, and disregard the reticle points over epoxy at the clinker periphery. Thus, the clinker void space (porosity), if determined in the point count, does not include cavities on the surface of the clinker particle. As one steps over irrelevant areas (such as epoxy exterior to the clinker or severally damaged portions of the polished surface that obscure the phase identification) the count is temporarily suspended until a suitable clinker surface again falls under the reticle grid points. Artifacts (for example, blot marks, residual liquids) on the section surface are not to be counted. If the identity of the phase is obscured by the area formed by the grid intersection, one should consistently use a specified corner of the intersection where the phase can be clearly observed.

When the edge of the mount is reached at the end of a line of traverse, the mount is translated one stepping interval perpendicular to that line and counting continues in the opposite direction, or the mount is repositioned to a point at the original starting boundary to keep the same direction of travel. As one progresses along the lines of traverse the data are accumulated until 3000–4000 points (N) are recorded.

11. Calculation of Results

11.1 Calculate the volume fraction of each phase in the sample by dividing the number of points counted for that phase by the total number of points counted. This number multiplied by 100 yields the phase content in volume per cent.

11.2 The number of points to be counted is to be between 3000 and 4000 **(2).** The absolute error at the 96 % confidence interval has been shown to be:

$$\delta = 2.0235 \sqrt{\frac{P(100 - P)}{N}} \quad (1)$$

where:

δ = absolute measuring error in percentage for a given constituent,
P = phase percentage, and
N = total number of points counted.

Therefore for any error percentage deemed acceptable and expected value of P, the required number of points, N, can be calculated:

$$N = \left(\frac{2.0235}{\delta}\right)^2 \times (100 - P)P \quad (2)$$

If an estimate of P is not available, the above equation takes on a maximum when $P = 50$. Using this value will provide a conservative estimate for the number of points required.

www.technobetar.ir

11.3 To express phase abundance in terms of mass fraction, multiply phase volume fractions by their respective mass density (see Table 1) and normalize the totals to 100 %.

12. Reporting Results

12.1 The report of the point count results to microscopically determine the phase percentages in portland cement clinker should include the following information:

12.1.1 Identify the source of the samples, including sampling location and type of sample.

12.1.2 State how the sample was treated. If the sample was sieved, give the sieve designation size for the final sample. Indicate the type of each etchant used and etch time.

12.1.3 State the number of data points and percentages of each determined phase.

TABLE 1 Mass Densities in g/cm³ for Clinker Phases (7)

Phase	Density
alite	3.18
belite	3.31
aluminate	3.03
ferrite	3.73
free lime	3.35
periclase	3.58
alkali sulfate	2.66

13. Precision and Bias

13.1 *Within-Laboratory Precision*—Single operator values of the one-sigma limit in percent (1S %), defined in accordance with Practice C 670 determined for volume fraction determination by point count analysis (see Note 4) have been found to be 0.71 % (1S) (**6**). Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 2.58 % (D2S) from the average of the two results.[5]

NOTE 4—These levels of precision are based on data from the NIST RM Clinker certificate data. A bias statement is not available as these data are used to establish the phase abundance compositions of the RM clinkers.

13.2 A multi-laboratory round robin is planned to generate data for use in a precision and bias statement in accordance with Practice C 670.

14. Keywords

14.1 alite; aluminate; belite; ferrite; periclase; portland-cement clinker; reflected light microscopy

[5] Supporting data pertaining to this precision statement have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C01-1005.

APPENDIXES

(Nonmandatory Information)

X1. SAMPLING

X1.1 The task of obtaining a representative clinker sample for microscopical examination from the stream of material leaving the kiln presents special problems, and the solution depends greatly on local conditions. When sampling from a conveyor belt, an entire cross section of the material should be taken. When the sample is collected from material in free fall, for example at the end of the conveyor belt or at the discharge of a bucket elevator, all the particles falling during the sampling operation shall be included, and sampling devices and containers shall be of sufficient volume to contain the resulting amount. One litre is recommended for the initial clinker sample.

X1.2 If continuous sampling of a clinker flow is impractical, samples representing more extended periods of operation shall be composites of two of more grab samples obtained according to X1.1. The period of time covered and the frequency of sampling will depend on local conditions and the purpose of the test, but the procedure for obtaining each individual grab sample shall be identical.

X1.3 Material judged atypical for the period, the process, or the equipment under study (kiln dust, kiln coating, etc.) may be removed prior to microscopical examination, but the removal of such material should be noted.

X2. SAMPLE IMPREGNATION AND POLISHING

X2.1 Label a sample cup with the sample identification (a tag may also be embedded in the epoxy) and coat the interior with a mold release agent. Place 10 to 20 g of the clinker sample in the cup and add low-viscosity epoxy resin previously mixed with the hardener. Place the sample cup under the vacuum jar and operate the vacuum pump to obtain adequate penetration of the resin. Break the vacuum several times to permit atmospheric pressure to force the epoxy into the material.

X2.2 Cure the epoxy as recommended by the manufacturer in an oven at a temperature not higher than 70°C. Some epoxies will harden rapidly at room temperature or under ultraviolet light.

X2.3 Remove the specimen from the cup and, if necessary, label with a diamond engraver or indelible pen.

X2.4 Cut the encapsulation with the diamond-rimmed wafering saw to expose the clinker particle cross sections.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:33:15 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Preparation liquids retained in clinker voids may interfere with etching and staining; therefore, a second application of vacuum impregnated epoxy on the polished surface may be necessary. A cyanoacrylate resin, smeared over the polished surface, may be used. The encapsulation is then reground and polished.

X2.5 Grind the exposed surface by lapping with each of the selected grinding media (see 7.1), beginning with the coarsest, for 2 to 4 min each. Use propylene glycol, isopropanol, or other liquids as lubricants during grinding. After each step, wash the surface with a forceful spray of isopropyl alcohol. Do not use water in cutting, grinding, polishing, or cleaning the encapsulated clinkers.

X2.6 Polish the surface with each of the chosen polishing media, beginning with the coarsest, for 2 to 4 min. Wash the surface after each polishing step with a forceful isopropyl alcohol spray. Clean the specimen ultrasonically after the last wash, using isopropyl alcohol as the cleaning fluid. Rinse again with the alcohol spray. Dry the surface with a forced warm air current. Blotting is not recommended because of the production of blot marks.

X3. ETCHES AND STAINS

X3.1 Certain liquids or vapors applied to the polished surface will produce a preferential phase coloration. One versatile liquid is nital (1 mL nitric acid in 99 mL isopropyl alcohol). Other commonly used stains and etchants are hydrofluoric acid vapor, potassium hydroxide, distilled water, aqueous ammonium chloride, dimethyl ammonium citrate, and others. Details of various etches and stains, immersion times, and techniques are given in Ref (**1**)**.** The choice of etchant, etch time, and temperature of etchant can affect results. Therefore, these choices should be consistent for all specimens prepared for point counting. (**Warning**—Appropriate safety precautions must be observed when preparing and using stains and etchants. Review all Material Safety Data Sheets and always use suitable personal protective equipment including eye protection, apron, and gloves.)

X3.2 For aluminate and free-lime coloration, the application of distilled water at 40 °C for 5 s with the specimen at room temperature, or 0.1 molar KOH for 20 to 30 s is recommended. The polished surface can also be placed on a water-saturated, clean, low-nap polishing cloth for 2 to 3 s and then quickly washed with a forceful isopropyl alcohol spray. This technique produces a structure etch on the silicates. The polishing cloth may be attached to a rotating wheel or may be stationary on a glass plate.

X3.3 For a clear differentiation of the silicates, alite and belite, a 6- to 8-s immersion in nital is recommended, quickly followed by an alcohol spray wash. One may choose to carry out a high magnification point count (550× or more) on the water-stained matrix, followed by a relatively low-magnification point count (approximately 300×) of the silicates on a nital-etched surface.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last isse, C 1356 – 96(2001), that may impact the use of this test method. (Approved June 1, 2007)

(*1*) Added new paragraph 3.4.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1362 – 09

Standard Test Method for Flow of Freshly Mixed Hydraulic-Cement Concrete[1]

This standard is issued under the fixed designation C 1362; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers determination of the flow of a sample of freshly mixed concrete, either in the field or in the laboratory.

1.2 This test method is applicable to concrete having coarse aggregate up to 37.5 mm in size. If the coarse aggregate is larger than 37.5 mm in size, the test method is applicable when the fraction of concrete larger than 37.5 mm is removed in accordance with Practice C 172.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C 172 Practice for Sampling Freshly Mixed Concrete

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Summary of Test Method

3.1 A flow apparatus comprising an outer partially perforated hollow tube and an inner calibrated floating rod is inserted into a sample of freshly mixed concrete to a preset level and held in place by a collar floater. A portion of the concrete is allowed to flow into the hollow tube through its perforations for a period of 40 s. The inner floating rod is then lowered onto the concrete surface that has penetrated the hollow tube. The height of the concrete in the hollow tube is read from the scale on the upper portion of the floating rod protruding from the top of the hollow tube. With increasing fluidity of the concrete a higher flow reading is obtained on a scale from zero to one hundred divisions.

4. Significance and Use

4.1 This test method permits a rapid assessment of the flow and consistency of freshly mixed concrete (see Note 1).

4.2 This test method also provides information on the change in flow and consistency, with time, of concrete containing superplasticizer admixtures.

4.3 This test method can be used to measure the uniformity characteristics of flow and consistency of freshly mixed concrete and its change with time.

NOTE 1—This test method may not be appropriate for use in evaluating gap-graded aggregate concrete.

5. Apparatus

5.1 Details of the apparatus are shown in Fig. 1. The apparatus consists of (*1*) measuring rod, (*2*) scale datum, (*3*) hollow tube with round holes and longitudinal slots, (*4*) holding pin, (*5*) collar floater, and (*6*) tube point.

5.2 Measuring rod is a hollow tube, 13 mm in outside diameter, 336 mm long with a wall thickness of 1.5 mm and it is capped at both ends with a cap 15 mm in outside diameter. A scale datum is 45 mm in outside diameter and 25 mm wide and fabricated to fit hollow tube and accommodate measuring rod. Hollow tube has an outside diameter of 33 mm, and it is 310 mm long with a wall thickness of 4 mm and has 16 round holes, 9.4 mm in diameter, and 4 longitudinal slots, 9.4 mm wide by 50 mm long, which are distributed around the circumference of the tube as shown in Fig. 1. A pin which is a rivet, 3.2 mm in diameter, protrudes 3.2 mm inside tube. Collar floater, made of a plate 5 mm thick, has an outside diameter of 90 mm and inside diameter of 33 mm, is connected to hollow tube. Tube point is machined from a rod stock and fashioned into a conical shape. It is secured to the bottom end of hollow tube, and it is used to facilitate the insertion of the assembly

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.60 on Testing Fresh Concrete.

Current edition approved June 1, 2009. Published July 2009. Originally approved in 1997. Last previous edition approved in 2004 as C 1362–04.

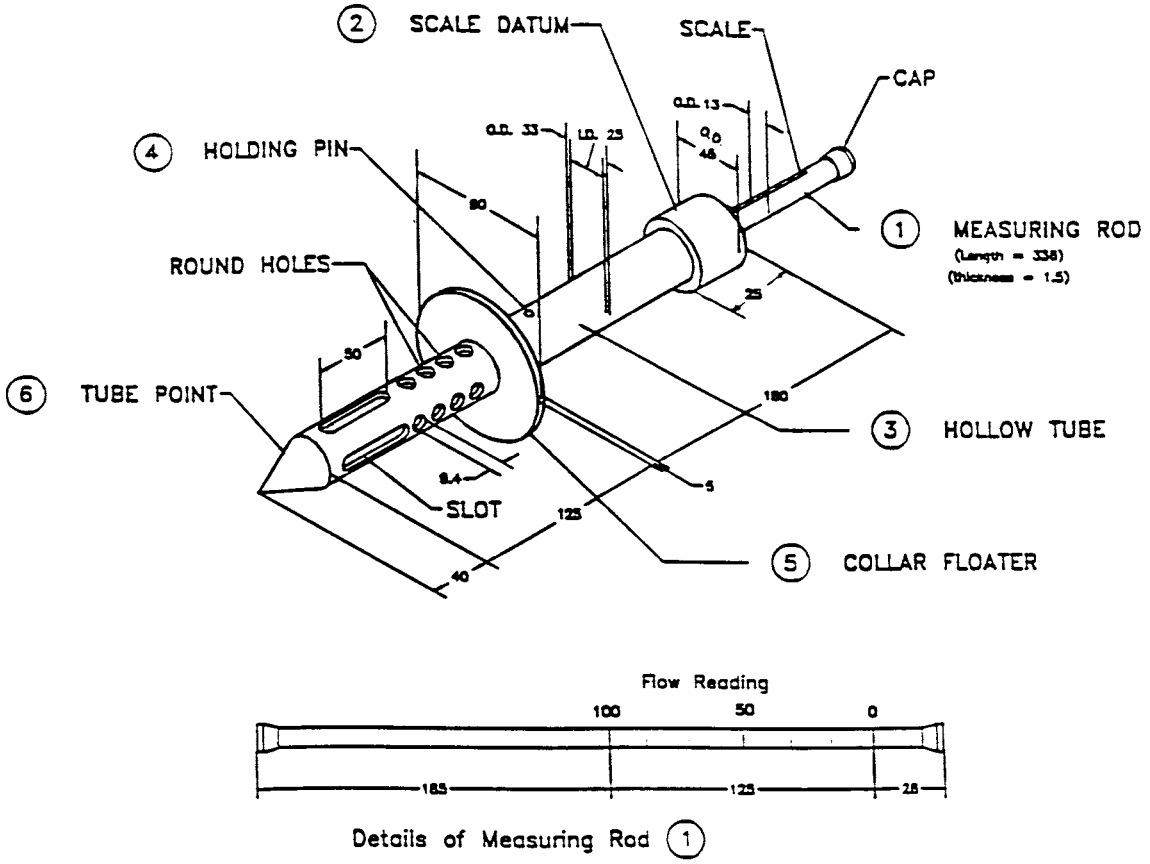

FIG. 1 Apparatus for Flow Test

into the fresh concrete. All individual dimensions shall have a tolerance of ±1 % of their value. Make all parts of the apparatus of non-corrosive materials that are not affected by chemicals found in the fresh concrete.

6. Sampling

6.1 Determine the flow either as the concrete is placed in the forms prior to any manipulation or in a suitable container such as a can, a hopper, a pail, or a wheelbarrow. The sample of concrete from which determination of flow is made shall be representative of the entire batch. Obtain the sample in accordance with the requirements of Practice C 172.

7. Procedure

7.1 Bring the surface of the concrete to a smooth and level condition. Use a small wood float or screed, but work the surface as little as possible to avoid formation of mortar layers. The minimum depth of concrete at testing shall be 175 mm, and the distance from the tube to the nearest edge of the level surface of the concrete on which the flow or consistency is to be determined shall be a minimum of 75 mm. During the flow measurement protect the concrete against vibration, jarring, or agitation. Wet the apparatus, and shake off all excess water. Raise the measuring rod, and let it rest on the pin inside the apparatus. Insert the apparatus slowly and vertically downward until the collar floater rests at the surface of the concrete. Do not rotate the apparatus while inserting it into the concrete. After 40 s of complete insertion lower the measuring rod slowly until it rests on the surface of the concrete that entered into the hollow tube. Read and record the level of the measuring rod to the nearest division in percent on the scale which represents the flow of the concrete.

8. Report

8.1 Record the flow in terms of the number of divisions of 1 % on the scale; if more than one test reading is taken on the same concrete, report the average to the nearest division in percent.

9. Precision and Bias [4]

9.1 *Precision*—Based on data from 150 tests, with a flow of 10 to 90 % the pooled standard deviation is 8 %[4] for a single operator using the same test device. Therefore, the range of two tests on the same material should not exceed 23 %.[4]

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1011.

NOTE 2—These numbers represent, respectively, the (1 s %) and (d2s %) limits as defined in Practice C 670.

9.2 *Bias*—This test method has no bias because the values determined can be defined only in terms of this test method.

10. Keywords

10.1 concrete; consistency; flow; fluidity; fresh concrete; uniformity

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1362 – 04, that may impact the use of this test method. (Approved June 1, 2009)

(*1*) Revised 1.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1365 – 06

Standard Test Method for Determination of the Proportion of Phases in Portland Cement and Portland-Cement Clinker Using X-Ray Powder Diffraction Analysis[1]

This standard is issued under the fixed designation C 1365; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers direct determination of the proportion by mass of individual phases in portland cement or portland-cement clinker using quantitative X-ray (QXRD) analysis. The following phases are covered by this standard: alite (tricalcium silicate), belite (dicalcium silicate), aluminate (tricalcium aluminate), ferrite (tetracalcium aluminoferrite), periclase (magnesium oxide), gypsum (calcium sulfate dihydrate), bassanite (calcium sulfate hemihydrate), anhydrite (calcium sulfate), and calcite (calcium carbonate).

1.2 This test method specifies certain general aspects of the analytical procedure, but does not specify detailed aspects. Recommended procedures are described, but not specified. Regardless of the procedure selected, the user shall demonstrate by analysis of certified reference materials (CRM's) that the particular analytical procedure selected for this purpose qualifies (that is, provides acceptable precision and bias) (see Note 1). The recommended procedures are ones used in the round-robin analyses to determine the precision levels of this test method.

NOTE 1—A similar approach was used in the performance requirements for alternative methods for chemical analysis in Test Methods C 114.

1.3 The values stated in SI units shall be regarded as the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For specific hazards, see Section 9.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

E 691 Practice for Conducting an Interlaboratory Study to Determine the Precision of a Test Method

3. Terminology

3.1 *Definitions are in accordance with Terminology C 219.*

3.2 *Phases* (**1**):[3]

3.2.1 *alite*, *n*—tricalcium silicate (C_3S)[4] modified in composition and crystal structure by incorporation of foreign ions; occurs typically between 30 to 70 % (by mass) of the portland-cement clinker; and is normally either the M_1 or M_3 crystal polymorph, each of which is monoclinic.

3.2.2 *alkali sulfates*, *n*—arcanite (K_2SO_4) may accommodate Na^+, $Ca2^+$, and CO_3 in solid solution, aphthitalite (K_{4-x},Na_x)SO_4 with x usually 1 but up to 3), calcium langbeinite ($K_2Ca_2[SO_4]_3$) may occur in clinkers high in K_2O, and thenardite (Na_2SO_4) in clinkers with high Na/K ratios (**1**).

3.2.3 *aluminate*, *n*—tricalcium aluminate (C_3A) modified in composition and sometimes in crystal structure by incorporation of a substantial proportion of foreign ions; occurs as 2 to 15 % (by mass) of the portland-cement clinker; is normally cubic when relatively pure and orthorhombic or monoclinic when in solid solution with significant amounts of sodium (**2**).

3.2.4 *anhydrite*, *n*—calcium sulfate ($C\overline{S}$) and is orthorhombic (see Note 2).

NOTE 2—Calcium sulfate is added to the clinker during grinding to control setting time, strength development, and volume stability. Several phases may form as a result of dehydration of gypsum. The first 1.5

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.23 on Compositional Analysis.
Current edition approved Dec. 15, 2006. Published January 2007. Originally approved in 1998. Last previous edition approved in 2004 as C 1365 - 98 (2004).

www.technobetar.ir

molecules of water are lost between 0 and 65 °C with minor changes in structure; and, above 95 °C, the remaining 0.5 molecules of water are lost transforming the structure to the metastable γ polymorph of anhydrite (sometimes referred to as 'soluble anhydrite') and subsequently the orthorhombic form (**3**).

3.2.5 *bassanite*, *n*—calcium sulfate hemihydrate ($C\bar{S}H_{1/2}$) and is monoclinic.

3.2.6 *belite*, *n*—dicalcium silicate (C_2S) modified in composition and crystal structure by incorporation of foreign ions; occurs typically as 15 to 45 % (by mass) of the portland-cement clinker as normally the β polymorph, which is monoclinic. In lesser amounts, other polymorphs can be present.

3.2.7 *calcite*, *n*—calcium carbonate is trigonal and may be present in a cement as an addition or from carbonation of free lime.

3.2.8 *ferrite*, *n*—tetracalcium aluminoferrite solid solution of approximate composition $C_2(A,F)$ modified in composition by variation in the Al/Fe ratio and by substantial incorporation of foreign ions as $C_4A_XF_{2-X}$ where $0 < x < 1.4$; constituting 5 to 15 % (by mass) of a portland-cement clinker; and is orthorhombic.

3.2.9 *free lime*, *n*—free calcium oxide (C); cubic (see Note 3).

NOTE 3—Free lime (CaO) may be present in clinker and cement but readily hydrates to form portlandite ($Ca(OH)_2$). Portlandite may carbonate to form calcium carbonate, generally as calcite. Heat-treating a freshly-ground sample to 600 °C is useful to convert any portlandite back to free lime but will also dehydrate the hydrous calcium sulfate phases (gypsum and bassanite) to anhydrite.

3.2.10 *gypsum*, *n*—calcium sulfate dihydrate ($C\bar{S}H_2$) and is monoclinic .

3.2.11 *periclase*, *n*—free magnesium oxide (M); cubic.

3.3 *Definitions of Terms Specific to This Standard:*

3.3.1 *Certified Reference Material (CRM)*, *n*—a material whose properties (in this case phase abundance, XRD peak position or intensity, or both) are known and certified (see Note 4).

NOTE 4—NIST Standard Reference Material (SRM®) Clinkers 2686, 2687, and 2688 are suitable CRMs for qualification.[5]

3.3.2 *diffractometer*, *n*—the instrument, an X-ray powder diffractometer, for determining the X-ray diffraction pattern of a crystalline powder.

3.3.3 *phase*, *n*—a homogeneous, physically distinct, and mechanically separable portion of a material, identifiable by its chemical composition and crystal structure.

3.3.3.1 *Discussion*—Phases in portland-cement clinker and cements that are included in this test method are four major phases (alite, belite, aluminate, and ferrite) and one minor phase (periclase).

3.3.3.2 *Discussion*—Precision values are provided for additional phases (gypsum, bassanite, anhydrite, arcanite, and calcite). Values for these constituents may be provided using this method but are considered informational until suitable certified reference materials for qualification are available.

[5] Portland cement clinker SRM's® from the Standard Reference Material Program, National Institute of Standards and Technology.

3.3.4 *qualification*, *n*—process by which a QXRD procedure is shown to be valid.

3.3.5 *Rietveld analysis*, *n*—process of refining crystallographic and instrument variables to minimize differences between observed and calculated X-ray powder diffraction patterns for one or more phases, estimating their relative abundance.

3.3.6 *standardization*, *n*—process of determining the relationship between XRD intensity and phase proportion for one or more phases (see Note 5).

NOTE 5—In the literature of X-ray powder diffraction analysis, the standardization process has been commonly referred to as calibration; however, we have determined that standardization is a more accurate term.

3.3.6.1 *Discussion*—Rietveld analysis uses crystal structure models to calculate powder diffraction patterns of phases that serve as the reference patterns. The pattern-fitting step seeks the best-fit combination of selected pattern intensities to the raw data. The relative pattern intensities along with the crystallographic attributes of each phase are used to calculate relative abundance. The standardization approach uses powdered samples of pure phases to assess the relationship between diffraction intensity ratios and mass fraction ratios of two or more constituents; and is referred to here as the traditional method.

3.3.7 *X-ray diffraction (XRD)*, *n*—the process by which X-rays are coherently scattered by electrons in a crystalline material.

4. Background

4.1 This test method assumes general knowledge concerning the composition of cement and portland-cement clinker. Necessary background information may be obtained from a number of references (**1, 4**).

4.2 This test method also assumes general expertise in XRD and QXRD analysis. Important background information may be obtained from a number of references (**5-10**).

5. Summary

5.1 This test method covers direct determination of the proportion by mass of individual phases in cement or portland-cement clinker using quantitative X-ray powder diffraction analysis. The following phases are covered by this standard: alite (tricalcium silicate, C_3S), belite (dicalcium silicate C_2S), aluminate (tricalcium aluminate, C_3A), ferrite (tetracalcium aluminoferrite, C_4AF), periclase (magnesium oxide, M), arcanite (potassium sulfate, ($K\bar{S}$)), gypsum (calcium sulfate dihydrate, ($C\bar{S}H_2$)), bassanite (calcium sulfate hemihydrate, ($C\bar{S}H_{1/2}$)), anhydrite (calcium sulfate ($C\bar{S}$)), and calcite (calcium carbonate, $CaCO_3$.

A QXRD test procedure includes some or all of the following: *(a)* specimen preparation; *(b)* data collection and phase identification; *(c)* standardization (for the standardization approach); *(d)* collecting a set of crystal structure models for refinement (for the Rietveld approach); *(e)* use of an internal or external standard (to correct for various effects on intensity besides phase proportion); *(f)* analysis of the sample (in which the powder diffraction pattern is measured and/or the intensity

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

of selected XRD peaks or patterns are measured); and *(g)* calculation of the proportion of each phase.

5.2 This test method does not specify details of the QXRD test procedure. The user must demonstrate by analysis of certified reference materials that the particular analytical procedure selected for this purpose provides acceptable levels of precision and bias. Two recommended procedures (the Rietveld approach and the traditional approach used to determine the acceptable levels of precision and bias) are given in Appendix X1 and Appendix X2.

6. Significance and Use

6.1 This test method allows direct determination of the proportion of some individual phases in cement or portland-cement clinker. Thus it provides an alternative to the indirect estimation of phase proportion using the equations in Specification C 150 (Annex A1).

6.2 This test method assumes that the operator is qualified to operate an X-ray diffractometer and to interpret X-ray diffraction spectra.

6.3 This test method may be used as part of a quality control program in cement manufacturing.

6.4 This test method may be used in predicting properties and performance of hydrated cement and concrete that are a function of phase composition.

6.5 QXRD provides a bulk analysis (that is, the weighted average composition of several grams of material). Therefore, results may not agree precisely with results of microscopical methods.

7. Apparatus

7.1 *X-Ray Diffractometer*—The X-ray diffractometer allows measurement of the X-ray diffraction pattern from which the crystalline phases within the sample may be qualitatively identified and the proportion of each phase may be quantitatively determined. X-ray diffractometers are manufactured commercially and a number of instruments are available. The suitability of the diffractometer for this test method shall be established using the qualification procedure outlined in this test method.

8. Materials

8.1 *Standardization Phases*—The use of standardization phases is recommended for establishing the intensity ratio/mass ratio relationships when using the traditional quantitative method. These phases must usually be synthesized **(12, 13)**.

8.2 *CRM Clinker*—The use of three CRM clinkers is required to qualify the QXRD procedure.

8.3 *Internal Standard*—The use of an internal standard is recommended for the standardization approach. Suitable materials include chemical reagents (see 8.4) or CRM's (see Appendix X1).

8.4 *Reagent Chemicals*—Reagent grade chemicals, if used either as an internal standard or during chemical extraction of certain phases, shall meet the specifications of the Committee on Analytical Reagents of the American Chemical Society where such specifications are available.[6] Other grades may be used, provided it is first ascertained that the chemical is sufficiently pure to permit its use without lessening the accuracy of the determination.

9. Hazards

9.1 The importance of careful and safe operation of an X-ray diffractometer cannot be overemphasized. X-rays are particularly hazardous. An X-ray diffractometer must be operated safely to avoid serious injury or death. The X-rays are generated by high voltages, perhaps as high as 55 kV peak, requiring care to avoid serious electric shock. Klug and Alexander **(6)** (pp. 58–60) state, "*The responsibility for safe operation rests directly on the individual operator*" (italics are theirs).

10. Sampling and Sample Preparation

10.1 Take samples of cement in accordance with the applicable provisions of Practice C 183. Take samples of portland-cement clinker so as to be representative of the material being tested.

10.2 Prepare samples as required for the specific analytical procedure (see Appendix X2).

11. Qualification and Assessment

11.1 *Qualification of Test Procedure*:

11.1.1 When analytical data obtained in accordance with this test method are required, any QXRD test procedure that meets the requirements described in this section may be used.

11.1.2 Prior to use for analysis of cement or portland-cement clinker, qualify the QXRD test procedure for the analysis. Maintain records that include a description of the QXRD procedure and the qualification data (or, if applicable, re-qualification data). Make these records available to the purchaser if requested in the contract or order.

11.1.3 If more than one X-ray diffractometer is used in a specific laboratory for the same analysis, even if the instruments are substantially identical, qualify each separately.

11.1.4 If more than one procedure is used to mount specimens for QXRD, the use of each procedure shall constitute a separate test procedure and each procedure shall be qualified separately.

11.1.5 Qualification shall consist of replicate determinations of the three SRM® clinkers, re-mounting the specimen for each analysis, (see Note 6) for the proportions of C_3S, C_2S, C_3A (cubic and orthorhombic), C_4AF, and M using the desired QXRD procedure (see Note 7).

NOTE 6—Prior to qualification, it may be convenient to carry out a preliminary assessment in which one or more mixtures of synthetic phases are analyzed. Such a preliminary assessment should produce no more than the permissible variation described in 11.2.

[6] *Reagent Chemicals, American Chemical Society Specifications* , American Chemical Society, Washington, DC. For suggestions on the testing of reagents not listed by the American Chemical Society, see *Analar Standards for Laboratory Chemicals*, BDH Ltd., Poole, Dorset, U.K., and the *United States Pharmacopeia and National Formulary*, U.S. Pharmacopeial Convention, Inc. (USPC), Rockville, MD.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 7—It is recommended that at least two replicate analyses be carried out, but three determinations may be used for assessing permissible variation.

11.2 *Permissible Variation*:

11.2.1 The values of permissible variation were computed from the within-laboratory standard deviation values obtained in round robin analyses of mixtures of SRM® clinkers and synthetic phases (see 14.2).

11.2.1.1 *Discussion*—Qualification limits in Table 2 are prediction intervals (95 %) for a future mean and are designed to bracket values of a mean of k (=2,3,4) future measurements of the relevant phases. The intervals are based upon the performance of the 11 round robin participants.

11.2.2 Replicate analyses shall differ from each other by no more than the within-lab repeatability value shown in Table 1.

11.2.3 The mean result shall differ from the known value by no more than the value shown in Table 2 for the particular number of replicates.

11.2.4 *Known Values*—The known values of each phase in the SRM® clinkers provided by NIST was determined using quantitative X-ray powder diffraction and optical microscopy (**11**).

11.3 *Partial Results*:

11.3.1 QXRD procedures that provide acceptable results for some phases but not for others shall be used only for those phases for which acceptable results are obtained. However, it is not expected that a QXRD procedure would provide acceptable results for some phases and not for others, and such a result may indicate that the procedure is not, in fact, valid.

11.4 *Assessing the Diffractometer*:

11.4.1 The procedures described in the Annex shall be used to assess the diffractometer. Note that assessment is different from qualification or re-qualification.

11.4.2 The diffractometer shall be assessed each month that this test method is used.

11.4.3 The diffractometer shall be assessed after any substantial modification in the instrument (see Note 8).

NOTE 8—Substantial modification of the diffractometer includes changing the X-ray tube, changing a detector, adding or removing a monochromator, and realignment.

11.4.4 QXRD procedure shall be assessed upon receipt of evidence that the test procedure is not providing data in accordance with the permissible variation.

TABLE 1 Permissible Maximum Difference Between Replicate Values (percent of clinker or cement)[A]

	Repeatability Within-Lab		Reproducibility Between-Lab	
	s-within	d2s-within	s-between	d2s-between
alite	0.74	2.04	2.27	6.30
belite	0.64	1.77	1.40	3.87
aluminate	0.47	1.31	0.79	2.19
ferrite	0.49	1.36	0.89	2.47
periclase	0.23	0.63	0.50	1.39
arcanite	0.22	0.60	0.34	0.94
gypsum	0.21	0.59	0.59	1.65
bassanite	0.39	1.08	0.58	1.60
anhydrite	0.27	0.74	0.64	1.77
calcite	0.99	2.73	0.50	1.50

[A] As described in Practice C 670.

TABLE 2 Permissible Maximum Difference Between Mean Value and Known Value (Mass percent) Expressed at a 95 % Confidence Level for the Mean of a Selected Number of Replicates (k) = 2, 3, 4[A]

Phase	2 replicates	3 replicates	4 replicates
alite	5.93	4.91	4.31
belite	3.70	3.06	2.69
aluminate	2.14	1.77	1.55
ferrite	2.46	2.04	1.79
periclase	0.77	0.64	0.56
arcanite	0.85	0.70	0.61
gypsum	1.55	1.28	1.12
bassanite	1.52	1.26	1.11
anhydrite	1.67	1.38	1.21
calcite	0.68	0.56	0.49

[A] Computed from within-laboratory standard deviation using 95 % confidence interval and 30 df.

11.5 *Re-qualification of QXRD Procedure*:

11.5.1 If assessment shows that the X-ray diffractometer is not properly aligned (as discussed in Annex A1), it shall be realigned following the manufacturer's instructions. When subsequent assessment shows that the X-ray diffractometer is properly aligned (or was not properly aligned when the QXRD procedure was previously qualified), qualification of the QXRD procedure shall be repeated.

12. Recommended Procedure

12.1 For required analytical data see Section 11 and the recommended QXRD procedures described in Appendix X1.

13. Report

13.1 Report the following information:

13.1.1 The phase and its proportion, and which method (Rietveld or standardization) was used. Round figures to the number of significant places required in the report only after calculations are completed, in order to keep the final results substantially free of calculation errors. Follow the rounding procedure outlined in Practice E 29.

14. Precision and Bias

14.1 *Analysis*—A round-robin analysis by Rietveld refinement of the SRM® clinkers with calcium sulfate and calcium carbonate additions has been carried out following experimental procedures described in Appendix X1. An earlier cooperative standardization of mixtures of synthetic phases and a round-robin analysis[7] of the RM clinkers have been carried out (**12, 13**) following the experimental procedures described in Appendix X2 (see Note 9). Results were analyzed statistically according to Practices E 691 and C 670 to determine precision levels.

NOTE 9—Analysis of clinker is likely to include variance in addition to that found in analysis of mixtures of synthetic phases.

14.1.1 The precision values are all expressed as percentage points by mass relative to the total clinker or cement.

[7] SRM's from the Standard Reference Material Program, National Institute of Standards and Technology are Certified Reference Materials.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:33:18 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

14.2 *Precision*—The within-laboratory standard deviation and the between-laboratory standard deviation for all phases are given in Table 1, representing pooled results from the four test mixtures. The within-laboratory standard deviation for each phase is reported as 's-within.' Results of two properly conducted tests by the same operator should not vary more than d2s-within in 95 % of comparisons, where d2s-within = $1.96 \cdot \sqrt{2} \cdot_{swithin}$. The multi-laboratory standard deviation for each phase is reported as 's-between.' Results of two properly conducted tests on the same clinker or cement by two different laboratories should not differ from each other by more than d2s-between in 95 % of comparisons, where d2s-between $=1.96 \cdot \sqrt{2} \cdot_{sbetween}$.

14.3 *Bias*—The difference between the estimate of true mean phase concentration and the accepted reference values.

14.4 *Discussion*—Eleven laboratories participated in a co-operative round-robin analysis of mixtures of four separate reference materials. Reference values were that of the SRM® clinkers adjusted for the known amounts of added calcium sulfates and calcite. Taylor (**1**) concluded that the four major phases in portland-cement clinker may be determined using QXRD with an absolute accuracy of 2 to 5 percentage points (by mass) for alite and belite and 1 to 2 percentage points (by mass) for aluminate and ferrite. The SRM® clinkers do not contain gypsum, bassanite, anhydrite or calcite so these data are provided for informational purposes. The qualification requires assessment of certified phases in the clinker SRMs® only. As new SRMs® become available, additional phase qualifications will be added to the test method. There is insufficient data to estimate method bias at this time.

15. Keywords

15.1 alite; alkali sulfate; aluminate; belite; cement; clinker; diffractometer; ferrite; periclase; phase analysis; quantitative X-ray powder diffraction analysis; QXRD; Rietveld analysis; X-ray powder diffraction; XRD

ANNEX

(Mandatory Information)

A1. ASSESSING THE X-RAY DIFFRACTOMETER

A1.1 *Introduction*—This Annex provides a procedure for assessing the diffractometer to assure the validity of the QXRD procedure over a long period of time (several years or longer). A QXRD analysis of portland cement and portland-cement clinker is made particularly difficult by the fact that individual clinker phases used for standardization are not stable over long periods of time, because they hydrate easily, and are not easily synthesized. Thus it is difficult to assess standardizations directly by reanalysis of one or more standardization specimens. In addition, it is not desirable to repeat the standardization unless absolutely necessary. A more reasonable strategy is to use an external standard to assess the diffractometer and to decide when it is necessary to re-qualify a particular procedure. This Annex provides a procedure for assessing the diffractometer to assure the validity of the QXRD procedure over a long period of time (several years or longer).

A1.2 *Overview*:

A1.2.1 As long as certain aspects of the procedure are not changed, the relationship between peak intensity ratio and mass ratio is assumed to be universal (that is, valid over an indefinite period of time, even after changes in the diffractometer such as realignment and replacement of the X-ray tube, and transferable from one diffractometer to another).

A1.2.2 The requirements for the QXRD standardization to be universal are: *(1)* specimens are free from preferred orientation, primary extinction, and microabsorption, *(2)* the irradiated volume of the specimen is constant and independent of scattering angle, *(3)* monochromator polarization effects are corrected, *(4)* integrated peak intensity is used, *(5)* when using an internal standard, standardization and analyses are carried out with an internal standard from the same lot because differences in the particle size distribution between lots of the same material can cause significant difference in peak intensity, and *(6)* standardization and analyses are carried out with the diffractometer in proper geometric alignment.

A1.2.3 If analyses are carried out using only the instrument on which the standardization was carried out, then it is necessary only that preferred orientation, extinction, microabsorption, irradiated volume, and integrated peak intensity are reproducible. In that case, the standardization is valid (though not universal, in that it cannot be transferred from one diffractometer to another) as long as methods of specimen preparation, specimen mounting, and data collection are suitable and are not changed. For example, thus the use of a variable divergence slit for traditional standardization-based analyses is acceptable, because it provides reproducible irradiated volume (see Note A1.1).

NOTE A1.1—Variable divergence slits maintain a fixed irradiated area on the specimen surface. For lower angle regions, they keep the beam from spreading beyond the specimen, while at higher angles they provide a larger irradiated area (and so, volume) than do fixed slit systems. However, Rietveld analysis requires the constant volume provided by a fixed divergence slit. Therefore, data collected with a variable slit needs to be transformed to fixed slit by multiplying by $\sin\Theta$ (**7**).

A1.3 *Terminology*:

A1.3.1 *extinction*—a decrease in intensity during diffraction due to interference by successive crystal planes.

A1.3.1.1 *Discussion*—Extinction is affected by the crystallite size and is negligible for specimens ground to a particle diameter of 5 or 10 μm.

A1.3.2 *irradiated volume*—the volume of specimen that produces XRD signal.

A1.3.2.1 *Discussion*—Irradiated volume is constant from specimen to specimen as long as the proper geometric alignment is maintained and the specimen is sufficiently thick.

A1.3.3 *microabsorption*—an increase or decrease in intensity produced by a combination of phases that differ in absorption coefficient.

A1.3.3.1 *Discussion*—Microabsorption is affected by the extent to which the absorption coefficients differ and by the crystallite size. For phases whose mass absorption coefficients differ by less than 100, microabsorption is not significant for specimens ground to a particle diameter of <10 μm.

A1.3.4 *pattern intensity measurements*—the scale factor for a diffraction pattern of an individual phase determined by a least-squares procedure on a point-by-point basis.

A1.3.5 *peak intensity measurements*—the integrated intensity of the particular diffraction peak.

A1.3.6 *preferred orientation*—the nonrandom orientation of grains relative to the specimen surface.

A1.3.6.1 *Discussion*—Preferred orientation causes major changes in intensity of certain XRD lines, and therefore may be a source of error in QXRD analysis. Preferred orientation is not thought to be a major problem with portland cement clinker phases because they do not typically cleave along crystallographic directions. Preferred orientation is reduced (but not prevented) by prolonged grinding. The mounting procedure must be one that reduces preferred orientation, such as the procedure as described by Klug and Alexander (**6**, pp. 372–374) or Bish and Post (**7**)

A1.4 *Alignment*:

A1.4.1 Loss of proper alignment causes systematic variations in peak intensity with 2θ angle, thus rendering the QXRD procedure invalid.

A1.4.2 In order to assess alignment, an external standard shall be analyzed each month that this test method is used. Measurements shall include peak position, intensity, and resolution (that is, peak width or the ratio of the peak to valley intensity of partially overlapping peaks) of two or more peaks at widely separated 2θ angles. Suitable external standards include SRM® 1976 or polished specimens of novaculite quartz or silicon (**7**).

A1.4.3 Proper alignment is indicated by all of the following: *(1)* correct peak position, *(2)* suitable peak intensity, *(3)* suitable ratio of peak intensity of one or more peaks, and *(4)* suitable peak resolution. These must all be determined for suitably intense peaks. The correct peak position is within 0.01°2θ (Cu Kα) of its nominal value; for the (101) line of novaculite quartz, this value is 26.64°2θ (Cu Kα). Suitable peak intensity depends on many aspects besides alignment and therefore must be determined for a particular diffractometer based on experience; 1000 counts per second per mA is a reasonable expected value for the (101) line of novaculite quartz. Suitable peak intensity ratio is within 5 % of the nominal value. Suitable peak resolution must likewise be determined for a particular diffractometer based on experience. A reasonable indication is provided by clear separation of the five quartz peaks [(122) α_1, (122) α_2, (203) α_1, (203) α_2 plus (301) α_1, and (301) α_2] that appear at about 68°2θ (Cu Kα) (**5**, p. 392–394). Another indication is provided by resolution of the (110) Kα1–2 doublet of tungsten that appears at about 40.4°2θ (Cu Kα); the valley between these peaks must be no greater than 0.5 times the intensity of the α_2 peak (**6**).

A1.4.4 NIST SRM® 1976 may be used for instrument sensitivity assessment (**16**). Certified relative intensities of diffraction peaks, by both peak height or peak area, may be used to assess and correct for instrument bias. Plotting the ratios of the observed to certificate relative intensities will allow assessment of instrument performance relative to a diffractometer deemed to be "in control." If the plot of intensity ratios is pattern-less and falls within the control limits, the diffractometer may be considered "in control."

A1.4.5 When a diffractometer is found to not be properly aligned, then it must be realigned according to the manufacturer's instructions.

APPENDIXES

(Nonmandatory Information)

X1. RIETVELD ANALYSIS OF X-RAY POWDER DIFFRACTION PATTERNS FROM CEMENTS

X1.1 *Introduction*—The Rietveld method employs a least-squares refinement to minimize the difference between a calculated and measured X-ray powder diffraction pattern based upon refinement of crystal structure, specimen, and instrument effects (**9**). The resulting refined crystal structure data for each phase include pattern intensity information used to calculate relative phase abundance. Chemical (solid solution) and structural properties (lattice parameters) of each phase may also be obtained. Crystal structure data describe the structure and chemical composition of crystalline phases that may occur in cements.

Quantitative phase determinations of cements and portland cement clinkers have been difficult to obtain from powder diffraction patterns because of the large number of phases and the large extent of diffraction peak overlap. Traditional peak area measurement approaches are relatively imprecise because of the difficulty in decomposing the highly-overlapped patterns. The advantages of the Rietveld method over these traditional standardization-based methods is the whole-pattern decomposition of simultaneous refinement of crystal structure data from X-ray powder diffraction patterns of multiple phases. This approach provides improved reproducibility in intensity measurement, accommodation of specimen displacement shifts in the pattern, adjustments in crystal lattice parameters affecting peak positions, and relative peak intensities affected by chemical substitution.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

The resulting set of relative phase scale factors, phase densities, and cell volumes are used to calculate relative phase abundance according to Eq X1.1:

$$W_p = \frac{S_p\,(ZMV)_p}{\sum_p [S_p\,(ZMV)_p]} \quad \text{(X1.1)}$$

where:

W_p = the mass fraction of phase p,
S_p = the Rietveld scale factor,
Z = the number of formula units per unit cell,
M = the mass of the formula unit, and
V = the unit cell volume.

X1.2 The minimum requirements for a successful analysis are *(1)* collection of accurate powder diffraction data by step scanning, *(2)* having crystal structure data that are close to the actual structures found in the specimens, and *(3)* a model that accurately reflects systematic errors in the pattern and peak shapes (**7**).

X1.3 Qualitative phase identification may be performed through the principal diagnostic peaks listed in Table X1.1, which lists peaks that are generally resolvable (not too highly overlapped) and unique. This approach is useful since the number of phases and the high degree peak overlap preclude traditional means for phase identification. Confirmation of each phase should be accomplished using the patterns from the ICDD reference database or some other reference patterns of pure phases.

X1.4 The following variables should be refined: *(1)* background, *(2)* specimen displacement, *(3)* individual phase scale (intensity), *(4)* individual phase lattice parameters, *(5)* alite preferred orientation (if necessary), and *(6)* individual phase peak shapes. Examination of the correlation matrix can generally identify variables with high correlation that may create difficulties in refining to the proper values.

X1.4.1 Suitable results can be achieved by refining only the variables listed in X1.4. Refinement of atom site occupancy (Fe–Al ratios) for the ferrite phase is possible but not necessary as the effect on phase fraction is generally small. In addition, the scale and site occupancy factors can be strongly-correlated. Refining preferred orientation for phases other than alite (lower-concentration phases) can create correlation problems that lead to incorrect refinements.

X1.5 Examination of the difference profile plot is considered the best means of assessing the progress of the refinement.

TABLE X1.1 Diagnostic Peaks and ICDD Entry Number for Common Cement Phases (15)

d-spacing (nm)	Two-Theta (CuKα)	Phase (rel. I)	ICDD No.

0.1757	52.004	alite, monoclinic (30)	

Numerical measures of the degree of fit include the reliability factor (R values), representing some measure of the degree of agreement between the observed and calculated data. This value is dependent upon the quality of the experimental data and so, the plots are ultimately the best means to assess the quality of the fit. Additional discussion may be found in Bish and Post (**7**), Young (**9**), and McCusker (**10**).

X2. STANDARDIZATION-BASED QXRD PROCEDURES USED TO DETERMINE ACCEPTABLE LEVELS OF PRECISION AND BIAS

X2.1 *Introduction*—During development of the traditional procedure, a round-robin analysis of the RM clinkers was carried out to determine acceptable levels of precision and bias (**12, 13**). Details of the QXRD procedure were specified during this analysis. Although this test method does not include detailed QXRD procedures, the procedures used in the cooperative standardization and round robins described in Appendix X1 or Appendix X2 are recommended.

www.technobetar.ir

X2.2 *Overview*—This QXRD procedure has a number of critical features: standardization using mixtures of synthetic phases, use of an internal standard, intensity measurement of a specified peak for each phase, measurement of peak area to determine intensity, grinding samples until at least 90 % (by mass) is smaller than 10 μm in diameter, and the use of chemical extractions in the analytical scheme (see Note X2.1).

NOTE X2.1—Alternative QXRD procedures may provide satisfactory precision and bias and thus be acceptable under this test method. An external standard may be used rather than an internal standard. Intensity of each phase may be measured using many peaks or even the entire pattern. Chemical extractions need not be used in the analytical scheme. The particular procedure described in this appendix simply constitutes a recommendation.

X2.3 *Standardization Mixtures*:

X2.3.1 Three standardization mixtures were prepared using cubic C_3A, orthorhombic C_3A, C_4AF, and M. These individual phases were obtained from the Construction Technology Laboratories, and procedures used to prepare these individual phases and standardization mixtures were described by Struble and Kanare (**12**).

X2.3.2 The proportions in each mixture are listed in Table X2.1. The phases in this standardization are the principal phases in a clinker that has been chemically extracted using maleic acid or salicylic acid (see X2.3.3).

X2.3.3 Standardization phases were ground such that at least 95 % (by mass) was finer than 10 μm and not more than 5 % were finer than 1 μm in diameter. This particle size was selected to minimize microabsorption preferred orientation and to avoid loss of X-ray intensity due to grinding to particle sizes <1 μm.

X2.4 *Internal Standard*:

X2.4.1 Participants were required to use an internal standard—a pure, stable material, 95 % of which is finer than 10 μm. One recommended material was SRM® 640c (silicon).[8] However, it should be noted that silicon intensity may be affected by particle size distribution. Also recommended were any one of the materials in SRM® 674.[8] Another suitable material is SRM® 676.[8]

X2.4.2 Standardization mixtures were mixed with the internal standard material in recommended proportions of 0.1200 g internal standard per 1.0000 g standardization or unknown mixture, corresponding to 0.0200 g internal standard per 1.0000 g clinker. These proportions assume that the standardization mixture and unknown mixtures represent 17 % (by mass) of a clinker.

X2.5 *Blending*—Components must be blended to provide homogeneous specimens. The recommended procedure was to blend each standardization mixture for approximately 10 min using a vibratory-type mill with approximately 5 mL of a nonaqueous solvent (see Note X2.2) for each gram of powder and with appropriate grinding media.

NOTE X2.2—Suitable solvents include cyclohexane or alcohol (ethanol, methanol, or 2-propanol). Alcohol often contains sufficient water to cause hydration, so this water must be removed (**17**).

X2.6 *Diffraction Procedures*—Participants were instructed to use their normal procedures for preparing specimens and for collecting diffraction patterns. Specimen preparation procedures should minimize preferred orientation. Procedures to collect diffraction patterns should provide reproducible peak intensity measurements (for example, slow scanning speeds and moderately large receiving-slit widths).

X2.7 *Peak Selection*—Participants were required to measure intensity of the peaks specified in Table X2.2 plus one or more peaks for the internal standard, though they were encouraged to measure additional peaks, as many as possible for each phase. Analysis using a manual diffractometer is probably limited to the few peaks in Table X2.2, whereas analysis using a computer-controlled diffractometer can utilize many peaks for each phase.

TABLE X2.2 Peaks Recommended for QXRD Analysis

Phase	hkl	*d*-spacing (nm)	Position (°2θ) using Cu Kα
Orthorhombic C_3A[A]	(113)	0.4210	21.1
Cubic C_3A	(023)	0.4236	21.0
	(213)	0.4083	21.8
C_4AF	(130)	0.3654	24.3
M	(200)	0.2106	42.9

[A] Note that the intensity of the (113) peak of orthorhombic C_3A must be corrected for any contribution from the (023) peak of cubic C_3A. The intensity of the (023) peak is calculated by multiplying the (213) peak by a correction factor. The correction factor is determined by measuring the intensity ration of the (023) peak to the (213) peak in a sample containing cubic C_3A and no orthorhombic C_3A.

X2.8 *C_3A Correction*—The intensity of the (113) peak of orthorhombic C_3A must be corrected for any contribution from the (023) peak of cubic C_3A. This (023) intensity contribution is calculated by multiplying the (213) peak by a correction factor, which is the intensity ratio of the (023) peak to the (213) peak for cubic C_3A using Sample A (which contains no orthorhombic C_3A).

X2.9 *Intensity Measurement*—Integrated intensity above the background must be measured for each peak. There are a number of procedures for measuring integrated intensity, and no specific procedure is required for this standardization.

X2.10 *Standardization Curve*—Once the standardization mixtures have been analyzed, standardization curves relating the measured intensity of each peak, relative to the intensity of the internal standard peak, to the known proportion of the

[8] In this test method, SRM clinkers refer specifically to SRM 2686, SRM 2687, and SRM 2688. These are available from the Standard Reference Material Program, National Institute of Standards and Technology.

TABLE X2.1 Proportion of Phases in Standardization Mixtures

Phase	Percent of Mixture			Percent of Clinker		
	A	B	C	A	B	C
Orthorhombic C_3A	0	51	7	0.00	8.67	1.19
Cubic C_3A	65	11	29	11.05	1.87	4.93
C_4AF	35	11	60	5.95	1.87	10.20
M	0	27	4	0.00	4.59	0.68

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

phase must be developed. These curves may be prepared graphically or using accepted statistical procedures to determine the best-fitting curve. When an internal standard is used, it is assumed that the peak intensity is linearly related to the phase proportion. However under certain circumstances it may be found that the relationship is not linear, but is better described by some other mathematical function.

X2.11 *Analysis of Unknown Mixtures*—Two additional mixtures of the standardization phases were analyzed using the same QXRD procedures to provide a preliminary assessment of the standardization.

X2.12 *Analysis of Cement or Clinker*—The following procedures were followed during analysis of the SRM® clinkers and are recommended for analysis of any portland cement or portland-cement clinker.

X2.12.1 *Grinding*—The clinker samples were ground such that at least 95 % was finer than 10 µm and not more than 5 % was finer than 1 µm. The following procedure has been found to be suitable: grind using a tungsten carbide ring and puck mill, with approximately 5 drops ethylene glycol as a grinding aid, for 4 to 6 min. It is necessary to start with enough sample to provide sufficient powder for the specimen mount, considering that extraction of the calcium silicates will leave ca. 15 to 20 % (by mass) for XRD analysis.

X2.12.2 *Ignition*—In the case of analyzing portland cement for C_3A, C_4AF, and M, gypsum ($C\bar{S}H_2$) and hemihydrate ($C\bar{S}H_{1/2}$) must be converted to anhydrite ($C\bar{S}$) before QXRD analysis to eliminate interfering XRD peaks. This conversion can be carried out by igniting the cement for 30 min at 500 °C.

X2.12.3 *Blending with Internal Standard*—The ground sample was blended with the internal standard using the same procedure as used during the standardization. The recommended proportion was 0.0200 g internal standard per gram of clinker to approximate the 12 % (by mass) recommended for the standardization mixtures.

X2.12.4 *Extraction*—The calcium silicates were extracted chemically using salicylic acid or maleic acid and methanol using procedures described by Struble (**17**). This extraction was not quantitative; because the internal standard was added relative to unextracted clinker, the phase contents were determined relative to the un-extracted clinker.

X2.12.5 *XRD Analysis*—The clinkers were analyzed using the same procedures (for example, collection of the diffraction pattern, measurement of peak intensities, and calculation of phase proportions) that were used in the standardization.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 1365 – 05, that may impact the use of this test method. (Approved December 15, 2006)

(*1*) The standard was extensively revised to include new development in X-ray powder diffraction analysis as well as provide for a more complete analysis, and to include a precision statement.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1381/C 1381M – 97 (Reapproved 2008)ε1

Standard Specification for Molded Glass Fiber Reinforced Gypsum Parts[1]

This standard is issued under the fixed designation C 1381/C 1381M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—The units statement in subsection 1.2 was corrected and the standard was changed to a dual designation editorially in July 2008.

1. Scope

1.1 This specification covers molded glass fiber reinforced gypsum (GRG) parts, which are nonload-bearing, thin-shell, ornamental shapes for architectural embellishment of interior building construction.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 The information presented refers to the molded surface of the part.

1.4 The text of this standard references footnotes, which provide explanatory material. These footnotes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 1355/C 1355M Specification for Glass Fiber Reinforced Gypsum Composites

3. Terminology

3.1 *Definitions*—Definitions of terms shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *control thickness*, *n*—the thickness of the GRG part where abutting other GRG parts, other products or at fastening points.

3.2.2 *embedments*, *n*—materials encapsulated into the part for the purpose of suspension, attachment, and stiffening.

3.2.3 *finish surface*, *n*—a surface against a mold.

3.2.4 *GRG part*, *n*—an individual molded component used as architectural embellishment.

3.2.5 *GRG product*, *n*—combination of GRG parts used as architectural embellishment.

3.2.6 *mock-up*, *n*—a presentation assembly of GRG parts defined by the purchase agreement.

3.2.7 *part thickness*, *n*—thickness of a part at any measurement point.

4. Materials and Manufacture

4.1 *Materials*—GRG parts shall be produced using the same materials used to make the composites in conformance with Specification C 1355/C 1355M.

4.2 *Manufacture*:

4.2.1 *GRG* parts shall be manufactured from the mixed slurry of alpha gypsum cement, potable water and additives, when used, and not less than 5 % by weight glass fiber reinforcement using either the hand lay-up or the spray-up process in a mold.

4.2.2 *GRG* parts shall be produced according to approved shop drawings.

4.2.3 Shop drawings shall specify part dimensions, quantities, recommended attachment points and methods, reinforcements, embedments, and tolerance.

5. Mechanical Properties

5.1 *GRG* parts shall be made from materials to make composites having properties in accordance with Specification C 1355/C 1355M.

6. Dimensions and Tolerances of GRG Parts

6.1 *Part Thickness*—The thickness of the GRG part shall be not less than 3⁄16 in. [5 mm].

6.2 *Control Thickness*, shall be not less than 5⁄16 in. [8 mm].

6.3 *Straightness*—At any point on a line generally along a plane, an edge, or a surface, the molded side of the part shall not vary from straight ± 1⁄8 in. in 8 linear ft [1 mm in 750 mm].

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved May 1, 2008. Published July 2008. Originally approved in 1998. Last previous edition approved in 2002 as C 1381 – 97(2002)ε1.

6.4 *Dimensions*, as specified in approved shop drawings, pertaining to the individual part.

6.4.1 *Overall Width*, ± ⅛ in. [3 mm].

6.4.2 *Dimensions Within the Overall Width*, ± 1⁄16 in. [2 mm].

6.4.3 *Overall Length*, ± ⅛ in. [3 mm].

6.4.4 *Dimensions Within the Overall Length*, ± 1⁄16 in. [2 mm].

7. Workmanship, Finish and Appearance

7.1 *GRG* parts shall be produced to quality, tolerances, and surface standards set within this specification.

7.2 The standard finished surface shall be suitable to receive flat paint.

7.3 Finishes with sheen, direct light or special lighting conditions require additional coats of primer, sanding and finishing by the installer or painter.

8. Sampling

8.1 When specified by the purchase agreement, samples of the GRG part shall be taken at the place of manufacture for measuring in accordance with Section 6.

8.2 *Mock-Up*—When specified by the purchase agreement, a mock-up shall be supplied.

9. Inspection

9.1 Inspection of the GRG parts shall be agreed upon between the purchaser and the supplier as part of the purchase agreement.

10. Rejection and Rehearing

10.1 Rejection of GRG parts that fail to conform to the requirements of this specification shall be reported in writing to the producer or supplier within 14 calendar days from receipt of parts and prior to installation.

11. Certification

11.1 When specified in the purchase agreement, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase agreement, a report of test results shall be furnished.

12. Quality Assurance

12.1 Each manufacturer's measuring of samples shall be representative of actual production procedures and materials. The GRG manufacturer shall certify that the materials are the same as those used to produce the composite according to C 1355/C 1355M.

13. Marking

13.1 Each GRG part shall be marked clearly according to the project shop drawings.

14. Packaging

14.1 Packaging shall ensure that the GRG parts arrive at the jobsite in good condition when handled and shipped according to industry operating standards.

15. Keywords

15.1 glass fiber reinforced gypsum; glass fiber reinforced gypsum composite; glass fiber reinforced gypsum parts; GRG; GRG composites; GRG parts

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1383 – 04

Standard Test Method for Measuring the P-Wave Speed and the Thickness of Concrete Plates Using the Impact-Echo Method[1]

This standard is issued under the fixed designation C 1383; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers procedures for determining the thickness of concrete slabs, pavements, bridge decks, walls, or other plate-like structure using the impact-echo method.

1.2 The following two procedures are covered in this test method:

1.2.1 *Procedure A: P-Wave Speed Measurement*—This procedure measures the time it takes for the P-wave generated by a short-duration, point impact to travel between two transducers positioned a known distance apart along the surface of a structure. The P-wave speed is calculated by dividing the distance between the two transducers by the travel time.

1.2.2 *Procedure B: Impact-Echo Test*—This procedure measures the frequency at which the P-wave generated by a short-duration, point impact is reflected between the parallel (opposite) surfaces of a plate. The thickness is calculated from this measured frequency and the P-wave speed obtained from Procedure A.

1.2.3 Unless specified otherwise, both Procedure A and Procedure B must be performed at each point where a thickness determination is made.

1.3 The values stated in SI units are to be regarded as the standard.

1.4 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.1 *ASTM Standards:* [2]

C 597 Test Method for Pulse Velocity Through Concrete

E 1316 Terminology for Nondestructive Examinations

3. Terminology

3.1 *Definitions:*

3.1.1 *acoustic impedance*—the product of P-wave speed and density that is used in computations of characteristics of stress wave reflection at boundaries.

3.1.2 *amplitude spectrum*—a plot of relative amplitude versus frequency that is obtained from the waveform using a Fourier transform technique.

3.1.3 *Fourier transform*—a numerical technique used to convert digital waveforms from the time domain to the frequency domain.

3.1.3.1 *Discussion*—The peaks in the amplitude spectrum correspond to the dominant frequencies in the waveform.

3.1.4 *impact-echo method*—a send-receive nondestructive test method based on the use of a short-duration mechanical impact to generate transient stress waves and the use of a broadband receiving transducer placed adjacent to the impact point.

3.1.4.1 *Discussion*—Waveforms are converted to the frequency domain and the resulting amplitude spectra are analyzed to obtain the dominant frequencies in the structure's response to the impact. These frequencies are used to determine the thickness of the structure or the presence of flaws.

3.1.5 *impact duration*—the time that the impactor used to generate stress waves is in contact with the test surface. Also referred to as contact time.

3.1.5.1 *Discussion*—The impact duration is a critical aspect in the success of the two procedures covered by this method. Recommended impact durations are given. In practice, the impact duration will depend on the type of impactor and the condition of the concrete at the point of impact. Smooth, hard

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.64 on Nondestructive and In-Place Testing.

www.technobetar.ir

surfaces will result in shorter impact durations than rough, soft surfaces. The user should verify that the impact durations are within the recommended ranges. An approximate measure of the impact duration can be obtained from the portion of the waveform corresponding to the surface wave arrival.[3] Fig. 1

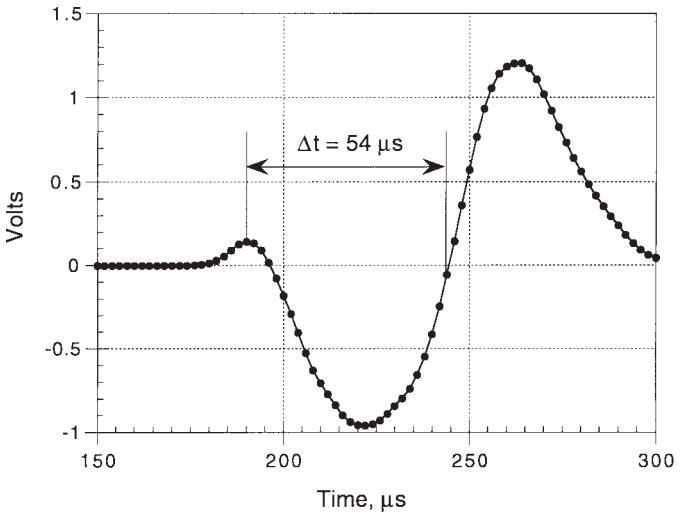

FIG. 1 Expanded View of Surface-Wave Portion of Waveform Showing the Width of the Surface Wave Signal as an Approximation of the Contact Time of the Impact

shows an example of the surface-wave portion of a waveform and the approximate contact time is indicated.

3.1.6 *P-wave*—the dilatational (longitudinal or primary) stress wave that causes particle displacement parallel to the direction of wave propagation. This wave produces normal stresses (tensile or compressive) as it propagates.

3.1.7 *P-wave speed*—the speed with which the P-wave propagates through a semi-infinite solid.

3.1.7.1 *Discussion*—The P-wave speed is the same as the compressional pulse velocity measured according to Test Method C 597.

3.1.8 *sampling frequency*—the rate at which the points that comprise the waveform are recorded; the inverse of the sampling interval, expressed in Hz or samples/s (also referred to as *sampling rate*).

3.1.9 *sampling period*—the duration of the waveform, which equals the number of points in the waveform multiplied by the sampling interval.

3.1.10 *sampling interval*—the time difference between any two adjacent points in the waveform.

3.1.11 *surface wave*—a stress wave in which the particle motion is elliptical and the amplitude of particle motion decreases rapidly with depth. Also known as *Rayleigh wave* (or *R-wave*).

3.1.12 *waveform*—a recorded signal from a transducer that is a plot of voltage versus time.

3.1.13 Refer to Terminology E 1316 for additional definitions, related to nondestructive ultrasonic examination, that are applicable to this test method.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *apparent P-wave speed in a plate*[3,4]—a parameter that is 0.96 of the P-wave speed:

$$C_{p,\,plate} = 0.96\,C_p \tag{1}$$

where:

$C_{p,\,plate}$ = the apparent P-wave speed in a plate, m/s, and
C_p = the P-wave speed in concrete that is obtained from Procedure A, m/s.

3.2.1.1 *Discussion*—This parameter is used in thickness calculations in impact-echo measurements on plates. The P-wave speed in a material (concrete) is converted to the apparent P-wave speed in a plate that is used to calculate the plate thickness by the following equation:

$$T = \frac{C_{p,\,plate}}{2f} \tag{2}$$

where:

T = the thickness of the plate, m, and
f = the frequency of the P-wave thickness mode of the plate obtained from the amplitude spectrum, Hz.

3.2.2 *plate*—any prismatic structure where the lateral dimensions are at least six times the thickness.

3.2.2.1 *Discussion*—Minimum lateral dimensions are necessary to prevent plate modes[3] of vibration from interfering with the identification of the thickness mode frequency in the amplitude spectrum. The minimum lateral dimensions and acceptable sampling period are related, as explained in Note 11.

4. Significance and Use

4.1 This test method may be used as a substitute for, or in conjunction with, coring to determine the thickness of slabs, pavements, decks, walls, or other plate structures. There is a certain level of systematic error in the calculated thickness due to the discrete nature of the digital records that are used. The absolute systematic error depends on the plate thickness, the sampling interval, and the sampling period.

4.2 Because the wave speed can vary from point-to-point in the structure due to differences in concrete age or batch-to-batch variability, the wave speed is measured (Procedure A) at each point where a thickness determination (Procedure B) is required.

4.3 The maximum and minimum thickness that can be measured is limited by the details of the testing apparatus (transducer response characteristics and the specific impactor). The limits shall be specified by manufacturer of the apparatus, and the apparatus shall not be used beyond these limits. If test equipment is assembled by the user, thickness limitations shall be established and documented.

www.technobetar.ir

4.4 This test method is not applicable to plate structures with overlays, such as a concrete bridge deck with an asphalt or portland cement concrete overlay. The method is based on the assumption that the concrete plate has the same P-wave speed throughout its depth.

4.5 Procedure A is performed on concrete that is air dry as high surface moisture content may affect the results.

4.6 Procedure B is applicable to a concrete plate resting on a subgrade of soil, gravel, permeable asphalt concrete, or lean portland cement concrete provided there is sufficient difference in acoustic impedance[3] between the concrete and subgrade or there are enough air voids at the interface to produce measurable reflections. If these conditions are not satisfied, the waveform will be of low amplitude and the amplitude spectrum will not include a dominant peak at the frequency corresponding to the thickness (Eq 2). If the interface between the concrete and subgrade is rough, the amplitude spectrum will have a rounded peak instead of a sharp peak associated with a flat surface.

4.7 The procedures described are not influenced by traffic noise or low frequency structural vibrations set up by normal movement of traffic across a structure.

4.8 The procedures are not applicable in the presence of mechanical noise created by equipment impacting (jack hammers, sounding with a hammer, mechanical sweepers, and so forth) on the structure.

4.9 Procedure A is not applicable in the presence of high amplitude electrical noise, such as may produced by a generator or some other source, that is transmitted to the data-acquisition system.

PROCEDURE A—P-WAVE SPEED MEASUREMENT

5. Summary of Procedure

5.1 An impact on the concrete surface is used to generate transient stress waves. These waves propagate along the surface of the concrete past two transducers, placed on a line through the impact point and at a known distance apart.

5.2 The time difference between the arrival of the P-wave (stress wave with highest speed) at each transducer is used to determine the P-wave speed by dividing the time difference (travel time) by the known distance between the transducers.

6. Apparatus [5]

6.1 *Impactor*—The impactor shall be spherical or spherically tipped. It shall produce an impact duration of 30 ± 10 μs with sufficient energy to produce surface displacements due to the P-wave that can be recorded by the two transducers (see Note 1). The impactor shall be positioned to strike on the centerline passing through the two transducers at a distance of 150 ± 10 mm from the first transducer.

NOTE 1—Hardened steel balls ranging from 5 to 8 mm in diameter and attached to steel spring rods have been found to produce suitable impacts.

6.2 *Transducers*—Two broadband transducers that respond to displacements normal to the surface. These transducers must be capable of detecting the small displacements that correspond to the arrival of the impact-generated P-wave traveling along the surface. A small contact area between the piezoelectric element and the concrete surface is required to record accurately the arrival of the P-wave (see Note 2). Use a suitable material to couple the transducer to the concrete.

NOTE 2—A commercially available displacement transducer made from a conical piezoelectric element with a tip diameter of 1.5 mm and the larger end attached to a brass backing block has been found suitable.[6] A lead sheet approximately 0.25 mm thick is a suitable coupling material for such a transducer.

6.2.1 Acceptable transducers shall be previously documented to produce accurate results for plate thicknesses similar to those being measured by this test method.

6.3 *Spacer Device*—A spacer device shall be provided to hold the transducers a fixed distance apart. It shall not interfere with the ability of the transducers to measure surface displacement. It shall be manufactured to minimize the possibility of P-wave transmission through it so as to prevent interference with measurement of the P-wave travel time. The transducer tips shall be placed about 300 mm apart. Measure and record to the nearest 1 mm the actual distance between the centers of the transducer tips.

NOTE 3—The accuracy of the measurement is affected if the distance between the tips of the two transducers is not known accurately. The materials and design of the spacer device should be chosen to minimize the change in separation of the transducers due to changes in temperature.

6.4 *Data-Acquisition System*—Hardware and software for acquiring, recording, and processing the output of the two transducers. This system can be a portable computer with a two-channel data-acquisition card, or it can be a portable two-channel waveform analyzer.

6.4.1 The sampling frequency for each channel shall be 500 kHz or higher (sampling interval of 2 μs or less). The system shall be capable of triggering on the signal from one of the recording channels.

6.4.2 The voltage range and voltage resolution of the data acquisition system shall be matched with the sensitivity of the transducers so that the arrival of the P-wave is determined accurately.

NOTE 4—For example, a computer data acquisition card with a voltage range of ±2.5 V and 12-bit resolution has been found to be suitable for the transducer described in Note 2.

6.4.3 The display system shall include cursors, including a corresponding readout of time and voltage, that can be positioned at the point in each waveform corresponding to the P-wave arrival.

6.4.4 The data-acquisition system shall be operated by a power source that does not produce electrical noise detectable by the transducers and data acquisition system when the system is set at the voltage sensitivity required to detect the arrivals of the P-wave.

NOTE 5—Battery-powered data acquisition systems have been found suitable.

[5] Suitable apparatus is available commercially.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.5 *Cables and Connectors*—To connect the transducers to the data acquisition system. Connectors shall be high quality and tightly connected to the cables. The cables shall be shielded to reduce electrical noise.

6.6 *Functionality Check Apparatus*—Apparatus to verify that all components of test system are functioning properly prior to the start of testing.

NOTE 6—This may include a reference test specimen whose impact response has been determined and can be compared with the output of the test system.

7. Preparation of Test Surface

7.1 The test surface shall be dry. Remove dirt and debris from the surface where the P-wave speed is to determined.

7.2 If the test surface is extremely rough so that it is difficult to achieve good contact between the transducer tips and the concrete, grind the surface so that good contact is achieved. Remove loose material prior to coupling the transducers to the surface.

NOTE 7—Surface roughness may be a problem when testing highway pavements with roughly textured or grooved surfaces. On new construction, curing compounds may have to be removed at test locations to permit proper coupling of the transducers and to obtain short duration impacts.

8. Procedure

8.1 Fig. 2 shows a schematic of the test set-up for Procedure A.

8.2 Assemble the apparatus (transducers, spacer device, impactor). Verify that the test system is functioning properly. Position the apparatus on the concrete surface, and position the impactor to strike on the line passing through the two transducers and at a distance of 150 ± 10 mm from the first (triggering) transducer. If testing on a grooved surface, test parallel to the grooves, so that the line through the transducers and the impactor does not cross a groove. If cracks are present, position the apparatus so that no cracks intersect the line passing through the impact point and the two transducers.

8.3 Ready the data-acquisition system with correct data acquisition parameters (sampling frequency, voltage range, triggering level, delay, and so forth).

NOTE 8—For some systems, it is advisable to set the data acquisition parameters so that about 100 points are recorded before the trigger point. This pre-trigger information permits an assessment of the baseline value in the waveform before P-wave arrival. Due to electrical noise, the signal may fluctuate before P-wave arrival, and knowing the amplitude of those fluctuations assists in identifying P-wave arrival.

8.4 Perform the impact. Examine the acquired waveforms. If the waveforms from both transducers are valid, store the data for subsequent analysis. If the P-wave arrivals cannot be identified with certainty, repeat the test at the same position or move to a different position to achieve good coupling between the transducers and concrete.

NOTE 9—Fig. 3 is an example to illustrate a valid set of waveforms with the arrows positioned at the points corresponding to the P-wave arrivals in each waveform. In this case the arrivals of the P-wave at the transducer locations are clearly identified by the rise of the waveforms above background levels. The calculated P-wave speed is 0.3/(0.000076) = 3950 m/s, which is a reasonable value.

9. Data Analysis and Calculations

9.1 Display on the screen of the data acquisition system the waveforms from the two transducers so that they are plotted against the same time axis.

9.2 Identify the arrival time of the direct P-wave in each waveform. The arrival of the P-wave is identified as the first point where the voltage changes from the base line value (see Fig. 3). Use the cursors to display the voltage and time readings at the points corresponding to the P-wave arrivals. Determine the time difference, Δt, between the arrival of the P-wave in

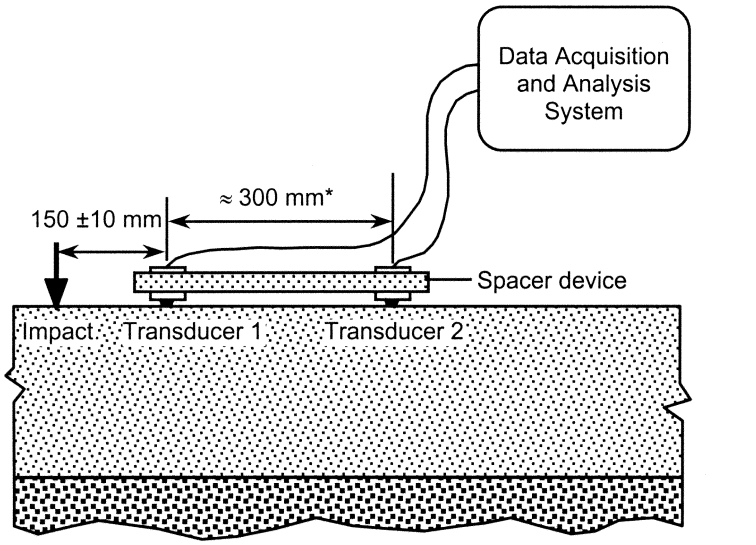

FIG. 2 Schematic of Testing Configuration for Procedure A

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

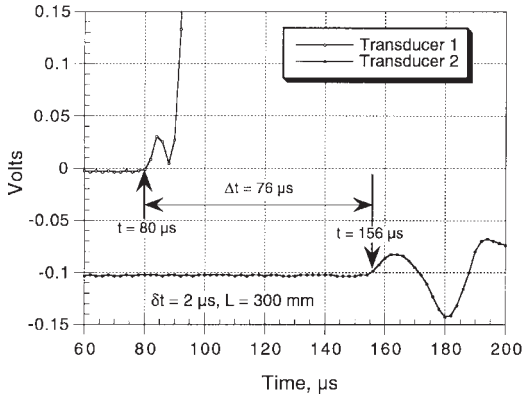

FIG. 3 Example of waveforms obtained using Procedure A (Only Early Part of Waveforms are Plotted)

each waveform. This time difference is the travel time. Automated detection of the P-wave arrivals in the waveforms is permitted provided the waveforms are stable (do not contain noise) before the P-wave arrivals.

9.3 Use the measured travel time, Δt, and measured spacing between the transducers, L, to calculate the P-wave speed:

$$C_p = \frac{L}{\Delta t} \tag{3}$$

9.4 Perform two replicates of the test at each test location. If the measured travel time is the same in both cases, then proceed to other test points. If the two travel times differ by one sampling interval or more, perform a third test and accept that travel time that repeats as the correct value. If two of the three measurements do not agree, ensure that the transducers are making good contact with the surface, and repeat the test.

9.5 Calculate the apparent P-wave speed in a plate using Eq 1.

9.6 *Alternative Procedure*—Under circumstances where maximum accuracy in measured thickened is not critical, the apparent P-wave speed in the concrete is permitted to be determined by direct calibration with measured thickness at points in the structure. Determine the thickness of the structure, determine the thickness frequency at the same point in accordance with Procedure B, and use Eq 2 to solve for the apparent wave speed. The purchaser of testing services and the testing agency shall agree on whether this alternative is permitted. They shall agree further on the number and location of calibration points and the method of determining concrete thickness. When this alternative procedure is used, the interpretation procedure in Section 15 is not applicable.

PROCEDURE B—IMPACT-ECHO TEST

10. Summary of Test Method

10.1 Impact on the surface of the concrete generates stress waves, of which the P-wave is of primary importance. The P-wave propagates into the plate and is reflected from the opposite surface.

10.2 Multiple reflections of the P-wave between the plate surfaces give rise to a transient thickness resonance with a frequency related to the plate thickness.

10.3 A receiving transducer, located adjacent to the impact point, records the surface displacement caused by the arrival of the reflected waves. The output of the transducer is captured as a time domain waveform.

10.4 The recorded waveform is transformed into the frequency domain using a Fourier transform technique and an amplitude spectrum is obtained. The thickness resonance produces one dominant peak in the spectrum, which can be readily identified. The frequency value of this peak is used in conjunction with the apparent P-wave speed obtained from Procedure A to calculate the thickness of the plate by using Eq 2.

11. Apparatus

11.1 *Impactor*—The impactor shall be spherical or spherically tipped. It shall deliver sufficient energy to a solid plate so that a well defined amplitude spectrum is obtained with a single predominant peak. The impact duration, t_c, must be less (see 3.1.5) than the round-trip travel time for a P-wave, that is:

$$t_c < \frac{2T}{C_p} \tag{4}$$

NOTE 10—Hardened steel balls with diameters ranging from 8 to 16 mm in diameter and attached to steel spring rods and spherically tipped mechanical impactors have been used as suitable impactors for typical highway pavements.

11.2 *Transducer*—A broadband transducer that responds to displacements normal to the surface. This transducer is the same as that described under Procedure A.

11.3 *Data-Acquisition System*—For acquiring, recording and processing the output of the transducer. This system can be the same as that described under Procedure A.

11.3.1 The typical sampling frequency is between 500 kHz (2 μs interval) and 250 kHz (4 μs interval).

11.3.2 The typical number of data points in the recorded waveform is 1024 or 2048.

11.3.3 The typical duration of the recorded waveform (the sampling period) is 4096 μs or 8192 μs.

NOTE 11—The sampling period is the product of the number of recorded points and the sampling interval. The inverse of the sampling period establishes the frequency interval in the amplitude spectrum obtained by the fast Fourier transform method. A sampling period of 4096 μs corresponds to a frequency interval of 244 Hz and a sampling period of 8192 μs corresponds to 122 Hz. A smaller frequency interval results in a more accurate thickness measurement. However, the sampling period should be chosen considering the lateral dimensions of the plate relative to the thickness of the plate. If the smaller lateral dimension is at least 20 times the thickness, a sampling period of 8192 μs may be used. If the smaller lateral dimension is at least 10 times the thickness, a sampling period of 4096 μs may be used. For smaller lateral dimensions, a shorter sampling period will have to be used, resulting in a greater uncertainty in the measured thickness. These limitations are necessary to assure that the waveform does not include motion associated with other modes of vibration that would interfere with the ability to identify the thickness frequency of the plate in the amplitude spectrum.

11.3.4 The voltage range for data acquisition shall be such that the amplitude of the waveform is sufficient to permit visual examination of its key features, such as the surface wave signal and the subsequent oscillations.

NOTE 12—A voltage range that is too high may result in a displayed

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:33:23 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

waveform with small amplitude making it difficult to examine. A voltage range that is too low may result in clipping of the transducer signal. A digitizer with at least 12-bit resolution is recommended.

11.3.5 Software shall be provided for acquiring, recording, displaying, and analyzing data. The software shall compute the amplitude spectrum from the recorded waveform. The amplitude spectrum shall be displayed immediately after the waveform has been captured. A cursor for manually determining the thickness frequency shall be included. It is permitted to use software to determine the thickness frequency.

11.3.6 The data-acquisition system shall be operated by a power source that does not produce electrical noise that is detected by the transducer and data acquisition system when the system is set at the voltage range used for testing (see Note 5).

11.4 *Cables and Connectors*, as described under Procedure A.

11.5 *Functionality Check Apparatus*, as described under Procedure A.

12. Preparation of Test Surface

12.1 Remove dirt and debris from the surface where the thickness is to determined.

12.2 If the test surface is extremely rough so that it is difficult to achieve good contact between the transducer tip and the concrete, grind the surface so that good contact is achieved (see Note 7).

13. Procedure

13.1 Fig. 4 is a schematic of an impact-echo test on a plate.

13.2 Position the transducer on the concrete surface where thickness is to be measured. Position the impactor to strike at a distance less than 0.4 of the nominal plate thickness away from the transducer.

13.3 Ready the data-acquisition system with correct data acquisition parameters (sampling frequency, voltage range, triggering level, delay, and so forth). Data acquisition shall be triggered by the transducer signal or by an instrumented impact device. If necessary, establish data acquisition parameters by trial tests.

NOTE 13—For some systems, it is advisable to set the data acquisition parameters so that about 100 points are recorded before the trigger point. The initial portion of the waveform provides information on the contact time of the impact and can help identify invalid waveforms due to improper coupling, electrical noise, or other factors.

13.4 Perform the impact. Examine the acquired waveform and corresponding amplitude spectrum. In making a judgment about the validity of the waveform, examine whether the portion of the waveform corresponding to the surface wave is of the correct shape and that the surface wave is followed by periodic oscillations corresponding to multiple reflections between the plate boundaries. The amplitude spectrum of a valid waveform will have a single dominant peak at a frequency corresponding to the plate thickness.

NOTE 14—Fig. 5 shows an example of a valid time domain waveform and its corresponding amplitude spectrum for a test of a concrete slab on grade. The sampling interval is 4 μs and the number of points in the complete waveform (not shown) is 2048.

13.5 If a valid waveform and amplitude spectrum have been obtained, store the waveform and amplitude spectrum. Repeat the test to verify the results. If the results are repeatable and valid, move to the next test point. If the waveform and amplitude spectrum are not valid (see Note 15), check that the test surface is free of dust and debris and that the transducer is coupled properly to the test surface. Also check that the impact point is flat and free of debris, and that the correct size of impactor is being used. Repeat the test until a valid waveform and amplitude spectrum are obtained.

NOTE 15—Fig. 6 shows an example of invalid impact-echo test results. The waveform lacks periodic oscillations and the amplitude spectrum does not contain a single dominant peak.

14. Data Analysis

14.1 Determine the frequency of the high-amplitude peak in the amplitude spectrum.

14.2 Calculate the thickness of the plate using Eq 2.

15. Interpretation of Results (Systematic Errors)

15.1 There are systematic errors in determining the wave speed and the thickness of concrete plates because of the digital

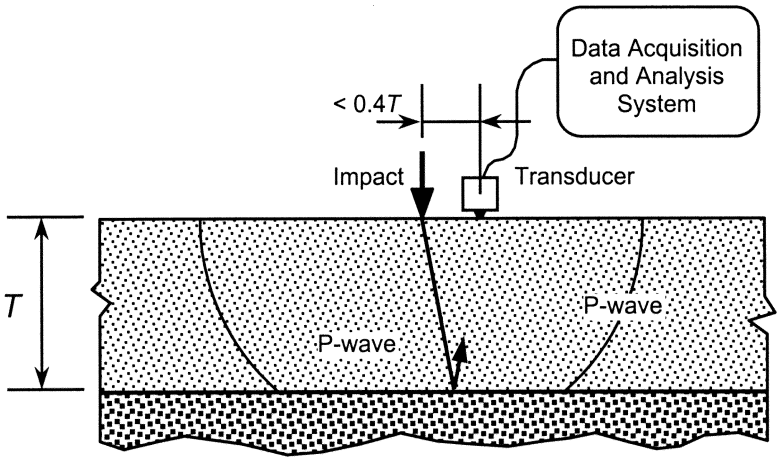

FIG. 4 Schematic of Testing Configuration for Impact-Echo Test (Procedure B)

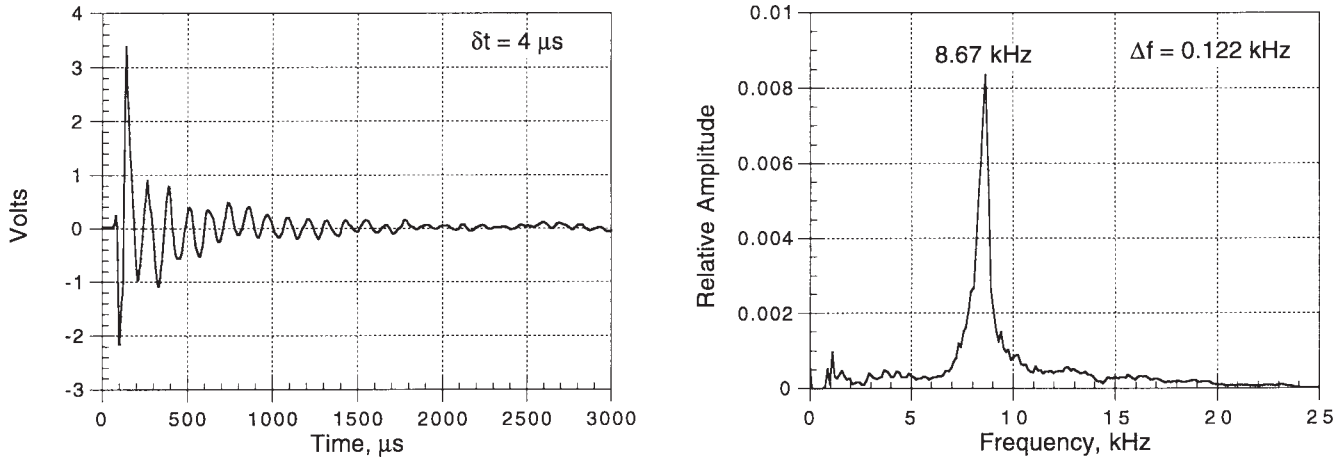

FIG. 5 Waveform and Amplitude Spectrum for a Valid Impact-Echo Test of 250-mm Thick Concrete Slab

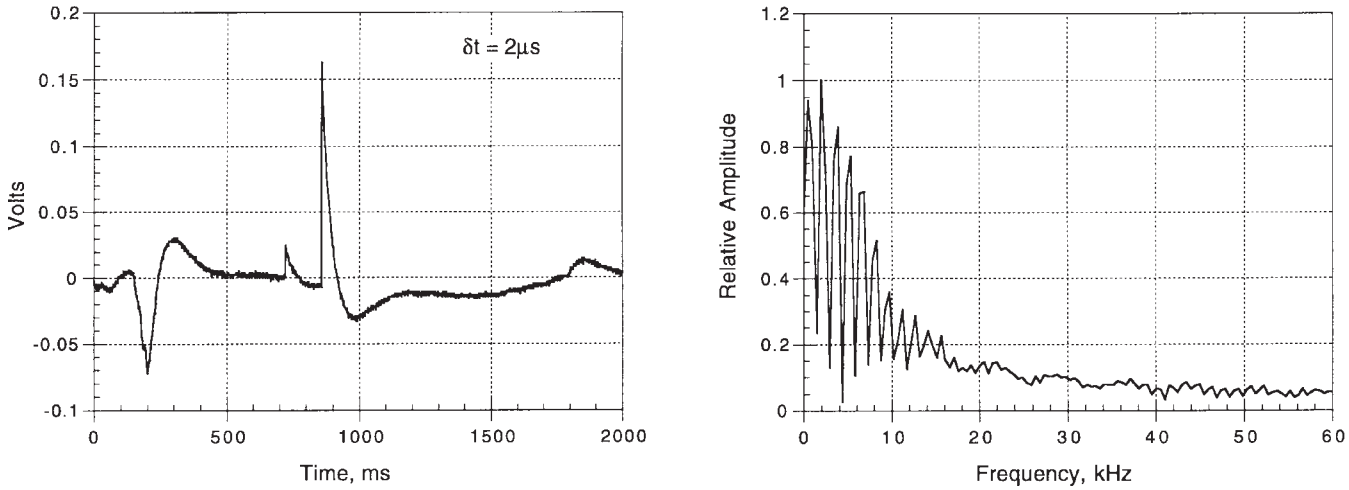

FIG. 6 Example of an Invalid Impact-Echo Test, the Waveform Does Not Display Periodic Oscillations and the Amplitude Spectrum does not have a Single Dominant Peak

nature of the waveforms and amplitude spectra. Thus there is an inherent systematic error in the computed P-wave speeds and plate thicknesses. The appendix provides derivations of the expressions for maximum systematic errors.

15.2 *Systematic Error in Procedure A*—The maximum systematic error in the calculated P-wave speed is given by:

$$e_p = \pm \frac{\delta t}{\Delta t} \tag{5}$$

where:

δt = sampling interval, and
Δt = measured P-wave travel time.

15.2.1 Eq 5 is based on the assumption that there is no electrical noise in the waveforms, so that the P-wave arrival can be identified easily. Fig. 7 shows the maximum systematic error due to the sampling interval as a function of the travel time. Report the P-wave speed calculated according to Eq 3 as follows:

$$C_p \pm e_p C_p \tag{6}$$

15.3 *Systematic Error in Procedure B*—The maximum systematic error in the calculated thickness due to frequency resolution is given by the following equation:

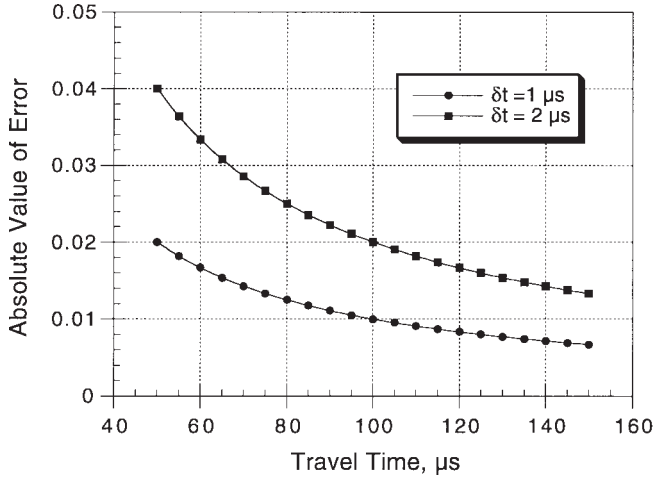

FIG. 7 Maximum Systematic Error Due to Sampling Interval as a Function of the Travel Time

$$e_f = \pm \frac{\Delta f}{2f} \tag{7}$$

where:

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Δf = the frequency interval in the amplitude spectrum, and
f = the frequency corresponding to the high amplitude peak in the amplitude spectrum.

15.3.1 Fig. 8 shows the maximum systematic error in the calculated thickness due to the frequency resolution as a function of the measured frequency. A higher frequency corresponds to a lower thickness, and there is less systematic error in the computed thickness as the thickness decreases.

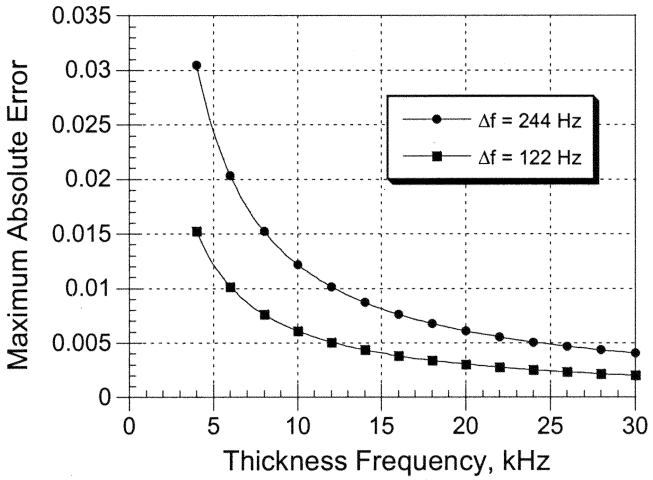

FIG. 8 Maximum Systematic Error Due to Frequency Interval as a Function of Thickness Frequency

15.4 *Combined Systematic Error*—An estimate of the maximum expected systematic error in the calculated thickness that accounts for both sources of error is given by the following equation:[7]

$$e = \sqrt{e_p^2 + e_f^2} \tag{8}$$

15.5 *Reporting Thickness*—Report plate thickness, which is calculated according to Eq 2, as follows:

$$T \pm eT \tag{9}$$

16. Report

16.1 Report the data acquisition parameters that were used. These include the sampling interval, the voltage range, the voltage resolution, the number of points in the waveform, and the frequency interval in the amplitude spectrum.

16.2 The location of each test point on the structure, a description of the condition of the test surface, and whether grinding was required.

16.3 For concrete slabs on grade, report the type of material supporting the slab, if known.

16.4 The P-wave speed in accordance with 15.2.1.

16.5 The plate thickness in accordance with 15.5.

16.6 If the alternative procedure in 9.6 was used to establish the apparent P-wave speed, provide the calibration data and report how the data were used to estimate concrete thickness.

17. Precision and Bias

17.1 The precision and bias of this test method are unknown at this time. Data comparing core lengths with pavement thicknesses obtained by an earlier version of this test method are given in the reference cited in footnote 3. That reference indicates that the differences in pavement thickness by measurement of cores and by this test method were within ±3 % for pavement thickness varying from 200 to 290 mm.

18. Keywords

18.1 concrete plate; impact-echo; nondestructive testing; P-wave speed; thickness measurement

APPENDIX

(Nonmandatory Information)

X1. SYSTEMATIC ERRORS

X1.1 General

X1.1.1 This test method is based on using digital sampling and digital signal analysis methods. As a result, the time-domain waveforms and amplitude spectra are composed of discrete points with fixed spacings that depend upon the data acquisition parameters. This results in systematic errors between the measured travel times or thickness frequencies and their true values. The following sections explain how to determine the maximum values of these systematic errors. Because of these systematic errors, the P-wave speeds and plate thicknesses obtained from this test method are reported as ranges of values.

X1.2 Systematic Error in P-Wave Speed

X1.2.1 Fig. X1.1 shows a schematic of the early part of the waveforms (voltage versus time) obtained from the two transducers in Procedure A. The solid circles represent the points recorded by the data acquisition system. The solid lines represent the true surface displacements as a function of time. The travel time is measured as the time difference Δt between the two points at which the voltages rises above the background values. The measured travel time differs from the true travel time $\Delta t'$. From Fig. X1.1, it can be shown that:

$$\Delta t = \Delta t' - \epsilon_1 + \epsilon_2 \tag{X1.1}$$

$$\Delta t' - \Delta t = \epsilon_1 - \epsilon_2 \tag{X1.2}$$

The relative error in the calculated P-wave speed due to the differences between the measured and true travel time can be expressed as follows:

$$e_p = \frac{C_p - C'_p}{C'_p} = \frac{\frac{L}{\Delta t} - \frac{L}{\Delta t'}}{\frac{L}{\Delta t'}} = \frac{\Delta t'}{\Delta t} - 1 = \frac{\Delta t' - \Delta t}{\Delta t} = \frac{\epsilon_1 - \epsilon_2}{\Delta t} \tag{X1.3}$$

The maximum absolute value of the error e_p occurs when either $\epsilon_1 = 0$ and $\epsilon_2 = \delta t$; or when $\epsilon_1 = \delta t$ and $\epsilon_2 = 0$. When $\epsilon_1 = 0$ and $\epsilon_2 = \delta t$:

$$e_p = \frac{-\delta t}{\Delta t} \tag{X1.4}$$

When $\epsilon_1 = \delta t$ and $\epsilon_2 = 0$:

$$e_p = \frac{+\delta t}{\Delta t} \tag{X1.5}$$

Therefore, the maximum systematic error in the P-wave speed due to sampling in the time domain is:

$$e_p = \pm \frac{\delta t}{\Delta t} \tag{X1.6}$$

X1.2.2 The above derivation assumes that the two waveforms are obtained by simultaneous sampling of the two channels. Fig. X1.2 is a schematic of the waveforms obtained by a data acquisition system that alternately samples the two channels. It can be shown that the maximum systematic error

www.technobetar.ir

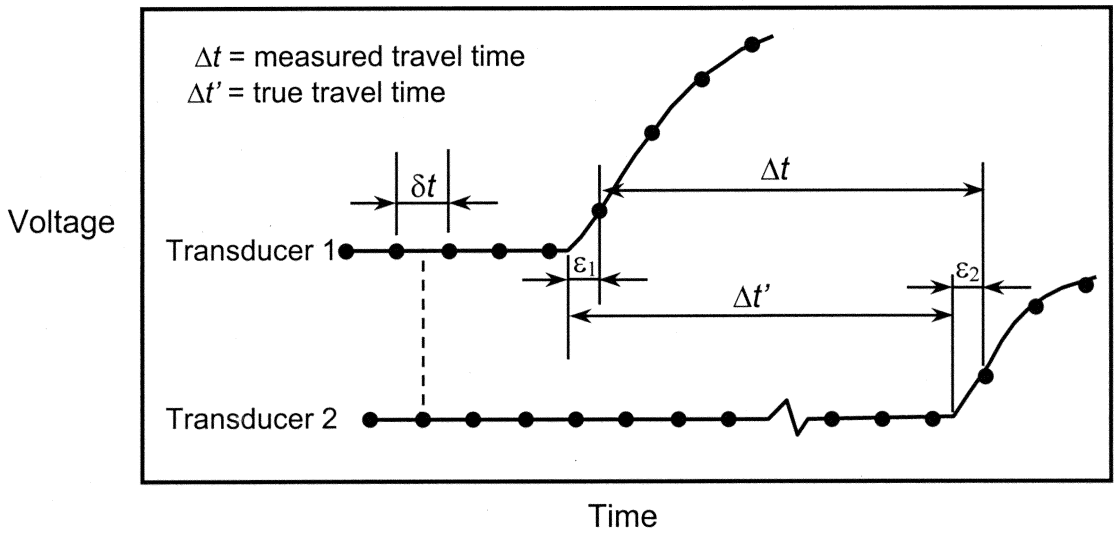

FIG. X1.2 Schematic of Early Part of Waveforms Obtained from Procedure A With a Data Acquisition System That Samples Each Channel Alternately

is the same as given by Eq X1.6 provided the sample interval δt is the time interval between adjacent points in each of the waveforms.

X1.3 Systematic Error in Thickness Due to Frequency Interval in the Amplitude Spectrum

X1.3.1 Fig. X1.3 is a schematic of the amplitude spectrum obtained from an impact-echo test of a solid plate. The high amplitude peak corresponds to the thickness frequency of the plate. The solid circles are the digital values displayed on the computer display, and the solid curve represents the true amplitude spectrum. The measured frequency f differs from the true frequency f'. This difference leads to a systematic error in plate thickness computed using the measured frequency.

X1.3.2 The relative error in the calculated plate thickness is related to the measured frequency and the true frequency as follows:

$$e_f = \frac{T - T'}{T'} = \frac{\frac{0.96\,C_p}{2f} - \frac{0.96\,C_p}{2f'}}{\frac{0.96\,C_p}{2f'}} = \frac{f'}{f} - 1 = \frac{f' - f}{f} \qquad \text{(X1.7)}$$

where:

T = calculated thickness based on measured thickness frequency, f, and

T' = calculated thickness based on true thickness frequency, f'.

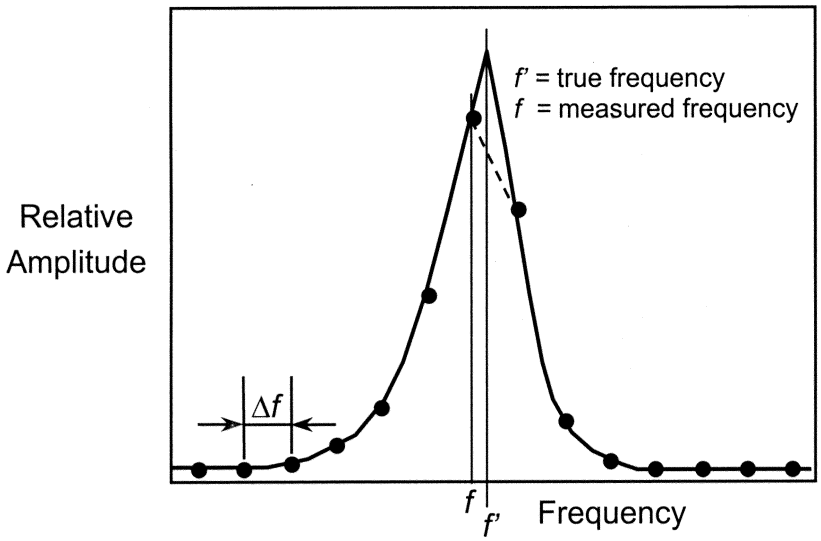

FIG. X1.3 Schematic of Amplitude Spectrum Resulting from an Impact-Echo (Procedure B) Test on a Solid Plate

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:33:23 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

The absolute value of the maximum difference between f and f' is $\Delta f/2$. Therefore, the maximum systematic error in the calculated thickness due to the frequency interval in the amplitude spectrum is:

$$e_f = \pm \frac{\Delta f}{2f} \quad \text{(X1.8)}$$

X1.3.3 Eq X1.8 shows that systematic error in the calculated frequency is reduced by reducing the frequency interval Δf. As explained in Note 11 of this test method, the frequency interval is controlled by the duration of the waveform, that is, the record length. Thus, when doing the impact-echo test to measure plate thickness, use the longest record length that is practicable. However, the record length must not be too long, otherwise motions due to other plate modes, set up by reflections of the lateral boundaries, may contribute to the waveform. This is the intent of the guidelines in Note 11.

X1.4 Systematic Error in Calculated Thickness

X1.4.1 The thickness calculated from the P-wave speed and peak frequency includes two sources of systematic errors. The approach taken in this test method is to obtain the combined systematic error, e, as follows:

$$e = \sqrt{e_p^2 + e_f^2} \quad \text{(X1.9)}$$

X1.4.2 The relative error in the plate thickness due to the two sources of systematic error is as follows:

$$\frac{T - T'}{T'} = \pm e \quad \text{(X1.10)}$$

that can be rearranged as follows:

$$T' = \frac{T}{1 \pm e} \quad \text{(X1.11)}$$

For small values of $|e|$:

$$\frac{1}{1 \pm e} \approx 1 \pm e \quad \text{(X1.12)}$$

Therefore to account for the systematic error that is inherent in this test method, report the thickness calculated according to Eq 2 as follows:

$$T \pm T\,e \quad \text{(X1.13)}$$

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this standard since the last issue, C 1383 – 98a, that may impact its use. (Approved June 2004)

(1) Added the term “sampling frequency” under 3.1.
(2) Moved the last sentence in 6.6 to new Note 6.
(3) Added new Note 8 to explain the usefulness of pre-trigger data and removed mandatory requirement for pre-trigger data.
(4) Added a sentence to 9.2 to permit automated detection of P-wave arrivals when waveforms are not contaminated with noise.
(5) Added a new 9.6 to permit an alternative procedure for determining apparent P-wave speed when there is agreement between the seller and the purchaser of testing services.
(6) Added new Note 13 to explain the usefulness of pre-trigger data and removed mandatory requirement for pre-trigger data.
(7) Added 16.6 on reporting results when the alternative procedure is used.
(8) Provided information on reported differences between core lengths and slab thicknesses determined by this method.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1385/C 1385M – 98 (Reapproved 2004)$^{\epsilon 1}$

Standard Practice for Sampling Materials for Shotcrete[1]

This standard is issued under the fixed designation C 1385/C 1385M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ϵ^1 NOTE—The title was changed to a dual designation editorially to reflect the existing measurements in the standard in September 2004.

1. Scope

1.1 This practice covers procedures for obtaining representative samples of materials to be shotcreted. The practice covers sampling from stationary and truck mixers, volumetric and continuous mixing equipment, and bag and bulk delivery.

1.2 The values stated in either inch-pound or SI units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with this practice.

2. Significance and Use

2.1 This practice is used to obtain representative samples of materials delivered to the shotcrete machine. These samples are used to perform tests to determine compliance with the specifications under which the material is furnished.

3. Procedure

3.1 Composite samples are required by this practice, unless specifically made exempt by procedures governing the tests to be performed, such as tests to determine uniformity of consistency and mixer efficiency. Procedures used to select the specific test batches are not described in this practice, but it is recommended that random sampling be used to determine overall specification compliance.

3.2 The size of an individual sample shall be a minimum of 25 lb [12 kg], the size of the composite sample shall be a minimum of 75 lb [35 kg]. The composite sample shall be large enough to perform the required tests.

3.3 Sampling shall be performed as the shotcrete material is delivered to the shotcrete machine. The procedures used in sampling shall include the use of every precaution that will assist in obtaining samples that are truly representative of the nature and condition of the material sampled as follows:

3.3.1 *Sampling Dry Process Shotcrete Materials*—Sample the material by collecting two or more portions taken at regularly spaced intervals during discharge of the middle of the batch or two or more random portions from the discharge of continuous mixers. Combine the portions into one sample for testing purposes. Do not obtain portions of the composite sample from the first 15 % or the last 15 % of the discharge.

3.3.2 *Sampling Wet Process Shotcrete Material*—Sample as described in 3.3.1 within the following limits.

3.3.2.1 The elapsed time between obtaining the first and last portions of the composite sample shall be as short as possible but in no instance shall exceed 15 min.

3.3.2.2 Start test for slump or air content, or both, within 5 min after obtaining last portion of the composite.

3.3.3 *Alternative Procedure for Truck and Stationary Mixers*—The mixer shall be stopped and material portions removed by any suitable means at approximately equal distances from the front and back of the drum. Composite the portions into one sample for testing. Do not obtain portions from the very front and back of the drum. Sample wet process shotcrete material within the time limits described in 3.3.2.1 and 3.3.2.2.

3.3.4 *Sampling Bagged Prepackaged Material*—Randomly select a single package, or more if required to perform the specified tests, from a lot. A lot is the quantity normally placed on a pallet. In general, this quantity will weigh from 2000 to 4000 lbs [900 to 1300 kg].

3.3.5 *Sampling Bulk Prepackaged Material*—Sample the material at the point of delivery to the shotcrete machine by collecting three or more portions at regular intervals during discharge of the container or transportation unit. Obtain portions from the first, middle, and last third of the unit. Do not sample the first 15 % or last 15 % of the discharge. Combine portions for testing.

4. Keywords

4.1 dry process; sampling; shotcrete; wet process

Designation: C1396/C1396M – 09a

Standard Specification for Gypsum Board[1]

This standard is issued under the fixed designation C1396/C1396M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the gypsum boards described in 1.1.1-1.1.9.

NOTE 1—Specifications C840, C841, C844 and C1280 contain application procedures for gypsum board.

1.1.1 *Gypsum wallboard*, designed for use on walls, ceilings, or partitions and that affords a surface suitable to receive decoration.

1.1.2 *Predecorated gypsum board*, designed for use as the finished surfacing for walls, ceilings, or partitions.

1.1.3 *Gypsum backing board, coreboard, and shaftliner board*, designed for use as a base in multilayer systems or as a gypsum stud or core in semisolid or solid gypsum board partitions, or in shaft wall assemblies.

NOTE 2—The terms backing board, coreboard, and shaftliner board refer to different end uses. The term gypsum backing board, as used in this specification, shall include gypsum coreboard and gypsum shaftliner board unless otherwise stated.

1.1.4 *Water-resistant gypsum backing board*, designed primarily to be used as a base for the application of ceramic or plastic tile on walls or ceilings. This product is also suitable for decoration.

1.1.5 *Exterior gypsum soffit board*, designed for use on exterior soffits and carport ceilings that are completely protected from contact with liquid water.

1.1.6 *Gypsum sheathing board*, designed for use as sheathing on buildings.

1.1.7 *Gypsum base for veneer plaster*, designed for use as a base for the application of gypsum veneer plaster.

1.1.8 *Gypsum lath*, designed for use as a base for the application of gypsum plaster.

1.1.9 *Gypsum ceiling board*, designed for use on interior ceilings with framing spaced not more than 24 in. [610 mm] on center and that affords a surface suitable to receive water-based texture and other decoration. This product is also suitable for use on interior walls.

1.2 Specifications applicable to all gypsum boards are located in Section 1-4 and 13-15. Specifications applicable to specific gypsum boards are located in the following sections:

	Section
Gypsum wallboard, predecorated gypsum board	5
Gypsum backing board, gypsum coreboard, gypsum shaftliner board	6
Water-resistant gypsum backing board	7
Exterior gypsum soffit board	8
Gypsum sheathing board	9
Gypsum base for veneer plaster	10
Gypsum lath	11
Gypsum Ceiling Board	12

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard

E84 Test Method for Surface Burning Characteristics of Building Materials
E96/E96M Test Methods for Water Vapor Transmission of Materials
E119 Test Methods for Fire Tests of Building Construction and Materials

3. Terminology

3.1 Definitions used in this specification shall be in accordance with Terminology C11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *decorative coating*, *n*—a paint or other liquid material with or without aggregate.

3.2.2 *decorative sheet or film*, *n*—a plastic film, either backed or unbacked; plastic sheet; or combination of these.

3.2.3 *edge*, *n*—the bound edge as manufactured.

3.2.4 *gypsum backing board*, *n*—a ¼ to ⅝-in. [6.4 to 15.9-mm] gypsum board used as a backing for gypsum wallboard, acoustical tile, or other dry cladding.

3.2.5 *gypsum coreboard*, *n*—a ¾ to 1-in. [19.0 to 25.4-mm] gypsum board used as a gypsum stud or core in semisolid or solid gypsum board partitions.

3.2.6 *nominal thickness*, *n*—the manufacturer-stated fractional value of thickness of the gypsum panel product expressed in decimal value to the nearest one-thousandth (1/1000) of an inch.

4. Materials and Manufacture

4.1 Gypsum board shall consist of a noncombustible core of gypsum complying with Specification C22/C22M, surfaced with paper bonded to the core.

4.1.1 Gypsum sheathing board shall consist of a noncombustible water-resistant core of gypsum complying with Specification C22/C22M, surfaced on both the face and back with water-repellant paper bonded to the core.

4.1.2 Gypsum coreboard shall be either a single board or composed of two factory-laminated gypsum boards to provide up to 1 in. [25.4 mm] total nominal thickness.

4.1.3 Water-resistant gypsum backing board shall consist of a noncombustible water-resistant core of gypsum complying with Specification C22/C22M, surfaced on both the back and face with water-repellant paper bonded to the core.

4.1.4 Predecorated gypsum board shall consist of a noncombustible core of gypsum complying with Specification C22/C22M, surfaced with paper bonded to the core with the face covered with a decorative sheet, film, or coating.

4.1.4.1 Class I predecorated gypsum board shall have a decorative sheet or film laminated to the face.

4.1.4.2 Class II predecorated gypsum board shall have a decorative coating applied to the face.

4.2 The back surface of foil-backed gypsum board shall in addition be covered with aluminum foil.

4.3 *Gypsum Board, type X* (Special Fire-Resistant):

4.3.1 *Gypsum Board*, type X, designates gypsum board, except gypsum lath, gypsum coreboard, and gypsum shaftliner board, complying with this specification that provides not less than 1 h fire-resistance rating for boards ⅝ in. [15.9 mm] thick or ¾ h fire-resistance rating for boards ½ in. [12.7 mm] thick, applied parallel with and on each side of load bearing 2 by 4 wood studs spaced 16 in. [406 mm] on centers with 6d coated nails, 1⅞ in. [48 mm] long, 0.0915-in. [2.3-mm] diameter shank, ¼-in. [6.4-mm] diameter heads, spaced 7 in. [178 mm] on centers with gypsum board joints staggered 16 in. [406 mm] on each side of the partition and tested in accordance with Test Methods E119.

4.3.2 *Gypsum Lath*, type X designates gypsum lath complying with this specification that provides not less than a 1-h fire-resistance rating for gypsum lath ⅜ in. [9.5 mm] thick, when applied at right angles to and on each side of loadbearing 2 × 4 wood studs spaced 16 in. [406 mm] on centers with blue lath nails spaced 5 in. [127 mm] on centers over which is applied ½ in. [12.7 mm] 1:2 gypsum sand plaster and tested in accordance with the requirements of Test Method E119.

NOTE 3—Consult producers for independent test data on assembly details and fire-resistance ratings for other types of construction. See fire test reports or listings from recognized fire testing laboratories for assembly particulars, materials, and ratings.

4.3.3 Gypsum shaftliner board, type X, designates gypsum shaftliner board complying with this specification that meets the acceptance criteria for temperature rise for not less than 1-½ h for boards ¾-in. [19.0 mm] thick or 2 h for boards 1-in. [25.4 mm] thick, when applied in a double layer solid nonload bearing partition as described in 4.3.3.1 and tested in accordance with Test Methods E119 with thermocouple locations as specified in 4.3.3.2.

4.3.3.1 Two layers of gypsum shaftliner board applied vertically and friction fit into vertical 25-gage steel "H" members, 1-½-in. [38.1 mm] deep for boards ¾-in. [19.0 mm] thick or 2-in. [50.8 mm] deep for boards 1-in. [25.4 mm] thick, spaced 24-in. [610 mm] on centers and 25-gage steel track at the perimeter of the partition. "H" members shall be formed with a single web or shall be two pieces of perimeter track fastened together along the web with screws spaced 24-in. [610 mm] on centers.

4.3.3.2 Temperature rise on the unexposed surface shall be measured using not less than five thermocouples; one shall be located at the center of the assembly and one shall be located at the center of each quadrant. Thermocouples shall be located not less than 3-in. [76 mm] from an "H" member.

4.4 Gypsum wallboard, gypsum backing board, exterior gypsum soffit board, and gypsum ceiling board shall have a flame spread index of not more than 25 when tested in accordance with Test Method E84.

4.5 *Physical Properties, Dimensions, and Tolerances of Gypsum Board*:

4.5.1 Specimens shall be taken from the samples obtained in accordance with Specification C1264.

4.5.1.1 Specimens shall be tested in accordance with Test Methods C473.

4.5.2 *Core, End, and Edge Hardness*—The specimens shall have an average hardness of not less than 15 lbf [67 N] when tested by Method A and 11 lbf [49 N] when tested by Method B.

4.5.3 *Edges and Ends*—The edges and ends shall be straight.

4.5.4 *Length*—The tolerance in length shall be ±¼ in. [±6 mm].

4.5.5 *Tapered Edge Depth*—The average thickness of the edge of recessed or tapered edge gypsum board shall be not less than 0.020 in. [0.51 mm] but not more than 0.090 in. [2.29 mm] less than the average thickness of the gypsum board.

5. Gypsum Wallboard and Predecorated Gypsum Board

5.1 *Physical Properties of Gypsum Wallboard and Predecorated Gypsum Board*:

5.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
¼ [6.4]	50 [222]	20 [89]	46 [205]	16 [71]
5⁄16 [7.9]	65 [289]	25 [111]	62 [276]	21 [93]
⅜ [9.5]	80 [356]	30 [133]	77 [343]	26 [116]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]
¾ [19.0]	170 [756]	60 [267]	167 [743]	56 [249]

5.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
¼ [6.4]	not required
5⁄16 [7.9]	not required
⅜ [9.5]	15 [48]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]
¾ [19.0]	5 [16]

5.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
¼ [6.4]	40 [178]	36 [160]
5⁄16 [7.9]	50 [222]	46 [205]
⅜ [9.5]	60 [267]	56 [249]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]
¾ [19.0]	100 [445]	97 [432]

5.1.4 *Foil-Backed Gypsum Wallboard and Foil-Backed Predecorated Gypsum Board*:

5.1.4.1 Foil-backed gypsum wallboard and foil-backed predecorated gypsum board shall meet all of the requirements for gypsum wallboard and predecorated gypsum board.

5.1.4.2 When tested in accordance with Test Methods E96/E96M, the permeance of foil-backed gypsum wallboard and foil-backed predecorated gypsum board shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the board, and 0 % relative humidity on the back (foil-covered) side of the board.

5.2 *Dimensions and Tolerances of Gypsum Wallboard and Predecorated Gypsum Board*:

5.2.1 *Thickness*—The thickness shall be from ¼ to ¾ in. [6.4 to 19.0 mm] with tolerances of ± 0.015 in. [± 0.40 mm], and with local variations of ± 0.030 in. [± 0.80 mm].

5.2.2 *Width*—The width shall be up to 48 in. [1220 mm], or up to 54 in. [1370 mm], with a tolerance of 3⁄32 in. [3 mm] under the specified width.

5.2.3 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [±3 mm] in the full width of the board.

5.3 *Edges*:

5.3.1 The edges of gypsum wallboard shall be either square, beveled, featured, tapered, or featured and tapered.

5.3.2 The edges of predecorated gypsum board shall be either square, beveled, or featured.

6. Gypsum Backing Board, Gypsum Coreboard, and Gypsum Shaftliner Board

6.1 *Physical Properties of Gypsum Backing Board, Gypsum Coreboard, and Gypsum Shaftliner Board*:

6.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
¼ [6.4]	50 [222]	20 [89]	46 [205]	16 [71]
⅜ [9.5]	80 [356]	30 [133]	77 [343]	26 [116]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	140 [622]	50 [222]	137 [609]	46 [205]
¾ [19.0]	170 [756]	60 [267]	167 [743]	56 [249]
1 [25.4]	230 [1023]	80 [356]	228 [1014]	77 [343]

6.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
¼ [6.4]	not required
⅜ [9.5]	15 [48]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]
¾ [19.0]	not required
1 [25.4]	not required

6.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
¼ [6.4]	40 [178]	36 [160]
⅜ [9.5]	60 [267]	56 [249]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]
¾ [19.0]	not required	not required
1 [25.4]	not required	not required

6.1.4 *Foil-Backed Gypsum Backing Board, Foil-Backed Gypsum Coreboard, and Foil-Backed Gypsum Shaftliner Board*:

6.1.4.1 Foil-backed gypsum backing board, foil-backed gypsum coreboard, and foil-backed gypsum shaftliner board shall meet all of the requirements for gypsum backing board, gypsum coreboard, and gypsum shaftliner board.

6.1.4.2 When tested in accordance with Test Methods E96/E96M, the permeance of foil-backed gypsum backing board and foil-backed gypsum coreboard shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the board, and 0 % relative humidity on the back (foil-covered) side of the board.

6.2 *Dimensions and Tolerances of Gypsum Backing Board, Gypsum Coreboard, and Gypsum Shaftliner Board*:

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.2.1 *Thickness*—The thickness shall be from ¼ to 1 in. [6.4 to 25.4 mm] with tolerances of ± 0.030 in. [± 0.80 mm], and with local variations of ± 0.060 in. [± 1.6 mm].

6.2.2 *Width*—The width shall be from 16 to 48 in. [406 to 1220 mm] with a tolerance of ⅛ in. [3.2 mm] under the specified width.

6.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

6.3 *Edges*—The edges shall be either square, beveled, round, V-tongue and groove, or featured.

7. Water-Resistant Gypsum Backing Board

7.1 *Physical Properties of Water-Resistant Gypsum Backing Board*:

7.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]

7.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]

7.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]

7.1.4 *Water Resistance*—The specimens shall have an average water absorption of not more than 5 weight % after 2-h immersion.

7.2 *Dimensions and Tolerances of Water-Resistant Gypsum Backing Board*:

7.2.1 *Thickness*—The thickness shall be ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances of ± 0.015 in. [± 0.40 mm], and with local variations of ± 0.030 in. [± 0.80 mm].

7.2.2 *Width*—The width shall be up to 48 in. [1220 mm], or up to 54 in. [1370 mm], with a tolerance of 3/32 in. [3 mm] under the specified width.

7.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

7.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

8. Exterior Gypsum Soffit Board

8.1 *Physical Properties of Exterior Gypsum Soffit Board*:

8.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]

8.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
½ [12.7]	7 [22]
⅝ [15.9]	4 [13]

8.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]

8.2 *Dimensions and Tolerances of Exterior Gypsum Soffit Board*:

8.2.1 *Thickness*—The thickness shall be ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances of ± 0.015 in. [± 0.40 mm], and with local variations of ± 0.030 in. [± 0.80 mm].

8.2.2 *Width*—The width shall be up to 48 in. [1220 mm] with a tolerance of 3/32 in. [3 mm] under the specified width.

8.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

8.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

9. Gypsum Sheathing Board

9.1 *Physical Properties of Gypsum Sheathing Board:*

9.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
⅜ [9.5]	80 [356]	30 [133]	77 [343]	26 [116]
4/10 [10.2]	88 [391]	32 [142]	85 [378]	28 [125]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]

9.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
⅜ [9.5]	15 [48]
4/10 [10.2]	12 [38]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.1.3 *Nail-Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
⅜ [9.5]	60 [267]	56 [249]
4/10 [10.2]	70 [312]	67 [298]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]

9.1.4 *Water Resistance of Gypsum Sheathing Board*—The specimens shall have an average water absorption of not more than 10 weight % after 2-h immersion.

9.2 *Dimensions and Tolerances of Gypsum Sheathing Board:*

9.2.1 *Thickness*—The thickness shall be from ⅜ to ⅝ in. [9.5 to 15.9 mm] with tolerances of ± 0.030 in. [± 0.80 mm], and with local variations of ± 0.060 in. [± 1.6 mm].

9.2.2 *Width*—The nominal width shall be 24 or 48 in. [610 or 1220 mm] with a tolerance of ⅛ in. [3.2 mm] under the specified width.

9.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

9.3 *Edges*—The edges shall be either square or V-tongue and groove.

10. Gypsum Base for Veneer Plaster

10.1 *Physical Properties of Gypsum Base for Veneer Plaster*:

10.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
⅜ [9.5]	80 [356]	30 [133]	77 [343]	26 [116]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]

10.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [m]
⅜ [9.5]	15 [48]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]

10.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
⅜ [9.5]	60 [267]	56 [249]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]

10.1.4 *Foil-Backed Gypsum Base for Veneer Plaster*:

10.1.4.1 Foil-backed gypsum base for veneer plaster shall meet all of the requirements for gypsum base for veneer plaster.

10.1.4.2 When tested in accordance with Test Methods E96/E96M, the permeance of foil-backed gypsum base for veneer plaster shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the board, and 0 % relative humidity on the back (foil-covered) side of the board.

10.2 *Dimensions and Tolerances of Gypsum Base for Veneer Plaster*:

10.2.1 *Thickness*—The thickness shall be from ⅜ to ⅝ in. [9.5 to 15.9 mm] with tolerances ± 0.015 in. [± 0.40 mm], and with local variations of ± 0.030 in. [± 0.80 mm].

10.2.2 *Width*—The width shall be 48 in. [1220 mm] with a tolerance of 3/32 in. [3 mm] under the specified width.

10.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

10.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

11. Gypsum Lath

11.1 *Physical Properties of Gypsum Lath*:

11.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
⅜ [9.5]	60 [267]	25 [111]	56 [249]	21 [93]
½ [12.7]	100 [445]	35 [156]	97 [431]	31 [138]

11.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [m]
⅜ [9.5]	15 [48]
½ [12.7]	10 [32]

11.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
⅜ [9.5]	50 [222]	46 [205]
½ [12.7]	70 [312]	66 [294]

11.1.4 *Foil-Backed Gypsum Lath*:

11.1.4.1 Foil-backed gypsum lath shall meet all of the requirements for gypsum lath.

11.1.4.2 When tested in accordance with Test Methods E96/E96M, the permeance of foil-backed gypsum lath shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the board, and 0 % relative humidity on the back (foil-covered) side of the board.

11.2 *Dimensions and Tolerances of Gypsum Lath*:

11.2.1 *Thickness*—The thickness shall be ⅜ or ½ in. [9.5 or 12.7 mm] with tolerances of ± 0.030 in. [± 0.80 mm], and with local variations of ± 0.060 in. [± 1.6 mm].

11.2.2 *Width*—The nominal width shall be up to 48 in. [1220 mm] with a tolerance of 3/16 in. [4.8 mm] under and ⅛ in. [3.2 mm] over the specified width.

11.2.3 *End Squareness*—Corners shall be square with a tolerance of ±¼ in. [±6.4 mm] in the full width of the board.

11.3 *Edges*—The edges shall be either round or square.

12. Gypsum Ceiling Board

12.1 *Physical Properties of Gypsum Ceiling Board*:

12.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall not be less than the following:

	METHOD A		METHOD B	
Thickness in. [mm]	Load, lbf [N] Bearing Edges Across Fiber of Surfacing	Load, lbf [N] Bearing Edges Parallel to Fiber of Surfacing	Load, lbf [N] Bearing Edges Across Fiber of Surfacing	Load, lbf [N] Bearing Edges Parallel to Fiber of Surfacing
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]

12.1.2 *Humidified Deflection*—The specimens shall have an average humidified deflection of not more than 5⁄16 in. [8 mm].

12.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than 80 lbf [356 N] when tested by Method A and 77 lbf [343 N] when tested by Method B.

12.2 *Dimensions and Tolerances of Gypsum Ceiling Board*:

12.2.1 *Thickness*—The thickness shall be ½ in. [12.7 mm] with tolerances of ± 0.015 in. [± 0.40 mm] with local variations of ± 0.030 in. [± 0.80 mm].

12.2.2 *Width*—The width shall be up to 48 in. [1220 mm] with a tolerance of 3⁄32 in. [3 mm] under the specified width.

12.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [3 mm] in the full width of the board.

12.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

13. Finish and Appearance

13.1 The surfaces of gypsum board shall be true and free from imperfections that would render it unfit for use with or without decoration.

14. Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage

14.1 Sampling, inspection, rejection, certification, packaging, marking, shipping, handling, and storage of gypsum board shall be in accordance with Specification C1264.

15. Keywords

15.1 ceiling; coreboard; drywall; exterior gypsum soffit board; foil-backed; gypsum; gypsum backing board; gypsum base; gypsum board; gypsum ceiling board; gypsum coreboard; gypsum lath; gypsum sheathing; gypsum sheathing board; gypsum wallboard; partitions; plaster; predecorated gypsum board; shaftliner; sheathing; type X; veneer base; veneer plaster; wall; wallboard; water-resistant gypsum board

APPENDIXES

(Nonmandatory Information)

This appendix gives general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this specification.

The definition of type X as given in 4.3.1-4.3.3 and the alternate definition given in this appendix, are intended only as a test to define the gypsum board as meeting the requirements of type X products. These tests do not indicate a preferred application nor do they limit the use of the product in other fire rated assemblies.

All gypsum panel products for which type X is defined, except gypsum lath and gypsum shaftliner board, use the same test for type X products, therefore the type X definition indicates a consistent level of fire resistance.

X1. ALTERNATE DEFINITION FOR TYPE X

X1.1 Gypsum board, type X (special fire-resistant) designates gypsum board, except gypsum lath, providing a greater fire-resistance than regular gypsum board of the same thickness. Type X (special fire-resistant) gypsum board, when tested in accordance with Test Methods E119, shall provide the following minimum fire resistance ratings for the assemblies described:

X1.1.1 One hour for a 5⁄8-in. [15.9-mm] thickness applied to a partition in a single-layer application on each side of 3 5⁄8-in. [92-mm] deep non-loadbearing galvanized steel studs complying with Specification C645, spaced 24 in. [610 mm] on center. The 5⁄8-in. [15.9-mm] thick gypsum board 48 in. [1220 mm] wide shall be attached using 1-in. [25-mm] long drywall screws spaced 8 in. [203 mm] on center along the edges and ends, and 12 in. [305 mm] along intermediate studs. All joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly, and

X1.1.2 Two hours for a ½-in. [12.7-mm] thickness applied to a partition in a double-layer application on each side of 2½-in. [64-mm] deep non-loadbearing galvanized steel studs complying with Specification C645, spaced 24 in. [610 mm] on center. The 48-in. [1220-mm] wide base layer shall be attached using 1-in. [25-mm] long drywall screws spaced 12 in. [305 mm] on center along board edges, ends, and along intermediate studs. Joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly. The 48-in. [1220-m] wide face layer shall be attached using 1 5⁄8-in. [41-mm] long drywall screws spaced 12 in. [305 mm] along board edges, ends, and along intermediate studs. Joints shall be

oriented parallel to and located over studs, offset 24 in. [610 mm] from the base layer joints, and staggered on opposite sides of the assembly.

X2. TABLE OF WITHDRAWN ASTM STANDARDS REPLACED BY SPECIFICATION C1396/C1396M

X2.1 As of December 1, 2004, a single ASTM International reference, Specification C1396/C1396M, has replaced nine standards previously used to designate specific gypsum boards employed in commercial and residential construction. The chart below identifies the withdrawn standard and its corresponding section within Specification C1396/C1396M.

	Withdrawn ASTM Standard	C1396/C1396M Section
C36/C 36/M	Specification for Gypsum Wallboard	5
C37/C37M	Specification for Gypsum Lath	11
C79/C79M	Specification for Gypsum Sheathing Board	9
C442/C442M	Specification for Gypsum Backing Board, Gypsum Coreboard, and Gypsum Shaftliner Board	6
C588/C588M	Specification for Gypsum Base for Veneer Plasters	10
C630/C630M	Specification for Water-Resistant Gypsum Backing Board	7
C931/C931M	Specification for Exterior Gypsum Soffit Board	8
C960/C960M	Specification for Predecorated Gypsum Board	5
C1395/C1395M	Specification for Gypsum Ceiling Board	12

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C1396/C1396M – 09, that may impact the use of this specification. (Approved November 15, 2009)

(*1*) Deleted 7.1.5 and 9.1.5 on water absorption.

Committee C11 has identified the location of selected changes to this specification since the last issue, C1396/C1396M – 06a, that may impact the use of this specification. (Approved September 1, 2009)

(*1*) Revised 4.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C1396/C1396M – 09a

Standard Specification for Gypsum Board[1]

This standard is issued under the fixed designation C1396/C1396M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the gypsum boards described in 1.1.1-1.1.9.

NOTE 1—Specifications C840, C841, C844 and C1280 contain application procedures for gypsum board.

1.1.1 *Gypsum wallboard*, designed for use on walls, ceilings, or partitions and that affords a surface suitable to receive decoration.

1.1.2 *Predecorated gypsum board*, designed for use as the finished surfacing for walls, ceilings, or partitions.

1.1.3 *Gypsum backing board, coreboard, and shaftliner board*, designed for use as a base in multilayer systems or as a gypsum stud or core in semisolid or solid gypsum board partitions, or in shaft wall assemblies.

NOTE 2—The terms backing board, coreboard, and shaftliner board refer to different end uses. The term gypsum backing board, as used in this specification, shall include gypsum coreboard and gypsum shaftliner board unless otherwise stated.

1.1.4 *Water-resistant gypsum backing board*, designed primarily to be used as a base for the application of ceramic or plastic tile on walls or ceilings. This product is also suitable for decoration.

1.1.5 *Exterior gypsum soffit board*, designed for use on exterior soffits and carport ceilings that are completely protected from contact with liquid water.

1.1.6 *Gypsum sheathing board*, designed for use as sheathing on buildings.

1.1.7 *Gypsum base for veneer plaster*, designed for use as a base for the application of gypsum veneer plaster.

1.1.8 *Gypsum lath*, designed for use as a base for the application of gypsum plaster.

1.1.9 *Gypsum ceiling board*, designed for use on interior ceilings with framing spaced not more than 24 in. [610 mm] on center and that affords a surface suitable to receive water-based texture and other decoration. This product is also suitable for use on interior walls.

1.2 Specifications applicable to all gypsum boards are located in Section 1-4 and 13-15. Specifications applicable to specific gypsum boards are located in the following sections:

	Section
Gypsum wallboard, predecorated gypsum board	5
Gypsum backing board, gypsum coreboard, gypsum shaftliner board	6
Water-resistant gypsum backing board	7
Exterior gypsum soffit board	8
Gypsum sheathing board	9
Gypsum base for veneer plaster	10
Gypsum lath	11
Gypsum Ceiling Board	12

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard

E119 Test Methods for Fire Tests of Building Construction and Materials

3. Terminology

3.1 Definitions used in this specification shall be in accordance with Terminology C11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *decorative coating*, *n*—a paint or other liquid material with or without aggregate.

3.2.2 *decorative sheet or film*, *n*—a plastic film, either backed or unbacked; plastic sheet; or combination of these.

3.2.3 *edge*, *n*—the bound edge as manufactured.

3.2.4 *gypsum backing board*, *n*—a ¼ to ⅝-in. [6.4 to 15.9-mm] gypsum board used as a backing for gypsum wallboard, acoustical tile, or other dry cladding.

3.2.5 *gypsum coreboard*, *n*—a ¾ to 1-in. [19.0 to 25.4-mm] gypsum board used as a gypsum stud or core in semisolid or solid gypsum board partitions.

3.2.6 *nominal thickness*, *n*—the manufacturer-stated fractional value of thickness of the gypsum panel product expressed in decimal value to the nearest one-thousandth (1/1000) of an inch.

4. Materials and Manufacture

4.1 Gypsum board shall consist of a noncombustible core of gypsum complying with Specification C22/C22M, surfaced with paper bonded to the core.

4.1.1 Gypsum sheathing board shall consist of a noncombustible water-resistant core of gypsum complying with Specification C22/C22M, surfaced on both the face and back with water-repellant paper bonded to the core.

4.1.2 Gypsum coreboard shall be either a single board or composed of two factory-laminated gypsum boards to provide up to 1 in. [25.4 mm] total nominal thickness.

4.1.3 Water-resistant gypsum backing board shall consist of a noncombustible water-resistant core of gypsum complying with Specification C22/C22M, surfaced on both the back and face with water-repellant paper bonded to the core.

4.1.4 Predecorated gypsum board shall consist of a noncombustible core of gypsum complying with Specification C22/C22M, surfaced with paper bonded to the core with the face covered with a decorative sheet, film, or coating.

4.1.4.1 Class I predecorated gypsum board shall have a decorative sheet or film laminated to the face.

4.1.4.2 Class II predecorated gypsum board shall have a decorative coating applied to the face.

4.2 The back surface of foil-backed gypsum board shall in addition be covered with aluminum foil.

4.3 *Gypsum Board, type X* (Special Fire-Resistant):

4.3.1 *Gypsum Board*, type X, designates gypsum board, except gypsum lath, gypsum coreboard, and gypsum shaftliner board, complying with this specification that provides not less than 1 h fire-resistance rating for boards ⅝ in. [15.9 mm] thick or ¾ h fire-resistance rating for boards ½ in. [12.7 mm] thick, applied parallel with and on each side of load bearing 2 by 4 wood studs spaced 16 in. [406 mm] on centers with 6d coated nails, 1⅞ in. [48 mm] long, 0.0915-in. [2.3-mm] diameter shank, ¼-in. [6.4-mm] diameter heads, spaced 7 in. [178 mm] on centers with gypsum board joints staggered 16 in. [406 mm] on each side of the partition and tested in accordance with Test Methods E119.

4.3.2 *Gypsum Lath*, type X designates gypsum lath complying with this specification that provides not less than a 1-h fire-resistance rating for gypsum lath ⅜ in. [9.5 mm] thick, when applied at right angles to and on each side of loadbearing 2 × 4 wood studs spaced 16 in. [406 mm] on centers with blue lath nails spaced 5 in. [127 mm] on centers over which is applied ½ in. [12.7 mm] 1:2 gypsum sand plaster and tested in accordance with the requirements of Test Method E119.

NOTE 3—Consult producers for independent test data on assembly details and fire-resistance ratings for other types of construction. See fire test reports or listings from recognized fire testing laboratories for assembly particulars, materials, and ratings.

4.3.3 Gypsum shaftliner board, type X, designates gypsum shaftliner board complying with this specification that meets the acceptance criteria for temperature rise for not less than 1-½ h for boards ¾-in. [19.0 mm] thick or 2 h for boards 1-in. [25.4 mm] thick, when applied in a double layer solid nonload bearing partition as described in 4.3.3.1 and tested in accordance with Test Methods E119 with thermocouple locations as specified in 4.3.3.2.

4.3.3.1 Two layers of gypsum shaftliner board applied vertically and friction fit into vertical 25-gage steel "H" members, 1-½-in. [38.1 mm] deep for boards ¾-in. [19.0 mm] thick or 2-in. [50.8 mm] deep for boards 1-in. [25.4 mm] thick, spaced 24-in. [610 mm] on centers and 25-gage steel track at the perimeter of the partition. "H" members shall be formed with a single web or shall be two pieces of perimeter track fastened together along the web with screws spaced 24-in. [610 mm] on centers.

4.3.3.2 Temperature rise on the unexposed surface shall be measured using not less than five thermocouples; one shall be located at the center of the assembly and one shall be located at the center of each quadrant. Thermocouples shall be located not less than 3-in. [76 mm] from an "H" member.

4.4 Gypsum wallboard, gypsum backing board, exterior gypsum soffit board, and gypsum ceiling board shall have a flame spread index of not more than 25 when tested in accordance with Test Method E84.

4.5 *Physical Properties, Dimensions, and Tolerances of Gypsum Board*:

4.5.1 Specimens shall be taken from the samples obtained in accordance with Specification C1264.

4.5.1.1 Specimens shall be tested in accordance with Test Methods C473.

4.5.2 *Core, End, and Edge Hardness*—The specimens shall have an average hardness of not less than 15 lbf [67 N] when tested by Method A and 11 lbf [49 N] when tested by Method B.

4.5.3 *Edges and Ends*—The edges and ends shall be straight.

4.5.4 *Length*—The tolerance in length shall be ±¼ in. [±6 mm].

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

4.5.5 *Tapered Edge Depth*—The average thickness of the edge of recessed or tapered edge gypsum board shall be not less than 0.020 in. [0.51 mm] but not more than 0.090 in. [2.29 mm] less than the average thickness of the gypsum board.

5. Gypsum Wallboard and Predecorated Gypsum Board

5.1 *Physical Properties of Gypsum Wallboard and Predecorated Gypsum Board*:

5.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
¼ [6.4]	50 [222]	20 [89]	46 [205]	16 [71]
5⁄16 [7.9]	65 [289]	25 [111]	62 [276]	21 [93]
⅜ [9.5]	80 [356]	30 [133]	77 [343]	26 [116]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]
¾ [19.0]	170 [756]	60 [267]	167 [743]	56 [249]

5.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
¼ [6.4]	not required
5⁄16 [7.9]	not required
⅜ [9.5]	15 [48]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]
¾ [19.0]	5 [16]

5.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
¼ [6.4]	40 [178]	36 [160]
5⁄16 [7.9]	50 [222]	46 [205]
⅜ [9.5]	60 [267]	56 [249]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]
¾ [19.0]	100 [445]	97 [432]

5.1.4 *Foil-Backed Gypsum Wallboard and Foil-Backed Predecorated Gypsum Board*:

5.1.4.1 Foil-backed gypsum wallboard and foil-backed predecorated gypsum board shall meet all of the requirements for gypsum wallboard and predecorated gypsum board.

5.1.4.2 When tested in accordance with Test Methods E96/E96M, the permeance of foil-backed gypsum wallboard and foil-backed predecorated gypsum board shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the board, and 0 % relative humidity on the back (foil-covered) side of the board.

5.2 *Dimensions and Tolerances of Gypsum Wallboard and Predecorated Gypsum Board*:

5.2.1 *Thickness*—The thickness shall be from ¼ to ¾ in. [6.4 to 19.0 mm] with tolerances of ± 0.015 in. [± 0.40 mm], and with local variations of ± 0.030 in. [± 0.80 mm].

5.2.2 *Width*—The width shall be up to 48 in. [1220 mm], or up to 54 in. [1370 mm], with a tolerance of 3⁄32 in. [3 mm] under the specified width.

5.2.3 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [±3 mm] in the full width of the board.

5.3 *Edges*:

5.3.1 The edges of gypsum wallboard shall be either square, beveled, featured, tapered, or featured and tapered.

5.3.2 The edges of predecorated gypsum board shall be either square, beveled, or featured.

6. Gypsum Backing Board, Gypsum Coreboard, and Gypsum Shaftliner Board

6.1 *Physical Properties of Gypsum Backing Board, Gypsum Coreboard, and Gypsum Shaftliner Board*:

6.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
¼ [6.4]	50 [222]	20 [89]	46 [205]	16 [71]
⅜ [9.5]	80 [356]	30 [133]	77 [343]	26 [116]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	140 [622]	50 [222]	137 [609]	46 [205]
¾ [19.0]	170 [756]	60 [267]	167 [743]	56 [249]
1 [25.4]	230 [1023]	80 [356]	228 [1014]	77 [343]

6.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
¼ [6.4]	not required
⅜ [9.5]	15 [48]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]
¾ [19.0]	not required
1 [25.4]	not required

6.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
¼ [6.4]	40 [178]	36 [160]
⅜ [9.5]	60 [267]	56 [249]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]
¾ [19.0]	not required	not required
1 [25.4]	not required	not required

6.1.4 *Foil-Backed Gypsum Backing Board, Foil-Backed Gypsum Coreboard, and Foil-Backed Gypsum Shaftliner Board*:

6.1.4.1 Foil-backed gypsum backing board, foil-backed gypsum coreboard, and foil-backed gypsum shaftliner board shall meet all of the requirements for gypsum backing board, gypsum coreboard, and gypsum shaftliner board.

6.1.4.2 When tested in accordance with Test Methods E96/E96M, the permeance of foil-backed gypsum backing board and foil-backed gypsum coreboard shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the board, and 0 % relative humidity on the back (foil-covered) side of the board.

6.2 *Dimensions and Tolerances of Gypsum Backing Board, Gypsum Coreboard, and Gypsum Shaftliner Board*:

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.2.1 *Thickness*—The thickness shall be from ¼ to 1 in. [6.4 to 25.4 mm] with tolerances of ± 0.030 in. [± 0.80 mm], and with local variations of ± 0.060 in. [± 1.6 mm].

6.2.2 *Width*—The width shall be from 16 to 48 in. [406 to 1220 mm] with a tolerance of ⅛ in. [3.2 mm] under the specified width.

6.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

6.3 *Edges*—The edges shall be either square, beveled, round, V-tongue and groove, or featured.

7. Water-Resistant Gypsum Backing Board

7.1 *Physical Properties of Water-Resistant Gypsum Backing Board*:

7.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]

7.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]

7.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]

7.1.4 *Water Resistance*—The specimens shall have an average water absorption of not more than 5 weight % after 2-h immersion.

7.2 *Dimensions and Tolerances of Water-Resistant Gypsum Backing Board*:

7.2.1 *Thickness*—The thickness shall be ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances of ± 0.015 in. [± 0.40 mm], and with local variations of ± 0.030 in. [± 0.80 mm].

7.2.2 *Width*—The width shall be up to 48 in. [1220 mm], or up to 54 in. [1370 mm], with a tolerance of 3/32 in. [3 mm] under the specified width.

7.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

7.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

8. Exterior Gypsum Soffit Board

8.1 *Physical Properties of Exterior Gypsum Soffit Board*:

8.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]

8.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
½ [12.7]	7 [22]
⅝ [15.9]	4 [13]

8.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
½ [12.7]	80 [356]	77 [343]
⅝ [15.9]	90 [400]	87 [387]

8.2 *Dimensions and Tolerances of Exterior Gypsum Soffit Board*:

8.2.1 *Thickness*—The thickness shall be ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances of ± 0.015 in. [± 0.40 mm], and with local variations of ± 0.030 in. [± 0.80 mm].

8.2.2 *Width*—The width shall be up to 48 in. [1220 mm] with a tolerance of 3/32 in. [3 mm] under the specified width.

8.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [±3 mm] in the full width of the board.

8.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

9. Gypsum Sheathing Board

9.1 *Physical Properties of Gypsum Sheathing Board:*

9.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
⅜ [9.5]	80 [356]	30 [133]	77 [343]	26 [116]
4/10 [10.2]	88 [391]	32 [142]	85 [378]	28 [125]
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
⅝ [15.9]	150 [667]	50 [222]	147 [654]	46 [205]

9.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [mm]
⅜ [9.5]	15 [48]
4/10 [10.2]	12 [38]
½ [12.7]	10 [32]
⅝ [15.9]	5 [16]

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.1.3 *Nail-Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
3/8 [9.5]	60 [267]	56 [249]
4/10 [10.2]	70 [312]	67 [298]
1/2 [12.7]	80 [356]	77 [343]
5/8 [15.9]	90 [400]	87 [387]

9.1.4 *Water Resistance of Gypsum Sheathing Board*—The specimens shall have an average water absorption of not more than 10 weight % after 2-h immersion.

9.2 *Dimensions and Tolerances of Gypsum Sheathing Board:*

9.2.1 *Thickness*—The thickness shall be from 3/8 to 5/8 in. [9.5 to 15.9 mm] with tolerances of ± 0.030 in. [± 0.80 mm], and with local variations of ± 0.060 in. [± 1.6 mm].

9.2.2 *Width*—The nominal width shall be 24 or 48 in. [610 or 1220 mm] with a tolerance of 1/8 in. [3.2 mm] under the specified width.

9.2.3 *End Squareness*—Corners shall be square with a tolerance of ±1/8 in. [±3 mm] in the full width of the board.

9.3 *Edges*—The edges shall be either square or V-tongue and groove.

10. Gypsum Base for Veneer Plaster

10.1 *Physical Properties of Gypsum Base for Veneer Plaster*:

10.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
3/8 [9.5]	80 [356]	30 [133]	77 [343]	26 [116]
1/2 [12.7]	110 [489]	40 [178]	107 [476]	36 [160]
5/8 [15.9]	150 [667]	50 [222]	147 [654]	46 [205]

10.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [m]
3/8 [9.5]	15 [48]
1/2 [12.7]	10 [32]
5/8 [15.9]	5 [16]

10.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
3/8 [9.5]	60 [267]	56 [249]
1/2 [12.7]	80 [356]	77 [343]
5/8 [15.9]	90 [400]	87 [387]

10.1.4 *Foil-Backed Gypsum Base for Veneer Plaster*:

10.1.4.1 Foil-backed gypsum base for veneer plaster shall meet all of the requirements for gypsum base for veneer plaster.

10.1.4.2 When tested in accordance with Test Methods E96/E96M, the permeance of foil-backed gypsum base for veneer plaster shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the board, and 0 % relative humidity on the back (foil-covered) side of the board.

10.2 *Dimensions and Tolerances of Gypsum Base for Veneer Plaster*:

10.2.1 *Thickness*—The thickness shall be from 3/8 to 5/8 in. [9.5 to 15.9 mm] with tolerances ± 0.015 in. [± 0.40 mm], and with local variations of ± 0.030 in. [± 0.80 mm].

10.2.2 *Width*—The width shall be 48 in. [1220 mm] with a tolerance of 3/32 in. [3 mm] under the specified width.

10.2.3 *End Squareness*—Corners shall be square with a tolerance of ±1/8 in. [±3 mm] in the full width of the board.

10.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

11. Gypsum Lath

11.1 *Physical Properties of Gypsum Lath*:

11.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A Bearing Edges Perpendicular to Panel Length, lbf [N]	Method A Bearing Edges Parallel to Panel Length, lbf [N]	Method B Bearing Edges Perpendicular to Panel Length, lbf [N]	Method B Bearing Edges Parallel to Panel Length, lbf [N]
3/8 [9.5]	60 [267]	25 [111]	56 [249]	21 [93]
1/2 [12.7]	100 [445]	35 [156]	97 [431]	31 [138]

11.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, eighths of an inch [m]
3/8 [9.5]	15 [48]
1/2 [12.7]	10 [32]

11.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A, lbf [N]	Method B, lbf [N]
3/8 [9.5]	50 [222]	46 [205]
1/2 [12.7]	70 [312]	66 [294]

11.1.4 *Foil-Backed Gypsum Lath*:

11.1.4.1 Foil-backed gypsum lath shall meet all of the requirements for gypsum lath.

11.1.4.2 When tested in accordance with Test Methods E96/E96M, the permeance of foil-backed gypsum lath shall be not more than 0.30 perm [17 ng/Pa·s·m^2] (Desiccant Method) for the condition of 50 % relative humidity on the face of the board, and 0 % relative humidity on the back (foil-covered) side of the board.

11.2 *Dimensions and Tolerances of Gypsum Lath*:

11.2.1 *Thickness*—The thickness shall be 3/8 or 1/2 in. [9.5 or 12.7 mm] with tolerances of ± 0.030 in. [± 0.80 mm], and with local variations of ± 0.060 in. [± 1.6 mm].

11.2.2 *Width*—The nominal width shall be up to 48 in. [1220 mm] with a tolerance of 3/16 in. [4.8 mm] under and 1/8 in. [3.2 mm] over the specified width.

11.2.3 *End Squareness*—Corners shall be square with a tolerance of ±1/4 in. [±6.4 mm] in the full width of the board.

11.3 *Edges*—The edges shall be either round or square.

12. Gypsum Ceiling Board

12.1 *Physical Properties of Gypsum Ceiling Board*:

12.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall not be less than the following:

	METHOD A		METHOD B	
Thickness in. [mm]	Load, lbf [N] Bearing Edges Across Fiber of Surfacing	Load, lbf [N] Bearing Edges Parallel to Fiber of Surfacing	Load, lbf [N] Bearing Edges Across Fiber of Surfacing	Load, lbf [N] Bearing Edges Parallel to Fiber of Surfacing
½ [12.7]	110 [489]	40 [178]	107 [476]	36 [160]

12.1.2 *Humidified Deflection*—The specimens shall have an average humidified deflection of not more than 5⁄16 in. [8 mm].

12.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than 80 lbf [356 N] when tested by Method A and 77 lbf [343 N] when tested by Method B.

12.2 *Dimensions and Tolerances of Gypsum Ceiling Board*:

12.2.1 *Thickness*—The thickness shall be ½ in. [12.7 mm] with tolerances of ± 0.015 in. [± 0.40 mm] with local variations of ± 0.030 in. [± 0.80 mm].

12.2.2 *Width*—The width shall be up to 48 in. [1220 mm] with a tolerance of 3⁄32 in. [3 mm] under the specified width.

12.2.3 *End Squareness*—Corners shall be square with a tolerance of ±⅛ in. [3 mm] in the full width of the board.

12.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

13. Finish and Appearance

13.1 The surfaces of gypsum board shall be true and free from imperfections that would render it unfit for use with or without decoration.

14. Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage

14.1 Sampling, inspection, rejection, certification, packaging, marking, shipping, handling, and storage of gypsum board shall be in accordance with Specification C1264.

15. Keywords

15.1 ceiling; coreboard; drywall; exterior gypsum soffit board; foil-backed; gypsum; gypsum backing board; gypsum base; gypsum board; gypsum ceiling board; gypsum coreboard; gypsum lath; gypsum sheathing; gypsum sheathing board; gypsum wallboard; partitions; plaster; predecorated gypsum board; shaftliner; sheathing; type X; veneer base; veneer plaster; wall; wallboard; water-resistant gypsum board

APPENDIXES

(Nonmandatory Information)

This appendix gives general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this specification.

The definition of type X as given in 4.3.1-4.3.3 and the alternate definition given in this appendix, are intended only as a test to define the gypsum board as meeting the requirements of type X products. These tests do not indicate a preferred application nor do they limit the use of the product in other fire rated assemblies.

All gypsum panel products for which type X is defined, except gypsum lath and gypsum shaftliner board, use the same test for type X products, therefore the type X definition indicates a consistent level of fire resistance.

X1. ALTERNATE DEFINITION FOR TYPE X

X1.1 Gypsum board, type X (special fire-resistant) designates gypsum board, except gypsum lath, providing a greater fire-resistance than regular gypsum board of the same thickness. Type X (special fire-resistant) gypsum board, when tested in accordance with Test Methods E119, shall provide the following minimum fire resistance ratings for the assemblies described:

X1.1.1 One hour for a 5⁄8-in. [15.9-mm] thickness applied to a partition in a single-layer application on each side of 3 5⁄8-in. [92-mm] deep non-loadbearing galvanized steel studs complying with Specification C645, spaced 24 in. [610 mm] on center. The 5⁄8-in. [15.9-mm] thick gypsum board 48 in. [1220 mm] wide shall be attached using 1-in. [25-mm] long drywall screws spaced 8 in. [203 mm] on center along the edges and ends, and 12 in. [305 mm] along intermediate studs. All joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly, and

X1.1.2 Two hours for a ½-in. [12.7-mm] thickness applied to a partition in a double-layer application on each side of 2½-in. [64-mm] deep non-loadbearing galvanized steel studs complying with Specification C645, spaced 24 in. [610 mm] on center. The 48-in. [1220-mm] wide base layer shall be attached using 1-in. [25-mm] long drywall screws spaced 12 in. [305 mm] on center along board edges, ends, and along intermediate studs. Joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly. The 48-in. [1220-m] wide face layer shall be attached using 1 5⁄8-in. [41-mm] long drywall screws spaced 12 in. [305 mm] along board edges, ends, and along intermediate studs. Joints shall be

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

oriented parallel to and located over studs, offset 24 in. [610 mm] from the base layer joints, and staggered on opposite sides of the assembly.

X2. TABLE OF WITHDRAWN ASTM STANDARDS REPLACED BY SPECIFICATION C1396/C1396M

X2.1 As of December 1, 2004, a single ASTM International reference, Specification C1396/C1396M, has replaced nine standards previously used to designate specific gypsum boards employed in commercial and residential construction. The chart below identifies the withdrawn standard and its corresponding section within Specification C1396/C1396M.

	Withdrawn ASTM Standard	C1396/C1396M Section
C36/C 36/M	Specification for Gypsum Wallboard	5
C37/C37M	Specification for Gypsum Lath	11
C79/C79M	Specification for Gypsum Sheathing Board	9
C442/C442M	Specification for Gypsum Backing Board, Gypsum Coreboard, and Gypsum Shaftliner Board	6
C588/C588M	Specification for Gypsum Base for Veneer Plasters	10
C630/C630M	Specification for Water-Resistant Gypsum Backing Board	7
C931/C931M	Specification for Exterior Gypsum Soffit Board	8
C960/C960M	Specification for Predecorated Gypsum Board	5
C1395/C1395M	Specification for Gypsum Ceiling Board	12

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this specification since the last issue, C1396/C1396M – 09, that may impact the use of this specification. (Approved November 15, 2009)

(*1*) Deleted 7.1.5 and 9.1.5 on water absorption.

Committee C11 has identified the location of selected changes to this specification since the last issue, C1396/C1396M – 06a, that may impact the use of this specification. (Approved September 1, 2009)

(*1*) Revised 4.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1397 – 09

Standard Practice for Application of Class PB Exterior Insulation and Finish Systems (EIFS) and EIFS with Drainage[1]

This standard is issued under the fixed designation C 1397; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers the minimum requirements and procedures for field or prefabricated application of Class PB Exterior Insulation and Finish Systems (EIFS) and EIFS with Drainage. Class PB EIFS are systems applied over insulation board, in which the base coat ranges from not less than 1/16 in. (1.6 mm) to 1/4 in. (6.4 mm) in dry thickness, depending upon the number of nonmetallic reinforcing mesh layers encapsulated in the base coat (see Specification E 2568). The base coat is then covered with a finish coat of varying thickness in a variety of textures and colors. EIFS with Drainage provides a mechanism to drain incidental moisture

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 The text of this practice references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as a requirement of the standard.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

4. Significance and Use

4.1 This practice provides minimum requirements for the application of Class PB EIFS and EIFS with Drainage (see Specification E 2568). The requirements for materials, mixtures, and details shall be contained in the project plans and specifications. See Guide E 1825 for guidance.

5. Delivery of Materials

5.1 All materials shall be delivered in packages, containers, or bundles with the identification and markings intact.

6. Inspection

6.1 Inspection of the materials shall be agreed upon between the purchaser and the supplier as part of the purchase agreement.

6.2 Inspection shall verify that the EIFS materials supplied are as required for the Class PB EIF System or EIFS with Drainage System specified. Mixing of EIFS materials from different manufacturers is not allowed.

7. Rejection

7.1 Materials that are damaged, frozen or in any way defective shall not be used. Rejection of materials shall be promptly reported verbally to the manufacturer and immediately reported in writing. The notice of rejection shall contain a statement documenting the basis for material rejection.

8. Certification

8.1 When specified in the contract documents, the producer shall furnish a report certifying that the materials are in conformance with product and material standards and contract documents.

8.2 *Insulation Boards*:

8.2.1 Insulation boards shall comply with Specification E 2430.

8.2.2 The insulation boards shall have been subjected to a third party quality control inspection and shall be marked as approved for use within the EIFS.

8.2.3 Prior to installation, the insulation board shall be inspected for conformance with contract documents. Nonconforming insulation board shall not be used.

8.2.4 The insulation board manufacturer shall furnish, for each shipment, a written certificate of conformance with the EIFS manufacturer's specifications.

9. Storage of Materials

9.1 All materials shall be kept dry by storage under cover and protected from the weather. When outside storage is required, materials shall be stacked off the ground, supported on a level platform and protected from the weather, surface contamination or physical damage in accordance with the EIFS manufacturer's written instructions.

9.2 Materials shall be protected from exposure to direct sunlight and temperatures less than 40 °F (4 °C), unless otherwise specified by the manufacturer.

9.3 Portland Cement shall meet Specification C 150 and shall be kept dry until ready for use. It shall be kept off the ground, under cover and away from damp walls and surfaces.

9.4 Insulation board shall be stacked flat with care taken to avoid damage to edges, ends, or surfaces; or exposure to direct sunlight (ultraviolet radiation).

10. Environmental Conditions

10.1 *Cold Weather Conditions*:

10.1.1 Wet materials shall not be applied when the temperature is less than 40 °F (4 °C), unless otherwise specified by the manufacturer, unless temporary heat and enclosures are provided to maintain minimum 40 °F (4 °C) for a minimum period of not less than 24 h before, during, and after application (see Annex A1.9.3).

10.1.2 Materials shall not be applied to a base containing frost. Substrate surface temperature shall be not less than 40 °F (4 °C). Mixtures for application shall not contain any frozen ingredients.

11. Assessment of Condition of Substrates to Receive Water-Resistive Barrier Coating (if applicable) or Exterior Insulation and Finish Systems or Both

11.1 The substrate shall be as required by the project plans and specifications and as recommended by the EIFS manufacturer for the particular system specified.

11.1.1 Insulation boards shall be as required by the EIFS manufacturer's specification and in the thickness specified.

11.2 The substrate shall be inspected by the applicator and general contractor to ensure that it meets the project plans and specifications and the requirements of 11.3-11.8.

11.3 Sheathing materials shall be inspected to ensure that:

11.3.1 The specified sheathing thickness has been installed for the stud spacing used.

11.3.2 Fastener type and fastener spacing are as specified.

11.3.3 All Specification C 1396/C 1396M gypsum sheathing boards shall have a water-resistant core.

11.3.4 Tongue and groove water-resistant treated core gypsum sheathing boards conforming to Specification C 1396/C 1396M shall be installed with the tongue edge oriented to the top.

11.3.5 Gypsum sheathing shall be installed in accordance with Specification C 1280.

11.3.6 Gypsum sheathing shall be protected from moisture at all penetrations and terminations.

11.3.7 Glass mat gypsum sheathing complying with Specification C 1177/C 1177M shall be installed in accordance with the sheathing manufacturer's written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheathing orientation and spacing.

11.3.8 Plywood shall be not less than ½ in. (12.7 mm) nominal in thickness, exterior or exposure 1 wood-based panel sheathing. The plywood shall be installed with a ⅛ in. (3.2 mm) space between sheets.

11.3.9 Oriented Strand Board (OSB) shall be nominal 7⁄16 in. (11.1 mm) thick APA Exposure 1 rated.

11.3.10 Fiber-cement sheets complying with Specification C 1186, Type A, shall be installed in accordance with the sheet manufacturer's written installation instructions, which include details of stud type and spacing, fastener type and spacing, and sheet spacing recommendations.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11.3.11 Water-resistant exterior fiber-reinforced gypsum sheathing complying with Specification C 1278/C 1278M shall be installed in accordance with the sheathing manufacturer's written installation instructions, which include details of stud type and spacing, fastener type and spacing, and sheathing orientation and spacing.

11.3.12 Fiber-mat reinforced cement sheets complying with Specification C 1325, type A, shall be installed in accordance with the sheet manufacturer's written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheet orientation and spacing.

11.3.13 Sheathing shall be continuous.

11.4 *Alignment*—All substrate surfaces shall be straight and true within ¼ in. (6.4 mm) in 10 ft (3048 mm). More stringent requirements by the EIFS manufacturer shall supersede the above stated requirements.

11.5 *Suitability for Use*—The substrate surface shall be firm, sound, and undamaged in order to receive the Water-Resistive Barrier Coating or EIFS.

11.5.1 Loose, spalling or crumbling concrete or masonry shall be removed by sandblasting or other appropriate means. If the surface condition of the substrate is at all in doubt, an alternative attachment surface or method shall be provided.

11.5.2 Broken, cracked or delaminated substrate boards shall be replaced or restored to a condition equal to adjacent undamaged boards.

11.5.3 All rotted, decayed, or delaminated wood and plywood sheathing shall be replaced.

11.5.4 Paper-faced gypsum sheathing that has been installed and exposed to the elements for more than 30 days shall be checked at not less than two locations, or every 5000 ft^2 (465 m^2), whichever is greater, for integrity of the surface. The procedures for evaluating the gypsum sheathing are found in Annex A2.

NOTE 1—Gypsum sheathing conforming to Specification C 1396/C 1396M is sometimes not recommended for adhesive attachment by the gypsum sheathing manufacturer. Consult with the gypsum board manufacturer before use.

11.6 *Cleanliness*—The surface of all substrates shall be clean and free from any foreign materials such as paint, form release agents, curing compounds, dust, dirt, frost, oil or grease, efflorescence and laitance that would affect the EIFS or EIFS with Drainage application.

11.6.1 All sheathing board substrates shall have all loose dirt and dust removed by cleaning methods appropriate for the job and job conditions.

11.6.2 Efflorescence and laitance on concrete, masonry, stucco or clay tile substrates shall be removed prior to EIFS application. Concrete masonry shall be cleaned by light sandblasting, pressure washing, or brushing. Heavy deposits shall be removed through use of hand or power impact tools followed by washing with an appropriate cleaner. Light deposits shall be removed by washing with an appropriate cleaner. All loose particles and cleaner residue shall be removed by washing with clean, potable water. The surface shall be allowed to dry.

11.6.3 Existing paint on concrete or masonry surfaces shall be removed by sandblasting or grit blasting. If removal of existing paint is not practical, an alternate attachment surface or method shall be provided.

11.7 *Dryness*:

11.7.1 Newly constructed concrete or masonry surfaces shall be allowed to cure for a minimum of 28 days prior to application of the EIFS or EIFS with Drainage. Repaired areas on existing (aged) walls shall meet the same 28-day curing time.

11.7.2 Sheathing must be dry prior to EIFS or EIFS with Drainage application.

11.7.3 Substrate surfaces shall be free of visible water.

11.8 *Metal Lath*—If metal lath is used, it shall be installed in conformance with Specification C 1063, except lath edges shall be butted, not lapped. Metal lath shall be 3.4 lb/yd^2 (1.3 kg/m^2) or 2.5 lb/yd^2 (1.0 kg/m^2), self furring or flat, G 60 galvanized.

11.8.1 Metal members shall be properly attached, straight, and true unless required by the system design.

11.8.2 Metal members shall be free of rust, oil, or other foreign matter or contaminants, which cause bond failure or unsightly discoloration.

12. Water-Resistive Barrier (WRB) Coating (When Specified) (See Test Methods E 2570)

12.1 Manufacturer's Recommended Joint Treatment (not required with concrete or masonry substrates)

NOTE 2—Joint treatment materials and methods differ among manufacturers. Some manufacturers use self-adhesive membrane tapes and others use fluid-applied flexible coatings with embedded reinforcing mesh or fabric.

12.1.1 For sheathing substrates, apply manufacturer's recommended treatment along all joints in sheathing, inside and outside corners, and exposed edges of sheathing at terminations in accordance with manufacturers recommended details .

12.1.2 Center the treatment on sheathing joints, edges, etc. For self-adhesive membrane tapes and self-adhesive mesh, apply with the pressure-sensitive adhesive backing in contact with the sheathing surface.

12.1.3 When applicable, use a stainless steel trowel or spatula to apply water-resistive barrier coating over tape and spot all fastener heads. (Spotting of fasteners is not required when applying water-resistive barrier with a trowel.)

12.1.4 After the first pass has dried, check joints and spot any voids that may be present with additional coating to achieve a continuous film.

12.2 Water-Resistive Barrier Coating

12.2.1 Roller Application

12.2.1.1 Use a roller recommended by manufacturer.

12.2.1.2 Apply a uniform, continuous film of the water-resistive barrier coating over the entire surface of the sheathing, concrete, or masonry, including previously treated areas.

NOTE 3—For concrete and masonry ensure that a continuous film of uniform thickness is applied across the entire surface including mortar joints. Substrates with a surface texture or high porosity will require additional material.

12.2.2 Trowel Application

12.2.2.1 Using a stainless steel trowel, apply a continuous film of the water-resistive barrier coating onto the entire wall

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

surface. The material shall be applied at a smooth, uniform, continuous film at the coverage rate specified by the manufacturer.

12.2.3 Spray Application

12.2.3.1 Using a handheld hopper gun or other suitable spray equipment, spray a layer of water-resistive barrier coating onto the wall surface.

12.2.3.2 In order to create a smooth continuous film, use a roller as described in 12.2.1 when specified by the manufacturer.

13. Drainage Means (If Applicable)

13.1 EIFS with Drainage require a means of drainage. This can be accomplished by one of the following methods; vertical notch trowel adhesive application, grooved insulation board, drainage mat, sheet type water-resistive barriers designed for drainage, metallic lath or non-metallic lath.

13.2 The EIFS shall be installed such that EIFS components, including sealants and flashings, do not hinder the drainage capability of the EIFS.

14. Insulation Board Installation

14.1 Method of attachment shall be approved by the system manufacturer.

14.2 *Adhesive Attachment Method*—The adhesive shall be applied to the back of the insulation board by one of the following methods:

14.2.1 *Notched Trowel (Required when Installing EIFS over Sheathing Substrates)*:

14.2.1.1 For EIFS with Drainage the notches shall be oriented vertically when using adhesive as the means to create the drainage plane. Refer to EIFS manufacturer for proper size of notch trowel and applications over lath.

14.2.2 *Ribbon and Dab (Acceptable over Concrete and Masonry)*:

14.2.2.1 The adhesive shall be applied to the entire perimeter of the insulation board in a ribbon fashion that is not less than 2 in. (50.8 mm) wide by not less than ⅜ in. (9.5 mm) thick. Dabs not less than 4 in. (101.6 mm) in diameter by not less than ⅜ in. (9.5 mm) thick shall be applied not more than 8 in. (203.2 mm) on center over the remainder of the board. Refer to EIFS manufacturer for applications over lath.

15. Adhesive and Mechanical Attachment Method

15.1 Adhesive shall be applied using the ribbon and dab method, the notched trowel method, or in accordance with system manufacturer's current published instructions.

15.2 Mechanical fasteners shall be installed into the framing or nailable substrate.

15.3 Fasteners shall penetrate not less than 5⁄16 in. (8.0 mm) into steel framing members, 1 in. (25 mm) into wood framing members, and 1 in. (25.4 mm) into masonry substrates.

15.4 Mechanical fasteners shall be corrosion resistant. Fastener type and spacing shall be in accordance with system manufacturer's current published instructions.

15.5 Selection and frequency of fasteners and fastener type will vary depending on substrate type, insulation board thickness and design wind load and whether used in combination with an adhesive attachment. Therefore fastener type, patterns, and use shall be in accordance with the EIFS manufacturer's written instructions and shall be included in the project plans and specifications.

16. Mechanical Attachment Method

16.1 Mechanical fasteners shall be installed into the framing or nailable substrate.

16.2 Mechanical fasteners shall be corrosion resistant. Fastener type and spacing shall be in accordance with the EIFS manufacturer's current published instructions.

NOTE 4—Wind-load requirements shall be considered for mechanically fastened systems.

17. General Requirements

17.1 Insulation boards shall be placed from a level base line with vertical joints staggered in a running bond pattern and butted tightly.

17.2 Insulation board joints at all inside and outside corners shall be staggered and interlocked.

17.3 Insulation boards must abut without gaps, eliminating space for adhesive or base coat intrusion between the board edges and ends.

17.4 Fenestration openings and other wall openings shall be cut out of a single insulation board. Board joints shall not be aligned at corners with head, sill or jambs of windows, doors, similar openings, and aesthetic reveals.

17.5 *Adhesively Attached*:

17.5.1 The final insulation board thickness shall be not less than ¾ in. (19.1 mm).

17.5.2 Insulation board joints shall be offset not less than 6 in. (152.4 mm) from horizontal sheathing board joints.

17.6 *Mechanically Fastened*:

17.6.1 The insulation board thickness shall be not less than ½ in. (38.1 mm).

17.6.2 Insulation board joints shall be offset from horizontal sheathing board joints.

17.7 When attachment is by adhesive or adhesive and mechanical fasteners, each insulation board shall be installed by sliding it into place until it abuts the adjoining insulation board tightly. Pressure shall be applied over the entire surface of the insulation board to achieve uniform contact and an overall level surface. The insulation board shall be occasionally checked for proper contact with the substrate by removing a piece of insulation board. Proper contact has been achieved when approximately equal portions of the adhesive remain on both the substrate and the insulation board when the board is removed from the wall. The insulation board shall remain undisturbed for no less than 24 h prior to proceeding with the installation of mechanical fasteners or the base coat. Cool, damp weather conditions extend minimum curing or drying time.

17.8 When the boards are attached only with mechanical fasteners, they shall be affixed to a nailable substrate or structural members with the proper fasteners, ensuring that all insulation boards abut tightly. Fastening patterns shall be in accordance with the EIFS manufacturer's recommendation.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

When installed, the portion of the fastener left flush with the face of the insulation board shall not fracture the insulation board.

18. Aesthetic Reveals

18.1 Aesthetic reveals shall be cut into the insulation board prior to applying the reinforcing mesh.

18.2 The insulation board thickness in the bottom of a reveal shall be not less than ¾ in. (19.1 mm).

18.3 Aesthetic reveals shall be cut true and straight.

18.4 Horizontal aesthetic reveal configuration shall provide for outward positive drainage.

18.5 Aesthetic reveals shall not occur at the abutment of two pieces of insulation board.

18.6 The reveal shall be reinforced with base coat and reinforcing mesh prior to application of the full base coat and reinforcing mesh.

19. Reinforced Base Coat Application

19.1 Inspect the insulation board surface to ensure that it is clean, dry, free of all foreign materials, and damage of any type. Insulation board planar irregularities of more than 1/16 in. (1.6 mm) shall be corrected. All board joints shall be tightly abutted or shall be filled with an insulating material. The entire wall area shall be sanded or rasped to minimize any irregularities.

19.2 *Base Coat Preparation*—All materials requiring field preparation shall be mixed in accordance with the EIFS manufacturer's specifications.

19.3 *Base Coat Application*—The prepared base coat shall be uniformly spread over the entire surface of the insulation board.

19.4 *Nonmetallic Reinforcing Mesh*—The single layer reinforcing mesh shall be fully embedded in wet base coat in the field of the wall, at corners, edges, and joints. While the base coat is wet, trowel from the center to the edge of the reinforcing mesh to avoid wrinkles. Mesh shall not be installed before base coat. The single layer of reinforcing mesh shall be continuous at all corners.

19.4.1 The surface shall be free of voids, projections, trowel marks and other surface irregularities. The base coat thickness shall be sufficient to totally embed the reinforcing mesh.

19.5 *Reinforcing Mesh Overlap*—All reinforcing mesh edges shall be overlapped not less than 2½ in. (63.5 mm).

19.6 *Impact Layers*—When required, higher impact performance shall be achieved with multiple layers of reinforcing mesh or by incorporating heavier weight reinforcing mesh. All areas requiring higher impact performance shall be detailed on the project plans and specifications. When overlapping of high impact mesh is not required, a complete second layer of reinforcing mesh shall be applied over the layer of high impact mesh.

19.7 *Corners*—Reinforcing mesh shall not be lapped within 8 in. (203.2 mm) of any corner. Double wrap the mesh 8 in. (203.2 mm) onto each side of the building's interior and exterior corners, not including small openings such as doors and windows.

19.8 *Wall Penetrations*—All edges of the insulation board at penetrations of the EIFS, such as at windows, doors, HVAC, pipes, ducts, electrical boxes, and at the base of the wall shall be wrapped with either the base coat and reinforcing mesh or trim, or as specified by the EIFS manufacturer. Wall openings such as doors, windows, and HVAC sleeves shall be diagonally reinforced at corners with mesh not less than 9 in. (228.6 mm) by 12 in. (304.8 mm).

19.8.1 The corners of returns to windows, doors, and similar wall openings shall have reinforcing mesh the full width of the return and extending not less than 2½ in. (63.5 mm) on both sides of the corner.

19.9 *Expansion Joints*—All edges of the insulation board at expansion joints shall be wrapped with either the base coat and reinforcing mesh or trim as specified by the EIFS manufacturer for the particular EIFS or EIFS with Drainage. The reinforcing mesh shall be fully embedded in the base coat material.

19.10 *Aesthetic Reveal*—The reinforcing mesh shall be continuous and care shall be taken to ensure that the reinforcing mesh is fully embedded in the base coat material at the base of the reveal and that the reinforcing mesh shall not be cut during application of the base coat.

19.11 *Reinforced Base Coat*—The reinforcing mesh shall be fully embedded in the base coat material throughout the field of the wall, at corners, edges, and joints. The surface shall be free of voids, projections, trowel marks and other surface irregularities.

19.12 *Special Insulation Shapes*—Nonmetallic reinforcing mesh embedded in the base coat material shall be used over specially shaped insulation board.

NOTE 5—Materials other than specified by EIFS manufacturer are not acceptable.

20. Finish Coat Application

20.1 The reinforced base coat shall be allowed to dry and harden for not less than 24 h prior to finish coat application, unless specifically allowed by the EIFS manufacturer.

20.2 *Material Preparation*—The finish coat shall be mixed in accordance with the EIFS manufacturer's specifications. Only clean potable water shall be added to adjust workability. Always add the same amount of water to each container within a given lot of finish.

20.3 *Execution*—Finish shall be applied with a stainless steel trowel or appropriate equipment as specified by the EIFS manufacturer. Tools and equipment shall be kept clean at all times. Finish shall be applied continuously to a natural break such as corners, joints or tape line. Apply finish to the base coat maintaining a wet edge. Sufficient manpower and scaffolding shall be provided to continuously finish a distinct wall area. Scaffolding shall be spaced a distance from the wall, consistent with safety standards, that will allow uniform texturing of the finish without staging marks. On hot windy days, misting is permitted with clean, potable water to cool the wall. Work shall precede the sun whenever possible. Water shall not be added to the finish once it is applied to the wall. Use the same tool and hand motion and match the texture of the surrounding area. The finish coat thickness shall be as specified by the EIFS manufacturer. Protect all finish work from damage until fully dried.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

20.4 *Joints*—The application of finish into the joints shall be consistent with the EIFS manufacturer's recommendations and job conditions.

20.5 *Sealant Joints*—The application of finish into the sealant joint is not allowed.

21. Curing Time Between Application Steps

21.1 Manufacturer's recommendations for climatic conditions, mixing, and application practices shall be followed to allow respective coats sufficient time to cure or dry before any subsequent coats are applied. Each application step shall be permitted to cure or dry to prevent degradation to the system integrity with subsequent steps.

21.2 Auxiliary protection (tenting, supplemental heat, shading) from adverse environmental conditions shall be utilized to minimize deviations from standard, expected cure or dry times. (See Annex A1.9.3.)

21.3 All substrates shall be sound and cured or dry before continuing on to the next application step.

22. Cleanup

22.1 Adjacent materials, surfaces, and the work area shall be cleaned of foreign materials resulting from the work.

22.2 All excess EIFS materials shall be removed from the job site.

23. Keywords

23.1 Class PB; coating; drainage; EIFS; exterior insulation and finish system; water-resistive barrier; WRB

ANNEXES

(Mandatory Information)

A1. GENERAL INFORMATION

A1.1 *General:*

A1.1.1 The work includes all labor, materials, services, equipment and scaffolding required to complete the EIFS or EIFS with Drainage installation on the project in accordance with the project drawings and specifications, except electrical power and potable water.

A1.1.2 Where a specific fire resistance rating is required for the EIFS or EIFS with Drainage assemblies and construction, details of construction shall be in accordance with official reports of tests conducted by recognized testing laboratories and a part of approved plans and specifications.

A1.1.3 The installation of the EIFS or EIFS with Drainage is to be coordinated by the owner's authorized agent with work of other trades.

A1.1.4 Surfaces and accessories to receive EIFS or EIFS with Drainage components shall be examined and accepted as provided in 11.2 before the EIFS or EIFS with Drainage components are installed thereto. The proper authorities shall be notified about unacceptable conditions. The unsatisfactory conditions shall be corrected prior to the application of the EIFS or EIFS with Drainage components. Unsatisfactory conditions shall be corrected by the party or parties responsible for such conditions.

A1.1.5 The construction specifier shall describe, in the proper section of the project specifications, the physical characteristics of the surfaces to receive the EIFS or EIFS with Drainage.

A1.2 *Design Considerations:*

A1.2.1 EIFS or EIFS with Drainage are attached to outside surfaces of all types of structures to provide weather resistant, energy efficient, and durable claddings. The claddings will be subjected to various exposures such as abrasion, vibration, moisture, freezing, thawing, negative and positive wind loading, ultraviolet light, acid rain, thermally induced expansion and contraction, and impact.

A1.2.2 Provide sufficient slope on faces of EIFS or EIFS with Drainage surfaces to prevent water, snow or ice from accumulating or standing. A minimum 6 in. (152.4 mm) in 12 in. (304.8 mm) (1:2) pitch is recommended. Length of sloped surfaces shall not be more than 12 in. (304.8 mm).

A1.2.3 Provide parapet cap made only from corrosion resistant materials. The parapet cap shall extend not less than 2½ in. (63.5 mm) over the faces of the EIFS or EIFS with Drainage, not including wood blocking and shall include a drip edge detail. Detailed requirements for furnishing and installing the parapet cap shall be in the appropriate section of the project specifications. Parapet caps shall be clearly shown in large scale details. Parapet caps shall be installed as soon as practical after the installation of the EIFS or EIFS with Drainage.

A1.2.4 Provide for sealing of expansion joints, panel joints, system terminations and all interfaces of the EIFS or EIFS with Drainage with other building components.

A1.2.5 At soffits, window and door heads provide for a drip edge.

A1.2.6 Windows installed in EIFS or EIFS with Drainage walls shall have metal sill flashing.

A1.2.7 The specifier shall evaluate the potential of the EIFS or EIFS with Drainage surface being subjected to abnormal stresses or impacts.

A1.2.8 Wall assemblies have properties that in certain applications make a dew point analysis critical to ensure successful performance of the wall system. The specifier shall evaluate these conditions.

A1.2.9 Sheathing must be continuous over floor slabs, intersecting walls, columns, beams and similar constructions.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

The EIFS or EIFS with Drainage shall not be installed over areas without sheathing. If the sheathing cannot be continuous, the installation of expansion joints shall be considered.

A1.2.10 Where the sheathing is interrupted or out of plane, corrections must be made prior to EIFS or EIFS with Drainage application.

A1.2.11 A water-resistive barrier and flashing may be required as specified in moist and water sensitive applications. The EIFS manufacturer, design professional, and specifier shall evaluate the conditions and the need.

A1.2.12 Refer to EIFS manufacturer for appropriate drainage means and method of installation.

A1.3 *Relief from Stress:*

A1.3.1 Where the EIFS or EIFS with Drainage and dissimilar types of substrates, materials and building components interface, provide for appropriate size and location of expansion joints.

A1.3.2 Where roof elevations change, provide for appropriate size and location of expansion joints.

A1.4 *Bonding Agents:*

A1.4.1 Bonding compounds or agents are sometimes applied to a substrate surface to receive the adhesive. Follow the EIFS manufacturer's instructions and specifications for their use.

A1.5 *Adhesives:*

A1.5.1 The types of adhesives and the methods of installation used will vary depending on the substrate to which the insulation boards will be attached. Therefore, the adhesive type and application method used shall be in accordance with the EIFS manufacturer's written instructions.

A1.6 *Mechanical Fasteners:*

A1.6.1 The types of mechanical fasteners used and the methods of installation will vary depending on the substrate to which the insulation boards are to be fastened.

A1.6.2 Fastener washers shall be installed flush with the insulation board surface.

A1.6.3 Fastener spacing shall be specified by the design professional consistent with wind load requirements on the specific project.

A1.7 *Reinforced Base Coats:*

A1.7.1 Base coat thickness is a function of various conditioins including the thickness of the reinforcing mesh, application techniques, and base coat properties.

A1.7.2 A small amount of base coat shrinkage is normal. Due to color variations, it shall not be unusual to see a very slight telegraphing of the reinforcing mesh pattern after the base coat cures. Bare mesh shall not be visible and the mesh pattern shall not be tactile.

A1.7.3 The EIFS manufacturer's instructions shall be followed to ensure that the base coat and cement is properly proportioned. The proper portioning of cement based material is important. Excess cement may cause the base coat to become hard and stiff as the cement hydrates over time.

A1.7.4 The minimum amount of water to form a workable mix shall be used. Excess water will cause the base coat to be porous and less weather resistant. Never add more water than recommended by the EIFS manufacturer. Measure water in containers of known volume.

A1.7.5 Mix materials only at low speed with paddles designed to reduce air entrapment.

A1.7.6 EIFS manufacturer's recommendations for climatic conditions, mixing and application practices to allow respective coats sufficient time to cure or dry before any subsequent coats are applied shall be followed. Each application step shall be cured or dried to prevent degradation to the system integrity with subsequent steps.

A1.7.7 Trowel aesthetic reveals and corners with a trowel shaped to fit the profiles.

A1.8 *Finish Textures:*

A1.8.1 Textures, as a description of surface appearance, generally are identified with the method and tools used to achieve the finish appearance. Texture is sometimes varied by the size and shape of the aggregate contained in the finish, equipment or tools employed, the consistency of the finish mix, the condition of the base to which it is applied and by decorative and protective treatments.

A1.8.2 With almost limitless variations possible for finish appearance or texture, the same term sometimes does not have the same meaning to the specifier, contractor or applicator. Sample panels of sufficient size including components and features specified shall be constructed using the methods, tools and techniques to be used in the actual construction. It is recommended that in the case of prefabrication, two panels be constructed. One panel remains at the jobsite. One panel remains at the fabrication site. The samples shall be approved by the architect and owner in writing.

A1.8.3 To provide some guidance, the following categories are generally understood and recognized to imply a particular method of application or finished appearance.

A1.8.3.1 *Sand Finish*—A finish material devoid of coarse aggregate applied in a thin coat completely covering the base coat and floated to a true plane, yielding a relatively fine-textured finish.

A1.8.3.2 *Trowel Texture*—A freshly applied finish is given various textures, designs or stippled effects by hand motion and trowel used. The effects achieved are individualized and it is sometimes difficult for different applicators to duplicate.

A1.8.3.3 *Standard Finish*—A finish with various size aggregates, applied in a thin coat completely covering the base coat and floated in a random pattern. The applicators are cautioned to use the same type texturing tools to help ensure a consistent texture.

A1.8.3.4 *Exposed Aggregate*—Varying sizes of natural or manufactured stone, gravel, shell or ceramic aggregates are embedded by hand or by machine propulsion into a freshly applied "bed coat." The size of the aggregate shall not be more than ½ in. (12.7 mm) in diameter. The size of the aggregate determines the thickness of the bedding coat. The bedding coat shall be no less than one-half the thickness of the aggregate to be embedded.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:08 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

A1.8.3.5 *Spray Texture*—A machine applied finish material. The texture achieved depends on many factors some of which are the consistency of the sprayed mixture, the angle and distance of the spray nozzle to the surface, the pressure of the machine, orifice size used, operator expertise, climatic conditions (wind specifically), and base coat conditions.

A1.8.3.6 *Miscellaneous Types*—Similar to trowel textures except that the freshly applied finish is textured with instruments other than a trowel, such as swept with a broom or brush, or corrugated by raking or combing. A variation of texturing a finish involves waiting until the applied finish has partially dried and then lightly troweling the unevenly applied finish. The effects achieved are sometimes difficult for different applicators to duplicate.

A1.9 *Conditions for EIFS Application:*

A1.9.1 The amount of water used to mix materials is to be within the allowable range published by the EIFS manufacturer. Factors such as the drying conditions and finishing operations must be considered in determining water usage. The applicator is cautioned that the use of excessive water results in fall off or slide off, excessive shrinkage, higher porosity, lower strength, and inconsistent color.

A1.9.2 Timing between coats will vary with climatic conditions and types of materials used. Temperature and relative humidity extend or reduce the curing and drying time. Cold or wet weather lengthens, and hot or dry weather shortens the drying period. Moderate changes in temperature and relative humidity are overcome by providing additional heating during cold weather and by pre-wetting the base during hot, dry weather.

A1.9.3 Heated enclosures require adequate air circulation to prevent hot or cold spots that allow too rapid drying or freezing. When using heated enclosures it is important to control the relative humidity as well as the temperature. Maintain relative humidity at not more than 90 %.

A1.9.4 Staining and discoloration of finishes or other building components that are caused by free water draining from one plane to another, dissimilar materials, or other building components, are minimized by providing sufficient depth and angle for drip caps and drip edges.

A2. EVALUATION OF PAPER-FACED GYPSUM SHEATHING FOR SURFACE ACCEPTABILITY

A2.1 The following procedure is valid only if, at the time of the test, the gypsum sheathing has not been wetted or exposed to high humidity in the previous 24 h.

A2.2 Using a sharp knife or razor blade, cut a 3-in. (76.2-mm) long diagonal in the middle of the gypsum sheathing. The cut must be sufficient to cut through the paper face and just into the underlying gypsum. Make a 3-in. (76.2-mm) cut at a right angle to the first, forming an “X”.

A2.3 Using the sharp edge of the cutting tool, peel the paper face (in one quadrant) back approximately ¼ in. (6.4 mm) from the intersection of the two lines.

A2.4 Firmly holding this peeled edge between the thumb and forefinger, lift the paper face and continue removing the facing material.

A2.5 If the paper splits cohesively so that part is still adhering to the underlying gypsum, the gypsum sheathing has not been overly exposed to the weather or moisture. If the paper lifts and directly exposes the gypsum, the gypsum sheathing has been exposed to the weather beyond the required limit and shall be replaced.

A3. SEALANT SYSTEMS

A3.1 The size and location of joints and selection of the sealant to be used is the responsibility of the design professional and shall be consistent with project conditions and guidelines of the EIFS manufacturer. See Guide C 1472 for guidance.

A3.2 The sealant system must be tested for compatibility with the specified EIFS or EIFS with Drainage by an independent laboratory and found to be compatible with the EIFS or EIFS with Dranage. See Test Method C 1382 for guidance.

A3.3 The sealant system is recommended by the EIFS and sealant manufacturer. Non-recommended sealant systems must be jointly approved by the design professional and the sealant manufacturer.

A3.4 Base the joint design and surface preparation on the sealant manufacturer’s recommendations and project conditions. See Guide C 1481 for guidance.

A3.5 Allow the EIFS material to cure prior to sealant system installation.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this practice since the last issue, C 1397 – 05, that may impact the use of this practice. (Approved July 15, 2009)

(*1*) Revised the standard throughout, including the title, to include EIFS with Drainage.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1398 – 07

Standard Test Method for The Laboratory Determination of the Time of Setting of Hydraulic-Cement Mortars Containing Additives for Shotcrete by the Use of Gillmore Needles[1]

This standard is issued under the fixed designation C 1398; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This is a laboratory test method that covers the determination of the time of setting of hydraulic–cement mortars containing additives for shotcrete for comparison with control mixes containing no additives or to compare the performance of shotcrete mixtures which contain additives that produce rapid setting or rapid stiffening of shotcrete.

1.2 The values stated in SI units (see IEEE/ASTM SI 10) are the standard.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this test method, refer to Terminology C 125.

4. Summary of Test Method

4.1 A mortar consisting of the sand, hydraulic cement, and water to be tested is proportioned by mass. The appropriate admixture or admixtures are added and a specimen is prepared from the mortar and tested for time of setting by means of Gillmore initial and final needles. A time of setting determination is then made for initial and final time of setting for each specimen. The time of setting shall be compared to a treated control mixture to demonstrate the effect of the admixture if such a comparison is the purpose of the study.

5. Significance and Use

5.1 The performance of an admixture for shotcrete in the field varies with the composition of the hydraulic cement and sand combination. Since this test method involves the determination of time of setting of a particular combination of hydraulic cement, sand and an admixture, it therefore provides information on the suitability for use of that particular combination in the field.

5.2 The time of setting of the combination established in the laboratory does not necessarily indicate the time of setting this combination will produce in actual shotcreting in the field.

5.3 This method is used to determine the effect on time of setting of mortars containing admixtures as compared to a control mortar.

5.4 The test method is used for comparison in laboratory pre–evaluation studies to demonstrate the effect of shotcrete admixtures in mortar compared with plain mortar and can be

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.46 on Shotcrete.

www.technobetar.ir

used to demonstrate or compare the performance of shotcrete admixtures which produce rapid setting or rapid rheological stiffening of shotcrete.

5.5 The test method is used to evaluate the relative performance of more than one shotcrete admixture for comparison of performance.

5.6 The test method is used to determine or verify that no adverse effects on setting time may be experienced with the use of admixtures that are not intended to accelerate or are used to produce stiffening of shotcrete mixtures.

5.7 Although specific environmental conditions are indicated, the testing environment can be varied to simulate the performance of admixtures in mortars at different temperatures. Such variations are reported as indicated in Section 11.

6. Apparatus

6.1 *Trowel*, having a steel blade 100 to 150 mm in length with a straight edge.

6.2 *Mixer, Bowl, Paddle with Scraper*, shall conform to the requirements of Practice C 305.

6.3 *Glass Graduates*, shall conform to the requirements of Practice C 490.

6.4 *Scales and Weights*, shall conform to the requirements of Specification C 1005.

6.5 *Disposable, Round, Plastic Petri Dishes*, 15 mm by 100 mm.

6.6 *Gillmore Needles*, shall conform to the requirements of Test Method C 266.

6.7 *Spoon*—a metal restaurant spoon as described in Test Method C 185.

6.8 *Stopwatch*.

7. Materials

7.1 *Mixing Water*— Potable water is satisfactory for routine tests. For referee and cooperative tests, use reagent water conforming to the requirements for Type II or Type IV of Specification D 1193.

7.2 *Fine Aggregate*. Use 20-30 sand in conformance with the requirements of Specification C 778.

7.3 *Portland cement* conforming to the requirements of Specification C 150.

7.4 *Accelerating shotcrete*, admixtures conforming to the requirements of Specification C 1141.

8. Conditioning

8.1 The temperature of the room, dry materials, paddle, bowl, and disposable plastic petri dishes shall be maintained between 20 and 28 °C . The temperature of the mixing water shall not vary from 23 ± 2 °C.

8.2 The relative humidity of the laboratory shall be 50 % ± 5 %.

8.3 The test area shall be free of airflow and drafts.

9. Mixing Procedure – Dry-Mix Shotcrete

9.1 *Preparation of the control mortar*—Proportion 200 g of cement, 400 g of standard 20–30 sand, with 70 mL (w/c = 0.35) water following the mixing procedure for cement mortars described in 9.2 except without the addition of admixture.

9.2 *Preparation of Mortar Containing Admixtures*:

9.2.1 *Mortar with non–liquid*—Proportion the sand and cement as in 9.1. Add the prescribed amount of non-liquid admixture to the mixing bowl with the dry sand and cement.

9.2.2 *Mortar with liquid admixtures*—Proportion the sand and cement as in 9.1 adding the mixture to the mixing bowl. Add mixing water to the prescribed amount of admixture to obtain a volume of 70 mL. This solution is added to the mortar as described in 9.3.3.

9.3 *Mixing of Mortar*— The mixing shall be done in the mechanical mixer as follows:

9.3.1 Place the appropriate dry materials in the mixing bowls, as in 9.2.1 or 9.2.2 and hand mix them with a spoon until a homogeneous mixture is achieved.

9.3.2 Position the bowl in the mixer and set the paddle in place.

9.3.3 With the mixer operating at medium speed, add 70 mL of mixing water to the non-liquid admixture as in 9.2.1 or 70 mL of mixing water and liquid admixture as in 9.2.2, start the stopwatch when the water contacts the dry mixture in the bowl. Mix for 10s.

9.4 *Preparation of Test Specimens*:

9.4.1 Stop the mixer and immediately remove the bowl from the mixer. With a spoon, quickly fill the plastic petri dish, and with the trowel, using the flat surface, cover three quarters of the dish surface and press straight down forcing the excess out of the remaining uncovered quarter. Draw the straight edge of the trowel across the surface in one motion.

10. Mixing Procedure – Wet–Mix Shotcrete

10.1 *Preparation of control mortar*—mix 200 g of cement and 400 g of standard 20–30 sand, with 70 mL of water (w/c = 0.35) following the mixing procedure for cement mortars described in 10.2 except without the addition of admixture.

10.2 *Preparation of Mortar Containing Admixtures*—Use a mechanical mixer as follows,

10.2.1 Place the sand and cement in the dry bowl, and hand mix the material with a spoon for a few seconds or until a homogeneous mixture is produced.

10.2.2 Position the bowl in the mixer, and set the paddle in place.

10.2.3 With the mixer operating at a slow speed add the entire quantity of mixing water within 15 s and continue mixing for 1 min, starting the stopwatch and timing from the first addition of water.

10.2.4 Stop the mixer, quickly scrape down the sides of the mixing bowl with the rubber scraper. Restart the mixer and mix for 15 s.

10.2.5 Stop the mixer, change to a medium speed. Start the mixer and quickly add the specified amount of admixture, continue mixing the mortar for 10 s.

10.3 Preparation of Test Specimens

10.3.1 Stop the mixer and immediately remove the bowl from the mixer. With a spoon, quickly fill the plastic petri dish, and with a trowel using the flat surface, cover three quarters of the dish surface and press straight down forcing the excess out of the remaining uncovered quarter. Draw the straight edge of the trowel across the surface in one motion.

www.technobetar.ir

11. Time of Setting Determination

11.1 After filling the plastic petri dish, immediately place the initial Gillmore needle in contact with surface of the mortar near the center of the dish. Release the needle. The mortar has reached time of setting when the surface will bear, without appreciable indentation, the initial Gillmore needle. The difference in hours, minutes, and seconds between the time of contact of the mortar with the liquid admixture, and the time at which the initial Gillmore needle makes no appreciable indentation is the initial time of setting.

11.2 Use the final Gillmore needle to determine the final time of setting, following the same procedure. For dry-mix shotcrete, the difference in hours, minutes, and seconds between the time of contact of the mortar and mixing water, and the time at which the final Gillmore needle makes no appreciable indentation is the final time of setting. For wet–mix shotcrete, the difference, in hours, minutes, and seconds between the time of contact of the mortar with the added liquid admixture, and the time at which the final Gillmore needle makes no appreciable indentation is the final time of setting

NOTE 1—When using admixtures that cause rapid rheological stiffening, prolonging the time of mixing or, not starting the Gillmore needle testing immediately may result in erroneous results in the determination of initial time of setting.

12. Report

12.1 Report the following information:

12.1.1 The times of initial and final setting in hours, minutes, and seconds for both the control specimen and specimen that was treated with admixtures if desired,

12.1.2 Brand and type of cement,

12.1.3 Brand and type of admixture,

12.1.4 Admixture dose,

12.1.5 Mix Temperature,

12.1.6 Room Temperature, and

12.1.7 Room Humidity.

13. Precision and Bias

13.1 It is not practical to specify the precision of this test method for measuring time of setting because test data are unavailable. A statement will be included at such time that sufficient test data have been obtained and analyzed.

13.2 The procedure in this test method has no bias because the value of time of setting of mortars is defined in terms of this test method.

14. Keywords

14.1 admixture; dry–mix shotcrete; mortar; quick—setting accelerating admixture; shotcrete; time of setting; wet-mix shotcrete

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1398 – 98$^{\epsilon 1}$, that may impact the use of this test method. (Approved July 15, 2007)

(*1*) Added terminology section and renumbered subsequent sections.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Designation: C1399/C1399M – 10

Standard Test Method for Obtaining Average Residual-Strength of Fiber-Reinforced Concrete[1]

This standard is issued under the fixed designation C1399/C1399M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of residual strength of a fiber–reinforced concrete test beam. The average residual strength is computed using specified beam deflections that are obtained from a beam that has been cracked in a standard manner. The test provides data needed to obtain that portion of the load–deflection curve beyond which a significant amount of cracking damage has occurred and it provides a measure of post–cracking strength, as such strength is affected by the use of fiber–reinforcement.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C31/C31M Practice for Making and Curing Concrete Test Specimens in the Field

C42/C42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C78 Test Method for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)

C172 Practice for Sampling Freshly Mixed Concrete

C192/C192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C823 Practice for Examination and Sampling of Hardened Concrete in Constructions

C1609/C1609M Test Method for Flexural Performance of Fiber-Reinforced Concrete (Using Beam With Third-Point Loading)

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *deflection*—mid–span deflection of the test beam obtained in a manner that excludes deflection caused by the following: (*1*) the flexural test apparatus, (*2*) crushing and seating of the beam at support contact points, and (*3*) torsion of the beam; sometimes termed net deflection.

3.1.2 *initial loading curve*—the load–deflection curve obtained by testing an assembly that includes both the test beam and a specified steel plate (Fig. 1); plotted to a deflection of at least 0.20 mm [0.008 in.] (Fig. 2).

3.1.3 *reloading curve*—the load–deflection curve obtained by reloading and retesting the pre-cracked beam, that is, after the initial loading but without the steel plate. (Fig. 2)

3.1.4 *reloading deflection*—deflection measured during the reloading of the cracked beam and with zero deflection referenced to the start of the reloading.

3.1.5 *residual strength*—the flexural stress on the cracked beam section obtained by calculation using loads obtained from the reloading curve at specified deflection values (See Note 1).

NOTE 1—Residual strength is not a true stress but an engineering stress computed using the flexure formula for linear elastic materials and gross (uncracked) section properties.

3.1.6 *average residual strength*—the average stress–carrying ability of the cracked beam that is obtained by calculation using the residual strength at four specified deflections.

4. Summary of Test Method

4.1 Cast or sawed beams of fiber–reinforced concrete are cracked using the third–point loading apparatus specified in Test Method C78 modified by a steel plate used to assist in support of the concrete beam during an initial loading cycle

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.42 on Fiber-Reinforced Concrete.

Current edition approved Jan. 1, 2010. Published February 2010. Originally approved in 1998. Last previous edition approved in 2007 as C1399–07a. DOI: 10.1520/C1399_C1399M-10.

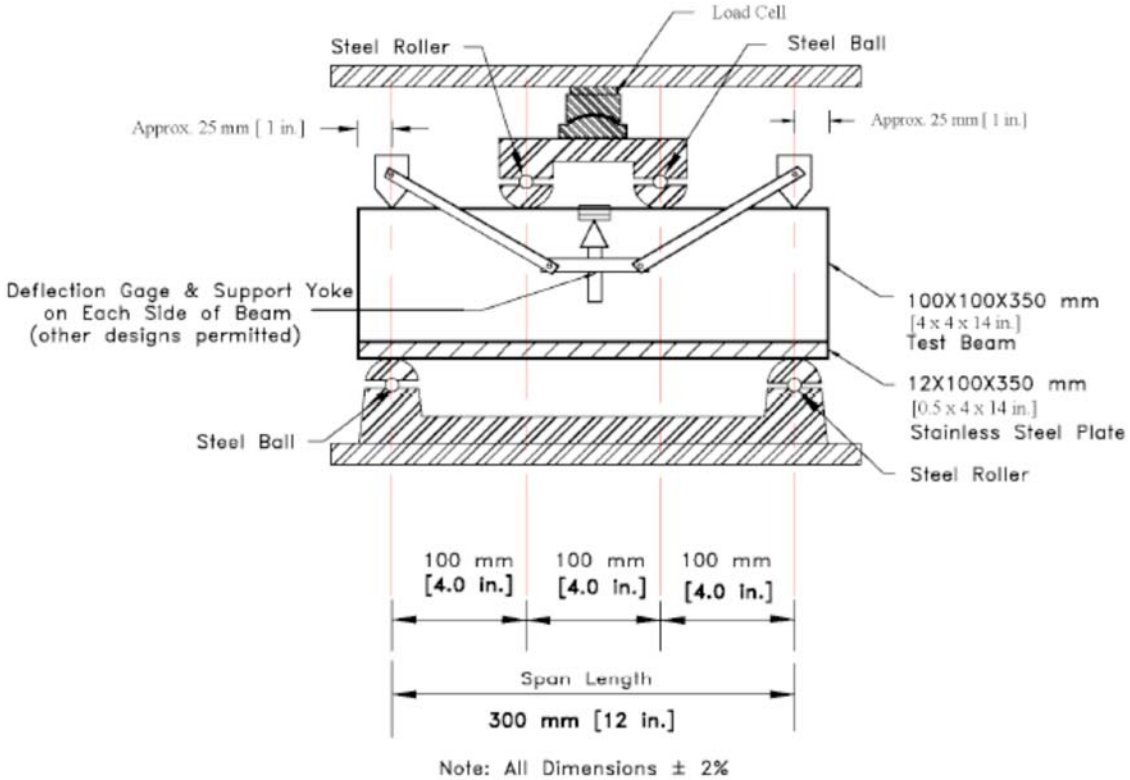

FIG. 1 Schematic of a Suitable Apparatus Where the Deflection Gauge Support Frame is Seated on the Beam

(Fig. 1). The steel plate is used to help control the rate of deflection when the beam cracks. After the beam has been cracked in the specified manner, the steel plate is removed and the cracked beam is reloaded to obtain data to plot a reloading load–deflection curve. Load values at specified deflection values on the reloading curve are averaged and used to calculate the average residual strength of the beam.

5. Significance and Use

5.1 This test method provides a quantitative measure useful in the evaluation of the performance of fiber–reinforced concrete. It allows for comparative analysis among beams containing different fiber types, including materials, dimension and shape, and different fiber contents. Results can be used to optimize the proportions of fiber–reinforced concrete mixtures, to determine compliance with construction specifications, to evaluate fiber–reinforced concrete which has been in service, and as a tool for research and development of fiber–reinforced concrete (See Note 2).

NOTE 2—Banthia and Dubey[3] compared results using this test method with residual strengths at the same net deflections using a test protocol that is similar to that described in Test Method C1609/C1609M on 45 beams with a single fiber configuration at proportions of 0.1, 0.3, and 0.5 % by volume. The results by this test method were on average 6.4 % lower than by the procedure of Test Method C1609/C1609M.

[3] Banthia, N. and Dubey, A., "Measurement of Flexural Toughness of Fiber Reinforced Concrete Using a Novel Technique, Part I: Assessment and Calibration," In Press, *Materials Journal*, American Concrete Institute.

5.2 Test results are intended to reflect either consistency or differences among variables used in proportioning the fiber–reinforced concrete to be tested, including fiber type (material), fiber size and shape, fiber amount, beam preparation (sawed or molded), and beam conditioning.

5.3 In molded beams fiber orientation near molded surfaces will be affected by the process of molding. For tests of fiber-reinforced concrete containing relatively rigid or stiff fibers of length greater than 35 mm [1.4 in.], the use of sawed beams cut from samples with an initial width and depth of at least 3 times the length of the fiber is required to minimize effects of fiber orientation. When sawed beams are employed, and to avoid the effects of fiber orientation, care shall be applied to ensure that the flexural tensile surface of the beam is a sawed surface.

6. Apparatus

6.1 *Either Screw Gear or Hydraulic Testing Apparatus*, with the ability to control the rate of motion of the loading head and meeting the requirements of Test Method C78. A load cell with a 44.5 kN capacity [10,000 lbf] will generally be required. Closed-loop feed-back controlled deflection apparatus is not required.

6.2 *Flexural-Loading Beam-Support Apparatus*, conforming to the requirements of Test Method C78.

6.3 *Load and Deflection–Measuring Devices*, such as load cells and electronic transducers, capable of producing electronic analog signals and having support apparatus located and arranged in a manner that provides determination of applied load and mid-span deflection (See 3.1.5) of the beam. Measure

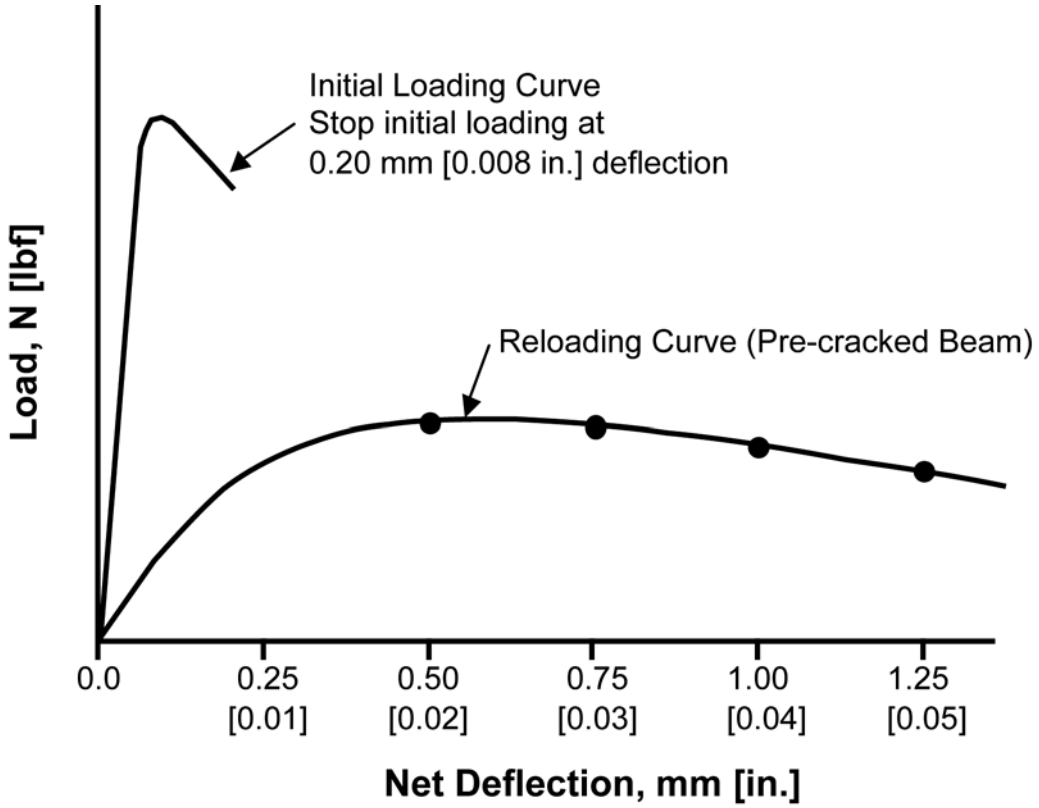

FIG. 2 Load-Deflection Curves

deflection using a device capable of measuring net deflection at the beam mid–span with a minimum resolution of 0.025 mm [0.001 in.] by one of the following alternative methods.

NOTE 3—The deflection measurement requires care in the arrangement of displacement transducers in order to minimize extraneous contributions such as might be caused by seating or twisting of the specimen. Experience has shown that apparatus designed to support deflection measuring devices that eliminate extraneous deflections is acceptable. Methods to accomplish this measurement use spring-loaded electronic displacement transducers mounted on suspension frames or support frames as shown in Fig. 1.

6.3.1 *Three Electronic Transducers*, mounted on a support frame. The support frame positions the transducers along the centerline of the top surface of the test beam at locations so as to contact the beam at mid-span and each support location. Average the measured support deflections and subtract this value from the recorded mid-span deflection to obtain the net deflection.

6.3.2 *Two Electronic Transducers*, mounted on a support frame. The support frame either (*1*) surrounds the test beam and is clamped to the sides of the beam at points on a line passing vertically through the beam support locations, or (*2*) is seated on top of the beam and is itself supported at points directly over the beam supports. In each case one transducer is located on each side of the test beam at mid-span, recording deflection between the mounted transducers and contact points that are rigid attachments located on the beam at the center of the span. The average of the transducer measurements are the net deflection.

6.4 *Data Acquisition Equipment*, capable of simultaneously recording data from the load and deflection transducers by either of the following alternative methods.

6.4.1 *X-Y Plotter*, driven by analog signals from load and deflection transducers to record the load–deflection curve.

6.4.2 *Analog Signal Sampling and Digital Conversion Using Automatic Data Acquisition Equipment With a Minimum Sampling Frequency of 2.5 Hz*, to record load and corresponding deflection values from which load–deflection curves can be produced.

6.5 *Stainless Steel Plate*, nominally 100 by 12 by 350 mm [4 by ½ by 14 in.].

6.6 *Mechanical Dial Gauge*, with 0.025 mm [0.001 in.] resolution.

6.7 *Magnetic–Mount Dial Gauge Holder*.

6.8 *Beam Molds*, conforming to the requirements of Practice C192/C192M that will produce 100 mm by 100 mm by 350 mm [4 in. by 4 in. by 14 in.] beams.

7. Sampling, Test Beams, and Test Units

7.1 Prepare a set of at least five beams from each sample of fresh or hardened concrete.

7.2 *Freshly Mixed Concrete*:

7.2.1 Obtain samples of freshly mixed fiber–reinforced concrete in accordance with Practice C172.

7.2.2 Mold beams in accordance with Practice C31/C31M or Practice C192/C192M and cast in one layer using a vibrating table for consolidation. Internal vibration or rodding may produce non–uniform fiber distribution.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.2.3 Cure samples for a minimum of 7 days in accordance with the standard curing procedure in Practice C31/C31M or the procedure in Practice C192/C192M. Use the same curing time when comparison between or among laboratories is desired.

7.3 *Hardened Concrete*:

7.3.1 Select samples of hardened fiber-reinforced concrete from structures in accordance with Practice C823.

7.3.2 Prepare and condition sawed beams in accordance with Test Method C42/C42M. The sawed beams shall have dimensions 100 mm by 100 mm by 350 mm [4 in. by 4 in. by 14 in.].

8. Procedure

8.1 Set the rate of platen or cross-head movement at 0.65 ± 0.15 mm/min [0.025 ± 0.005 in/min.] before the beam is loaded.

NOTE 4—When necessary use the mechanical dial gauge to establish the setting for the rate of platen or cross–head movement.

8.2 Place the specimen on the top of the steel plate to be loaded with the specimen (see Note 5). Molded specimens or specimens sawed from molded specimens shall be turned on their side from the position as cast before placing on the support system (see Fig. 3(a)). Specimens sawed from in-place

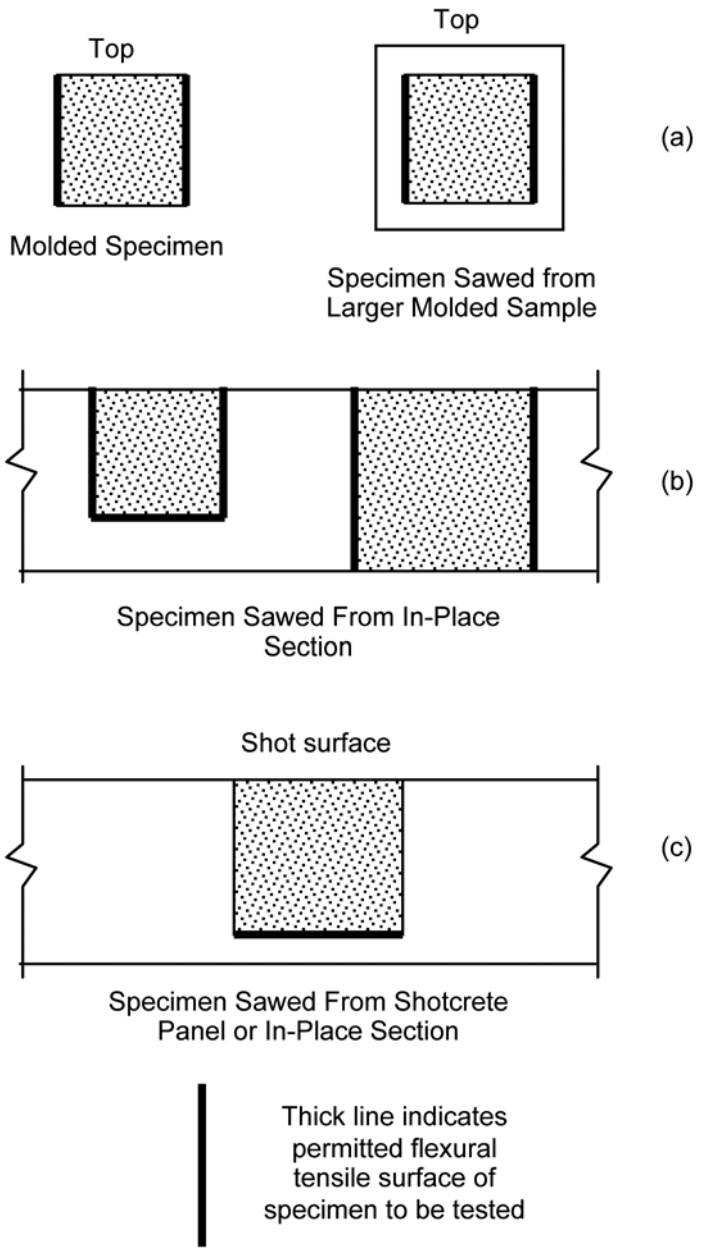

FIG. 3 Schematic of Specimen Cross Sections to Indicate Permitted Flexural Tensile Surfaces During Testing

www.technobetar.ir

concrete shall be loaded so that a sawed surface is the flexural tensile surface (see Fig. 3(b)). Specimens representing shotcrete shall be loaded in the same direction as the specimen was shot (see Fig. 3(c)).

NOTE 5—The purpose of the stainless steel plate is to support the test beam during the initial loading cycle to help control the expected high rate of deflection of the beam upon cracking.

8.3 Place the plate and beam on the support apparatus so that the steel plate is centered on the lower bearing blocks and the concrete beam is centered on the steel plate. Adjust the displacement transducer(s) according to the chosen apparatus for obtaining net deflection.

8.4 Ensure that the X–Y plotter or alternate data acquisition system is activated and responding to signals from all load and displacement transducers.

8.5 Begin loading the beam and steel plate combination at the set rate and continue loading until reaching a deflection of 0.20 mm [0.008 in.]. If cracking has not occurred after reaching a deflection of 0.20 mm [0.008 in.] the test is invalid. The maximum load is not to be used to calculate modulus of rupture in accordance with Test Method C78 as this load includes load carried by the steel plate as well as by the concrete beam.

8.6 In anticipation of reloading the cracked beam only, remove the steel plate and center the cracked beam on the lower bearing blocks retaining the same orientation as during the initial loading test cycle. Adjust the displacement transducer(s) to lightly contact the beam in accordance with the chosen method for obtaining net deflection so that readings will immediately be obtained upon beam reloading. Zero the deflection recording device.

8.7 Begin reloading at the specified rate used for the initial loading. Terminate the test at a deflection of 1.25 mm [0.050 in.] as measured from the beginning of reloading.

8.8 Measure the beam and crack location as in Test Method C78.

9. Calculation

9.1 Calculate the average residual strength (ARS) for each beam to the nearest 0.01 MPa [2 psi] using the loads determined at reloading curve deflections of 0.50, 0.75, 1.00, and 1.25 mm [0.020, 0.030, 0.040, and 0.050 in.] as follows:

$$ARS = ((P_A + P_B + P_C + P_D)/4) \times k \quad (1)$$

where:

k = L/bd^2, mm^{-2} [in^{-2}]
ARS = average residual strength, MPa [psi],
$P_A+P_B+P_C+P_D$ = sum of recorded loads at specified deflections, N [lbf],
L = span length, mm [in.],
b = average width of beam, mm [in.], and
d = average depth of beam, mm [in.].

9.2 Calculate the mean ARS for each set of beams to the nearest 0.05 MPa [5 psi].

10. Report

10.1 The test report shall include the following information. If specific information is unknown at the time of the test then the word "UNKNOWN" shall be used.

10.1.1 Concrete mixture proportions.
10.1.2 Type and amount of fiber reinforcement.
10.1.3 Test beam information including:
10.1.3.1 beam identification labels,
10.1.3.2 type of beam (molded or sawed),
10.1.3.3 average width of beam to the nearest 1.0 mm [0.05 in.],
10.1.3.4 average depth of beam to the nearest 1.0 mm [0.05 in.],
10.1.3.5 beam age at time of test,
10.1.3.6 curing history and moisture condition at time of test,
10.1.3.7 defects in beam or abnormalities during testing,
10.1.3.8 loads obtained at reloading deflections of 0.50, 0.75, 1.00, and 1.25 mm [0.020, 0.030, 0.040, and 0.050 in.],
10.1.3.9 Average Residual Strength (ARS) for each beam to the nearest 0.01 MPa [2 psi],
10.1.3.10 plots of the reloading curves from which the average residual strengths (ARS) were determined, and
10.1.3.11 mean value of the ARS found for each set of beams to the nearest 0.05 MPa [5 psi].

11. Precision and Bias

11.1 *Precision*—Criteria for judging the acceptability of test results obtained for this test method are given in Table 1 (See Note 6).

NOTE 6—The precision statements are based on tests conducted in ten laboratories on sets of three duplicate samples of four different mixtures.[4]

11.2 *Bias*—The test method has no bias because the values determined can be defined only in terms of this test method.

12. Keywords

12.1 fiber–reinforced concrete; residual strength; flexure testing; post cracking strength

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR:C09-1018.

TABLE 1 Precision Data for Test Samples[4]

ARS (MPa)	Standard Deviation (MPa)	Acceptable Range of Two Results (MPa)	Acceptable Range Difference Between High and Low, Three Results (MPa)
Single Operator Precision:			
0.50	0.10	0.28	0.33
1.00	0.12	0.34	0.40
2.00	0.28	0.78	0.92
3.50	0.45	1.26	1.49
Multilaboratory Precision:			
0.50	0.22	0.62	0.73

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C1399 – 07a, that may impact the use of this test method. (Approved January 1, 2010)

(*1*) Revised the standard as a dual units test method.
(*2*) Reduced the fiber length in 5.3 to 35 mm [1.4 in.].
(*3*) Deleted old Figure 2 and Note 4 because that method of measuring deflection is no longer permitted.
(*4*) Revised Figs. 1 and 2 to be consistent with the format of a dual units standard.
(*5*) Revised the description for orienting the specimen in the loading apparatus in 8.2 and added a new Fig. 3 for clarity.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1404/C 1404M – 98 (Reapproved 2003)

Standard Test Method for Bond Strength of Adhesive Systems Used With Concrete as Measured by Direct Tension[1]

This standard is issued under the fixed designation C 1404/C 1404M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the laboratory determination of the bond strength of adhesive systems used to adhere freshly mixed mortar to hardened portland-cement concrete.

1.2 The values stated, in either SI units or other units shall be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore each system must be used independently of the other, without combining values in any way.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

A 333/A 333M Specification for Seamless and Welded Steel Pipe for Low-Temperature Service

C 33 Specification for Concrete Aggregates

C 39 Test Method for Compressive Strength of Cylindrical Concrete Specimens

C 42 Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 109 Test Method for Compressive Strength of Hydraulic Cement Mortars using 2-in. [50 mm] Cube Specimens

C 150 Specification for Portland Cement

C 171 Specification for Sheet Materials for Curing Concrete

C 192 Practice for Making and Curing Concrete Specimens in the Laboratory

C 305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C 494 Specification for Chemical Admixtures for Concrete

C 881 Specification for Epoxy-Resin-Base Bonding Systems for Concrete

C 670 Practice for Preparing Precision Statements for Test Methods for Construction Materials

3. Summary of Test Method

3.1 Each specimen consists of a base and overlay, bonded together with the adhesive being tested. The base is half of a 3-in. [75-mm] by 6-in. [150-mm] hardened-concrete cylinder mounted inside of a steel-pipe nipple. The overlay consists of freshly mixed mortar placed in a steel-pipe nipple positioned on top of the base.

3.2 The prepared surface of the base is coated with the adhesive, onto which freshly mixed mortar is applied. After curing, the assembly is pulled in tension to measure the bond strength of the adhesive. The tensile strength is calculated, and the location of failure is determined visually.

4. Significance and Use

4.1 The bonding properties of adhesives are important for concrete repair applications. This test method provides a means to measure the adhesive characteristics of materials used to bond freshly mixed mortar to hardened concrete.

4.2 In addition to providing information on bond strength, the location of failure is determined visually and is thus instructive regarding the weakest element in the composite tested.

4.3 The bond strength that is measured is limited by the tensile strength of the base concrete and mortar. While an attempt has been made to choose materials that are strong enough to force a bond failure, there may be cases where failure occurs in concrete or mortar. In these situations, the actual bond strength exceeds the measured result.

5. Apparatus

5.1 *Testing Machine*—The testing machine shall be of the hydraulic or screw-type and capable of measuring tensile loads up to 5000 lbf [22 kN] in increments of 45 lbf [200 N] at rates described in 9.3.

5.2 *Steel-Pipe Nipples*—The steel-pipe nipples shall conform to Specification A 333/A 333M, be nominally 3 in. [75 mm] in diameter by 3 in. [75 mm] long Schedule 40, threaded;

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates , and is the direct responsibility of Subcommittee C09.25 on Organic Materials for Bonding.

Current edition approved Sept. 10, 1998. Published April 1999. Originally approved in 1998. Last previous edition approved in 1998 as C 1404/C 1404M – 98.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

two per specimen. The inside surface of the steel-pipe nipples shall be clean and free of oil or other contaminants that could inhibit bond. The inside surface shall be sandblasted to gray metal condition.

5.3 *Steel-Pipe Cap*—Two steel-pipe caps nominally 3 in. [75 mm] in diameter, and threaded to fit the steel-pipe nipple molds. Each cap shall be fitted with a steel rod or eye bolt with at least one universal joint for connection to the testing machine. The assembly shall have a tensile capacity of at least 5000 lbf [22 kN]. See Fig. 1 for details of preparation.

5.4 *Base Assembly*—Concrete cylinder and steel pipe nipple, prepared according to Section 7; one for each specimen.

5.5 *O-rings*—Rubber, 2-⅞ in. [73 mm] inside diameter× 3-¼ in. [83 mm] outside diameter; 3⁄16 in. [5 mm] thick; one for each specimen.

5.6 *Concrete Mixer*—As described in Practice C 192.

5.7 *Mixer, Bowl, and Paddle*—A mechanical mortar mixer, as described in Practice C 305.

5.8 *Small Tools*—Tools and items such as a straightedge, scoops, rubber gloves, and metal mixing bowls.

5.9 *Tamping Rod*—The tamping rod shall be a round steel rod, ⅜ in. [10 mm] in diameter, conforming to Practice C 192.

5.10 *Saw*, as described in Test Method C 42, with diamond saw blade and plain water as the only cutting fluid.

5.11 *Cylinder Molds*—The cylinder molds shall be 3-in. [75-mm] diameter by 6-in. [150-mm] long, as described in Practice C 192.

6. Materials

6.1 *Cement*—The cement shall be portland cement meeting the requirements of Specification C 150.

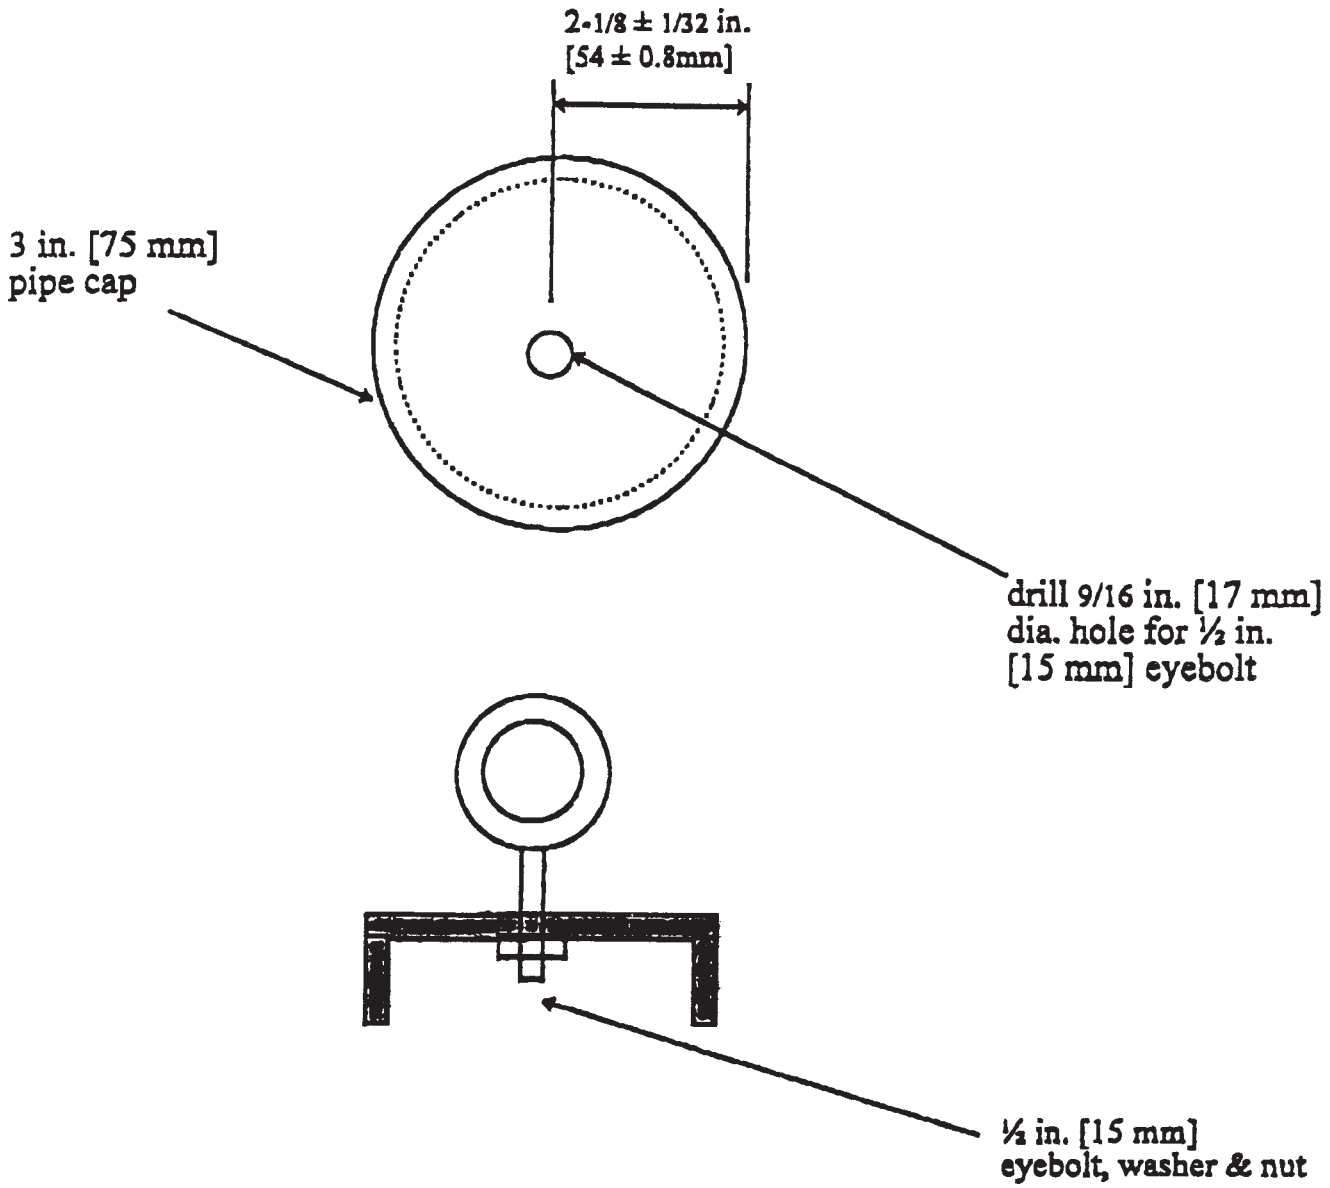

FIG. 1 Pipe Cap Detail

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.2 *Aggregate*—The aggregate shall conform to Specification C 33; the coarse aggregate shall conform to Size No. 7.

6.3 *Mortar*—Prepare and test the mortar in accordance with Test Method C 109, and each specimen tested shall have a compressive strength of at least 4500 psi [31 MPa] at seven days age.

6.4 *Concrete*—The concrete shall be non air-entrained, prepared and cured in accordance with Practice C 192, tested according to Test Method C 39, and each specimen tested shall have a compressive strength of at least 6000 psi [41 MPa] at 28 days. Water-reducing admixtures, meeting Specification C 494, may be used.

6.5 For the purpose of qualifying the reference mortar and concrete, compressive strengths of all specimens tested shall exceed the minimum stated.

6.6 *Abrasive Paper*—Sandpaper, emery cloth, or other abrasive paper of grit No. 100.

6.7 *Tape*—Plastic tape, minimum 2 in. [50 mm] wide.

6.8 *Epoxy*—Type V, Grade 1 epoxy resin, Specification C 881, shall have low enough viscosity to flow into the annular space between the concrete base cylinder and steel-pipe nipple.

NOTE 1—A hot-air blower to heat the pipe nipple has been found useful to increase flow of the epoxy adhesive between the pipe and the concrete cylinder.

6.9 *Sealant*—Capable of sealing the rubber to the concrete to prevent the flow of the epoxy adhesive; an example is RTV silicone rubber.

6.10 *Polyethylene Film*—Meeting Specification C 171 and having a minimum thickness of 4 mil [0.1 mm].

7. Base Assembly Preparation

7.1 Prepare concrete as described in 6.4 and place in the cylinder molds, 3-in. [75-mm] diameter by 6-in [150-mm] long.

7.2 Cure in accordance with Practice C 192 except that moist curing shall be continuous for 28 days. After this time, and until the cylinders are cut, they shall be stored at 73.4 ± 3.0°F [23 ± 2°C] and 50 ± 10 % R.H.

7.3 Not more than seven days after completing the curing cycle, cut the cast cylinders so that two cylinders, 3 in. [75 mm] diameter by nominally 3 in. [75 mm] long, are produced. Take care that the edges are not chipped during the cutting operation. Discard any half-cylinders with chips or defects estimated to be greater than 5 % of the cross-sectional area. Store the acceptable half-cylinders with the cut surface down, on a clean, dry surface, at 73.4 ± 3.0°F [23 ± 2°C] and 50 ± 10 % R.H. until used.

7.4 Place a half-cylinder, cut end down, on a clean, nonporous surface and position the O-ring so that it rests snugly against the clean surface. Seal the O-ring to the side of the concrete half-cylinder with sealant. Before the sealant cures, place a 3 in. [75 mm] long steel pipe nipple onto the cylinder so that it rests against the O-ring and the sealant. After the sealant cures, pour epoxy into the annular space between the nipple and cylinder until the space is full. See Fig. 2 for details.

8. Preparation and Curing of Composite Specimens

8.1 After the epoxy has cured, invert the base assembly so that the cut surface of the concrete is up. Rub this surface with the abrasive paper to remove any extraneous material that could inhibit bond. Wipe this prepared surface with a damp cloth to remove any dust or powder that may have accumulated.

8.2 Place a 3 in. [75 mm] long nipple on this assembly and secure it to the bottom nipple with tape around the outside of both nipples.

8.3 Apply the adhesive being tested to the prepared surface of the concrete base using the manufacturer's recommendations for thickness and procedure, including moisture condition of substrate.

8.4 Mix mortar as described in Test Method C 109. Fill the nipple in two equal layers, and rod the mortar with 25 strokes per layer. Strike off the surface with a trowel and cover with polyethylene film.

8.5 Prepare a minimum of three specimens per test age.

8.6 Moist cure the specimens according to Practice C 192.

9. Procedure

9.1 Remove the tape from the specimens.

9.2 Screw the pipe caps (Fig. 1) onto the ends of the specimen (Fig. 2) and connect to the testing machine (see Fig. 3).

9.3 Set the testing machine so the specimen can be loaded into tension, at least 5000 lbf [22 kN] maximum load capability. For screw type, set cross-head speed at 0.04 in/min [1.0 mm/min]; for hydraulic type, load at 5 ± 2 psi/s [35 ± 15 kPa/s].

9.4 Load the specimen at constant rate until failure.

10. Calculation

10.1 Calculate the tensile strength to the nearest 10 psi [0.1 MPa] as follows:

$$T = P/A \quad (1)$$

where:

T = tensile strength at failure, psi [MPa],
P = maximum applied load, lbf [N], and
A = cross sectional area of concrete base.

10.2 Estimate the location of failure in percent of cross sectional area for each element of the specimen, that is, in concrete base, at bond line, in mortar overlay. The sum of the three values must equal 100.

11. Report

11.1 Report the following information:

11.1.1 Identification of specimen,

11.1.2 Identification of type of cement used to make the test mortar,

11.1.3 Identification of bonding agent tested,

11.1.4 Moisture condition of substrate,

11.1.5 Length of cure of overlay for each set of specimens,

11.1.6 Number of specimens, Mean and Coefficient of Variation of T for each set, and

11.1.7 Results of test in the following manner:

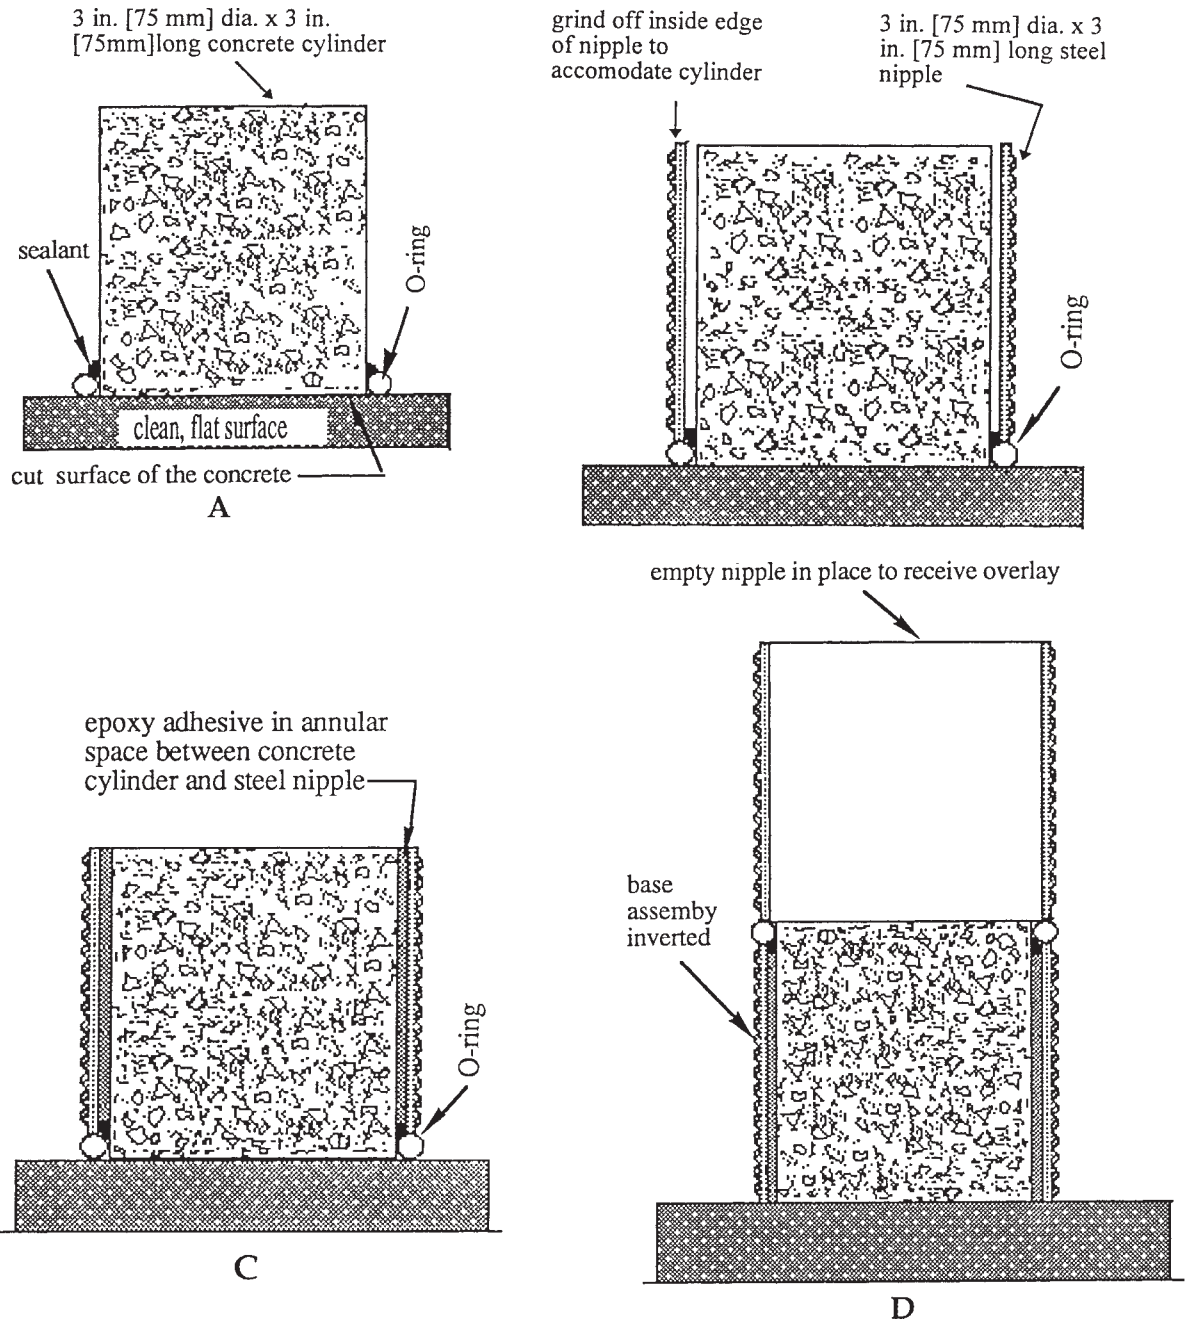
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir



NOTE 1—(A) Place the concrete cylinder on a clean, flat surface; seal the O-ring to the cylinder with the sealant; (B) Place a pipe nipple over the concrete cylinder; (C) Pour epoxy adhesive into the space between the cylinder and nipple; (D) after the epoxy adhesive cures, invert the base assembly and place the second pipe nipple on top.

NOTE 2—Tape is wrapped around the outside of this final assembly to keep the pieces aligned as well as protect the threads from being covered with the overlay.

FIG. 2 Specimen Preparation

Specimen No.	*T*, Tensile Strength at Failure, psi [MPa]	Location of Failure, % Area		
		In Mortar Overlay	At Bond Line	In Concrete Base

12. Precision and Bias

12.1 *Single Operator Precision*—The single operator within laboratory and multilaboratory standard deviations, as shown below, have been found to be the same:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:16 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

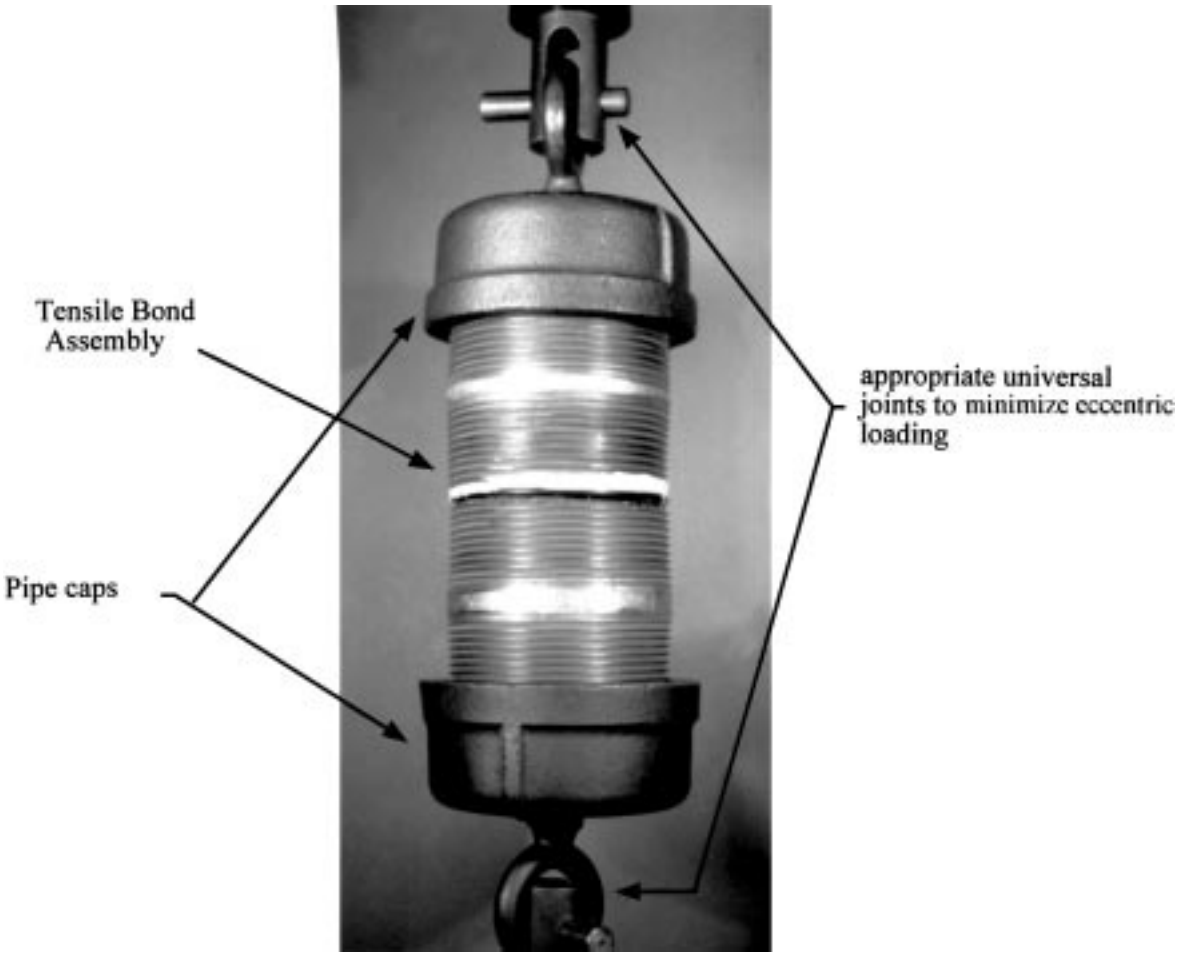


FIG. 3 Tensile Bond Assembly in Testing Machine

44 psi [0.30 MPa] for 3-day cure
52 psi [0.36 MPa] for 7-day cure
41 psi [0.28 MPa] for 28-day cure

Therefore, the results of two properly conducted tests from the same operator or from two different laboratories on similar batches should not differ from each other by more than shown below:

124 psi [0.84 MPa] for 3-day cure
145 psi [1.01 MPa] for 7-day cure
114 psi [0.78 MPa] for 28-day cure

NOTE 2—These numbers represent the (d2s) limit as described in Practice C 670. Data are from test of specimens that had strengths in the range of 246 to 522 psi [1.7 to 3.6 MPa].

12.2 *Bias*—The test method has no bias because the values determined can be defined only in terms of the test method.

13. Keywords

13.1 adhesives; bond strength; bonding agents; concrete-bonding; overlays; tensile bond

Designation: C 1435/C 1435M – 08

Standard Practice for Molding Roller-Compacted Concrete in Cylinder Molds Using a Vibrating Hammer[1]

This standard is issued under the fixed designation C 1435/C 1435M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers molding cylindrical test specimens from concrete when the standard procedures of rodding and internal vibration, as described in Practice C 31/C 31M and Practice C 1176, are not practicable. This practice is applicable to freshly-mixed concrete, prepared in the laboratory and the field.

1.2 Freshly-mixed concrete is molded in cylindrical molds using an electric vibrating hammer equipped with a shaft and circular plate.

1.3 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.4 The text of this practice references notes and footnotes, which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this practice.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

C 496/C 496M Test Method for Splitting Tensile Strength of Cylindrical Concrete Specimens

C 1170 Test Method for Determining Consistency and Density of Roller-Compacted Concrete Using a Vibrating Table

C 1176 Practice for Making Roller-Compacted Concrete in Cylinder Molds Using a Vibrating Table

2.2 *ACI Documents:*

207.5R Report on Roller-Compacted Concrete[3]

211.3 Practice for Selecting Proportions for No-Slump Concrete[3]

3. Summary of Practice

3.1 This practice describes molding cylindrical concrete test specimens using a vibrating hammer. Test specimens are molded vertically in cylindrical molds by compacting the stiff to very dry concrete mixture in four lifts using a vibrating hammer.

4. Significance and Use

4.1 This practice, intended for use in testing roller-compacted concrete, may be applicable to testing other types of cementitious material such as coarse-grained, soil-cement. This practice provides standardized requirements for molding stiff to very dry consistency concrete mixtures commonly used in roller compacted concrete construction. This practice is used instead of rodding or internal vibration, which cannot properly consolidate concrete of this consistency (Note 1).

NOTE 1—Further description of roller compacted concrete consistency is given in ACI 207.5R and 211.3. The consistency of concrete using a vibrating table may be determined in accordance with Test Methods C 1170.

4.2 This practice is used to mold cylindrical test specimens commonly used for testing compressive or tensile strength of concrete. Specimens tested for compressive strength and splitting tensile strength shall be in accordance with Test Methods C 39/C 39M and C 496/C 496M, respectively. Test specimens also may be used to determine density of fresh concrete.

[1] This practice is under the jurisdiction of Committee C09 on Concrete and Concrete Aggregates and are the direct responsibility of Subcommittee C09.45 on Roller-Compacted Concrete.

Current edition approved June 1, 2008. Published July 2008. Originally approved in 1999. Last previous edition approved in 2007 as C 1435/C 1435M – 07.

www.technobetar.ir

Specimens tested for density of fresh concrete shall be in accordance with Test Methods C 1170.

NOTE 2—For some extremely dry mixtures; (those with a consistency greater than 45 s when tested in accordance with Test Methods C 1170)[4] the density of specimens made in accordance with this practice may be greater than the in-place density of roller-compacted concrete due to the greater potential for voids at the bottom of the lifts in the field.

5. Apparatus

5.1 *Molds*:

5.1.1 *Type A Reusable Mold*—A cylindrical mold conforming to the requirements of Specification C 470/C 470M for 150-mm [6-in.] diameter by 300-mm [12-in.] high reusable molds.

5.1.2 *Type B Single-Use Mold*—A single-use plastic, cylindrical mold 150-mm [6-in.] diameter and 300-mm [12-in.] in height. The mold specifications shall conform to Specification C 470/C 470M for single-use, plastic molds.

5.1.2.1 *Mold Sleeve*—A Type B cylindrical mold shall be inserted into a rigid cylindrical sleeve. The cylindrical sleeve shall be made of steel or other hard metal resistant to cement paste corrosion. The sleeve shall be capable of firmly holding the plastic mold upright without deformation of the mold. The sleeve shall be split and hinged on one side so that it can be opened to remove the plastic mold; adjustable clamps shall be provided on the other side for tightening the sleeve around the mold. A metal base plate with brackets shall be provided in which to insert the bottom portion of the sleeve to hold the sleeve during compaction. The sleeve shall have a minimum wall thickness of 3 mm [⅛ in.], and a minimum base plate thickness of 6 mm [¼ in.]. The inside diameter of the mold sleeve shall be 3 ± 1 mm [⅛ ± 1/16 in.] larger than the outside diameter of the Type B mold and have a height 13 ± 6 mm [½ ± ¼ in.] less than the height of the Type B mold.

5.2 *Vibrating Hammer*—A vibrating compaction hammer having a mass (without tamping plate and shaft) of 10 ± 1.5 kg [22 ± 3.3 lb]. It also shall have a minimum power input of 900 W and be capable of providing 2000 ± 200 impacts/min.

NOTE 3—The vibrating hammer used to compact the specimens, such as shown in Fig. 1, is of the type used typically for breaking up concrete and masonry. It provides oscillatory motion in the axial direction that makes the hammer an effective vibratory compactor.

5.3 *Tamping Plate*—A circular steel plate attached to a steel shaft, which is inserted into the vibrating hammer chuck. The plate diameter shall be 140 ± 3 mm [5 ½ ± ⅛ in.] and the mass of the plate and shaft assembly shall be 3 ± 1 kg [6.6 ± 2.2 lb] (See Fig. 2).

5.4 *Small Tools*—A square-ended shovel, a hand scoop, a tamping rod, and a stopwatch.

6. Sampling

6.1 Samples of freshly-mixed concrete shall be obtained in accordance with Practice C 172.

6.2 Concrete samples shall have a maximum size aggregate of 50 mm [2 in.] or less. If the concrete has aggregate larger than 50 mm [2 in.] samples shall be obtained by wet sieving over a 50-mm [2-in.] sieve in accordance with Practice C 172.

6.3 Concrete test specimens shall be molded within 45 min after the completion of mixing unless otherwise specified.

6.4 *Technical Precautions*:

6.4.1 When obtaining samples, ensure that the samples are representative of the bulk production.

6.4.2 Concrete with stiff to very dry consistency is highly susceptible to segregation during handling. To minimize segregation, use care in obtaining samples and during transporting, remixing, and preparation of the specimens.

7. Calibration

7.1 Calibrate the vibrating hammer after any event, including repairs, that might affect its operation, after 300 h of service, or at least one time per year.

8. Molding Specimens

8.1 *Method A, Type A Molds*:

8.1.1 Coat Type A molds with a suitable lubricant or bond breaker prior to casting the test specimens to facilitate removal from the mold.

8.1.2 Hold the mold stationary either by clamping to a rigid, flat base or standing on the foot brackets and center the vibrating hammer so that the edges of the tamping plate do not touch the walls of the mold. Lower the vibrating hammer into the mold to check for proper clearance.

8.1.3 Place enough concrete in the mold so that the mold will be filled to one-fourth of its volume after consolidation, approximately 3.4 kg [7.5 lb]. Use a tamping rod to distribute the loose concrete as it is added. During filling, use square-ended shovels and scoops to obtain representative samples and handle the concrete in such a manner that larger sized coarse aggregates do not separate from the mortar.

8.1.4 Place the vibrating hammer with tamping plate onto the concrete (Fig. 1).

8.1.5 Start the vibrating hammer and allow the concrete to consolidate under the tamping plate. Observe the concrete in the annular space between the edge of the tamping plate and the inside wall of the mold. As the concrete consolidates, mortar should fill in the annular space between the outer edge of the tamping plate and the inside mold wall. Observe the mortar until it forms a ring around the total perimeter of the tamping plate. When the mortar ring forms completely around the tamping plate, stop the vibrating hammer.

8.1.6 If a rock pocket prevents the mortar ring from forming at one small location, even though it has formed in all other locations, the vibrating hammer can be stopped and the next layer of concrete added.

8.1.7 If a significant portion of the mortar ring does not form after 20 s, the vibrating hammer shall be stopped and the next layer of concrete added. This situation may be a result of insufficient mortar due to either improper sampling, segregation, or improper mixture proportioning. In these instances, the concrete should be inspected visually after stripping from the mold to determine if there is adequate mortar distribution and a decision made whether to accept or reject the specimen.

8.1.8 Repeat the procedure in 8.1.3-8.1.7 for the second and third lifts of concrete, filling the mold to approximately

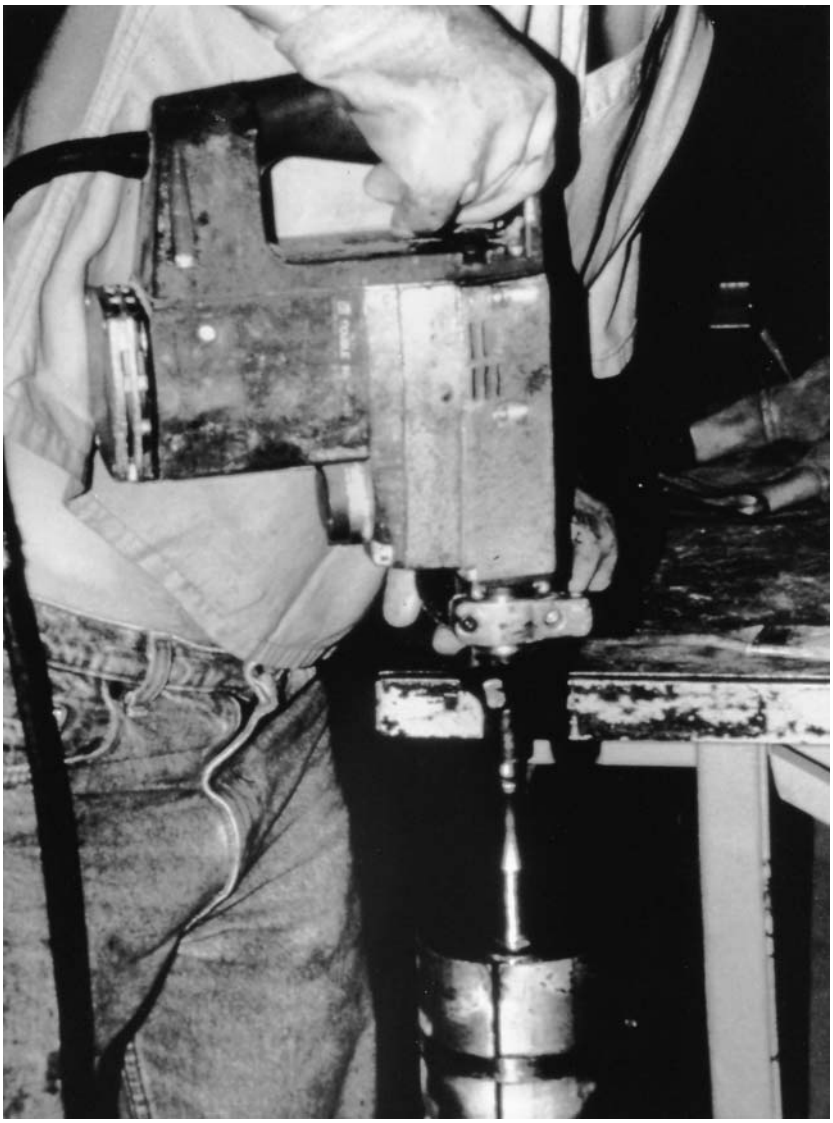

FIG. 1 Vibrating Hammer for Molding RCC Specimens

one-half and three-fourths of its volume, respectively. For the fourth lift, overfill the mold by mounding the concrete above the top of the mold. Again, place the tamping plate on the loose concrete and consolidate. If the tamping plate consolidates concrete below the top level of the mold, turn off the vibrating hammer. Place additional concrete in the mold so that, when consolidated, the concrete can be finished smooth and level with the top of the mold.

8.1.9 Finally, strike off the top of the concrete with the vibrating hammer and tamping plate. With the hammer in operation and the plate in contact with the rim of the cylinder mold, move the plate back and forth across the top of the cylinder to force excess material beyond the rim. Continue working the surface until it is smooth and level with the top of the cylinder mold. Avoid tearing the surface of the concrete.

9. Keywords

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1435/C 1435M – 07, that may impact the use of this practice. (Approved June 1, 2008)

(*1*) Revised Fig. 2.

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1435/C 1435M – 06, that may impact the use of this practice. (Approved November 1, 2007)

(*1*) Revised Fig. 2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1436 – 08

Standard Specification for Materials for Shotcrete[1]

This standard is issued under the fixed designation C 1436; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers materials for use in hydraulic-cement concrete mixtures to be placed by shotcreting. It does not cover mixing, placement, curing, or protection of the concrete placed by shotcreting.

1.2 This specification covers materials for both wet-mix and dry-mix shotcreting.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of the standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 33 Specification for Concrete Aggregates

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 150 Specification for Portland Cement

C 330 Specification for Lightweight Aggregates for Structural Concrete

C 595 Specification for Blended Hydraulic Cements

C 1116/C 1116M Specification for Fiber-Reinforced Concrete

C 1141/C 1141M Specification for Admixtures for Shotcrete

C 1157 Performance Specification for Hydraulic Cement

C 1385/C 1385M Practice for Sampling Materials for Shotcrete

C 1602/C 1602M Specification for Mixing Water Used in the Production of Hydraulic Cement Concrete

E 11 Specification for Wire Cloth and Sieves for Testing Purposes

3. Terminology

3.1 For definitions of terms used in this specification, refer to Terminology C 125.

4. Ordering Information

4.1 In the absence of designated applicable general specifications, the purchaser shall include the following information in the purchase contract or order, if applicable:

4.1.1 The specification designation and date of issue,

4.1.2 Specification for cement and type (see 5.1.1),

4.1.3 Grading number for total combined aggregates required (see 5.1.2),

4.1.4 Specification, type, and grade(s) for admixtures required (see 5.1.4), and

4.1.5 Specification, type, length, and, if appropriate, the diameter (or equivalent cross-sectional dimensions) of fiber required (see 5.1.5).

5. Material Requirements

5.1 In the absence of designated applicable specifications covering requirements for quality of materials, the following requirements shall govern:

5.1.1 *Cement*—Cement shall be in accordance with Specification C 150, Specification C 595, or Performance Specification C 1157. If special properties are required, the purchaser shall limit the choice of cements to those suitable for the special use.

5.1.2 *Aggregates*—Aggregates shall be in accordance with Specification C 33 or Specification C 330 if lightweight shotcrete is specified by the purchaser except that the grading of the total aggregate constituent of the shotcrete shall be in accordance with the requirements prescribed in Table 1 for the grading number specified.

NOTE 1—The ranges shown in Table 1 are by necessity wide in order to accommodate nationwide conditions. For quality control of any specific operation, a producer should develop an average grading for the particular source and production facilities, and control the grading within reasonable tolerances from this average.

5.1.3 *Water*—The mixing water shall be in accordance with Specification C 1602/C 1602M.

[1] This specification is under the jurisdiction of Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.46 on Shotcrete.

Current edition approved Dec. 15, 2008. Published January 2009. Originally approved in 1999. Last previous edition approved in 2004 as C 1436 – 99(2004).

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

TABLE 1 Grading Limits for Combined Aggregate for Shotcrete

Percent by Mass Passing Individual Sieve		
Sieve Size, U.S. Standard[A]	Grading, No. 1	Grading, No. 2
12.5 mm (½ in.)	-	100
9.5 mm (⅜ in.)	100	90 - 100
4.75 mm (No. 4)	95 - 100	70 - 85
2.36 mm (No. 8)	80 - 98	50 - 70
1.18 mm (No. 16)	50 - 85	35 - 55
600 µm (No. 30)	25 - 60	20 - 35
300 µm (No. 50)	10 - 30	8 - 20
150 µm (No. 100)	2 - 10	2 - 10

[A]The sieve designations in parentheses are provided for information only; the only standard sieve sizes are those stated in Specification E 11 in SI units.

5.1.4 *Admixtures*—Mineral and chemical admixtures shall be in accordance with Specification C 1141/C 1141M.

5.1.5 *Fibers*—Fibers shall be in accordance with the requirements for fibers prescribed in Specification C 1116/C 1116M.

6. Sampling

6.1 Access shall be provided to the purchaser for sampling, either at the point of manufacture or at the site of the work, as specified by the purchaser. Sampling of materials shall be in accordance with Practice C 1385/C 1385M.

7. Number of Tests and Retests

7.1 Testing, number of tests, and retests to be performed on specified materials shall be in accordance with the referenced ASTM standard.

8. Inspection

8.1 Inspection of the materials shall be agreed upon between the purchaser and the supplier as part of the purchase contract.

9. Rejection, Certification, and Product Marking

9.1 Rejection, certifications, and product markings on specified materials shall be in accordance with the referenced ASTM specification.

10. Keywords

10.1 dry-mix shotcrete, materials for; ordering; shotcrete; specification; testing; wet-mix shotcrete

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1436 – 99(2004), that may impact the use of this specification. (Approved December 15, 2008)

Designation: C 1437 – 07

Standard Test Method for Flow of Hydraulic Cement Mortar[1]

This standard is issued under the fixed designation C 1437; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of flow of hydraulic cement mortars.

1.2 The values stated in SI units are to be regarded as the standard. Values in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 185 Test Method for Air Content of Hydraulic Cement Mortar

C 230/C 230M Specification for Flow Table for Use in Tests of Hydraulic Cement

C 511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

3. Significance and Use

3.1 This test method is intended to be used to determine the flow of hydraulic cement mortars, and of mortars containing cementitious materials other than hydraulic cements.

3.2 While flow is not usually included in hydraulic cement specifications, it is commonly used in standard tests that require the mortar to have a water content that provides a specified flow level.

4. Apparatus

4.1 *Flow Table, Flow Mold*, Conforming to the requirements of Specification C 230.

4.2 *Caliper*, Conforming to the requirements of Specification C 230. Alternatively, any outside-measuring caliper constructed of corrosion-resistant material may be used, provided that it is incremented in millimetres and its maximum extent of measuring is at least 260 mm (10¼ in.).

4.3 *Tamper*, conforming to the requirements of Test Method C 109.

4.4 *Trowel*, having a steel blade 100 to 150 mm (4 to 6 in.) in length, with straight edges. The edges when placed on a plane surface shall not depart from straightness by more than 1 mm (0.04 in.) (Note 1).

4.5 *Straightedge*, made of steel, shall be at least 200 mm (8 in.) long and not less than 1.5 mm (0.06 in.) nor more than 3.5 mm (0.14 in.) in thickness. Its edge shall not depart from a plane surface by more than 1 mm (0.04-in.) (Note 1).

NOTE 1—The trowel specified in Test Method C 109 and the straightedge specified in Test Method C 185 may be used for this purpose, providing they comply with the planeness indicated.

5. Temperature and Humidity

5.1 The temperature and relative humidity of the air in the mixing room shall be as prescribed in Specification C 511.

6. Materials

6.1 *Hydraulic Cement Mortar*—A mortar for which the determination of flow is specified or desired.

7. Procedure

7.1 *Determination of Flow*:

7.1.1 Carefully wipe the flow table clean and dry, and place the flow mold at the center. Place a layer of mortar about 25 mm (1 in.) in thickness in the mold and tamp 20 times with the tamper. The tamping pressure shall be just sufficient to ensure uniform filling of the mold. Then fill the mold with mortar and tamp as specified for the first layer. Cut off the mortar to a plane surface flush with the top of the mold by drawing the straightedge or the edge of the trowel with a sawing motion across the top of the mold. Wipe the table top clean and dry, being especially careful to remove any water from around the edge of the flow mold. Lift the mold away from the mortar 1 min after completing the mixing operation. Immediately drop the table 25 times in 15 s, unless otherwise specified.

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.22 on Workability.

Current edition Nov. 1, 2007. Published December 2007. Originally approved in 1999. Last previous edition approved in 2001 as C 1437 - 01.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

***A Summary of Changes section appears at the end of this standard.**

Copyright. ©)ASTM International, 100 Barr Harbou Dr. PO box C-700 West Conshohocken, Pennsylvania 19428-2959, United States

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:34:21 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.1.2 If using the caliper specified in Specification C 230, measure the diameter of the mortar along the four lines scribed in the table top, recording each diameter as the number of caliper divisions, estimated to one tenth of a division. If some other caliper is being used, measure the diameter of the mortar along the four lines scribed in the table top, recording each diameter to the nearest millimetre.

8. Calculation

8.1 The flow is the resulting increase in average base diameter of the mortar mass, expressed as a percentage of the original base diameter.

8.2 If using the caliper specified in Specification C 230, add the four readings, and record the total. This gives the flow in percent. If using some other caliper, compute the flow in percent by dividing *"A"* by the original inside base diameter in millimetres and multiplying by 100.

where:

A = average of four readings in millimetres, minus the original inside base diameter in millimetres.

Report the flow to the nearest 1 %.

9. Precision and Bias

9.1 *Precision*—The single-operator, within-laboratory standard deviation has been found to be 4 % flow. Therefore, results of two properly conducted tests by the same operator on similar batches should not differ by more than 11 % (Note 2).

9.1.1 The multilaboratory standard deviation has been found to be 11 %. Therefore, results of two different laboratories on similar batches should not differ by more than 31 % flow (Note 2).

NOTE 2—Data produced when water content is being varied to obtain a given flow is not applicable for this purpose. Only data where flow has been determined using a given cement and fixed water content is applicable. Consequently, the only data currently available is that extracted from the CCRL Proficiency Sample Program for CS Flow on C 109 mortars (dropping the flow table 25 times in 15 s). The data for Sample Nos. 109, 110, 111, and 112 have been used to develop the precision statements given.

9.2 *Bias*—Since there is no accepted reference material suitable for determining flow available, no statement on bias is made.

10. Keywords

10.1 flow; hydraulic cement; mortar

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 1437 – 01, that may impact the use of this test method. (Approved November 1, 2007)

Designation: C1438 – 99 (Reapproved 2005)ε1

Standard Specification for Latex and Powder Polymer Modifiers for Hydraulic Cement Concrete and Mortar[1]

This standard is issued under the fixed designation C1438; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—Paragraphs 1.2 and 1.3 were revised editorially November 2005.

1. Scope

1.1 This specification covers performance criteria for latexes and redispersible powders when used as modifiers in hydraulic cement concretes and mortars to improve adhesion and reduce permeability (see Note 1).

NOTE 1—For further information concerning theory, benefits, limitations, and applications of polymer-modified hydraulic cementitious mixtures, refer to ACI 548.3R-95.

1.2 The performance criteria are based on certain property changes that are achieved by use of the polymer modifier when compared to reference concrete or mortar (Test Methods C 1439).

1.3 Prepackaged, proprietary mortar products are not included in this specification. Also, this specification covers only those materials contained in the reference or test mixtures listed in Test Methods C 1439.

1.4 The values stated in SI units are to be regarded as standard.

1.5 The following precautionary statement pertains only to the test method portion, Section 10, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 494/C 494M Specification for Chemical Admixtures for Concrete

C 1439 Test Methods for Polymer-Modified Mortar and Concrete

2.2 *ACI Standard:*

ACI 548.3R-95 State-of-the-Art Report on Polymer-Modified Concrete[3]

3. Terminology

3.1 *Definitions of Terms Specific to This Standard*—Terms used in this specification are defined in Terminology C 125 or in this section.

3.1.1 *latex*, *n*—a dispersion of organic polymer particles in water.

3.1.2 *polymer-modified concrete or mortar*, *n*—a hydraulic cement concrete or mortar containing a polymer modifier.

3.1.3 *polymer modifier*, *n*—latex or redispersible powder formulated for use with hydraulic cements.

3.1.4 *redispersible powder*, *n*—powder that redisperses in water to form a latex.

3.1.5 *reference concrete or mortar*, *n*—concrete or mortar having the amounts of cement and aggregates given in Test Methods C 1439 and having an amount of water to achieve the specified slump or flow.

3.1.6 *test concrete or mortar*, *n*—concrete or mortar containing a polymer modifier and having the same composition (except for water content) and slump or flow as the reference concrete or mortar.

4. Classification

4.1 Polymer modifiers are classified into two product types:

4.1.1 *Type I*—For use in areas not exposed to moisture.

4.1.2 *Type II*—For general use.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.44 on Polymer-Modified Concrete.

Current edition approved Nov. 1, 2005. Published January 2006. Originally approved in 1999. Last previous edition approved in 1999 as C 1438 – 99ε1.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

5. Ordering Information

5.1 The purchaser shall specify the type of polymer modifier desired and the size and type of containers in which the material is to be supplied.

6. Physical and Mechanical Properties

6.1 The polymer modifier shall produce test mortar or test concrete which conforms to the requirements listed in Table 1 for the type specified.

7. Lot Uniformity and Equivalence

7.1 When specified by the purchaser, the uniformity of a lot, or the equivalence of different lots from the same source shall be established by evaluation following Specification C 494, with the following exception:

7.1.1 *Residue by Oven Drying*—Within a range not greater than 2 percentage points of the initial sample.

TABLE 1 Requirements for Test Mortar and Concrete Made With Polymer Modifier

	MORTAR		CONCRETE
	Type I	Type II	Type II
Air Content, % maximum	12.0	12.0	7.0
Time of Setting, allowable deviation from reference mixture, h:min:			
Initial:			
not more than, earlier	1:00	1:00	1:00
nor, later	3:30	3:30	3:30
Final:			
not more than, earlier	1:00	1:00	1:00
nor, later	3:30	3:30	3:30
Compressive Strength, minimum % of reference mixture			
at each age	70	70	80
Bond Strength, minimum % of reference mixture			
at each age	140	140	140
Indication of Chloride Ion penetration, maximum % of reference mixture			
at each age	na[A]	25	25

[A] na = not applicable.

8. Storage

8.1 The supplier shall store the polymer modifier in such a manner as to permit easy access for proper inspection and identification of each shipment, in a suitable building that will protect the polymer modifier from dampness and freezing, and in accordance with manufacturer's recommendations.

9. Sampling and Inspection

9.1 The supplier shall provide facilities for proper sampling of the product as specified by the purchaser.

9.2 Sampling shall conform to the requirements of Specification C 494.

10. Test Methods

10.1 Test the polymer modifier in accordance with the requirements of Test Methods C 1439.

11. Rejection

11.1 The purchaser has the right to reject the polymer modifier if it fails to meet any of the applicable requirements of this specification.

11.2 It is permitted to reject packages that are more than 2 % below the mass or volume marked on them, and it is permitted to reject the entire shipment if the average mass of packages in any shipment, as shown by weighing 50 packages taken at random, is less than that marked on the packages.

12. Packaging and Package Marking

12.1 When the polymer modifier is delivered in packages and containers, the proprietary name of the polymer modifier, the type under this specification, and the net mass or volume shall be plainly marked thereon. Similar information shall be provided in the shipping papers accompanying bulk shipments of the polymer modifier.

13. Keywords

13.1 latex; polymer modifier; polymer-modified concrete or mortar

Designation: C 1439 – 08a

Standard Test Methods for Evaluating Polymer Modifiers in Mortar and Concrete[1]

This standard is issued under the fixed designation C 1439; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 These test methods provide a means of determining the effect of adding polymer modifiers to reference concrete or mortar.

1.2 Most sections of ASTM test methods and practices for hydraulic cement mortar and concrete apply to the preparation and testing of specimens made with polymer-modifiers. However, there are some exceptions, most notably curing, that need special procedures in order to develop the properties inherent with polymer-modification. These test methods cover these exceptions.

1.3 For testing polymer-modified mortar and concrete specimens, the procedures in this standard supersede those in the referenced ASTM test methods and practices. These test methods are not applicable to dry, packaged mortar and concrete.

1.4 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

specimens made from test mixtures of polymer-modified concrete or mortar with the properties of specimens made from reference mixtures. These test methods are not intended to simulate job conditions.

4. Materials

4.1 *polymer modifier*—the polymer modifier of the required type as furnished by the supplier.

4.2 *antifoam agent*—antifoam agent of the type recommended by the manufacturer, if one is not incorporated in the polymer modifier.

4.3 *cement*—portland cement conforming to Specification C 150; if necessary, blend into a single lot prior to test. Use same lot for both test and reference mixtures.

4.4 *aggregates*—fine and coarse aggregates for concrete conforming to Specification C 33; if necessary, blend each into a single lot prior to test. Use same lot for both test and reference mixtures.

4.5 *graded sand*—sand for mortar mixtures conforming to Specification C 778; if necessary, blend into a single lot prior to test. Use same lot for both test and reference mixtures.

5. Proportioning of Concrete and Mortar Mixtures

5.1 *Concrete Mixture Proportioning*—Make the test and reference concrete with proportions similar to those shown for a nominal cubic-meter batch.

5.1.1 *Test Concrete*—Make the test concrete conforming to the following requirements:

	Parts by Mass, kg
Portland cement	390 ± 3
Fine aggregate[A]	975 ± 6
Coarse aggregate #8[A]	780 ± 6
Polymer Modifier	[B]
Antifoam agent	[C]
Potable water	[D]

[A] Saturated-surface-dry basis as described in Test Methods C 127 and C 128.

[B] The level recommended by the manufacturer.

[C] If the polymer modifier does not contain an antifoam agent, add the type and dosage recommended by the manufacturer, to the polymer modifier prior to mixing the concrete.

[D] The amount of water to give a slump of 90 ± 15 mm.

5.1.2 *Reference Concrete*—Make the reference concrete conforming to the following requirements:

	Parts by Mass, kg
Portland cement	390 ± 3
Fine aggregate[A]	975 ± 6
Coarse aggregate #8[A]	780 ± 6
Air-entraining admixture	[B]
Potable water	[C]

[A] Saturated-surface-dry basis as described in Test Methods C 127 and C 128.

[B] The amount of air-entraining admixture, meeting Specification C 260, to give an air content within 2 % of the test concrete and not exceeding 7.0 %.

[C] The amount of water to give a slump of 90 ± 15 mm.

5.2 *Mortar Mixture Proportioning*:

5.2.1 *Test Mortar*—Make the test mortar conforming to the following proportions:

	Parts by Mass, kg
Portland cement	100 ± 2
Graded sand[A]	275 ± 10
Polymer modifier	[B]
Antifoam agent	[C]
Potable water	[D]

[A] Saturated-surface-dry basis as described in Test Methods C 128.

[B] The level recommended by the manufacturer.

[C] If the polymer modifier does not contain an antifoam agent, add the type and dosage recommended by the manufacturer, to the polymer modifier prior to mixing the mortar.

[D] The amount of water that produces a flow of 105 to 115 % when tested according to Test Method C 1437.

5.2.2 *Reference Mortar*—Make the reference mortar conforming to the following proportions:

	Parts by Mass, kg
Portland cement	100 ± 2
Graded sand[A]	275 ± 10
Air-entraining admixture	[B]
Potable water	[C]

[A] Saturated-surface-dry basis as described in Test Methods C 128.

[B] The amount of air-entraining admixture, meeting Specification C 260, to give an air content that is within 2 % of the test mortar and not exceeding 12.0 %.

[C] Amount of water that produces a flow of 105 to 115 % when tested according to Test Method C 1437.

6. Procedure

6.1 *General*—Mix concretes and mortars in mechanical mixers in batches of such size as to leave about 10 % excess after molding test specimens and testing the unhardened mixtures.

6.2 *Temperature*—Before mixing the concrete or mortar, bring the materials to a uniform temperature, as described in Practice C 192/C 192M for concrete and Test Method C 109/C 109M for mortar.

6.3 *Polymer Modifier*—Store the polymer modifier in a dry place, in moisture-proof containers. Mix the polymer modifier thoroughly before use to ensure uniformity.

6.4 *Reference Concrete and Mortar*—Prepare reference concrete or mortar in compliance with Practice C 192/C 192M or Test Method C 109/C 109M, respectively.

NOTE 1—For trial batches to establish the amounts of water and air-entraining admixture to achieve the specified fresh properties, it is permissible to add these ingredients in increments and remix the batches. With the first increment of water and air-entraining admixture, if applicable, follow the mixing procedures specified in the previous section. If the slump, or flow, or air content is less than required, add additional water or air-entraining admixture and remix the batch. For mortar mixtures, remix at slow speed for 30 s. For concrete, remix the batch for 1 min. Remixing is permitted as often as necessary, provided the elapsed time from the start of initial mixing to the completion of mixing does not exceed 30 min. Cover the mixer to minimize evaporation when tests of fresh properties are being performed. These are trial batches only and are not to be used for testing.

6.5 *Test Mortar*—For mixing test mortar, follow Practice C 305, with the following changes:

6.5.1 *For Latex Polymer Modifiers*:

6.5.1.1 Place all the polymer modifier (with antifoam agent, as required) and mixing water in the bowl.

6.5.1.2 Add the cement to the bowl; start the mixer and mix at the slow speed (140 ± 5 r/min) for 30 s.

6.5.2 *For Powder Polymer Modifiers*:

6.5.2.1 Blend all the polymer modifier (with antifoam agent, as required) and cement, within 1 h of mixing the mortar.

6.5.2.2 Place the water in the bowl.

6.5.2.3 Add the cement/polymer modifier blend to the water; start the mixer and mix at the slow speed (140 ± 5 r/min) for 30 s

6.6 *Test Concrete*—For mixing test concrete, follow Practice C 192/C 192M, with the following changes:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:06 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.6.1 *For Latex Polymer Modifiers*—Prior to starting rotation of the mixer, add the coarse aggregate, polymer modifier, and approximately half of the water. Rotate the mixer a few revolutions, then add the fine aggregate, cement and remaining water. Mix the concrete for 3 min, followed by a 1 minute rest, followed by 1 min final mixing. Cover the open end of the mixer during the rest period to prevent evaporation. Take precautions to compensate for mortar retained by the mixer so that the discharged batch, as used, will be correctly proportioned (see Note 2).

6.6.2 *For Powder Polymer Modifiers*—Blend all the polymer modifier (with antifoam agent, as required) and cement, within 1 h of mixing the concrete. Prior to starting rotation of the mixer, add the coarse aggregate and approximately half of the water. Rotate the mixer a few revolutions, then add the fine aggregate, cement/polymer modifier blend, and remaining water. Mix the concrete for 3 min, followed by a 1 min rest, followed by 1 min final mixing. Cover the open end of the mixer during the rest period to prevent evaporation. Take precautions to compensate for mortar retained by the mixer so that the discharged batch, as used, will be correctly proportioned (see Note 2).

NOTE 2—It is difficult to recover all of the mortar from mixers. To compensate for this difficulty one of the following procedures may be used to ensure the correct final proportions in the batch:

(1) "Buttering the Mixer"—Just prior to mixing the test batch, the mixer is "buttered" by mixing a batch proportioned to simulate closely the test batch. The mortar adhering to the mixer after discharging is intended to compensate for loss of mortar from the test batch.

(2) "Over-Mortaring" the Mixture—The test mixture is proportioned by the use of an excess mortar, the amount established in advance, to compensate for that which, on the average, adheres to the mixer. In this case the mixer is cleaned before mixing the test batch.

7. Tests of Freshly Mixed Concrete and Mortar

7.1 *Concretes*—Test samples of the freshly mixed concrete in accordance with the following methods:

7.1.1 *Slump*—Test Method C 143/C 143M.

7.1.2 *Air Content*—Test Method C 173/C 173M or C 231.

7.1.3 *Unit Weight*—Test Method C 138/C 138M.

7.1.4 *Time of Setting*—Test Method C 403/C 403M.

7.2 *Mortars*—Test samples of the freshly mixed mortar in accordance with the following methods:

7.2.1 *Flow*—Test Method C 1437.

7.2.2 *Unit Weight*—Test Method C 185.

7.2.3 *Time of Setting*—Test Method C 403/C 403M.

7.2.4 *Air Content*.

7.2.5 *Test Mortar*:

7.2.5.1 *Mass per 400 mL of Test Mortar*—When the quantity of mixing water has been found that produces a flow of 105 to 115 %, immediately determine the mass per 400 mL of mortar, following the procedures in Test Method C 185.

7.2.5.2 *Air Content Calculation*—Calculate the air content of the test mortar using the following formulas, which are based on the assumption that the specific gravities of the portland cement and sand are 3.15 and 2.65, respectively:

$$\text{air content, volume \%} = 100\,(1 - W_a / W_c) \quad (1)$$

where

W_a = measured density of test mortar, g/mL,
= W_t/400, where W_t is the mass in grams of 400 mL of the test mortar,

W_c = theoretical mass per unit volume, calculated on an air-free basis as follows:

$$= \frac{100 + 275 + L + A + D}{\frac{100}{3.15} + \frac{275}{2.65} + \frac{L}{S_L} + \frac{A}{S_A} + \frac{D}{1.0}} \quad (2)$$

where:

L = mass of polymer modifier (includes water), g/100 g cement,
S_L = specific gravity of polymer modifier,
A = mass of antifoam agent, g/100 g cement,
S_A = specific gravity of antifoam agent, and
D = mass of water added, g/100 g cement.

7.2.6 *Reference Mortar*:

7.2.6.1 *Mass per 400 mL of Reference Mortar*—When the quantity of mixing water has been found that produces a flow of 105 to 115 %, immediately determine the mass per 400 mL of mortar, following the procedures in Test Method C 185.

7.2.6.2 *Air Content Calculation*—Calculate the air content of the reference mortar using the following formulas, which are based on the assumption that the specific gravities of the portland cement and sand are 3.15 and 2.65, respectively:

$$\text{Air content, volume \%} = 100\,(1 - W_a / W_c) \quad (3)$$

where:

W_a = measured density of reference mortar, g/mL,
= W_r/400, where W_r is the mass in grams of 400 mL of the reference mortar,

W_c = theoretical mass per unit volume, calculated on an air-free basis as follows:

$$\frac{100 + 275 + AE + D}{\frac{100}{3.15} + \frac{275}{2.65} + \frac{AE}{S_{AE}} + \frac{D}{1.0}} \quad (4)$$

where:

AE = mass of air-entraining admixture, g/100 g cement,
S_{AE} = specific gravity of air-entraining admixture, and
D = mass of water added, g/100 g cement.

8. Preparation of Test Specimens

8.1 Prepare test specimens, from at least three separate batches of the mixtures being tested, according to the procedures in the test methods prescribed in Section 9. Three replicates shall be required for each test, except for Test Method C 1202, for which two replicates are acceptable. Complete the preparation of all specimens within three days.

8.2 *Manifestly Faulty Specimens*—Visually examine each specimen before testing. Do not test any specimen found to be manifestly faulty by such examination. Visually examine all specimens after testing, and discard the test result of any specimen found to be manifestly faulty. Should more than one specimen for a given test at a given age be found manifestly faulty either before or after testing, disregard the entire test and repeat. The test results reported shall be the average of the individual test results of the three specimens tested or, in the event that one specimen or one result has been disregarded, the average of the test results of the two remaining specimens.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.3 *Curing*:

8.3.1 *Reference Concrete and Mortar*—Cure reference concrete and mortar specimens in conformance with Practice C 192/C 192M and Test Method C 109/C 109M, respectively.

8.3.2 *Test Concrete and Mortar*—Unless otherwise specified, immediately cover the polymer-modified concrete and mortar specimens with polyethylene film (0.1 mm minimum thickness) and store at 23 ± 2°C for 24 ± 1 h. Remove the polyethylene cover and store the specimens at 23 ± 2°C and 50 ± 10 % R. H. until time of test.

9. Tests on Hardened Concretes and Mortars

9.1 *Concretes*—Test specimens of hardened concrete in accordance with the following methods:

9.1.1 *Compressive Strength*—Test Method C 39/C 39M.

9.1.2 *Bond Strength*—Use the procedure in Test Method C 1404/C 1404M to prepare the base assembly. After the top nipple has been taped to the bottom nipple, use the following procedure to complete the composite specimen.

9.1.2.1 Dampen the cut surface with water. A properly prepared surface will be damp but have no water sheen.

NOTE 3—Paper and cloth towels have been used to remove standing water.

9.1.2.2 Place approximately 50 mL of the test mixture onto the damp, cut surface and, using the brush, apply a uniform coating of paste to the concrete surface and the inside surface of the nipple.

9.1.2.3 Fill the top nipple in two equal layers, and rod each layer using 25 strokes. Strike off the surface with a trowel and cover with polyethylene film.

9.1.2.4 At the specified age, test the composite specimen, calculate the tensile strength at failure, and estimate the percentage of each mode of failure (base, bond line, or overlay), in accordance with Test Method C 1404/C 1404M.

9.1.3 *Indication of Chloride Ion Penetration*—Test Method C 1202. Use cylinders.

9.2 *Mortars*—test specimens of hardened mortar in accordance with the following methods:

9.2.1 *Compressive Strength*—Test Method C 109/C 109M.

9.2.2 *Bond Strength*—Test Method C 1404/C 1404M. Use the same procedure as described above for concrete.

9.2.3 *Indication of Chloride Ion Penetration*—Test Method C 1202.

10. Calculation

10.1 Calculate the water content, exclusive of water absorbed by the aggregates, of the test mixtures and the reference mixtures. Include the water in the polymer modifier, if applicable.

10.2 Calculate the water content of test concrete as a percentage of the reference concrete, and the test mortar as a percentage of the reference mortar, as follows:

$$WC_P = WC_t / WC_r \times 100 \quad (5)$$

where:

WC_P = water content of test concrete or mortar as a percentage of the reference concrete or mortar,

WC_t = water content of test concrete or mortar corrected to saturated-surface-dry condition of the aggregates, kg, and

WC_r = water content of reference concrete or mortar corrected to saturated-surface-dry condition of the aggregates, kg.

WC_t is calculated as follows:

$$WC_t = (WL + AW) \quad (6)$$

where:

WL = mass of water contributed by latex, and

AW = mass of water added to the mixer corrected to saturated-surface-dry condition of the aggregates.

WL is calculated as follows:

$$WL = [(100-P)/100]\,(ML) \quad (7)$$

where:

P = polymer content of latex (percent), measured by oven drying in accordance with Specification C 494/C 494M, and

ML = mass of latex added to batch.

11. Report

11.1 Report the following information:

11.1.1 Brand name, manufacturer's name, lot number, chemical composition, polymer content, type and dosage of polymer-modifier; brand name and dosage of any post-added antifoam agent.

11.1.2 Type of portland cement used.

11.1.3 Water content of the test mixture as a percent of the reference mixture.

11.1.4 Curing conditions and age of each specimen tested.

11.1.5 *For the Test Concretes*—Slump, air content, unit weight, time of setting, compressive strength, size of compressive strength cylinders, bond strength, indication of chloride penetration; as actual values, and percent of reference concrete.

11.1.6 *For the Test Mortars*—Flow, air content, unit weight, time of setting, compressive strength, bond strength, indication of chloride penetration; as actual values, and percent of reference mortar.

12. Precision and Bias

12.1 *Precision*—The precision of each of the procedures in this test method is being determined.

12.2 *Bias*—The procedures in this test method have no bias because the values are defined only in terms of this test method.

13. Keywords

13.1 latex; latex polymer; polymer-modified concrete; polymer-modified mortar; powder polymer

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to these test methods since the last issue, C 1439 – 08, that may impact the use of these test methods. (Approved September 1, 2008)

(*1*) Added a warning statement about fresh hydraulic cementitious mixtures in 1.5.

Committee C09 has identified the location of selected changes to these test methods since the last issue, C 1439 – 99(2008), that may impact the use of these test methods. (Approved August 1, 2008)

(*1*) Revised the title.
(*2*) Added new 1.1 and renumbered subsequent sections.
(*3*) Replaced references to Test Method C 109/C 109M with Test Method C 1437 in 5.2.1, 5.2.2, and 7.2.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1451 – 05

Standard Practice for Determining Uniformity of Ingredients of Concrete From a Single Source[1]

This standard is issued under the fixed designation C 1451; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers a procedure for determining the uniformity of properties of concrete materials from a single source. It includes recommendations on sampling, testing, analysis of data, and reporting.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 75 Practice for Sampling Aggregates

D 3665 Practice for Random Sampling of Construction Materials

2.2 *Other Document*

MNL 7 (STP 150) Manual on Presentation of Data and Control Chart Analysis, 6th edition

3. Terminology

3.1 *Definitions*—For definitions of terms relating to this practice refer to Terminology C 125, Terminology C 219, Descriptive Nomenclature C 294, and Descriptive Nomenclature C 638.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *lot*, *n*—a user-defined quantity, typically representing any amount of material for which uniformity information is to be calculated.

3.2.1.1 *Discussion*—The minimum lot size is generally the amount of material in a single conveyance, such as a truck load, a rail-car load, or a barge load. At the other extreme, a lot might be defined by a user as the total amount of material used in a single construction or by a supplier as the amount of material produced over a given interval of time.

3.2.2 *sampling unit*, *n*—amount of material from which a grab sample is taken.

3.2.2.1 *Discussion*—Generally a lot is subdivided into sampling units, and then sampling units are chosen at random for taking of grab samples. The size of the sampling unit is user-defined, depending on the purposes of the evaluation. The term *sub lot* is sometimes used to define this concept.

4. Significance and Use

4.1 This practice provides a systematic procedure for sampling and determining the uniformity of user-selected properties of ingredients of concrete. Results derived from application of the practice are generally intended for information only and are not requirements of any existing ASTM specification on concrete or concrete materials. A concrete materials specification may make reference to this practice as a means of obtaining uniformity information, but needs to define the properties to be measured and the lot size and sample unit to be used. The practice is applicable to both producers of concrete materials and to consumers of concrete materials, although details of application of the practice may vary, depending on the intended purpose of the user of the practice.

4.2 The procedure is applicable to any property of any concrete ingredient that can be described quantitatively, and for which conventional parametric statistics are applicable. The

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.94 on Evaluation of Data.

Current edition approved Nov. 1, 2005. Published November 2005. Originally approved in 1999. Last previous edition approved in 1999 as C 1451 – 99.

www.technobetar.ir

procedure is based on grab samples, which will tend to show the maximum amount of variation in the selected material property. The procedure was developed for application to materials from a single source, but it can be applied to a materials delivery stream from more than one source, depending on the purposes of the user of the practice. Calculations are corrected for testing error, therefore giving an estimate of the uniformity of the selected material property. The uniformity of the selected material property provides the user with one indicator of the source variation of the concrete ingredient.

4.3 Although variability in properties of concrete materials can be a significant cause of variability in concrete properties, this practice does not purport to give information on this relationship. This practice does give information on uniformity of ingredients from which the user can, along with supplementary information or correlative testing of concrete properties, develop quantitative estimates of the effects.

5. Sampling

5.1 The sampling plan underlying the analysis of uniformity is critical to the interpretation of results. The sampling plan will vary, depending on the details of concrete materials supply and user-defined purpose of the evaluation. The sampling plan should, at a minimum, address the lot size and sampling frequency, location and procedure of sampling from sampling unit, and handling of samples. All sampling is to be performed by personnel specifically trained for this purpose.

5.2 The first step in determining the sampling plan is to define the objective and scope of the evaluation. This requires considerable experience and knowledge of details involved with the particular production under evaluation. The objective and scope of the evaluation may vary between users and producers of materials. It may also range from determining the uniformity of materials during a relatively small production period to covering a very long production period. If there is no prior knowledge of the uniformity of a material property, or if it is suspected that the material might show considerable variation, a relatively intense sampling plan might be designed initially. If the prior knowledge indicates that the material property is relatively stable, then a less intense sampling plan might be designed.

5.3 The second step is to define the size of the *lot* and the size of the *sampling unit* (see 3.2). Typically a lot is divided into a number of sampling units; then sampling units are selected at random for the taking of grab samples. Typically, the number of sampling units is larger than the number actually sampled, although for small lot sizes, the number of sampling units may equal the number of samples being taken.

5.4 Take random grab samples from a point in the storage and handling process of the material that will accurately reflect the uniformity of the material as it will be used in concrete. Practice D 3665 provides general guidance. Additional guidance for specific materials is listed in 5.4.1-5.4.4. Identify samples by the date on which the material was shipped or received, its source, and designated type and applicable specifications.

5.4.1 Sample cement in accordance with Test Method C 917.

5.4.2 Sample fine and coarse aggregates in accordance with Practice D 75.

5.4.3 Sample chemical admixtures in accordance with Specification C 494/C 494M.

5.4.4 Sample pozzolan or ground granulated blast-furnace slag in accordance with Test Method C 917.

5.5 The required sampling frequency depends on how the data are being used and the nature of the material being evaluated. The sampling plan used should be described in the report (Section 8).

6. Procedure

6.1 *General*—Test all samples in accordance with the appropriate ASTM Test Method for the particular property being measured. Choose a property and method that has good precision so that the material uniformity is not masked by the testing error. It is also advisable to select a method that does not incur significant cost and is conducted frequently so the operators are proficient with the procedure. Variation within a single source is estimated by first calculating total variation from test data on grab samples, and then correcting this by subtracting variation inherent in the test method (testing error). Best results are obtained if all tests are conducted in the same laboratory, but guidance is provided if it is necessary to use data from more than one laboratory.

6.2 *Total Variation*—Test all samples in accordance with the appropriate ASTM Standard Test Method for the particular test property being measured. Choose a property and method that has good precision so that the material uniformity is not masked by the testing error. It is also advisable to select a method that does not incur significant cost and is conducted frequently so the operators are proficient with the procedure. Calculate the total variation among the samples, as directed in 7.1.2.

6.3 *Testing Error*—Testing error is composed of components due to within-laboratory variation and between-laboratory variation. If results are obtained from only one laboratory, then between-laboratory variation makes no contribution. If data are obtained from more than one laboratory, it is preferable to keep data from each one separate during data analysis, pooling estimates of variation at the end of the analysis.

6.3.1 To estimate within-laboratory testing error, duplicate tests made from a single sample are required. Samples must be tested in duplicate on different days until at least ten samples have been tested in duplicate. The rate of duplicate tests initially should be at least once in five samples and not less frequently than once per month. Calculate the testing error standard deviation and the coefficient of variation, as outlined in 7.1.3. If the testing error exceeds the single laboratory precision (1s or 1s%) reported in the precision statement for the applicable test method, but is less than 1.5 times this value, continue duplicate tests at this same rate. When the testing error is equal to or less than the testing error reported in the precision statement, reduce the frequency of duplicate testing. If the testing error exceeds 1.5 times the testing error reported in the precision statement, the data are of unacceptable precision, and the laboratory procedure and equipment should be thoroughly examined. Use the results of duplicate tests,

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

indicating acceptable precision to estimate the within-laboratory testing error for all other types of similar materials tested in that laboratory during the same period of time.

6.3.2 When two or more laboratories are used to evaluate the uniformity of a source, then additional tests of a standard sample or exchanged portions of the same sample may be necessary to determine differences in testing that are likely to be obtained in the different laboratories. When two laboratories exchange portions of the sample and run single tests, results from the laboratories shall not differ by more than the multi-laboratory precision (D2S value) of the average of the two laboratories. If a larger number of samples are exchanged, then the difference between laboratories exceed the D2S no more than 5 % of the time.

6.3.3 Calculate the testing error from duplicate tests conducted in each laboratory as outlined in 7.1.3.

6.4 *Single-Source Variation*—Calculate single-source variation according to 7.1.4.

7. Calculation

7.1 The calculations shall include the following (Note 1):

NOTE 1—Values for averages and standard deviations can be calculated by other methods that are available in MNL 7 (STP 150). Electronic calculators and spreadsheets are available for obtaining these statistics directly.

7.1.1 *Average Measurement*:

$$\bar{x} = \frac{x_1 + x_2 + \ldots + x_n}{n} \quad (1)$$

where:

$\bar{x}$ = average measurement,
$x_1, x_2, \ldots x_n$ = individual measurements, and
n = number of individual tests.

7.1.2 *Standard Deviation*:

$$s_t = \sqrt{\frac{(x_1 - \bar{x})^2 + (x_2 - \bar{x})^2 + \ldots + (x_n - \bar{x})^2}{(n-1)}} \quad (2)$$

where:

s_t = standard deviation in units of measurement.

7.1.3 *Testing Error:*

7.1.3.1 The standard deviation for testing error is calculated as follows (See Table 1):

$$s_e = \sqrt{\frac{\sum d^2}{2k}} \quad (3)$$

where:

s_e = standard deviation for testing error estimated from tests of duplicate measurements made in a single laboratory from the sample,
d = difference between duplicate determinations, and
k = number of sets of duplicate determinations.

7.1.3.2 The coefficient of variation for testing error is calculated as follows,

$$v_e = \frac{s_e}{\bar{x}_d} \quad (4)$$

where:

v_e = coefficient of variation for testing error estimated from tests of duplicate measurements made in a single laboratory from the sample, and
$\bar{x}_d$ = average measurement from duplicate tests.

7.1.4 *Single-Source Variation*:

7.1.4.1 Variation of material from a single source expressed in terms of standard deviation, corrected for testing error, is calculated as follows:

$$s_c = \sqrt{s_t^2 - s_e^2} \quad (5)$$

where:

s_c = standard deviation corrected for testing error,
s_t = standard deviation for all tests included in the calculation, and
s_e = standard deviation for testing error estimated from tests of duplicate measurements made in a single laboratory from the sample.

7.1.4.2 When data are collected from two laboratories, calculate the pooled single-source standard deviation as follows:

$$\bar{s}_c = \sqrt{\frac{(n_1 - 1){s_{c1}}^2 + (n_2 - 1){s_{c2}}^2}{n_1 + n_2 - 2}} \quad (6)$$

where:

$\bar{s}_c$ = pooled estimate of single-source standard deviation
s_{c1} *and* s_{c2} = standard deviation corrected for testing error from lab 1 and lab 2, respectively, and
n_1 *and* n_2 = number of tests in lab 1 and lab 2, respectively.

7.1.4.3 Single-source variation expressed as coefficient of variation, corrected for testing error, is calculated as follows:

$$v_c = \frac{s_c}{\bar{x}} \quad (7)$$

TABLE 1 Example Illustrating Calculation of Testing Error

Date	Samp. No.	Test "a," MPa	Test "b," MPa	Average, MPa	d^2
01/06	3	43.9	45.7	44.8	2.97
01/16	6	43.1	41.5	42.3	2.52
01/30	9	41.7	42.2	42.0	0.23
02/05	12	41.5	43.0	42.2	2.10
02/13	15	38.6	37.4	38.0	1.54
02/21	18	37.9	38.1	38.0	0.04
03/04	21	43.6	43.3	43.4	0.08
03/14	24	40.8	41.4	41.1	0.39
03/19	27	43.4	41.7	42.6	2.97
03/27	30	43.8	44.2	44.0	0.17
k = 10			Average, $\bar{x}_d$ = 41.9		
				Σd^2	13.0
			Testing Standard Deviation, s_e		0.81
			Testing Coefficient of Variation, v_e		1.9 %

8. Report

8.1 Sufficient information shall be provided to identify the material sampled including the following:

8.1.1 Name of manufacturer and location,

8.1.2 Classification or type of material,

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:09 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.1.3 Location of sampling,
8.1.4 Laboratory designation,
8.1.5 Period of time represented by the report, and
8.1.6 Description of sampling frequency.

8.2 For ongoing programs, the minimum period covered by the report shall include all tests made in the preceding three months, but in no instances less than that period of time necessary to include 20 consecutive samples.

8.2.1 The report shall not cover a period of time greater than one year or tests of more than 120 samples.

8.3 The report of results shall be either in tabular form as shown in Table 2, or in graphical form as shown in Fig. 1, at the option of the reporting organization (Note 2).

NOTE 2—For purposes of analyzing trends, the graphical presentation is to be preferred. The average and standard deviation, as calculated in Section 7, shall be shown.

8.4 Report the results of duplicate tests on the same sample within the period covered by the report. When duplicate tests are made from samples other than that being tested during the same period of time, by the same laboratory, these test results will not normally be reported on a regular basis, but results of such tests will be made available upon request. However, report the testing standard deviation.

8.5 The report shall include the following values calculated from the reported data. Each sample shall be represented only by a single result in these calculations. The second of a pair of duplicate test results shall not be included in the overall calculation, but shall be used only to establish testing error. (See Footnote A of Table 2.)

8.5.1 Calculate from the reported data:
8.5.1.1 $\bar{x}$ = the average,
8.5.1.2 s_t = the standard deviation,
8.5.1.3 s_e = testing standard deviation,
8.5.1.4 n = the number of samples tested,
8.5.1.5 s_c = the single source variation expressed in terms of standard deviation corrected for testing, and
8.5.1.6 x_5 = the moving averages of the five most recent results.

8.5.2 The calculations shall not be made and reported until five results are available. The moving average of the five most recent results should be updated with each successive result by adding the new value in the calculation and deleting the oldest previous value (see Table 2).

8.5.3 Whenever the reporting agency concludes that a consistent change in properties has occurred, at its option, it may discontinue calculation until results from five additional samples have been obtained. In this instance, the values calculated from samples prior to the change shall also be reported.

8.5.4 When there is a break in the calculation, the sampling dates included in each set of calculated values shall be clearly identified.

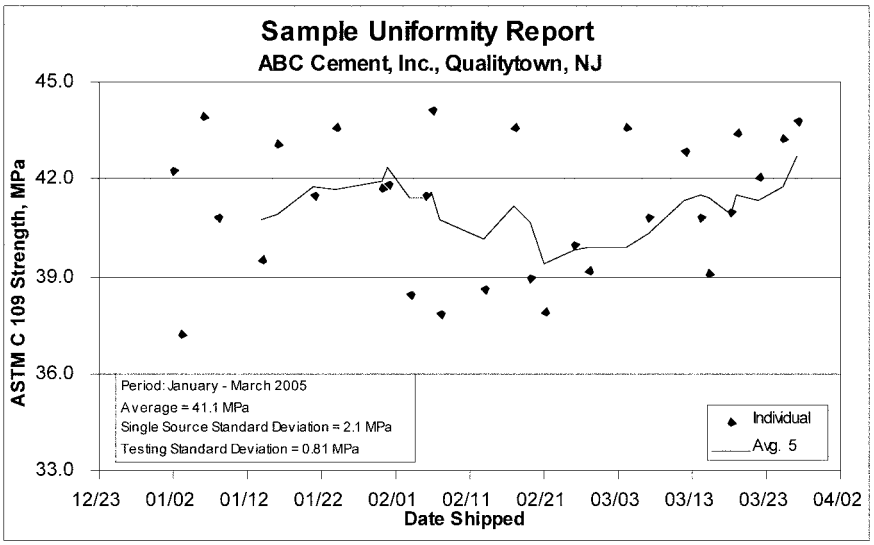

FIG. 1 Data Plots, Uniformity Test Report

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1467/C 1467M – 00 (Reapproved 2006)

Standard Specification for the Installation of Molded Glass Fiber Reinforced Gypsum Parts[1]

This standard is issued under the fixed designation C 1467/C 1467M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the installation of molded glass fiber reinforced gypsum (GRG) parts.

1.2 The values stated in either inch-pound units or SI (metric) are to be regarded separately as the standard. Within the text, SI units are shown in brackets. The values stated in each shall be used independent of the other. Values from the two systems shall not be combined.

1.3 All references to finishes, dimensions and tolerances shall refer to the finished surface of the part.

1.4 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 754 Specification for Installation of Steel Framing Members to Receive Screw-Attached Gypsum Panel Products

C 840 Specification for Application and Finishing of Gypsum Board

C 1007 Specification for Installation of Load Bearing (Transverse and Axial) Steel Studs and Related Accessories

C 1381 Specification for Molded Glass Fiber Reinforced Gypsum Parts

3. Terminology

3.1 *Definitions*— Definitions of terms shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *critical lighting*, *n*—strong side lighting from natural or artificial light sources.

3.2.2 *primer*, *n*—paint material formulated to fill the pores and equalize the suction difference between the GRG part and finishing compounds used.

4. Materials

4.1 Molded GRG parts shall meet the requirements of Specification C 1381.

5. Environmental Conditions

5.1 Room temperature shall be maintained at not less than 40 °F [4 °C] during the installation of GRG parts except when adhesive is used for the bonding or attachment of parts to each other or to a substrate. For the bonding of adhesive and joint treatment the room temperature shall be maintained at not less than 50 °F [10 °C] for 48 hours prior to application and continuously thereafter until completely dry.

5.2 When a temporary heat source is used, the temperature shall not exceed 95 °F [35 °C] in any given room or area.

5.3 Installed GRG shall be protected from direct exposure to rain, snow, sunlight and other excessive weather conditions.

NOTE 1—Installation in conditions of excessive humidity is not recommended. The ideal conditions to install molded GRG parts is 70 °F [21 °C] and 50 % RH.

6. Substrate Preparation

6.1 Substrates to accept GRG parts shall be installed straight and true within ⅛ in. in 8 ft [3 mm in 2500 mm] and shall be free of obstructions and interference that prohibits correct attachment of GRG parts.

6.2 Metal framing members shall be of the proper size and design for the intended use and shall be sufficient to properly support the installed GRG parts. Metal framing members shall be installed in accordance with Specification C 754 or C 1007 as required.

7. Tolerances of Installed GRG Parts

7.1 Parts shall be installed plumb and not be out of line more than ± ⅛ in. in 8 ft [3 mm in 2500 mm] in any direction.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for the Application of Gypsum and Other Products in Assemblies.

Current edition approved May 1, 2006. Published May 2006. Originally approved in 2000. Last previous edition approved in 2000 as C 1467/C 1467M – 00.

7.2 The planar surface of any part shall not vary by more than ⅛ in. [3 mm] from the planar surface of any adjacent part.

7.3 GRG parts shall be installed so that the joints between parts are not more than ¼ in. [6 mm] in width.

8. Installation of GRG Parts

8.1 GRG parts shall be installed to the tolerances stated in Section 7.

8.2 GRG parts shall be installed according to manufacturers' directions onto substrates and with fastening devices as specified by the GRG manufacturer.

9. Finishing of GRG Parts

9.1 GRG parts shall be finished in accordance with the manufacturers' directions.

9.2 GRG parts subject to critical lighting or scheduled to receive gloss or semi-gloss decoration shall be prepared as a Level 5 finish in accordance with Specification C 840.

NOTE 2—GRG parts are furnished with a primer-ready surface.

10. Handling and Storage

10.1 GRG parts shall be stored in accordance with the manufacturers' recommendations.

10.2 GRG parts shall be protected from rain, snow, sunlight, excessive weather conditions and jobsite damage during storage.

10.3 GRG parts shall be stored on a clean and dry surface.

10.4 GRG parts shall not be stacked or placed on other GRG parts unless approved by the manufacturer in writing.

NOTE 3—Parts improperly stored could be subject to warping, bowing and dimensional variations.

11. Keywords

11.1 GRG parts; installation

Designation: C 1480/C 1480M – 07

Standard Specification for Packaged, Pre-Blended, Dry, Combined Materials for Use in Wet or Dry Shotcrete Application[1]

This standard is issued under the fixed designation C 1480/C 1480M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers laboratory performance standards for pre-blended, dry, packaged, combined materials for use in wet or dry shotcrete applications that are delivered to a purchaser with the ingredients uniformly mixed. The use of supplemental materials, placement, curing, or protection of the shotcrete after delivery to the purchaser is not addressed by this specification.

1.2 The values stated in either SI units or inch-pound units shall be regarded separately as standard. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 The following safety hazards caveat pertains only to the test method portion of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 1012 Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution

C 1140 Practice for Preparing and Testing Specimens from Shotcrete Test Panels

C 1157 Performance Specification for Hydraulic Cement

C 1202 Test Method for Electrical Indication of Concrete's Ability to Resist Chloride Ion Penetration

C 1385/C 1385M Practice for Sampling Materials for Shotcrete

C 1399 Test Method for Obtaining Average Residual-Strength of Fiber-Reinforced Concrete

C 1436 Specification for Materials for Shotcrete

2.2 *National Institute of Standards and Technology:*

Handbook 44 Specifications, Tolerances, and Other Technical Requirements for Commercial Weighing Devices[3]

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *Packaged, pre-blended, dry, combined materials*—for use in wet or dry shotcrete applications consist primarily of hydraulic cement and concrete aggregates blended, in a dry state, with other ingredients to enhance one or more properties of the mixture.

4. Classification

4.1 Dry packaged shotcrete materials are categorized as to type and grade.

4.1.1 Shotcrete type is based on aggregate size.

4.1.2 Type FA shotcrete shall contain aggregate in accordance with the requirements of Specification C 1436 Grading #1. Aggregates failing to comply with Grading #1 can be used only if preconstruction testing proves that they give satisfactory results or if acceptable service records are available.

4.1.3 Type CA shotcrete shall contain coarse and fine aggregates in accordance with the requirements of Specification C 1436, Grading No. 2. Aggregates failing to comply with Grading #2 can be used only if preconstruction testing proves that they give satisfactory results or if acceptable service records are available.

[1] This specification is under the jurisdiction of ASTM committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.46 on Shotcrete.

Current edition approved Feb. 1, 2007. Published February 2007. Originally approved in 2000. Last previous edition approved in 2005 as C 1480 – 00(2005).

www.technobetar.ir

4.2 Shotcrete grade is based on the desired physical properties of the material.

4.2.1 Grade GU shotcrete is a general use product.

4.2.2 Grade SR shotcrete has sulfate resistance in accordance with the requirements of 7.4

4.2.3 Grade LP shotcrete has permeability values in accordance with the requirements of 7.5

4.2.4 Grade FR shotcrete has average residual strength values in accordance with the requirements of 7.6, Type I or II.

4.2.4.1 Class I shotcrete has average residual strength values in accordance with the requirements of 7.6.1.

4.2.4.2 Class II shotcrete has flexural strength and average residual strength values in accordance with the requirements of 7.6.2.

NOTE 1—Grade FR Class I shotcrete is intended to minimize plastic shrinkage cracking. Grade FR Class 2 shotcrete is intended to provide a minimum level of post-crack flexural load capacity for hardened shotcrete.

5. Ordering Information

5.1 The purchaser shall specify the type, grade, and class (if applicable) of shotcrete required.

NOTE 2—A single material may meet more than one grade. Other properties may be specified by the purchaser, but are beyond the scope of this specification.

5.2 At the request of the purchaser, the producer shall, prior to delivery, furnish laboratory performance data satisfactory to the purchaser that the product meets the specified type and grades.

6. Materials and Manufacture

6.1 Basic materials shall meet the requirements of Specification C 1436.

6.2 Additional materials shall be permitted only if adequate test data are available to insure that the ingredient has no deleterious effects on the specified properties.

6.3 Aggregates shall be dried, without disintegration, to a moisture content of less than 0.2 mass percent, computed on material dried substantially to constant mass at 105 to 110 °C [210 to 230 °F].

6.4 *Measurement of Materials*—Measure materials in accordance with 6.4.1-6.4.4.

6.4.1 Cementitious materials and aggregates shall be measured by mass (or by volume). Volumetric measurement shall be calibrated by mass.

6.4.2 Scales for batching ingredients shall conform to the applicable section of the current edition of the National Institute of Standards and Technology Handbook 44 Specifications, Tolerance, and Other Technical Requirements for Commercial Weighing Devices.

6.4.3 Measure fibers by mass.

6.4.4 Measure admixtures by mass or volume.

6.5 Shotcrete ingredients shall be thoroughly blended at a central location. Mixer performance tests shall be performed to establish the mixing time suitable for uniformity of mixing. Representative samples shall be obtained in accordance with Practice C 1385/C 1385M.

6.6 *Delivery*—Unless otherwise specified, delivery of the shotcrete materials shall conform to 6.6.1-6.6.3.

6.6.1 Thoroughly mix and deliver to the construction site materials without segregation or lumps of ingredients.

6.6.2 Temperature of pre-blended, dry, combined materials for shotcrete at time of delivery shall not exceed 65 °C [150 °F].

6.6.3 Delivery shall be in any size package as agreed between the purchaser and producer.

7. Physical Requirements

7.1 Type FA shotcrete shall meet the requirements of Table 1 when mixed and tested in accordance with the procedure for mixing and testing high strength mortar in accordance with Specification C 387/C 387M.

7.2 Type CA shotcrete shall meet the requirements of Table 1 when mixed and tested in accordance with the procedures for mixing and testing normal strength concrete in accordance with Specification C 387/C 387M.

7.3 Grade GU shotcrete shall meet the general requirements for type FA or type CA shotcrete.

7.4 Grade SR shotcrete shall have sulfate resistance as determined in one of the following ways:

7.4.1 Product shall be prepared with a cement meeting Specification C 150 types II or V, Specification C 595 cements with an MS designation or Performance Specification C 1157 types MS or HS

7.4.2 Product shall exhibit an expansion of less than 0.1 % at 180 days when tested in accordance with applicable portions of Test Method C 1012. Samples for testing shall be mixed and placed in accordance with this specification.

7.4.3 In Test Method C 1012 the samples are normally prepared at a fixed water content using standard sand. Those portions of the method will not apply in this case

7.5 Grade LP shotcrete shall have a chloride penetrability rating of "very low" (< 1000 coulombs) when tested at an age of 28 days in accordance with Test Method C 1202. Specimens for the test shall be either from laboratory prepared samples mixed and placed in accordance with this specification or from field samples obtained in accordance with Practice C 1140 and Test Method C 1202.

NOTE 3—Due to the potential differences between laboratory and field conditions it may be necessary to test field samples in order to verify performance with the applied material specifications. See appendix for a discussion of expected field performance vs. laboratory performance for wet mix vs. dry mix shotcrete.

7.6 Grade FR shotcrete shall have fiber reinforcement with the following minimum requirements:

7.6.1 Grade FR Class I shotcrete shall have a minimum 28-day average residual strength of 275 kPa [40 psi] when tested in accordance with Test Method C 1399.

TABLE 1 Physical Requirements

Property	Requirement for Type FA	Requirement for Type CA
Flow	105 to 115	- - -
Slump	- - -	50 to 75 mm [2 to 3 in.]
7 day Compressive strength (min)	21.0 MPa [3000 psi]	21.0 MPa [3000 psi]
28 day Compressive Strength (min)	35.0 MPa [5000 psi]	35.0 MPa [5000 psi]

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:13 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

7.6.2 Grade FR Class II shotcrete shall have a minimum 28-day flexural strength of 4MPa [600 psi] when 100 by 100 by 350 mm specimens are tested in accordance with Test Method C 78 and a minimum 28-day average residual strength of 2 MPa [300 psi] when tested in accordance with Test Method C 1399.

8. Sampling and Specimen Preparation

8.1 Samples of the finished product for testing shall be provided by the manufacturer or obtained in the field prior to the addition of water in accordance with Practice C 1385/C 1385M.

8.2 Specimens for testing for compliance with this specification shall be cast and tested in accordance with the applicable portions of Specification C 387/C 387M unless otherwise specified within this specification.

NOTE 4—Specimens for testing mixtures for compliance with this specification are laboratory mixtures cast in accordance to applicable portions of Specification C 387/C 387M, not mixtures that have been shotcreted. The values of test results may be higher or lower than the values of test results from nominally similar mixtures that have been shotcreted.

9. Rejection

9.1 The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer of supplier promptly and in writing.

9.2 The seller has no control over the application of the shotcrete material; therefore unsatisfactory field performance of the material shall not be used as a basis for rejection of the product.

NOTE 5—For instructions on the proper application of shotcrete refer to ACI 506.2[4].

10. Packaging and Package Marking

10.1 All packages shall be identified as conforming to Specification C 1480, and as to type, grade(s), and class (if applicable) of shotcrete material and the net mass in each package printed thereon.

10.2 The yield in cubic metres [cubic feet] and the approximate amount of water recommended for mixing shall be marked on the package.

NOTE 6—The amount of water recommended shall be the amount required to produce a 50 to 75-mm [2 to 3-in.] slump for Type CA or a flow of 105-115 for Type FA.

11. Keywords

11.1 average residual strength; compressive strength; dry mix shotcrete; flexural strength; packaged shotcrete materials; pre-blended shotcrete materials; shotcrete; wet mix shotcrete

[4] ACI 506.2, "Specification for Shotcrete," American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333.

APPENDIXES

(Nonmandatory Information)

X1. DIFFERENCE BETWEEN DRY-MIX AND WET-MIX SHOTCRETE

X1.1 Dry mix shotcrete (also known as gunite) is typically placed in the field at a water content that is 10 to 15 % lower than that required for laboratory testing. Therefore field performance of dry mix shotcrete under ideal conditions will provide substantially higher strengths than in the laboratory.

X1.2 Wet mix shotcrete will be more likely to be placed with a water content similar to that used in the laboratory. Wet mix shotcrete is sometimes modified at the nozzle by the addition of a shotcrete accelerator. This can affect the in-place results.

X2. FIELD TESTING

X2.1 It is recommended that job mock-ups be prepared by the contractor and tested prior to beginning a project to establish the expected in-place performance that will be achieved with the specified product. ACI Committee 506 provides extensive recommendations as to proper surface preparation and equipment as well as nozzlemen certification and proper shotcrete placement and curing procedures. See reference ACI 506R[5], 506.2[4], and CP-60[6], as well as Practice C 1140.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1480 – 00(2005), that may impact the use of this specification. (Approved February 1, 2007)

(*1*) Converted the standard into a combined units standard. (*2*) Deleted paragraph 10.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1489 – 01 (Reapproved 2008)$^{\varepsilon 1}$

Standard Specification for Lime Putty for Structural Purposes[1]

This standard is issued under the fixed designation C 1489; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε^1 NOTE—A units statement was added editorially as new subsection 1.2 in September 2008.

1. Scope

1.1 This specification covers lime putty products made from hydrated lime or quicklime products. Lime putty is suitable for use in masonry, plaster and stucco applications.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 5 Specification for Quicklime for Structural Purposes

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 51 Terminology Relating to Lime and Limestone (as used by the Industry)

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

C 185 Test Method for Air Content of Hydraulic Cement Mortar

C 206 Specification for Finishing Hydrated Lime

C 207 Specification for Hydrated Lime for Masonry Purposes

3. Terminology

3.1 *Definitions:*

3.1.1 *lime putty*—the product obtained by either slaking quicklime with water according to the direction of the manufacturer or by mixing hydrated lime and water to the desired consistency.

3.1.2 Unless otherwise specified, for definitions of terms used in this standard, refer to Terminology C 51.

4. Chemical Composition

4.1 The hydrated lime or quicklime products used to make lime putty shall conform to the following chemical composition requirements:

Calcium and magnesium oxides (non volatile basis)	92 % min.
Carbon dioxide (presoaked basis)	
If sample is taken at place of manufacture	5 % max.
If sample is taken at other place	7 % max.

4.2 Chemical composition of putty product of unknown composition must be determined by drying the sample in a CO_2 free atmosphere by a method such as Test Methods C 25, Section 21, (Free Moisture in Hydrated Lime).

5. Plasticity

5.1 Lime putty shall have a plasticity of not less than 200 Emley units when tested by the Emley method prescribed in Test Methods C 110. Vicat consistency of the putty should be adjusted to a penetration of 20 ± 5 mm prior to running the Emley test. If penetration results are above 25 mm, the consistency of the putty can be increased by allowing the putty to settle and decanting off the excess water or by the use of a suction pad such as the one used for the water retention test in Test Methods C 110. If the penetration is below 15 mm, water should be added to the lime putty to increase the penetration. When water is added to the putty, the putty should be mixed for a minimum of 15 s prior to testing the penetration.

6. Residue

6.1 Residue of lime putty shall not be more than 0.5 % on a 30 mesh sieve on a total putty weight basis. The residue of lime putty should be determined by the method in Test Methods C 110, Section 5, using an amount of lime putty equivalent to approximately 100 g of solids.

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved June 1, 2008. Published September 2008. Originally approved in 2001. Last previous edition approved in 2001 as C 1489 – 01.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

7. Soaking Period

7.1 Lime putty made from quicklime or hydrated lime must be soaked for a period of time prior to use of the product. The actual time required to ensure complete hydration of the lime putty is dependent on the reactivity of the unhydrated oxides used to make the putty.

7.1.1 Lime putty made from quicklime must be soaked for a minimum of two weeks prior to use in construction applications.

7.1.2 Lime putty made with Type N hydrated lime must be soaked for at least 16 h prior to use.

7.1.3 Lime putty made with Type S hydrated lime requires enough soaking to wet the lime particles (minimum of 20 min.).

8. Popping and Pitting

8.1 Lime putty shall show no pops or pits when tested in accordance with the method prescribed in Test Methods C 110. Vicat consistency of the lime putty should be adjusted to a penetration of 20 ± 5 mm prior to running the popping and pitting test. If penetration results are above 25 mm, the consistency of the putty can be increased by allowing the putty to settle and decanting off the excess water or by the use of a suction pad such as the one used for the water retention test in Test Methods C 110. If the penetration is below 15 mm, water should be added to the lime putty to increase the penetration. When water is added to the putty, the putty should be mixed for a minimum of 15 s prior to testing the penetration.

9. Density

9.1 The wet density of the lime putty shall be no less than 80 lbs/ft^3 and not more than 90 lbs/ft^3. The density of lime putty can be measured in the 400 ml cylindrical cup described in the Apparatus Section of Test Method C 185. Care should be taken when placing putty in the cup to minimize the entrapment of air. The cup should be filled in three lifts, tamping after each lift to remove entrapped air. The top surface of the putty should be struck and leveled with a metal spatula prior to weighing. The calculations used for the density determination can be found in Test Methods C 110, Section 16.

10. Sampling and Inspection

10.1 The sampling, inspection, rejection, retesting, packaging, and marking shall be conducted in accordance with Practice C 50.

11. Test Methods

11.1 Determine the properties enumerated in this specification in accordance with the following methods:

11.1.1 *Chemical Analysis*—Test Methods C 25.

11.1.2 *Physical Analysis*—Test Methods C 110.

12. Keywords

12.1 finish lime; lime putty; masonry; plaster; plasticity; popping and pitting; residue; stucco; unhydrated oxides

Designation: C1506 – 09

Standard Test Method for Water Retention of Hydraulic Cement-Based Mortars and Plasters[1]

This standard is issued under the fixed designation C1506; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method provides for the determination of water retention of hydraulic cement-based mortars and plasters.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C109/C109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C185 Test Method for Air Content of Hydraulic Cement Mortar

C230/C230M Specification for Flow Table for Use in Tests of Hydraulic Cement

C305 Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

C511 Specification for Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C1437 Test Method for Flow of Hydraulic Cement Mortar

3. Summary of Test Method

3.1 The flow of the mortar or plaster is determined. The mortar or plaster is then subjected to a controlled vacuum suction for 60 s, after which the flow is again determined. The water retention is the final flow divided by the initial flow expressed as a percentage.

4. Significance and Use

4.1 This test method provides a means for determining the ability of mortars and plasters to retain water under suction. Test results may be used to determine compliance with specifications.

4.2 The results obtained using this test method can be used to compare the relative ability of mortars and plasters to retain water under suction.

4.3 The results obtained using this test method for masonry mortars do not necessarily indicate the degree of water retention when used with masonry units, since the amount of water absorbed by the unit depends on the rate of absorption of the masonry unit.

4.4 The results obtained using this test method for plasters (stucco) do not necessarily indicate the degree of water retention when the plaster is applied as a second coat on the surface of a previously applied plaster base coat, since the amount of water absorbed from the second coat of plaster depends on the rate of absorption of the base coat. This is also true when a plaster is applied as a coating on masonry units.

5. Apparatus

5.1 *Tamper*, conforming to Test Method C109/C109M.

5.2 *Straightedge*, conforming to Test Method C185.

5.3 *Flow Table*, conforming to Specification C230/C230M.

5.4 *Mixing Apparatus*, conforming to the requirements prescribed in Practice C305.

5.5 *Filtration Assembly*, an apparatus essentially as shown in Fig. 1 shall be used. This apparatus consists of a perforated dish resting on a funnel, which is connected by a three-way stopcock to a vacuum flask, to which a controlled vacuum is applied. The perforated dish shall be made of metal not attacked by masonry mortar or plaster (Note 1). The metal base of the dish shall have a thickness of 2.0 ± 0.3 mm and shall conform to the requirements given in Fig. 1. The stopcock bore

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.22 on Workability.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 2001. Last previous edition approved in 2008 as C1506–08. DOI: 10.1520/C1506-09.

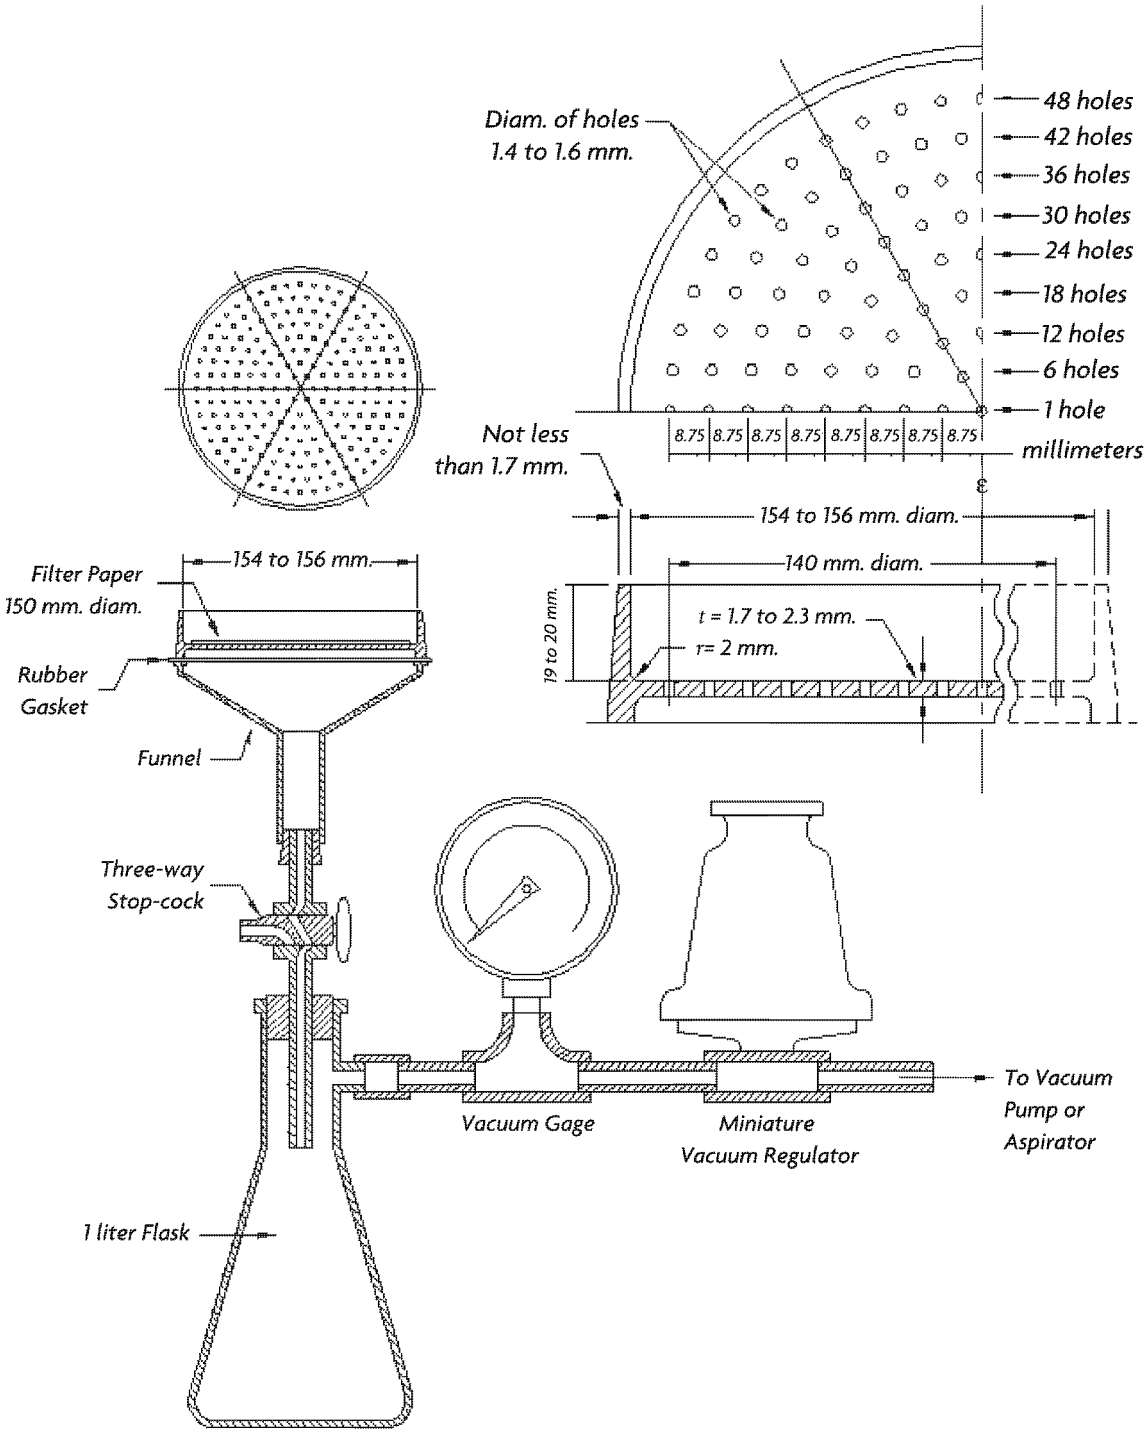
www.technobetar.ir



NOTE—The gasket is to be synthetic rubber. The stopcock and the bore of the tubing shall be at least 4-mm. A check valve or water trap, or both, is suggested for the connection to the vacuum source.

FIG. 1 Apparatus Assembly for the Water-Retention Test

shall have a 4.0 ± 0.5-mm diameter, and the connecting glass tubing shall have a minimum inside diameter of 4 mm. The length of the tubing projecting into the 1-L flask from the stopcock shall extend at least 25 mm below the center line of the vacuum connection. The contact surfaces of the funnel and perforated dish shall be plane and may need to be lapped to ensure intimate contact. An airtight seal shall be maintained between the funnel and the dish during the test. This shall be accomplished by either of the following procedures. (*1*) A synthetic (grease-resistant) rubber gasket may be permanently sealed to the top of the funnel using petrolatum or light grease to ensure a seal between the gasket and dish. (*2*) The top of the

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:17 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

funnel may be lightly coated with petroleum or light grease to ensure a seal between the funnel and dish. Care should be taken to ensure that none of the holes in the perforated dish become clogged. Hardened, smooth, not rapid filter paper shall be used. It shall be 150 mm in diameter and be placed so as to completely cover the perforations in the dish.

NOTE 1—Stainless steel, brass, and bronze are suitable metals for this purpose.

5.6 *Controlled Vacuum Source*:

5.6.1 A vacuum gage capable of reading at least 9-kPa pressure in 0.1-kPa increments (Note 2 and Note 3), connected to a miniature vacuum regulator having a maximum 55-kPa capacity, which is then connected to a vacuum pump or water aspirator as shown in Fig. 1. Connection is made between the vacuum flask and the vacuum gage.

NOTE 2—Vacuum values are all given as pressure relative to atmospheric pressure.

NOTE 3—Gages reading pressure in other units are acceptable as long as their capacity and scale increments comply with the levels specified here. (For example, a vacuum gage with a minimum capacity of 70 mm of Hg in 1-mm increments is acceptable. To convert mm of Hg to kPa, multiply by 0.1333. Thus the 7.0-kPa starting pressure is equivalent to 53-mm Hg.)

6. Temperature and Humidity

6.1 The temperature of the mixing room and the room containing the water retention apparatus shall conform to the requirements of Specification C511.

7. Materials

7.1 The composition of the mortar or plaster to be tested for water retention shall be that described in the specification of the material being considered, or that desired.

8. Mixing of Mortar and Plaster

8.1 The mortar or plaster to be tested for water retention shall be mixed as specified in the section on Procedure for Mixing Mortars of Practice C305, or as described in the specification for the material being considered.

9. Procedure

9.1 *Preparation of Apparatus*—Seat the perforated dish on the greased gasket or greased rim of the funnel. Place a wetted filter paper in the bottom of the dish. Turn the stopcock to apply the vacuum to the funnel and check the apparatus for leaks. Adjust the vacuum to 7.0 ± 0.4 kPa (Note 2). Turn the stopcock to shut off the vacuum from the funnel. Do not remove the dish from the funnel until instructed to do so in 9.5.

9.2 *Determination of Flow*—Determine the flow in accordance with Test Method C1437.

9.3 *Preparation of Mortar or Plaster Bed*—Immediately after making the flow test, return the mortar or plaster on the flow table to the mixing bowl and remix the entire batch for 15 s at medium speed. Immediately after remixing, fill the perforated dish with the material to slightly above the rim. Tamp 15 times with the tamper. Apply ten of the tamping strokes at approximately uniform spacing adjacent to the rim of the dish, and with the long axis of the tamping face held at right angles to the radius of the dish. Apply the remaining five tamping strokes at random points distributed over the central area of the dish. Use just enough tamping pressure to fill the dish with the top of the material extending slightly above the rim. Smooth off the material by drawing the flat side of the straightedge (with the leading edge slightly raised) across the top of the dish. Strike-off the material to a plane surface flush with the rim of the dish with the straightedge held in a perpendicular position; using a sawing motion, draw the straightedge across half of the surface of the dish; repeat the procedure on the other half of the unfinished surface. If the material is pulled away from the side of the dish during the process of drawing the straightedge across the dish, gently press the material back into contact with the side of the dish using the tamper. Complete the entire filling and strike-off operation in not more than 2 min.

9.4 *Application of Vacuum to Mortar or Plaster*—Turn the stopcock to apply the vacuum to the funnel. After suction for 60 s, quickly turn the stopcock to expose the funnel to atmospheric pressure.

9.5 *Determination of Flow After Suction*—Immediately slide the perforated dish off the funnel, touch the bottom of the dish momentarily on a damp cloth to remove droplets of water. Set the dish on a work table, plow and mix the mortar or plaster for 15 s, with the rubber scraper prescribed in Practice C305. Determine the flow in accordance with Test Method C1437. Remove the vacuum and complete the flow test in less than 2 min.

10. Calculation

10.1 Calculate the water retention value for the mortar or plaster as follows:

$$\text{Water retention, \%} = (A/B) \times 100$$

where:

A = flow after suction, and

B = flow immediately after initial mixing.

Report to the nearest 1 %.

11. Precision and Bias

11.1 *Precision*—The following precision values were calculated from results of tests reported to Cement and Concrete Reference Laboratory (CCRL) for masonry cement proficiency samples Number 3 through 42 (Note 4). Within- and among-laboratory standard deviations were calculated by CCRL for each sample pair. Values were pooled over all 40 samples for purposes of this analysis. Water retention test results (excluding outliers) ranged from 72 to 88 %. The average number of laboratories reporting was 69.

NOTE 4—These tests utilized a slightly different test pressure, 6.7 ± 0.4 kPa (50 ± 0.3 mm Hg).

11.1.1 *Single-laboratory Precision*—The single-laboratory standard deviation has been found to be 3.5 % (Note 5). Therefore, the results of two properly conducted tests in the same laboratory on the same material should not differ by more than 9.8 % (Note 5) in 95 % of such pairwise comparisons.

11.1.2 *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 5.1 % (Note 5).

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:17 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Therefore, the results of two properly conducted tests in different laboratories on the same material should not differ by more than 14.3 % (Note 5) in 95 % of such pairwise comparisons.

NOTE 5—These numbers represent, respectively, the 1s and d2s limits as described in Practice C670.

11.2 *Bias*—Since there is no accepted reference material suitable for determining bias in this test method, no statement on bias is being made.

12. Keywords

12.1 hydraulic cement; mortar; plaster; water retention

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C1506 – 08, that may impact the use of this test method. (Approved December 1, 2009)

(*1*) Revised 9.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

Designation: C 1513 – 04 (Reapproved 2009)ε1

Standard Specification for Steel Tapping Screws for Cold-Formed Steel Framing Connections[1]

This standard is issued under the fixed designation C 1513; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—The units statement in 1.2 was revised editorially in May 2009.

1. Scope

1.1 This specification covers steel self-drilling and self-piercing tapping screws for the connection of cold-formed steel members manufactured in accordance with Specifications C 645 and C 955. This specification also covers test methods for determining performance requirements and physical properties.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 The following safety hazards caveat pertains only to the test methods described in this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

A 370 Test Methods and Definitions for Mechanical Testing of Steel Products

A 510 Specification for General Requirements for Wire Rods and Coarse Round Wire, Carbon Steel

B 117 Practice for Operating Salt Spray (Fog) Apparatus

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 645 Specification for Nonstructural Steel Framing Members

C 955 Specification for Load-Bearing (Transverse and Axial) Steel Studs, Runners (Tracks), and Bracing or Bridging for Screw Application of Gypsum Panel Products and Metal Plaster Bases

F 1941 Specification for Electrodeposited Coatings on Threaded Fasteners (Unified Inch Screw Threads (UN/UNR))

2.2 *ANSI/ASME Documents:*

B18.18.1M Inspection and Quality Assurance for General Purpose Fasteners[3]

B18.6.4 Standard Specification for Thread Forming and Thread-Cutting Screws[3]

2.3 *SAE Standards:*

SAE J78-1998 Steel Self-Drilling Tapping Screws[4]

SAE J933 Mechanical and Quality Requirements for Tapping Screws[4]

3. Terminology

3.1 *Definitions*—For definitions relating to gypsum and related building materials and systems, use Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *bearing surface (of the screw)*, *n*—the supporting or locating surface of a fastener with respect to the part which it fastens (mates). The loading of the fastener is usually through the bearing surface, (that is, the bearing surface of the hex washer head style is under the head, the part that touches the top material being fastened).

3.2.2 *case depth (of the screw)*, *n*—the thickness of the hardened surface of the screw.

3.2.3 *countersunk head style (for a screw)*, *n*—all screw head designs that sink into the top material being fastened and that have the bearing surface (see 3.2.1), at the top of the head (that is, flat and bugle).

3.2.4 *crest (of the screw thread)*, *n*—the highest point of the screw thread.

3.2.5 *drill capacity (of the self-drilling screw)*, *n*—the total thickness of material the fastener is designed to drill through, including any space between the layers.

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.02 on Specifications and Test Methods for Accessories and Related Products.

Current edition approved May 1, 2009. Published September 2009. Originally approved in 2001. Last previous edition approved in 2004 as C 1513 – 04.

www.technobetar.ir

3.2.6 *head styles (of the screw)*, *n*—refer to Fig. 1 drawings.

3.2.6.1 *bugle head, n*—bugle shape countersinking head typically used for fastening gypsum panel products to wood and steel.

3.2.6.2 *hex washer head, n*—has an indented top surface and six flat sides formed integrally with a flat washer which projects beyond the sides and provides a flat bearing surface.

3.2.6.3 *lath head, n*—see *modified truss*.

3.2.6.4 *modified truss, n*—low profile round washer head.

3.2.6.5 *pan framing head, n*—flat top surface rounding into cylindrical sides and a flat bearing surface.

3.2.6.6 *pan head, n*—a slightly rounded top surface rounding into cylindrical sides and a flat bearing surface.

3.2.6.7 *pancake head, n*—lower profile head style than the hex washer and pan head with a larger flat bearing surface.

3.2.6.8 *wafer head, n*—a countersinking head style with a large lip at the top of the countersinking contour that will "flush" with the substrate creating a greater bearing surface, therefore a greater pull-over/pull-through value.

3.2.7 *point style*, *n*—of the self-drilling tapping screw is designated by a number (that is, 1, 2, 3, 4, or 5). The higher the number, the higher the drill capacity (see 3.2.5) of the screw.

3.2.8 *root (of the screw thread)*, *n*—the lowest point of the screw thread.

3.2.9 *self-drilling tapping screw*, *n*—externally threaded fasteners with the ability to drill their own hole and form or cut their own internal mating threads without breaking.

3.2.10 *self-piercing tapping screw*, *n*—externally threaded fasteners with the ability to pierce metallic material 33 mils (0.84 mm), or less, form a sleeve by extruding metallic material and "tap" their own mating threads when driven. Self-piercing screws have a sharp point with the point angle not more than 30 degrees.

3.2.11 *spin-out (for a screw)*, *n*—for a screw, the continued rotation of a screw without further penetration into the substrate.

3.2.12 *tapping screw*, *n*—externally threaded fasteners with the ability to "tap" their own internal mating threads when installed.

4. Classification

4.1 Steel tapping screws covered by this specification are two types:

4.1.1 Self-drilling.

4.1.2 Self-piercing.

5. Materials

5.1 Steel wire, Specification A 510–minimum grade 1018.

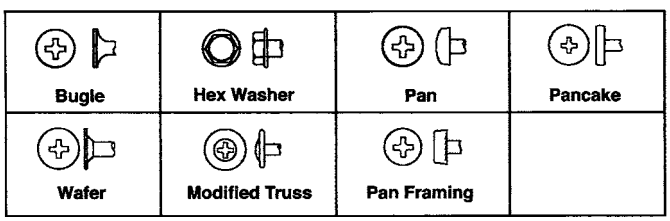

FIG. 1 Head Styles

6. Physical Properties

6.1 *Dimensions*:

6.1.1 Self-drilling tapping screws shall be in accordance with SAE J78.

6.1.2 Self-piercing tapping screws shall be in accordance with head dimensions as shown in ANSI/ASME B18.6.4.

6.2 *Total Case Depth*—Screws shall have a total case depth conforming to the tabulation in Table 1.

6.2.1 Case depth shall be measured at the mid-point between crest and root on the thread shank.

7. Packaging and Head Marking

7.1 Screws shall be marked with manufacturer's/supplier's head marking for traceability.

7.2 Screws shall be packaged in substantial commercial shipping containers, constructed so as to preserve the contents in good condition and to ensure acceptance and safe delivery by common or other carriers.

7.2.1 Individual packages shall be so constructed that the contents shall be able to be partially removed without destroying the container's ability to serve as a receptacle for the remainder of the contents.

7.2.2 Individual packages and shipping containers shall be marked with the type, size, use, and quantity of the screws contained therein, the name brand headmarking example and trademark of the producer or supplier, the ASTM designation, and any or all appropriate evaluation reports . Boxes shall be marked with the drill capacity of the self-drilling tapping screws.

8. Performance Requirements

8.1 *Hardness*:

8.1.1 The self-drilling tapping screws shall have a surface hardness of not less than Rockwell C 50 and core hardness of not less than Rockwell C 32 as tested in accordance with SAE J78.

8.1.2 The self-piercing screws shall have a surface hardness of not less than Rockwell C 45 and core hardness of not less than Rockwell C 28 as tested in accordance with SAE J933.

8.2 *Ductility*:

8.2.1 The self-drilling tapping screws shall have sufficient ductility to be able to withstand a 5° bend without visible signs of fracture as tested in accordance with SAE J78.

8.2.2 The self-piercing tapping screws shall have sufficient ductility to be able to withstand a 10° bend without visible signs of fracture as tested in accordance with SAE J933.

8.3 *Torsional Strength*:

8.3.1 Self-drilling tapping screws shall not fail the application of torque less than or equal to the torsional strength specified in Table 2, when tested in accordance with SAE J78.

8.3.2 Self-piercing tapping screws shall not fail with the application of torque less than the torsional strength specified

TABLE 1 Total Case Depth

Nominal Screw Size	Total Case Depth, Maximum, in. (mm)	Total Case Depth, Minimum, in. (mm)
8 through 12	0.009 (.2286 mm)	0.004 (.1016 mm)
¼ in.	0.011 (.2794 mm)	0.005 (.1270 mm)

TABLE 2 Torsional Strength–Self-Drilling Tapping Screws

Nominal Screw Size	Minimum lb-in. Type BSD[A]	Minimum lb-in. Type CSD[B]
6	24	24
8	42	48
10	61	65
12	92	100
¼ in.	150	156

[A] Type BSD–spaced threads referred to as coarse thread.
[B] Type CSD–machine screw threads referred to as fine thread.

in Table 3, as tested in accordance with ANSI/ASME B18.6.4, Section 2.9.1.2, for tapping screws.

8.4 *Drill Drive Performance Requirement*:

8.4.1 Self-drilling tapping screws shall not fail the drill-drive test requirements as noted in SAE J78 and shown in Table 4.

8.4.2 Self-drilling tapping screws shall be tested in accordance with SAE J78 as shown in Fig. 2.

8.5 *Self-Drilling Tapping Screw Drill Capacity*:

8.5.1 Screws shall be able to self-drill and thread into cold-formed steel thicknesses without breaking or stripping as specified by each specific manufacturer's published recommendations. Manufacturers shall provide a min-max recommendation with the drill capacity of each self-drilling point style screw.

9. Finish and Appearance

9.1 The threads shall be clean, smooth, and neatly formed.

9.2 Each fastener shall have manufacturer's/supplier's head marking for traceability.

9.3 Screws shall have a corrosion-resistant treatment. The finish shall not inhibit adhesion to finishing materials nor bleed through field-applied decoration. The screws shall meet a minimum requirement as listed in Specification F 1941 as tested in accordance with Practice B 117.

10. Sampling

10.1 Obtain not less than one randomly selected specimen of each type of screw to be tested from each of five containers, with not less than five screws per 250 000 screws, to constitute a lot for testing.

11. Test Methods

11.1 Screws shall be tested per SAE J78 Table number 4, Section 8.4, to determine the ability of the screws to self-drill through cold-formed steel without spinout, thread deformation, or breaking.

11.2 *Significance and Use*:

11.2.1 The test methods provide procedures for evaluating the physical properties and performance requirements of steel drill screws.

TABLE 3 Torsional Strength–Self-Piercing Tapping Screws

Nominal Screw Size	Minimum lb-in.
6	24
7	30
8	39
10	56

TABLE 4 Drill-Drive Test Requirements

Nominal Screw Size	Test Plate Thickness,[A] in., Max	Test Plate Thickness,[A] in., Min	Axial Loading,[B] lb, A, max	Axial Loading,[B] lb, B, Max	Axial Loading,[B] lb, C, Max	Time to Drill and Form Thread,[C] s, Max
4	0.068	0.062	25	30	40	2.0
6	0.068	0.062	30	35	45	2.5
8	0.068	0.062	30	35	45	3.0
10	0.068	0.062	35	40	50	3.5
12	0.068	0.062	45	50	60	4.0
¼	0.068	0.062	45	50	60	5.0

[A] Test plates shall be low carbon, cold rolled steel having a hardness of Rockwell B 80-85.
[B] Axial loads are varied to offset the detrimental effects on drilling capability created by finishes applied to screws in accordance with the following:
Column A—Axial loads tabulated shall apply to plain, oiled, and commercial phosphate coating and cadmium and zinc platings up to 0.0003 in. in thickness.
Column B—Axial loads tabulated shall apply to special electroplated finishes exceeding 0.0003 in. in thickness and to special coatings, such as thread sealing hot melts, and so forth.
Column C—Axial loads tabulated shall apply to chromium finish.
[C] Tool speed shall be 2500 rpm for screw sizes No. 4 through No. 10. Tool speed of 1800 rpm is recommended for screw sizes No. 12 and ¼; however, 2500 rpm may be used provided care is exercised to minimize influence of high heat buildup due to surface speed.

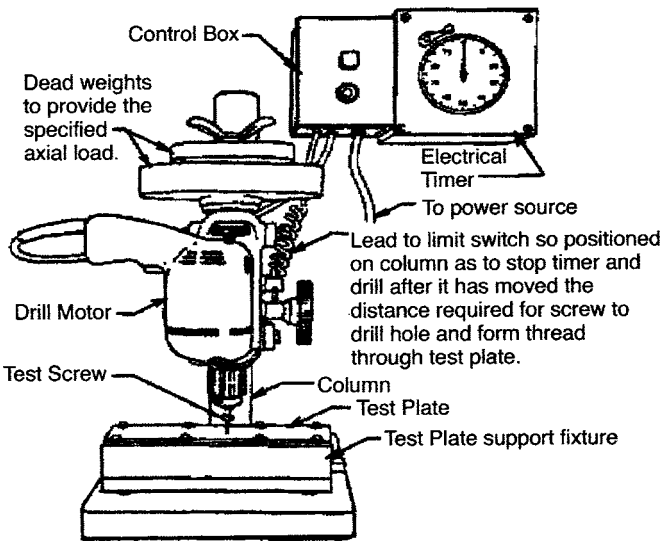

FIG. 2 Drill-Drive Test Apparatus

12. Test Materials

12.1 *Materials*:

12.1.1 Screw fasteners used in the tests shall be of standard manufacturer and representative of the product for which recognition is sought. Where tested fasteners are prototype, the fasteners shall be representative of later production. Fasteners shall meet the minimum and quality requirements for tapping screws in accordance with ANSI/ASME B18.6.4 and ANSI/ASME B18.18.1M, 1987 or the pertinent standard, whichever is more restrictive. Compliance is determined by test reports submitted by a qualified testing laboratory.

12.1.2 *Sheet Steel*—Steel description, including material specification, yield strength, and minimum uncoated steel thickness noted.

12.2 Sharp point screws shall be tested using 33 mil (0.84 mm) steel.

12.3 Drill point screws shall be tested using 54 mil (1.37 mm) steel.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

13. Specimen Preparation

13.1 Where the number of steel coupon specimens is not noted in the specific standard, a minimum of three steel coupon specimens shall be tested to show compliance with the appropriate standard and to determine the minimum uncoated steel thickness and strengths. Steel tension test shall be performed in accordance with Test Methods and Definitions A 370.

13.2 *Screw Fasteners*—A minimum of three test specimens are to be tested for tension (pull-out) and for the lap shear connection. If the result from any one test is more than 15 % higher or lower than the other two, the lowest test value is used, unless an additional three tests are performed. Then use the average results of all six tests, regardless of the variation.

14. Procedure

14.1 If any of the first lot on the drill-drive testing fails, test another lot. If two of that lot fail, the entire lot fails.

15. Dimensional Measurement

15.1 *Self-Piercing Screws*—ANSI/ASME B18.6.4.
15.2 *Self-Drilling Tapping Screws*—SAE J78.

16. Ductility Test

16.1 *Self-Piercing Screws*—ANSI/ASME B18.6.4.
16.2 *Self-Drilling Tapping Screws*—SAE J78.

17. Torsional Strength

17.1 *Self-Piercing Screws*—ANSI/ASME B18.6.4.
17.2 *Self-Drilling Tapping Screws*—SAE J78.

18. Inspection

18.1 Inspection of the steel screws shall be agreed upon between the purchaser and producer or supplier as part of the purchase agreement.

19. Rejection and Rehearing

19.1 Rejection of steel screws that fail to conform to the requirements of the specification shall be reported to the producer or supplier promptly and in writing within 10 working days from receipt of shipment. Notice of rejection shall contain a specific statement as to the respects in which the screws have failed to conform to the requirements of the specification. In case of dissatisfaction with the test results, and at the request of the producer or supplier, such notice of rehearing shall be supported by results of a test conducted by a mutually agreeable independent laboratory.

20. Certification

20.1 When specified in the purchase agreement, the producer or supplier shall furnish a report certifying that, at the time of shipment, the screws were in compliance with the requirements of this specification.

21. Keywords

21.1 bugle head; crest; hex washer head; modified truss; pancake head; pan head; root; screws; self-drilling; self-piercing; spin-out; wafer head drill capacity

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1516 – 05

Standard Practice for Application of Direct-Applied Exterior Finish Systems[1]

This standard is issued under the fixed designation C 1516; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers the minimum requirements and procedures for field application of Direct-applied Exterior Finish Systems (DEFS). Direct-applied exterior finish systems are coating systems applied over various substrates with non-metallic reinforcing mesh, in which the base coat ranges from not less than 1/16 in. (1.6 mm) to 3/32 in. (2.4 mm) in dry thickness, depending on the mass of the reinforcing mesh. This base coat is subsequently covered with a finish coat that is available in a variety of textures and colors.

1.2 The values stated in inch-pound units are to be regarded as the standard. The metric values given in parentheses are approximate and are provided for information purposes only.

1.3 *This standard may involve hazardous materials, operations and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 1063 Specification for Installation of Lathing and Furring to Receive Interior and Exterior Portland Cement-Based Plaster

C 1177/C 1177M Specification for Glass Mat Gypsum Substrate for Use as Sheathing

C 1186 Specification for Flat Non-Asbestos Fiber-Cement Sheets

C 1278/C 1278M Specification for Fiber-Reinforced Gypsum Panel

C 1325 Specification for Non-Asbestos Fiber-Mat Reinforced Cement Substrate Sheets

E 1825 Guide for Evaluation of Exterior Building Wall Materials, Products, and Systems

3. Terminology

3.1 Definitions used in this standard shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *accessories*, *n*—preformed metal, fiberglass or plastic members used to form corners, edges, control joints, or decorative effects.

3.2.2 *back wrapping*, *n*—a deprecated term. See *wrap*.

3.2.3 *base coat*, *n*—a material, either factory or field-mixed, used to cover the substrate and to encapsulate the reinforcing mesh.

3.2.4 *cold joint*, *n*—the visible junction in an exterior finish.

3.2.5 *cure*, *v*—to develop the ultimate properties of a wet state material by a chemical process.

3.2.6 *dry*, *v*—to develop the ultimate properties of a wet state material solely by evaporation of volatile ingredients.

3.2.7 *durability*, *n*—the capability of a building, assembly, component, product, or construction to maintain serviceability over not less than a specified time.

3.2.8 *embed*, *v*—to encapsulate a non-metallic reinforcing mesh in either the joint compound or exterior finish.

3.2.9 *expansion joint*, *n*—a structural separation between building elements that allows independent movement without damage to the assembly.

3.2.10 *factory mixed*, *n*—a material that is prepared at the point of manufacture and is ready to use without the addition of other materials, except possibly water to adjust consistency.

3.2.11 *field mix*, *n*—a material that is mixed in the field with other components and/or water.

3.2.12 *finish coat*, *n*—the final wet state material, that provides color or additional texture, applied over the reinforced base coat.

3.2.13 *flash set (quick set)*, *n*—the early hardening or stiffness in the working characteristics of a Portland-cement paste, mortar, or concrete, usually with the evolution of considerable heat; stiffness cannot be dispelled nor the plasticity regained by further mixing without addition of water; also known as "quick set."

[1] This practice is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.05 on Application of Exterior Insulating and Finish Systems and Related Products.

Current edition approved October 1, 2005. Published October 2005. Originally approved in 2002. Last previous edition approved in 2002 as C 1516 – 02.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

www.technobetar.ir

3.2.14 *framing member*, *n*—studs, joist, runners (tracks), bridging, bracing, and related accessories manufactured or supplied in wood or hot or cold formed steel.

3.2.15 *initial grab*, *n*—the ability of a wet state material to remain in place initially after it has been applied.

3.2.16 *initial set*, *n*—a time related set caused by the hydration process.

3.2.17 *lamina*, *n*—composite of base coat, reinforcement, and finish coat.

3.2.18 *mechanical fastener*, *n*—corrosion resistant component used to attach the substrate to the framing member.

3.2.19 *reinforcing mesh*, *n*—a non-metallic component of the DEFS encapsulated in the base coat to strengthen the system.

3.2.19.1 *Discussion*—Non-metallic reinforcing mesh is available in various weights to achieve different levels of impact and stress resistance.

3.2.20 *pot life*, *n*—the duration of time that the wet state material remains workable after it has been mixed.

3.2.21 *primers*, *n*—liquid coatings applied to improve the adhesion of the DEFS to the substrate.

3.2.21.1 *Discussion*—Primers are sometimes applied to improve the water resistance of cementitious base coats.

3.2.22 *reinforced base coat*, *n*—base coat that has been reinforced with a non-metallic reinforcing mesh.

3.2.23 *substrate*, *n*—surface to which the DEFS is applied.

3.2.24 *surface sealer*, *n*—material used to enhance weather resistance.

3.2.25 *temper*, *v*—to bring to a workable state by adding water.

3.2.26 *texture*, *n*—any surface appearance as contrasted to a smooth surface.

3.2.27 *wet edge*, *n*—the leading edge of a continuously applied wet state material.

3.2.28 *wet state materials*, *n*—the adhesive, base coat and finish coat components applied in liquid or semi-liquid state.

4. Significance and Use

4.1 This practice provides minimum requirements for the application of Direct-applied Exterior Finish Systems. The requirements for materials, mixtures, and details shall be contained in the project plans and specifications.

5. Delivery of Materials

5.1 All materials shall be delivered in packages, containers, or bundles with the identification and markings intact.

6. Inspection

6.1 Inspection of the materials shall be agreed upon between the purchaser and the supplier as part of the purchase agreement.

7. Rejection

7.1 Materials that are damaged, frozen or in any way defective shall not be used. Rejection of materials shall be promptly reported verbally to the producer and immediately reported in writing. The notice of rejection shall contain a statement documenting the basis for material rejection.

8. Certification

8.1 When specified in the contract documents, the exterior finish producer shall furnish a report certifying that the materials are in conformance with product and material standards and contract documents.

8.2 The substrate panels shall be marked as complying with the applicable product specification.

9. Storage of Materials

9.1 All materials shall be kept dry by storage under cover and protected from the weather.

9.1.1 When outside storage is required, substrate panels shall be stacked flat with care taken to avoid damage to edges, ends, or surfaces.

9.1.2 All other DEFS components shall be stacked off the ground, supported on a level platform and protected from the direct sunlight, weather, surface contamination or physical damage in accordance with the DEFS producer's written instructions.

9.2 Materials shall be protected from exposure to temperatures less than 40 °F (4 °C), unless otherwise specified by the manufacturer.

9.3 Portland Cement shall be kept dry until ready for use. It shall be kept off the ground, under cover and away from damp walls and surfaces.

10. Environmental Conditions

10.1 *Cold Weather Conditions*:

10.1.1 Wet materials shall not be applied when the temperature is less than 40 °F (4 °C) unless temporary heat and enclosures are provided to maintain a minimum temperature of 40 °F (4 °C) for a minimum period of not less than 24 h before, during and after application or unless otherwise specified by the manufacturer.

10.1.2 Materials shall not be applied to a base containing frost. Substrate surface temperature shall be not less than 40 °F (4 °C) unless otherwise specified by the manufacturer. Mixtures for application shall not contain any frozen ingredients.

11. Assessment of Condition of Substrates to Receive Direct Exterior and Finish Systems

11.1 The substrate shall be as required by the project plans and specifications and as specified by the DEFS producer for the particular system.

11.2 The substrate shall be inspected by the applicator and general contractor to ensure that it meets the project plans and specifications and the requirements of 11.3-11.8.2.

11.3 Sheathing materials shall be inspected to ensure that:

11.3.1 The specified sheathing thickness has been installed for the stud spacing used.

11.3.2 Fastener type and fastener spacing are as specified.

11.3.3 Water-resistant exterior fiber-reinforced gypsum sheathing panels complying with Specification C 1278/C 1278M, shall be installed in accordance with the sheet producer's written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheet orientation and spacing.

11.3.4 Glass mat gypsum sheathing complying with Specification C 1177/C 1177M, shall be installed in accordance with

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:22 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the sheet producer's written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheet orientation and spacing.

11.3.5 Fiber-cement sheets complying with Specification C 1186, Type A, shall be installed in accordance with the sheet producer's written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheet orientation and spacing.

11.3.6 Fiber-mat reinforced cement sheets complying with Specification C 1325, type A, shall be installed in accordance with the sheet producer's written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheet orientation and spacing.

11.4 *Alignment*—All substrate surfaces shall be straight and true within ¼ in. in 10 ft. (2 mm/m). More stringent requirements by the DEFS producer shall supersede the above stated requirements.

11.5 *Suitability for Use*—The substrate surface shall be firm, sound, and undamaged in order to receive the exterior finish.

11.5.1 Broken, cracked or delaminated substrate boards shall be replaced or restored to a condition equal to adjacent undamaged boards.

11.6 *Cleanliness*—The surface of all substrates shall be clean and free from any foreign materials such as form release agents, curing compounds, dust, dirt, frost, oil or grease, efflorescence and laitance.

11.6.1 All substrate panels shall have all loose dirt and dust removed by cleaning methods appropriate for the job and job conditions.

11.6.2 Efflorescence and laitance on substrate panels shall be removed prior to exterior finish application. Heavy deposits shall be removed using hand or power impact tools followed by washing with an appropriate cleaner. Light deposits shall be removed by washing with an appropriate cleaner. All loose particles and cleaner residue shall be removed by washing with clean, potable water. The surface shall be allowed to dry.

11.7 *Substrate Condition*—There shall be no visible water.

11.8 If furring or accessories are used, they shall be installed in conformance with Specification C 1063.

11.8.1 These members shall be properly attached, straight, and true unless required by the system design.

11.8.2 All accessories shall be free of rust, oil, or other foreign matter or contaminants, which cause bond failure or unsightly discoloration.

12. Reinforced Base Coat Application

12.1 Inspect the substrate panel surface to ensure that it is clean, dry, free of all foreign materials, and damage of any type. Substrate panel planar irregularities of more than 1/16 in. (1.6 mm) shall be corrected. All panel joints shall be tightly abutted or shall be filled with recommended joint bedding material.

12.2 *Base Coat Preparation*—All materials requiring field preparation shall be mixed in accordance with the DEFS producer's specifications.

12.3 *Base Coat Application*—The prepared base coat shall be uniformly spread over the entire surface of the substrate panel.

12.4 *Reinforcing Mesh*—The single layer reinforcing mesh, when specified, shall be fully encapsulated in the field of the wall, at corners, edges, and joints. Trowel from the center to the edge of the reinforcing mesh to avoid wrinkles. The single layer reinforcing mesh shall be continuous at all corners.

12.4.1 *Discussion*—The recommended method is to apply the base coat in two applications.

12.4.2 The surface shall be free of voids, projections, trowel marks and other surface irregularities. The base coat thickness shall be not less than 1/16 in. (1.6 mm) dry as measured from the surface of the substrate panel.

12.5 *Reinforcing Mesh Overlap*—-- All reinforcing mesh edges shall be overlapped not less than 2½ in. (64 mm).

12.6 *Impact Layers*—When required, higher impact performance shall be achieved with multiple layers of reinforcing mesh or by incorporating heavier weight reinforcing mesh. All areas requiring higher impact performance shall be detailed on the project plans and specifications. When overlapping of high impact mesh is not required, a complete second layer of reinforcing mesh shall be applied over the layer of high impact mesh.

12.7 *Corners*—Reinforcing mesh shall not be lapped within 8 in. (204 mm) of any corner.

12.8 *Wall Penetrations*—All edges of the substrate panel board at penetrations of the DEFS, such as at windows, doors, Heating, Ventilation and Air Conditioning (HVAC) sleeves, pipes, duct, electrical boxes, and at the base of the wall shall be wrapped with either the base coat and reinforcing mesh or trim, or as specified by the project plans and specifications. Wall openings such as doors, windows, HVAC sleeves, shall be diagonally reinforced at corners with mesh not less than 9 in. (230 mm) by 12 in. (305 mm).

12.8.1 The corners of returns to windows, doors, and similar wall openings shall have reinforcing mesh the full width of the return and extending not less than 2½ in. (64 mm) on both sides of the corner.

12.9 *Expansion Joints*—All edges of the substrate panels at expansion joints shall be wrapped with either the base coat and reinforcing mesh or trim as specified by the DEFS producer for the particular system. The reinforcing mesh shall be fully encapsulated.

12.10 *Reinforcing Mesh*—The reinforcing mesh shall be fully encapsulated in the base coat throughout the field of the wall, at corners, edges, and joints. The surface shall be free of voids, projections, trowel marks and other surface irregularities.

12.11 *Special Architectural Shapes*—When special EPS (expanded polystyrene) architectural shapes are installed, glass fiber reinforcing mesh encapsulated in the base coat shall be used.

13. Finish Coat Application

13.1 The reinforced base coat shall be allowed to dry and harden for not less than 24 h prior to finish coat application.

13.2 *Material Preparation*—The finish coat shall be mixed in accordance with the DEFS producer's specifications. Only clean potable water shall be added to adjust workability. Always add the same amount of water to each container within a given lot of finish.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:22 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

13.3 *Execution*—Reinforcing base coat and finish coats shall be applied with a stainless steel trowel or appropriate equipment as specified by the DEFS producer. Tools and equipment shall be kept clean. Finish coat shall be applied continuously to a natural break such as corners, joints or tape line. Apply supplementary finishes to the exterior finish maintaining a wet edge. Sufficient manpower and scaffolding shall be provided to continuously finish a distinct wall area. Scaffolding shall be spaced a distance from the wall, consistent with safety standards, that allows uniform texturing of the finish without staging marks. On hot windy days, it shall be permitted to fog the wall with clean, potable water to cool the wall. Work shall precede the sun whenever possible. Water shall not be added to the finish once it is applied to the wall. Use the same tool and hand motion and match the texture of the surrounding area. The finish coat thickness shall be as specified by the DEFS producer. Protect all finish work from damage until fully dried.

13.4 *Joints*—The application of finish coat into the joints shall be as required by the project plans and specifications.

14. Curing Time Between Application Steps

14.1 Manufacturer's recommendations for climatic conditions, mixing and application practices to allow respective coats sufficient time to cure or dry before any subsequent coats are applied shall be followed. Each application step shall be permitted to cure or dry to prevent degradation to the system integrity with subsequent steps.

14.2 Auxiliary protection (tenting, supplemental heat, shading) from adverse environmental conditions shall be utilized to provide expected curing or drying conditions as recommended by the DEFS manufacturer.

14.3 All substrates shall be sound and cured or dry before continuing on to the next application step.

15. Clean Up

15.1 Adjacent materials, surfaces and the work area shall be cleaned of foreign materials resulting from the work.

15.2 All excess DEFS materials shall be removed from the job site.

16. Keywords

16.1 DEFS; direct-applied; exterior finish

APPENDIXES

(Nonmandatory Information)

X1. GENERAL INFORMATION

INTRODUCTION

These Appendixes give general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this practice.

X1.1 General

X1.1.1 The work includes all labor, materials, services, equipment and scaffolding required to complete the DEFS installation on the project in accordance with the project drawings and specifications, except electrical power and potable water.

X1.1.2 Where a specific fire resistance rating is required for the DEFS assemblies and construction, details of construction shall be in accordance with official reports of tests conducted by recognized testing laboratories and a part of approved plans and specifications.

X1.1.3 The installation of the DEFS is to be coordinated by the owner's authorized agent with work of other trades.

X1.1.4 Surfaces and accessories to receive DEFS components shall be examined and accepted as provided in 11.1 before the DEFS components are installed thereto. The proper authorities shall be notified about unacceptable conditions. The unsatisfactory conditions shall be corrected prior to the application of the DEFS components. Unsatisfactory conditions shall be corrected by the party(ies) responsible for such conditions.

X1.1.5 The construction specifier shall describe, in the proper section of the project specifications, the physical characteristics of the surfaces to receive the DEFS.

X1.2 Design Considerations

X1.2.1 Guidance, for design professionals, for determining the suitability and use of direct-applied exterior finish systems, as an exterior building wall, is contained in Guide E 1825. DEFS are attached to outside substrates of all types of structures to provide weather resistant and durable surfaces. The surfaces will be subjected to various exposures such as abrasion, vibration, moisture, freezing, thawing, negative and positive wind loading , ultraviolet light, acid rain, thermally induced expansion and contraction, and impact.

X1.2.2 Provide sufficient slope on faces of DEFS surfaces to prevent water, snow or ice from accumulating or standing. A minimum 6 in. (152 mm) in 12 in. (305 mm) (1:2) pitch is recommended. Length of sloped surfaces shall not be more than 12 in. (305 mm).

X1.2.3 Provide parapet cap made only from corrosion resistant materials. The parapet cap shall extend not less than

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:22 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

2½ in. (64 mm) over the faces of the DEFS, not including wood blocking and include a drip edge detail. Detailed requirements for furnishing and installing the parapet cap shall be in the appropriate section of the project specifications. Parapet caps shall be clearly shown in large scale details. Parapet caps shall be installed as soon as practical after the installation of the DEFS.

X1.2.4 Provide for sealing of expansion joints, panel joints, system terminations and all interfaces of the DEFS with other building components.

X1.2.5 At soffits, window and door heads provide for a drip edge.

X1.2.6 Sills and headers shall be flashed.

X1.2.7 Windows installed in DEFS walls shall have sill pan flashing of corrosion-resistant material.

X1.2.8 The specifier shall evaluate the potential of the DEFS surface being subjected to abnormal stresses or impacts.

X1.2.9 Wall assemblies have properties that in certain applications make a dew point analysis critical to ensure successful performance of the wall system. The specifier shall evaluate these conditions.

X1.2.10 Substrate panels must be continuous over floor slabs, intersecting walls, columns, beams and similar constructions. The DEFS shall not be installed over areas without substrate panels.

X1.2.11 Where the substrate panel is interrupted or out of plane, corrections must be made prior to DEFS application. If the substrate panel cannot be continuous, the installation of expansion joints shall be considered.

X1.3 Relief From Stress

X1.3.1 Where the DEFS and dissimilar types of substrates, materials and building components interface, provide for appropriate size and location of expansion joints.

X1.3.2 Where roof elevations change, provide for appropriate size and location of expansion joints.

X1.4 Bonding Agents

X1.4.1 Bonding compounds or agents are sometimes applied to a substrate panel surface to receive exterior finish. Follow the DEFS producer's instructions and specifications for their use.

X1.5 Mechanical Fasteners

X1.5.1 The types of mechanical fasteners used and the methods of installation will vary depending on the framing to which the substrate panels are to be fastened.

X1.6 Reinforced Exterior Finish

X1.6.1 The basecoat thickness is permitted to exceed 3⁄32 in. (2.4 mm) dry depending on the type of reinforcing mesh and number of layers.

X1.6.2 A small amount of basecoat shrinkage is normal. Bare mesh shall not be visible.

X1.6.3 The proper portioning of hydraulic cement-based material is important. The producer's instructions shall be followed to ensure that the base coat cement is properly proportioned.

X1.6.4 The minimum amount of mix water to form a workable mix shall be used. Excess mix water causes the base coat to be porous and less weather resistant. Never add more water than recommended by the producer. Measure water in containers of known volume.

X1.6.5 Mix materials only at low speed with paddles designed to reduce air entrapment.

X1.6.6 Generally, the finish coat is applied after the base coat has sufficiently cured.

X1.7 Finish Textures

X1.7.1 Textures, as a description of surface appearance, generally are identified with the method and tools used to achieve the finish appearance. Texture is sometimes varied by the size and shape of the aggregate contained in the finish, equipment or tools employed, the consistency of the finish mix, the condition of the base to which it is applied and by decorative and protective treatments.

X1.7.2 With almost limitless variations possible for finish appearance or texture, the same term sometimes does not have the same meaning to the specifier, contractor or applicator. Sample panels of sufficient size including components and features specified shall be constructed using the methods, tools and techniques to be used in the actual construction.

X1.7.3 To provide some guidance, the following categories are generally understood and recognized to imply a particular method of application or finished appearance.

X1.7.3.1 *Sand Finish*—A finish material devoid of coarse aggregate applied in a thin coat completely covering the base coat and floated to a true plane, yielding a relatively fine-textured finish.

X1.7.3.2 *Trowel Texture*—A freshly applied finish is given various textures, designs or stippled effects by hand motion and trowel used. The effects achieved are individualized and it is sometimes difficult for different applicators to duplicate.

X1.7.3.3 *Standard Finish*—A finish with various size aggregates, applied in a thin coat completely covering the base coat and floated in a random pattern. The applicators are cautioned to use the same type texturing tools to help ensure a consistent texture.

X1.7.3.4 *Exposed Aggregate*—Varying sizes of natural or manufactured stone, gravel, shell or ceramic aggregates are embedded by hand or by machine propulsion into a freshly applied "bed coat." The size of the aggregate shall not be more than ½ in. (12.7 mm) diameter. The size of the aggregate determines the thickness of the bedding coat. The bedding coat shall be no less than one-half the thickness of the aggregate to be embedded.

X1.7.3.5 *Spray Texture*—A machine applied finish material. The texture achieved depends on many factors some of which are the consistency of the sprayed mixture, the angle and distance of the spray nozzle to the surface, the pressure of the machine, orifice size used, operator expertise, climatic conditions (wind specifically), and base coat conditions.

X1.7.3.6 *Miscellaneous Types*—Similar to trowel textures except that the freshly applied finish is textured with instruments other than a trowel, such as swept with a broom or brush, or corrugated by raking or combing. A variation of texturing a finish involves waiting until the applied finish has partially

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:22 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

dried and then lightly troweling the unevenly applied finish. The effects achieved are sometimes difficult for different applicators to duplicate.

X1.8 Conditions for DEFS Application

X1.8.1 The amount of water used to mix materials is to be within the allowable range published by the DEFS producer. Factors such as the drying conditions and finishing operations must be considered in determining water usage. The applicator is cautioned that the use of excessive water results in fall off or slide off, excessive shrinkage, higher porosity, lower strength, and inconsistent color.

X1.8.2 Timing between coats varies with climatic conditions and types of materials used. Temperature and relative humidity extend or reduce the curing and drying times. Cold or wet weather lengthens and hot or dry weather shortens these periods. Moderate changes in temperature and relative humidity are overcome by providing additional heating during cold weather and by pre-wetting the base during hot, dry weather.

X1.8.3 Heated enclosures require adequate air circulation to prevent hot or cold spots that allow too rapid drying or freezing. When using heated enclosures it is important to control the relative humidity as well as the temperature. Maintain relative humidity at not more than 90 percent.

X1.8.4 Staining and discoloration of finishes or other building components that are caused by free water draining from one plane to another, dissimilar materials, or other building components, are minimized by providing sufficient depth and angle for drip caps and drip edges.

X2. SEALANT SYSTEMS

X2.1 The size and location of joints and selection of the sealant to be used is responsibility of the Design Professional and shall be consistent with project conditions and guidelines of the DEFS producer.

X2.2 The sealant system must be tested for compatibility with the specified DEFS by an independent laboratory and found to be compatible with the DEFS.

X2.3 The sealant system is recommended by the DEFS and Sealant producer. Non recommended sealant systems must be jointly approved by the Architect and the sealant producer.

X2.4 Base the joint design and surface preparation on the sealant producer's recommendations and project conditions.

X2.5 Allow the DEFS material to cure prior to sealant system installation.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this practice since the last issue, C 1516 – 02, that may impact the use of this practice. (Approved October 1, 2005)

(*1*) Added Specification C 1325 to Referenced Documents.

(*2*) Added new paragraph 11.3.6.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1524 – 02a

Standard Test Method for Water-Extractable Chloride in Aggregate (Soxhlet Method)[1]

This standard is issued under the fixed designation C 1524; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method provides procedures for sampling and analysis of aggregate for water-extractable chloride using a Soxhlet extractor.

NOTE 1—This test method is to be used when significantly high chloride content has been found in aggregates, concretes, or mortars.

1.2 The values stated in SI units are to be regarded as standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 114 Test Methods for Chemical Analysis of Hydraulic Cement[2]

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials[3]

C 1152/C 1152M Test Method for Acid-Soluble Chloride in Mortar and Concrete[3]

C 1218/C 1218M Test Method for Water-Soluble Chloride in Mortar and Concrete[3]

D 75 Practice for Sampling Aggregates[4]

D 1193 Specification for Reagent Water[5]

E 11 Specification for Wire Cloth and Sieves for Testing Purposes[6]

2.2 *American Concrete Institute Standard:*

ACI 222.1–96 Provisional Standard Test Method for Water-Soluble Chloride Available for Corrosion of Embedded Steel in Mortar and Concrete Using the Soxhlet Extractor[7]

3. Significance and Use

3.1 Water-extractable chloride, when present in sufficient amount, has a potential to initiate or accelerate corrosion of metals, such as steel, embedded in or contacting a cementitious system, such as mortar, grout, or concrete. This test method is applicable when aggregates contain a high background of naturally occurring chloride (see ACI 222.1–96). Test Method C 1152/C 1152M determines acid-soluble chloride and Test Method C 1218/C 1218M determines water-soluble chloride. Both Test Methods C 1152/C 1152M and C 1218/C 1218M pulverize the sample to a fine powder or fine granular material. The Soxhlet method is intended to use nonpulverized material. Results with some aggregates have shown that the Soxhlet procedure extracts an extremely low amount of chloride, with most of it remaining in the rock, and therefore, it is not available for corrosion.

3.2 The Soxhlet extraction apparatus consists of three sections: the boiling flask, which contains reagent water at the beginning of the test; the extractor, which contains the sample inside a thimble; and, the condenser. The extractor functions by boiling the water, which condenses and drips on to the sample. When the water attains a fixed height above the sample, the extractor siphons the water from the thimble back to the boiling flask. The process repeats itself until the test is terminated. (Refer to Fig. 1.)

4. Apparatus

4.1 *Sampling Equipment*:

4.1.1 The apparatus required for obtaining aggregate samples is described in Practice D 75.

4.2 *Sampling Processing Apparatus*, the same as in Test Method C 1218/C 1218M without pulverization.

4.3 *Soxhlet Extractor Apparatus*, shall have the following minimum size and consist of the following (see Fig. 1).

4.3.1 *Reflux-Type Condenser*, with a 34/45-mm ground-glass fitting to the extractor, and having a 27-mm inside diameter by a 192-mm body length.

---

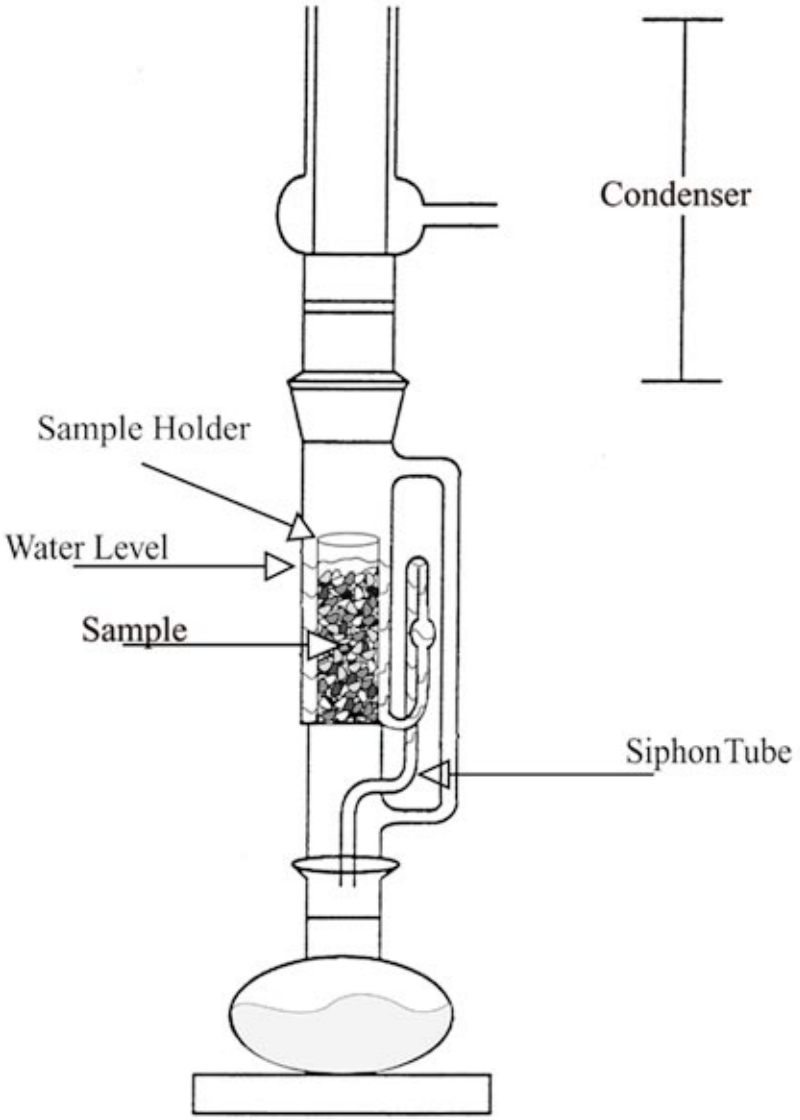

FIG. 1 Soxhlet Extraction Apparatus

4.3.2 *Soxhlet Extraction Tube*, with a 34/45-mm ground-glass fitting to the condenser and a 24/40-mm ground-glass fitting to the boiling flask, for holding sample thimbles 25 mm by 80 mm (diameter by height).

4.3.3 A 250-mL boiling flask with a 24/40-mm ground-glass fitting.

4.3.4 A heating mantel, burner, or hot plate configured for the flask capable of attaining 200°C.

4.3.5 *Suitable Sample Holder*, such as a porous extraction thimble having a 25-mm inside diameter and 80-mm external length.

4.4 The apparatus required for the chloride determination step is given in the test method for chloride in Test Methods C 114.

4.5 *pH Paper*, short-range 0.0-3.0.

4.6 *Drying Oven*, of sufficient size, capable of continuously heating at 110 ± 5°C.

4.7 *Sieve*, 25.0 mm, complying with Specification E 11.

5. Reagents

5.1 The reagents required for the chloride determination are given in the test method for chloride of Test Methods C 114, and the Procedure section of Test Method C 1218/C 1218M.

5.2 Reagent water is either deionized or distilled, conforming to the requirements of Specification D 1193 for Type III reagent water.

6. Sample Preparation

6.1 *Preparation*:

6.1.1 *For Nominal Maximum Aggregate Sizes 25.0 mm or Greater*:

Use a jaw crusher or hammer, and reduce the sample so that the particles pass a 25.0-mm sieve and are representative of the sample. Use a sample splitter or use coning and quartering to reduce the sample to between 200 and 500 g. Do not crush the sample to a powder. Oven dry the reduced sample at 110 ± 5°C for 2 h.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:24 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.1.2 *For Nominal Maximum Aggregate Sizes Less Than 25.0 mm* :

Use a sample splitter or use coning and quartering to reduce the sample to between 200 and 500 g. Do not crush the sample to a powder. Oven dry the reduced sample at 110 ± 5°C for 2 h.

7. Procedure

7.1 Mix and cone the reduced sample three times before sampling each replicate. Obtain a minimum mass of 30.0 g of the sample by sampling from at least four points, record the mass to the nearest 0.01 g, and transfer it to the porous sample holder of the Soxhlet extractor. Place at least 200 mL of reagent water in the lower flask. Conduct this procedure in triplicate. Make a blank determination by using the Soxhlet apparatus, with thimble but containing no sample.

NOTE 2—Replicate sample size can be larger than 30 g; however, the top of the sample in the thimble needs to be kept below the top of the siphon to properly extract the sample with solution. The sample will include aggregate particles and the fines produced by crushing.

7.1.1 Place the top of the thimble above the top of the glass tube regulating the level at which the water siphons off. Do not completely fill the thimble with the sample. Assemble the condenser complete with cooling water supply tubing to the extractor and place on the heater. Turn on both the heater and condenser cooling water and allow extraction to continue for 24 h; the heating rate shall be adjusted to give a cycle every 20 ± 5 min. The number of cycles shall be not less than 70. One cycle consists of the thimble filling with solution and discharging.

NOTE 3—Larger-sized Soxhlet apparatus are available; however, the cycle times will be longer and the total extraction time for 70 cycles will be about 1.5 to 3 days.

7.1.2 At the conclusion of the extraction stage, quantitatively transfer the solution to a 400-mL beaker by rinsing the boiling flask three times with 10 mL of reagent water, and transferring the washings to the beaker. Add 3 ± 0.1 mL of nitric acid that has been diluted one-on-one with water, and add 3 ± 0.1 mL 30 % solution hydrogen peroxide, to the extract. Using pH paper, determine the pH of the solution. If the pH of the solution is more than 2, add additional 1:1 nitric acid until the pH is less than 2. Cover the beaker with a watch glass. Add a stirring bar composed of polytetrafluoroethylene (PTFE) and allow to stand for 1 to 2 min. While stirring, heat the covered beaker rapidly to boiling. Do not boil for more than a few seconds. Remove from the hot plate.

NOTE 4—It is important to keep the beaker covered during heating and digestion to prevent the loss of volatile chloride.

7.1.3 Proceed in accordance with the reference test method for chloride in Test Methods C 114, starting with the procedure that follows removal of the sample from the hot plate.

8. Calculation and Reporting

8.1 Calculate percent chloride by mass of oven-dry aggregate by the reference test method for chloride in Test Methods C 114.

8.2 Report both the individual and average values of Soxhlet extracted chloride content.

8.3 The report shall state whether the sample was fractured or not fractured during preparation for testing.

9. Precision and Bias

9.1 *Precision*:

9.1.1 The single-laboratory standard deviation has been found to be 0.0004 % [8] chloride by mass of aggregate. Therefore, two acceptable test results are not expected to differ by more than 0.0015 %.

9.1.2 The multilaboratory standard deviation has been found to be 0.0006 % [8] chloride by mass of aggregate. Therefore, acceptable results obtained in two different laboratories are not expected to differ by more than 0.0020 %.

9.2 *Bias*—The procedure in this test method has no bias because the value of Soxhlet-extracted chloride is defined by the procedure (see Practice C 670).

10. Keywords

10.1 aggregate; chloride content

[8] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

APPENDIX

(Nonmandatory Information)

X1. Summary of Soxhlet Round Robin Precision Testing

X1.1 Round robin testing to determine within-laboratory and between-laboratory precision of the Soxhlet method was performed by six laboratories. Each laboratory was provided with three aggregates to analyze, two containing integral chloride and one aggregate containing chloride absorbed from a marine environment. The aggregates were analyzed as received using the Soxhlet method. The results of the interlaboratory study are found in Tables X1.1-X1.3.

NOTE X1.1—Data from Aggregate C was not used to calculate within-laboratory and between-laboratory precision.

X1.2 The Soxhlet method is intended for the analyses of limestone aggregates that contain a large amount of chloride that is encapsulated or integral within the aggregate shell. These are primarily aggregates from the Niagara Escarpment extending from southern Ontario down through New York,

Designation: C 1529 – 06a

Standard Specification for Quicklime, Hydrated Lime, and Limestone for Environmental Uses[1]

This standard is issued under the fixed designation C 1529; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers lime and limestone products and by-product alkaline materials suitable for environmental uses as shown in Table 1.

1.2 The buyer shall designate the use, as listed in Table 1, and may specify one or more of the type designations listed below Table 1.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 50 Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

C 400 Test Methods for Quicklime and Hydrated Lime for Neutralization of Waste Acid

D 6249 Guide for Alkaline Stabilization of Wastewater Treatment Plant Residuals

3. Terminology

3.1 *By-product alkaline materials*—By-product lime (such as lime kiln dust) or other secondary materials (such as high-lime fly ash) that contain adequate amounts and types of calcium and/or magnesium oxides or hydroxides to meet the physical and chemical requirements in this specification. It is advised that the specific compositions, physical properties, performance characteristics, and anticipated variabilities of such materials be evaluated for the service intended.

4. Chemical Composition and Physical Properties

4.1 The requirements for quicklime, hydrated lime, and limestone for the designated end uses are as shown in Table 1, and are on the basis of the weight of sample taken at the place of manufacture.

5. General Requirements

5.1 Quicklime shall be reasonably free of unslakable residues and shall be capable of disintegrating in water to form a suspension of finely divided material. The amount of residue shall not exceed that agreed upon between the manufacturer and the purchaser (the residue is the amount of material retained on a specified screen). The method for measuring quicklime residue appears in Test Methods C 110.

5.2 The slaking rate for the specified quicklime should be matched to the requirements of the slaking equipment. The method for measuring the slaking rate of quicklime appears in Test Methods C 110.

6. Sampling and Inspection

6.1 Conduct the sampling, inspection, rejection, retesting, packaging, and marking in accordance with Practice C 50.

7. Test Methods

7.1 The chemical analyses shall be made in accordance with Test Methods C 25.

7.2 The physical tests shall be made in accordance with Test Methods C 110.

7.3 The basicity-factor tests shall be made in accordance with Test Methods C 400.

8. Keywords

8.1 biosolids; by-product lime; calcium oxide; dolomitic lime; dolomitic limestone; drinking water; environmental; high calcium lime; high calcium limestone; hydrated lime; industrial waste; lime; limestone; magnesian lime; magnesian limestone; neutralization; quicklime; residuals; sewage sludge; stabilization; treatment; waste; wastewater; water; water softening

[1] This specification is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved Nov. 15, 2006. Published November 2006. Originally approved in 2002. Last previous edition approved in 2006 as C 1529 – 06.

		DL[D]	90.0[C]	. . .	. . .	0.56	. . .	. . .
		ML[D]	90.0[C]	. . .	. . .	0.48	. . .	. . .
Wastewater treatment plant residuals stabilization[E]	[F,G,H]	CQ, DQ, MQ	90.0	. . .	. . .	. . .	100	. . .
		CH, DH, MH	90.0[C]	. . .	. . .	. . .	. . .	95
		By-product alkaline materials	25.0[I,J]	. . .	. . .	. . .	100	. . .

CQ = Quicklime, high-calcium
DQ = Quicklime, dolomitic
MQ = Quicklime, magnesian
CH = Hydrated lime, high-calcium
DH = Hydrated lime, dolomitic
MH = Hydrated lime, magnesian
CL = Limestone, high-calcium
DL = Limestone, dolomitic
ML = Limestone, magnesian

[A] In the softening of drinking water, lime is used alone or with coagulant aids to produce a precipitate that assists in the clarification of water, removal of bacteria, and removal of hardness. Lime and soda ash may be used together for softening water. The lime serves as a chemical reagent in water softening. The only useful constituent of the lime is the calcium oxide content of the quicklime or hydrated lime capable of reacting with the other chemicals in the water or added to it. Inert material, besides reducing the value in proportion to its amount, also makes more sludge to be disposed of for a given amount of chemical action and thus reduces the capacity of the equipment in which it is used. In addition to water softening, lime is also used for color removal and clarification of water.

[B] When determining the quantity of liming material for the neutralization of liquid acidic wastes, use is made of an acid value-basicity factor relationship. Acid value and basicity factor test methods are in Test Methods C 400.

[C] On a nonvolatile basis.

[D] Limestone analyses are typically reported as carbonate (CO_3). The requirement that limestone contains a minimum of 90 % CaO + MgO on a non-volatile basis corresponds to approximately 95 % $CaCO_3$+ $MgCO_3$.

[E] Wastewater treatment plant residuals may be referred to as sewage sludge or biosolids.

[F] Also see “Standard Guide for Alkaline Stabilization of Wastewater Treatment Plant Residuals” (D 6249).

[G] Quicklime, hydrated lime, and alkaline by-product materials will raise the pH of biosolids.

[H] If quicklime or by-product alkaline materials containing calcium or magnesium oxide are used, the reaction with water will generate heat. High calcium quicklime will slake more quickly and achieve a higher total temperature rise than other alkaline materials, which generally facilitates treatment. Although slaking rate and total temperature rise are not part of this specification, they are critical site-specific factors that should be matched to the user’s treatment objective and technology. The methods for measuring the slaking rate of quicklime and total temperature rise appear in Test Methods C 110.

[I] Tested on an as received basis.

[J] The available lime index test in Test Methods C 25, which measures only calcium oxide and hydroxide, can be used.

SUMMARY OF CHANGES

Committee C07 has identified the location of selected changes to this specification since the last issue, C 1529 – 06, that may impact the use of this specification. (Approved November 15, 2006)

(*1*) Revised 1.1.

Committee C07 has identified the location of selected changes to this specification since the last issue, C 1529 – 02a, that may impact the use of this specification. (Approved September 1, 2006)

(*1*) Removed by-product hydrated lime from Table 1.

(*2*) Added a Terminology section.

Designation: C 1535 – 05

Standard Practice for Application of Exterior Insulation and Finish Systems Class PI[1]

This standard is issued under the fixed designation C 1535; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers the minimum requirements and procedures for field or prefabricated application of Class PI Exterior Insulation and Finish Systems (EIFS). Class PI EIFS are systems applied over polyisocyanurate insulation board, in which the base coat ranges from not less than 1/16 in. (1.6 mm) to 1/4 in. (6.4 mm) in dry thickness, depending upon the number of nonmetallic reinforcing mesh layers encapsulated in the base coat. The base coat is then covered with a finish coat of various thickness in a variety of textures and colors. The insulation board shall be applied over a substrate or over open framing.

1.2 This practice does not cover Class PI EIFS with drainage. Consult the EIFS producer for information.

1.3 The values stated in inch-pound units are to be regarded as the standard. The SI (metric) values given in parentheses are approximate and are provided for information purposes only.

1.4 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

1.5 *This standard may involve hazardous materials, operations and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

E 1825 Guide for Evaluation of Exterior Building Wall Materials, Products, and Systems

E 2110 Terminology for Exterior Insulation and Finish Systems (EIFS)

3. Terminology

3.1 Definitions used in this standard shall be in accordance with Terminologies C 11 and E 2110.

4. Significance and Use

4.1 This practice provides minimum requirements for the application of Class PI EIFS. The requirements for materials, mixtures, and details shall be contained in the project plans and specifications. See Guide E 1825 for guidance.

[1] This practice is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.05 on Application of Exterior Insulating and Finish Systems and Related Products.

Current edition approved October 1, 2005. Published October 2005. Originally approved in 2002. Last previous edition approved in 2004 as C 1535 – 04.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

5. Delivery of Materials

5.1 All materials shall be delivered in packages, containers, or bundles with the identification and markings intact.

6. Inspection

6.1 Inspection of the materials shall be agreed upon and be a part of the purchase agreement.

6.2 Inspection shall include the determination that the materials supplied are as required for the Class PI EIF System specified. Mixing of materials from different manufacturers is not allowed.

7. Rejection

7.1 Materials that are damaged, frozen or defective shall not be used. Rejection of materials shall be promptly reported verbally to the producer and immediately reported in writing. The notice of rejection shall contain a statement documenting the basis for material rejection.

8. Certification

8.1 When specified in the contract documents, the producer shall furnish a report certifying that the materials are in conformance with product and material standards and contract documents.

8.2 *Insulation Boards*:

8.2.1 Insulation boards shall be in compliance with Specification C 1289 , Type II, Class 2.

8.2.2 Insulation boards shall have been subjected to a third party quality control inspection and shall be marked as approved for use within the EIFS and in accordance with applicable building code.

8.2.3 Prior to installation, the insulation board shall be inspected for conformance with contract documents. Nonconforming insulation board shall not be used.

8.2.4 The insulation board producer shall furnish, for each shipment, a written certificate of conformance with the EIFS producer's specifications.

9. Storage of Materials

9.1 All materials shall be kept dry by storage under cover and protected from the weather. When outside storage is required, materials shall be stacked off the ground, supported on a level platform and protected from the weather, surface contamination or physical damage in accordance with the EIFS producer's written instructions.

9.2 Materials shall be protected from exposure to direct sunlight and temperatures less than 40 °F (4 °C) unless otherwise specified by the manufacturer.

9.3 Portland Cement shall meet Specification C 150 and shall be kept dry until ready for use. It shall be kept off the ground, under cover and away from damp walls and surfaces.

9.4 Insulation board shall be stacked flat with care taken to avoid damage to edges, ends, or surfaces; or exposure to direct sunlight (ultraviolet radiation).

10. Environmental Conditions

10.1 *Cold Weather Conditions*:

10.1.1 Wet materials shall not be applied when the temperature is less than 40 °F (4 °C) unless otherwise specified by the manufacturer or unless temporary heat and enclosures are provided to maintain minimum 40 °F (4 °C) for a minimum period of not less than 24 hours before, during and after application. (See X1.8.3)

10.1.2 Materials shall not be applied to a base containing frost. Substrate surface temperature shall be not less than 40 °F (4 °C). Mixtures for application shall not contain any frozen ingredients.

11. Assessment of Condition of Substrates to Receive Exterior Insulation and Finish Systems

11.1 The substrate shall be as required by the project plans and specifications and as recommended by the EIFS producer for the particular system specified.

11.1.1 Polyisocyanurate boards for use over open framing in conformance with the EIFS producer's specification shall not be less than 1.0 in. (25.4 mm) in thickness.

11.1.2 Polyisocyanurate boards for use over a substrate in conformance with the EIFS producer's specification shall not be less than ⅝ in. (15.9 mm) in thickness.

NOTE 1—Polyisocyanurate board thickness shall conform to building code requirements.

11.2 The substrate shall be inspected by the applicator and general contractor to assure that it meets the project plans and specifications and the requirements of 11.3-11.8.

11.3 Sheathing materials shall be inspected to ensure the following:

11.3.1 The specified sheathing thickness has been installed for the stud spacing used.

11.3.2 Fastener type and fastener spacing are as specified.

11.3.3 All Specification C 79/C 79M gypsum sheathing boards have a water-resistant treated core.

11.3.4 Tongue and groove water-resistant core gypsum sheathing boards conforming to Specification C 79/C 79M are installed with the tongue edge oriented to the top.

11.3.5 Gypsum sheathing shall be installed with the face paper exposed in accordance with Specification C 1280.

11.3.6 Gypsum sheathing shall be protected from moisture at all penetrations and terminations.

11.3.7 Glass mat gypsum sheathing complying with Specification C 1177 shall be installed in accordance with the sheathing producer's written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheathing orientation and spacing.

11.3.8 Plywood shall be not less than ½ in. (12.7 mm) nominal in thickness, exterior or exposure 1 panel sheathing. The plywood shall be installed with a ⅛ in. (3.2 mm) space between sheets at edges and ends.

11.3.9 Fiber-Cement sheets complying with Specification C 1186, Type A, shall be installed in accordance with the sheet producer's written installation instructions, which include details of stud type and spacing, fastener type and spacing, and sheet spacing recommendations.

11.3.10 Water-resistant exterior fiber-reinforced gypsum sheathing complying with Specification C 1278/C 1278M shall be installed in accordance with the sheathing producer's

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:35:31 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheathing orientation and spacing.

11.3.11 Fiber-mat reinforced cement sheets complying with Specification C 1325, type A, shall be installed in accordance with the sheet producer's written installation instructions, which include details of framing type and spacing, fastener type and spacing, and sheet orientation and spacing.

11.3.12 Sheathing shall be continuous.

11.4 *Alignment*—All substrate surfaces shall be straight and true within ¼ in./10 ft (2 mm/m). More stringent requirements by the EIFS producer shall supersede the above stated requirements.

11.5 *Suitability for Use*—The substrate shall be firm, sound, and undamaged in order to receive the EIFS.

11.6 *Cleanliness*—The surface of all substrates shall be clean and free from any foreign materials such as paint, form release agents, curing compounds, dust, dirt, frost, oil or grease, efflorescence and laitance that would affect the EIFS application.

11.7 *Dryness*:

11.7.1 Newly constructed concrete or masonry surfaces shall be allowed to cure not less than 28 days prior to application of the EIFS. Repaired areas on existing (aged) walls shall meet the same 28-day curing time.

11.7.2 Substrate surfaces shall be free of visible water.

11.8 *Metal Lath or Furring and Accessories*—If metal lath or furring and accessories are used, they shall be installed in conformance with Specification C 1063, except lath edges and ends shall be butted and not lapped. Metal lath shall be 3.4 lb/yd^2 (1.3 kg/m^2) self-furring, galvanized.

11.8.1 Metal members shall be properly attached, straight, and true unless otherwise required by the system design.

11.8.2 Metal members shall be free of rust, oil, or other foreign matter or contaminants, which cause bond failure or unsightly discoloration.

12. Insulation Board Installation

12.1 Method of Attachment shall be approved by the system producer and be in accordance with applicable building code.

12.2 *Mechanical Attachment Method*:

12.2.1 Mechanical fasteners shall be installed into the framing or nailable substrate.

12.2.2 Mechanical fasteners shall be corrosion resistant. Fastener type and spacing shall be in accordance with system producer's current published instructions.

NOTE 2—Specific consideration of building code wind load requirements shall be given for mechanically fastened systems.

12.3 Placement of a weather resistive barrier, if specified, shall be as required by the system producer.

13. General Requirements

13.1 Insulation boards shall be placed from a level base line with vertical joints staggered in a running bond pattern and butted tightly. Over open framing, joints shall occur over framing or horizontal blocking.

13.2 Insulation board joints at all inside and outside corners shall be staggered and interlocked.

13.3 Insulation boards must abut without gaps, eliminating space for base coat intrusion between the board edges and ends.

13.4 Fenestration opening corners and other wall penetrations shall be cut out of a single insulation board. Board joints shall not be aligned at corners with head, sill or jambs of windows, doors, similar openings, and aesthetic reveals.

13.5 *Mechanically Fastened*:

13.5.1 Insulation board joints shall be offset from sheathing board joints.

13.5.2 When the boards are attached only with mechanical fasteners, they shall be affixed to a nailable substrate or structural members with the proper fasteners, ensuring that all boards abut tightly. Fastening pattern shall be in accordance with the EIFS producer's recommendation and local building code requirements. When installed, the washer shall be left flush with the face of the insulation board and shall not fracture the face or core of insulation board.

14. Aesthetic Reveals

14.1 Aesthetic reveals shall be cut into the insulation board prior to applying the reinforcing mesh.

14.2 The insulation board thickness at the bottom of a reveal shall be not less than ¾ in. (19.0 mm). Over open framing, aesthetic reveals shall occur over framing or blocking.

14.3 Aesthetic reveals shall be cut true and straight.

14.4 Horizontal aesthetic reveal configuration shall provide for outward positive drainage.

14.5 Aesthetic reveals shall not occur at the abutment of two pieces of insulation board.

14.6 The reveal shall be reinforced with base coat and reinforcing mesh prior to application of the full base coat and reinforcing mesh.

15. Reinforced Base Coat Application

15.1 Inspect the insulation board surface to ensure that it is clean, dry, free of all foreign materials, and damage of any type. Insulation board planar irregularities of more than 1/16 in. (1.6 mm) shall be corrected. All board joints shall be tightly abutted or shall be filled with an insulating material.

15.2 *Base Coat Preparation*—All materials requiring field preparation shall be mixed in accordance with the EIFS producer's specifications.

15.3 *Base Coat Application*—The prepared base coat shall be uniformly spread over the entire surface of the insulation board.

15.4 *Non Metallic Reinforcing Mesh*—The single layer reinforcing mesh shall be fully encapsulated in the field of the wall, at corners, edges, and joints. Trowel from the center to the edge of the reinforcing mesh to avoid wrinkles. The single layer reinforcing mesh shall be continuous at all corners.

15.4.1 The surface shall be free of voids, projections, trowel marks and other surface irregularities. The base coat thickness shall be not less than 1/16 in. (1.6 mm) dry as measured from the surface of the insulation board. The base coat shall be applied in two applications unless otherwise recommended by the EIFS's producer.

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE 3—The recommended method is to apply the base coat in two applications.

15.5 *Reinforcing Mesh Overlap*—All reinforcing mesh edges shall be overlapped not less than 2 ½ in. (64 mm).

15.6 *Impact Layers*—When required, higher impact performance shall be achieved with multiple layers of reinforcing mesh or by incorporating heavier weight reinforcing mesh. All areas requiring higher impact performance shall be detailed on the project plans and specifications. When overlapping of high impact mesh is not required, a complete second layer of reinforcing mesh shall be applied over the layer of high impact mesh.

15.7 *Corners*—Reinforcing mesh shall not be lapped within 8 in. (200 mm) of any corner.

15.8 *Wall Penetrations*—All edges of the insulation board at penetrations of the EIFS, such as at windows, doors, HVAC sleeves, pipes, ducts, electrical boxes, and at the base of the wall shall be wrapped with either the base coat and reinforcing mesh or trim, or as specified by the project plans and specifications. Wall openings such as doors, windows, HVAC sleeves, shall be diagonally reinforced at corners with mesh not less than 9 in. (230 mm) by 12 in. (305 mm).

15.8.1 The corners of returns to windows, doors, and similar wall openings shall have reinforcing mesh the full width of the return and extending not less than 2½ in. (64 mm) on both sides of the corner.

15.9 *Expansion Joints*—All edges of the insulation board at expansion joints shall be wrapped with either the base coat and reinforcing mesh or trim as specified by the EIFS producer for the particular EIFS. The reinforcing mesh shall be fully encapsulated.

15.10 *Aesthetic Reveal*—The reinforcing mesh shall be continuous and care shall be taken to ensure that the reinforcing mesh is fully encapsulated into the reveal and that the reinforcing mesh shall not be cut during application of the base coat.

15.11 *Reinforced Base Coat*—The reinforcing mesh shall be fully encapsulated in the base coat throughout the field of the wall, at corners, edges, and joints. The surface shall be free of voids, projections, trowel marks and other surface irregularities.

15.12 *Special Insulation Shapes*—When special insulation shapes are installed over EIFS, nonmetallic reinforcing mesh encapsulated in the base coat shall be used to cover the shape.

16. Finish Coat Application

16.1 The reinforced base coat shall be allowed to dry and harden for not less than 24 h prior to finish coat application unless specifically allowed by the EIFS producer.

16.2 *Material Preparation*—The finish coat shall be mixed in accordance with the EIFS producer's specifications. Only clean potable water shall be added to adjust workability. Always add the same amount of water to each container within a given lot of finish.

16.3 *Execution*—Finish shall be applied with a stainless steel trowel or appropriate equipment as specified by the EIFS producer. Tools and equipment shall be kept clean at all times. Finish shall be applied continuously to a natural break such as corners, joints or tape line. Apply finish to the base coat maintaining a wet edge. Sufficient manpower and scaffolding shall be provided to continuously finish a distinct wall area. Scaffolding shall be spaced a distance from the wall, consistent with safety standards, that will allow uniform texturing of the finish without staging marks. On hot windy days, misting is permitted with clean, potable water to cool the wall. Work shall precede the sun whenever possible. Water shall not be added to the finish once it is applied to the wall. Use the same tool and hand motion and match the texture of the surrounding area. The finish coat thickness shall be as specified by the EIFS producer. Protect all finish work from damage until fully dried.

16.4 *Sealant Joints*—The application of finish into the sealant joint is not allowed.

17. Curing Time Between Application Steps

17.1 Manufacturer's recommendations for climatic conditions, mixing and application practices to allow respective coats sufficient time to cure or dry before any subsequent coats are applied shall be followed. Each application step shall be cured or dried to prevent degradation to the system integrity with subsequent steps.

17.2 Auxiliary protection (tenting, supplemental heat, shading) from adverse environmental conditions shall be utilized to provide curing and drying conditions as recommended by the producer (see X1.8).

17.3 All substrates shall be sound and cured or dry before continuing on to the next application step.

18. Clean Up

18.1 Adjacent materials, surfaces and the work area shall be cleaned of foreign materials resulting from the work.

18.2 All excess EIFS materials shall be removed from the job site.

19. Keywords

19.1 Class PI; EIFS; exterior insulation and finish system

APPENDIXES

(Nonmandatory Information)

X1. GENERAL INFORMATION

INTRODUCTION

These appendixes give general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this practice.

X1.1 General

X1.1.1 The work includes all labor, materials, services, equipment and scaffolding required to complete the EIFS installation on the project in accordance with the project drawings and specifications, except electrical power and potable water.

X1.1.2 Where a specific fire resistance rating is required for the EIFS assemblies and construction, details of construction shall be in accordance with official reports of tests conducted by recognized testing laboratories and a part of approved plans and specifications.

X1.1.3 The installation of the EIFS is to be coordinated by the owner's authorized agent with work of other trades.

X1.1.4 Surfaces and accessories to receive EIFS components shall be examined and accepted as provided in 11.2 before the EIFS components are installed thereto. The proper authorities shall be notified about unacceptable conditions. The unsatisfactory conditions shall be corrected prior to the application of the EIFS components. Unsatisfactory conditions shall be corrected by the party or parties responsible for such conditions.

X1.1.5 The construction specifier shall describe, in the proper section of the project specifications, the physical characteristics of the surfaces to receive the EIFS.

X1.2 Design Considerations

X1.2.1 EIFS are attached to outside surfaces of all types of structures to provide weather resistant, energy efficient, and durable claddings. The claddings will be subjected to various exposures such as abrasion, vibration, moisture, freezing, thawing, negative and positive wind loading , ultraviolet light, acid rain, thermally induced expansion and contraction, and impact.

X1.2.2 Provide sufficient slope on faces of EIFS surfaces to prevent water, snow or ice from accumulating or standing. A minimum 6 in. (152 mm) in 12 in. (305 mm) (1:2) pitch is recommended. Length of sloped surfaces shall not be more than 12 in. (305 mm).

X1.2.3 Provide parapet cap made only from corrosion resistant materials. The parapet cap shall extend not less than 2½ in. (64 mm) over the faces of the EIFS, not including wood blocking and include a drip edge detail. Detailed requirements for furnishing and installing the parapet cap shall be in the appropriate section of the project specifications. Parapet caps shall be clearly shown in large scale details. Parapet caps shall be installed as soon as practical after the installation of the EIFS.

X1.2.4 Provide for sealing of expansion joints, panel joints, system terminations and all interfaces of the EIFS with other building components.

X1.2.5 At soffits, window and door heads provide for a drip edge.

X1.2.6 Windows installed in EIFS walls shall have a sill pan flashing of corrosion-resistant material.

X1.2.7 The specifier shall evaluate the potential of the EIFS surface being subjected to abnormal stresses or impacts.

X1.2.8 Wall assemblies have properties that in certain applications make a dew point analysis critical to ensure successful performance of the wall system. The specifier shall evaluate these conditions.

X1.2.9 Sheathing must be continuous over floor slabs, intersecting walls, columns, beams and similar constructions. The EIFS shall not be installed over areas without sheathing. If the sheathing cannot be continuous, the installation of expansion joints shall be considered.

X1.2.10 Where the sheathing is interrupted or out of plane, corrections must be made prior to EIFS application.

X1.2.11 A weather resistive barrier and flashings may be required and specified in moisture and water sensitive construction. The EIFS producer, architect, and specifier shall evaluate the conditions and determine the need.

X1.3 Relief From Stress

X1.3.1 Where the EIFS and dissimilar types of substrates, materials and building components interface, provide for appropriate size and location of expansion joints.

X1.3.2 Where roof elevations change, provide for appropriate size and location of expansion joints.

X1.4 Bonding Agents

X1.4.1 Bonding compounds or agents are sometimes applied to the insulation board surface prior to base coat application. Follow the EIFS producer's instructions and specifications for their use.

X1.5 Mechanical Fasteners

X1.5.1 The types of mechanical fasteners used and the methods of installation will vary depending upon the substrate to which the insulation boards are to be fastened.

X1.5.2 Fastener washers shall be installed flush with the insulation board surface.

X1.5.3 Fastener spacing shall be specified by the design professional consistent with wind load requirements and the local building code on the specific project.

www.technobetar.ir

X1.6 Reinforced Base Coats

X1.6.1 Base coat thickness is permitted to exceed 1/16 in. (1.6 mm) dry depending on the type of base coat used and the impact resistance specified.

X1.6.2 A small amount of base coat shrinkage is normal. Due to color variations, a very slight telegraphing of the reinforcing mesh pattern may appear after the base coat cures. Bare mesh shall not be visible and the mesh pattern shall not be tactile.

X1.6.3 The producer's instructions shall be followed to ensure that the base coat and cement are properly proportioned. The proper portioning of cement-based material is important. Excess cement may cause the base coat to become hard and stiff as the cement hydrates over time.

X1.6.4 The minimum amount of mix water to form a workable mix shall be used. Excess mix water causes the base coat to be porous, less weather resistant, and contribute to shrinkage. Never add more water than recommended by the producer. Measure water in containers of known volume.

X1.6.5 Mix materials only at low speed with paddles designed to reduce air entrapment.

X1.6.6 Generally, when applying 2 layers of mesh, the second base coat layer is applied as soon as the first layer has dried sufficiently to receive the second base coat application. Depending upon material composition and weather conditions, this sometimes occurs within the first 24 h after the completion of the application of the initial base coat, and, in some cases, it will require waiting until the following day.

X1.6.7 Trowel aesthetic reveals and corners with a trowel shaped to fit the profiles.

X1.7 Finish Textures

X1.7.1 Textures, as a description of surface appearance, generally are identified with the method and tools used to achieve the finish appearance. Texture is sometimes varied by the size and shape of the aggregate contained in the finish, equipment or tools employed, the consistency of the finish mix, the condition of the base to which it is applied and by decorative and protective treatments.

X1.7.2 With almost limitless variations possible for finish appearance or texture, the same term sometimes does not have the same meaning to the specifier, contractor or applicator. Sample panels of sufficient size including components and features specified shall be constructed using the methods, tools and techniques to be used in the actual construction. It is recommended that in the case of prefabrication, two panels be constructed. One panel remains at the jobsite. One panel remains at the fabrication site. The samples shall be approved by the architect and owner in writing.

X1.7.3 To provide some guidance, the following categories are generally understood and recognized to imply a particular method of application or finished appearance.

X1.7.3.1 *Sand Finish*—A finish material devoid of coarse aggregate applied in a thin coat completely covering the base coat and floated to a true plane, yielding a relatively fine-textured finish.

X1.7.3.2 *Trowel Texture*—A freshly applied finish is given various textures, designs or stippled effects by hand motion and trowel used. The effects achieved are individualized and it is sometimes difficult for different applicators to duplicate.

X1.7.3.3 *Standard Finish*—A finish with various size aggregates, applied in a thin coat completely covering the base coat and floated in a random pattern. The applicators are cautioned to use the same type texturing tools to help ensure a consistent texture.

X1.7.3.4 *Exposed Aggregate*—Varying sizes of natural or manufactured stone, gravel, shell or ceramic aggregates are embedded by hand or by machine propulsion into a freshly applied "bed coat." The size of the aggregate shall not be more than ½ in. (12.7 mm) diameter. The size of the aggregate determines the thickness of the bedding coat. The bedding coat shall be no less than one-half the thickness of the aggregate to be embedded.

X1.7.3.5 *Spray Texture*—A machine applied finish material. The texture achieved depends on many factors some of which are the consistency of the sprayed mixture, the angle and distance of the spray nozzle to the surface, the pressure of the machine, orifice size used, operator expertise, climatic conditions (wind specifically), and base coat conditions.

X1.7.3.6 *Miscellaneous Types*—Similar to trowel textures except that the freshly applied finish is textured with instruments other than a trowel, such as swept with a broom or brush, or corrugated by raking or combing. A variation of texturing a finish involves waiting until the applied finish has partially dried and then lightly troweling the unevenly applied finish. The effects achieved are sometimes difficult for different applicators to duplicate.

X1.8 Conditions for EIFS Application

X1.8.1 The amount of water used to mix materials is to be within the allowable range published by the EIFS producer. Factors such as the drying conditions and finishing operations must be considered in determining water usage. The applicator is cautioned that the use of excessive water results in fall off or slide off, excessive shrinkage, higher porosity, lower strength, and inconsistent color.

X1.8.2 Timing between coats will vary with climatic conditions and types of materials used. Temperature and relative humidity extend or reduce the curing and drying time. Cold or wet weather lengthens and hot or dry weather shortens the drying period. Moderate changes in temperature and relative humidity are overcome by providing additional heating during cold weather and by pre-wetting the base during hot, dry weather.

X1.8.3 Heated enclosures require adequate air circulation to prevent hot or cold spots that allow too rapid drying or freezing. When using heated enclosures it is important to control the relative humidity as well as the temperature. Maintain relative humidity at not more than 90 %.

X1.8.4 Staining and discoloration of finishes or other building components that are caused by free water draining from one plane to another, dissimilar materials, or other building components, are minimized by providing sufficient depth and angle for drip caps and drip edges.

X2. SEALANT SYSTEMS

X2.1 The size and location of joints and selection of the sealant to be used is the responsibility of the design professional and shall be consistent with project conditions and guidelines of the EIFS producer. See Guide C 1472 for guidance.

X2.2 The sealant system must be tested for compatibility with the specified EIFS by an independent laboratory and found to be compatible with the EIFS. See Test Method C 1382 for guidance.

X2.3 The sealant system is recommended by the EIFS and sealant producer. Non-recommended sealant systems must be jointly approved by the architect and the sealant producer.

X2.4 Base the joint design and surface preparation on the sealant producer's recommendations and project conditions. See Guide C 1481 for guidance.

X2.5 Allow the EIFS material to cure prior to sealant system installation.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this practice since the last issue, C 1535 – 04, that may impact the use of this practice. (Approved October 1, 2005)

(*1*) Added Specification C 1325 to Referenced Documents.

(*2*) Added new paragraph 11.3.11.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1542/C 1542M – 02

Standard Test Method for Measuring Length of Concrete Cores[1]

This standard is issued under the fixed designation C 1542/C 1542M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the length of a core drilled from a concrete structure when the reason is other than measuring dimensional tolerances of concrete elements.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete[2]

C 174 Test Method for Measuring Thickness of Concrete Elements Using Drilled Concrete Cores[2]

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials[2]

3. Significance and Use

3.1 This test method provides two procedures for determining the length of a core as measured along its axis. This length is used in conjunction with length to diameter relationships, condition surveys, absorption, density and voids analysis, petrography, cement content analysis, and other applications. It does not meet requirements for determining the distance between two parallel surfaces, which represents the thickness of a structural element often used to establish compliance with design specifications as outlined by Test Method C 174.

4. Apparatus

4.1 *Jaw Caliper*, depth of jaw 65 mm [2.5 in.]. Measuring range 0 to 300 mm [0 to 12 in.]. Accuracy to 0.03 mm [0.001 in.].

4.2 *Ruler*, 300 to 380 mm [12 to 15 in.] divided into 1 mm [1⁄16 or 0.1 in.] graduations.

5. Procedure

5.1 *Jaw Caliper Procedure*:

5.1.1 Hold the specimen and place the open jaws of the caliper midpoint between the center and edge of the specimen. Measure and record the value to the nearest 0.25 mm [0.01 in.]. Rotate the specimen 90º, 180º, and 270º and repeat procedure. Obtain one measurement across the center of the specimen and record.

5.2 *Ruler Procedure*:

5.2.1 Position core with finished or formed face placed down against flat and level surface. Place ruler on flat surface against side of core and measure length to nearest 1 mm [1⁄16 or 0.1 in.] and record. Rotate core and repeat measurements at approximately 90º, 180º, and 270º.

NOTE 1—This procedure does not intend to include in the length measurement adhered pieces of material not part of the original concrete mixture.

6. Report

6.1 *Jaw Caliper*—Average five measurements and report to nearest 1 mm [0.1 in.].

6.2 *Ruler*—Average four measurements and report to nearest 1 mm [0.1 in.].

7. Precision and Bias

7.1 *Precision*:

7.1.1 With-and between-lab precision of the jaw caliper and ruler procedures was estimated from the results of an interlaboratory study that included 12 laboratories, each measuring three times a core from each of three concretes. The length of the cores ranged approximately from 64 to 117 mm [2.5 to 4.6 in.]. A report of the results of the interlaboratory study is available from ASTM International Headquarters.[3]

7.1.2 *Jaw Caliper Procedure*—The single-operator coefficient of variation (1S %)[4] has been found to be 1.02 %, therefore, two measures of the same core should not differ by

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.69 on Miscellaneous Tests.

Current edition approved Aug. 10, 2002. Published October 2002.

[2] *Annual Book of ASTM Standards*, Vol 04.02.

[3] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1024.

www.technobetar.ir

more than 2.89 % (D2S %)[4] of the mean length of the core. The between-laboratory coefficient of variation (1S %)[4] has been found to be 1.60 %, therefore, two measures of the same core by two different laboratories should not differ by more than 4.23 % (D2S %)[4] of the mean length of the core.

7.1.3 *Ruler Procedure*—The single-operator coefficient of variation (1S %)[4] has been found to be 1.94 %, therefore, two measures of the same core should not differ by more than 5.43 % (D2S %)[4] of the mean length of the core. The between-laboratory coefficient of variation (1S %)[4] has been found to be 4.35 %, therefore, two measures of the same core by two different laboratories should not differ by more than 12.18 % (D2S %)[4] of the mean length of the core.

7.2 *Bias*—Since there are not acceptable reference cores suitable for determining the bias of these procedures, no statement on bias is being made.

8. Keywords

8.1 concrete; core; jaw caliper; length; ruler

Designation: C1543 – 09

Standard Test Method for Determining the Penetration of Chloride Ion into Concrete by Ponding[1]

This standard is issued under the fixed designation C1543; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method determines the penetration of chloride ion into concrete from a sodium-chloride solution pond. This method is applicable to all types of concrete, as well as to concretes treated with systems such as sealants, penetrating sealers, or thin-bonded overlays.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C125 Terminology Relating to Concrete and Concrete Aggregates

C192/C192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C672/C672M Test Method for Scaling Resistance of Concrete Surfaces Exposed to Deicing Chemicals

C1152/C1152M Test Method for Acid-Soluble Chloride in Mortar and Concrete

C1202 Test Method for Electrical Indication of Concrete's Ability to Resist Chloride Ion Penetration

2.2 *AASHTO Standard:*

T 259 Method of Test for Resistance of Concrete to Chloride Ion Penetration

3. Terminology

3.1 Terms used in this standard are defined in Terminology C125.

4. Summary of Test Method

4.1 A sodium-chloride solution is ponded on the surface of concrete specimens. Samples from specified depths are periodically extracted and chemically analyzed to determine the chloride content of the concrete at those depths. The curing and moisture conditioning to which a specimen is subjected prior to ponding affects the mechanisms involved in chloride-ion penetration. These factors must be considered carefully in interpreting the results. Information on the mechanisms of chloride penetration into concrete is given in the appendix.

5. Significance and Use

5.1 This test method is suitable for evaluation of materials and material proportions for construction purposes as well as for research and development.

5.2 This test method can be used to establish the correlation between indirect measures of the chloride-ion penetration of concrete (see Test Method C1202) and the actual chloride-ion penetration under controlled conditions.

5.3 This test method is not intended to provide a measure of the length of service that may be expected from use of a specific concrete mixture or sealing material.

6. Apparatus

6.1 *Glass Plates or Polyethylene Sheets*, of sufficient size to cover the ponded surface of the specimen.

6.2 *Molds*, of the proper size for the test specimens to be used, and conforming to the applicable requirements of Practice C192/C192M.

7. Reagents

7.1 *Ponding Solution*—3 % reagent grade sodium chloride (NaCl) by mass in distilled water (see Note 1).

NOTE 1—Other chloride-bearing solutions or different sodium-chloride concentrations may be used when there is a need to evaluate their specific effects. The concentration of the solution can be checked using a hydrometer calibrated to indicate the mass fraction of sodium chloride.

8. Specimens

8.1 Use as ponding specimens in this test method slabs having a surface area of at least 0.030 m^2 and a thickness of 90 ± 15 mm. At least two replicate specimens shall be made for each combination of variables to be tested.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.66 on Concrete's Resistance to Fluid Penetration.

Current edition approved Dec. 15, 2009. Published February 2010. Originally approved in 2002. Last previous edition approved in 2002 as C1543–02. DOI: 10.1520/C1543-09.

www.technobetar.ir

8.2 Fabricate and cure molded ponding specimens in accordance with applicable sections of Test Method C672/C672M, unless otherwise specified.

8.3 Obtain a sample of concrete for use in determining the background chloride content. Cast a 100 by 200-mm cylinder from the concrete mixture for this purpose when fabricating ponding specimens.

8.4 Provide a dike approximately 20 mm high along the perimeter of the top surface of the specimen to retain the ponding solution. The dike shall be made of a material that adheres to the specimen or be integrally cast as a part of the specimen. It shall serve to keep the top of the specimen covered completely by ponding solution throughout the period of the ponding (see Note 2).

NOTE 2—Closed-cell polystyrene foam 12 to 25 mm thick and acrylic strips 6 mm thick, bonded to the specimen with an adhesive caulking compound or silicone sealant, have been used successfully.

8.5 Coat the sides of the specimens with a suitable material (see Note 3) to prevent lateral moisture migration. Do not coat the bottom of the specimen. Allow the coating to cure according to the manufacturer's instructions.

NOTE 3—A rapid setting epoxy sufficiently viscous to adhere to vertical surfaces without excessive running has been used successfully for this purpose.

9. Procedure

9.1 Following completion of curing, cover the surface of the specimen with the ponding solution to a depth of 15 ± 5 mm.

9.2 Place a glass plate or polyethylene sheet over the ponded specimen to retard evaporation of water from the solution.

9.3 Store the ponded specimens at 23.0 ± 2°C and 50 ± 5 % relative humidity. Provide for air circulation across the bottom of specimens.

9.4 Periodically monitor the depth of solution on the surface of the specimen and maintain at the specified depth by adding additional fresh solution. At 2-month intervals during the ponding, remove the solution and replace with fresh solution.

9.5 Select the duration of the ponding period and the sampling intervals to be appropriate for the purposes for which the tests are being made (see Note 4).

NOTE 4—It is recommended that the initial sampling be performed after 3 months ponding. Subsequent sampling can be performed after 6 and 12 months of ponding and at 12-month intervals thereafter.

9.6 *Sampling*:

9.6.1 Prior to sampling, remove the ponded solution and allow the specimen surface to dry. After drying is completed, remove the salt crystals from the surface by brushing with a wire brush.

9.6.2 Sample the specimen by coring. The diameter of the core shall be at least three times the nominal maximum aggregate size.

9.6.3 Alternatively, obtain powdered sample by rotary-impact hammer as described in Test Method C1152/C1152M.

9.6.4 Space the sampling point at least 25 mm away from the inside edge of the dike or the edge of any previous sampling point. Samples shall be obtained from at least the following depths to provide a profile of the chloride penetration:

Sampling Intervals, mm
10–20
25–35
40–50
55–65

9.6.5 If the purposes of the test require a precise profiling of the chloride penetration, the sampling shall be accomplished by removing a core from the specimen. The core shall be profiled by precision milling to obtain powdered concrete from horizons of the desired depth and thickness (see Note 5).

NOTE 5—Chloride penetration profiling on 1-mm thick horizons has been accomplished using this technique. An equation can then be fitted to the profile to calculate an effective diffusion coefficient using Fick's Second Law.[3] If a diffusion coefficient is to be calculated, at least 6 test points should be obtained.

9.6.6 If the specimen is to be re-ponded after sampling, patch the hole with a suitable low-permeability repair material (see Note 6). The location of the sampling point shall be clearly identifiable so it can be avoided during subsequent sampling.

NOTE 6—Epoxy mortar has been used successfully for this purpose.

9.7 Determine the chloride content of the sample from each depth of the ponded specimens and the background sample in accordance with Test Method C1152/C1152M. The background chloride content is subtracted from the value obtained for each depth of the ponded specimen to determine the penetrated chloride value.

10. Report

10.1 Report the following information:

10.1.1 Type and source of hydraulic cements,

10.1.2 Type and source of other cementitious materials,

10.1.3 Type and source of coarse and fine aggregates,

10.1.4 Type and source of chemical admixtures,

10.1.5 Concrete mixture proportions,

10.1.6 Type and manufacturer of any treatment system used,

10.1.7 Curing conditions and duration and other special specimen preparation procedures that were performed,

10.1.8 The moisture conditioning the specimen was subjected to prior to ponding,

10.1.9 The type and concentration of the ponding solution, if different from that specified in 7.1,

10.1.10 The chloride content of the specimen as a function of depth and the duration of ponding for each sample tested, and

10.1.11 The background chloride content of the concrete.

11. Precision and Bias

11.1 *Precision*—The precision of this test method has not been determined, but the subcommittee is planning to determine the precision in the future.

11.2 *Bias*—No information can be presented on the bias of the procedures in this test method because no material having an accepted reference value is available.

12. Keywords

12.1 chloride; chloride content; concrete; penetration; permeability

APPENDIX

(Nonmandatory Information)

X1. MASS TRANSFER IN CONCRETE

X1.1 This test measures the chloride-ion content at selected depths within a concrete specimen on which a sodium-chloride solution has been maintained over an extended period of time. Differences in the chloride-ion content with depth and over time indicate the movement of chloride ions from the solution ponded on the concrete surface into the specimen being tested. Several different mechanisms are involved to greater or lesser degrees in this transport, depending on the pore structure, moisture condition, and surface treatment of the specimen.

X1.1.1 Permeability is the characteristic that describes the ease with which a fluid moves through concrete.[4] The primary controlling parameter in concrete permeability is the pore system of the paste fraction of the concrete, including the paste-aggregate interface.[3] The connectivity of the pore system depends on the amount of original mixing-water-filled space and the degree to which it has been filled with hydration products. Capillary pores are those voids remaining that were originally filled with mixing water; that is, pores with diameters in the range of 3.2 to 3,000 nm.[5] These capillary pores will cease to be connected at different times in the age of the concrete as a function of w/c and curing conditions.[6] If stored moist, these times are approximately:

w/c	0.4	0.5	0.6	0.7	>0.7
Time	3 d	14 d	6 m	1 y	never

X1.1.2 Concretes containing a pozzolan or ground granulated blast-furnace slag show a continued decrease of pore size and continuity over a longer period of time than do portland-cement concretes not containing pozzzolans or slag.

X1.1.3 Fluid movement in the capillary-pore system depends on the moisture condition of the pore system. When the concrete is at or near saturation, movement is due to laminar flow. The rate of flow depends on the pressure head causing the flow (in this case, gravity) and the tortuosity of the interconnected pore space. As the partial vapor pressure (relative humidity) falls below 1 to a value of about 0.45, vapor diffusion and capillary tension (absorption and wicking) dominate moisture movement. At partial vapor pressures below 0.45, movement is controlled by adsorption and surface diffusion.[3]

X1.1.4 In conditions of incomplete saturation where part of the capillary system is exposed to the atmosphere and the other to water, capillary tension is most important in the movement of water from the saturated zone into the unsaturated zone. In this test method, capillary tension plays an important role in initial chloride penetration if the specimen is subjected to drying prior to ponding. However, even if the specimen is saturated when subjected to ponding, exposure of the non-ponded bottom surface to the atmosphere will result in drying. As a consequence, moisture from the interior will be drawn by capillary tension toward the bottom surface, increasing the flow from the sodium-chloride solution pond.

X1.1.5 Ionic diffusion is the movement of ions through a solution. In this test method, the driving mechanism for chloride-ion diffusion is the concentration gradient between the sodium-chloride solution pond and the interior of the concrete. Most concrete structures have sufficient moisture in the pore system to allow for the diffusion of dissolved ions even though the internal relative humidity is less than 100 %.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C1543–02, that may impact the use of this test method. (Approved December 15, 2009)

(*1*) Revised 9.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1546 – 02 (Reapproved 2008)ε1

Standard Guide for Installation of Gypsum Products in Concealed Radiant Ceiling Heating Systems[1]

This standard is issued under the fixed designation C 1546; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—The units statement in new subsection 1.2 was added editorially in July 2008.

1. Scope

1.1 This guide[2] provides information for trades installing gypsum products in conjunction with a concealed radiant ceiling heating system constructed from thin sheet flexible radiant heating panels, and for the installation of gypsum products after repair of existing concealed radiant ceiling heating systems constructed from heating cable or thin sheet flexible radiant heating panels.

1.2 The values stated in inch-pound units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 This guide does not purport to address any aspect of concealed radiant heating system design or performance, and is limited to the proper installation of gypsum products specified for use in a concealed radiant ceiling heating system.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use.*

1.5 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 840 Specification for Application and Finishing of Gypsum Board

C 841 Specification for Installation of Interior Lathing and Furring

C 842 Specification for Application of Interior Gypsum Plaster

3. Terminology

3.1 *Definitions:*

3.1.1 *concealed radiant heating system*, *n*—a system that operates by heating the building materials that conceal the heat source, which in turn transfer the heat into the heated area by radiant emission.

3.1.2 *facing*, *n*—the finished surface layer through which heat is transferred into a heated area.

3.1.3 *flexible radiant heating panel*, *n*—a thin sheet heating element intended to produce heat when connected to an electrical supply.

3.1.4 *furring*, *n*—spacer elements added to a building structure to facilitate fastening of gypsum panel products.

3.1.5 *gypsum product*, *n*—building material intended for use in radiant heated ceiling construction, containing gypsum in its composition or construction.

3.1.5.1 *Discussion*—The gypsum products most often associated with radiant heating systems are gypsum board and gypsum plaster.

3.1.6 *heating cable*, *n*—an electrically insulated cable intended to produce heat when connected to an electrical supply.

4. Significance and Use

4.1 The purpose of this guide is to provide information to gypsum product installers for the avoidance of hazards associated with the installation of gypsum products adjacent to, or surrounding, electric heating components and conductors; and to avoid damage to gypsum products when used in conjunction with a concealed radiant heating system.

4.2 The information given in this guide is applicable to repair of existing cable heating systems and to new construction of radiant heating systems constructed from flexible radiant heating panels.

[1] This guide is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.03 on Specifications for the Application of Gypsum and Other Products in Assemblies.

Current edition approved May 1, 2008. Published July 2008. Originally approved in 2002. Last previous edition approved in 2002 as C 1546 – 02.

[2] The first edition of this guide replaced Appendix X.7 of Specification C 840 - 99a.

5. Summary of Guide

5.1 *Heating System Design*:

5.1.1 The heating system shall be designed to satisfy the heating needs of the building and to work effectively with all building materials specified for use in the heating system installation.

NOTE 1—The architect bears the responsibility of preparing and correlating complete plans and specifications, and to engage a professional familiar with the heating system to design the system to meet the requirements of 5.1.1 and 5.1.2.

5.1.2 The heating system shall be designed so that a gypsum product is not exposed to a temperature more than 125°F (52°C) for periods of time sufficient to cause calcination.

NOTE 2—The foregoing requirement is intended to provide guidance to heating system designers, consistent with Specification C 840, in the absence of a comprehensive radiant heating system standard.

5.2 *Installation of Heating Equipment*:

5.2.1 Installation of radiant heating and related electrical equipment is governed by codes and regulations, and is the responsibility of other trades.

5.3 *General Installation Guidelines*:

5.3.1 The application of gypsum panel products under this guide shall be performed in accordance with Specification C 840, except as herein modified.

5.3.2 The radiant heating system shall be disconnected from the electric supply prior to the commencement of work.

NOTE 3—Disconnection from the electric supply is accomplished by switching the heating system circuit breakers off, or removing fuses. Lowering a thermostat setting until the heating system turns off is not supply disconnection.

5.3.3 Unless the concealed radiant heating system is no longer in use and has been permanently disconnected from the electrical supply, or unless the previous facing has been removed, gypsum panel products or gypsum plaster shall not be installed as a new facing on the heated area side of an existing concealed radiant heating system.

NOTE 4—The increased thickness resulting from addition of gypsum panel products or gypsum plaster to an existing concealed radiant heating system can impair heat transfer into the heated area, and may cause overheating of the electrical heat source.

5.3.4 All inspection and testing of the heating system shall be completed before application of gypsum facing materials.

5.3.5 Care shall be taken in the installation of fasteners to avoid the penetration of heating equipment and electrical conductors.

5.3.6 The radiant heating system shall not be operated to accelerate the drying of joint compound or texture finishes.

5.3.7 Follow the radiant heat-source manufacturer's start-up and operating instructions when operating the radiant heating system.

5.4 *Repair of Cable Heating Systems*:

5.4.1 Repair of heating cables is the responsibility of other trades.

5.4.2 The application of gypsum plaster shall conform to Specification C 842 except as herein modified.

5.4.3 Filler added to gypsum plaster used to repair a heating cable system, if any, shall be of sand or similar thermally conductive material. Thermal insulating fillers such as vermiculite or perlite, and foaming agents that impair heat transfer shall not be used in plaster applied to radiant heating systems.

5.4.4 Application of metal lath shall conform to Specification C 841. Metal lath and fasteners installed for repair of a cable heating system shall not contact heating cables.

5.4.5 Complete embedding of the heating cable in plaster is necessary after cable repair is completed.

5.5 *Flexible Radiant Heating Panel Systems*:

5.5.1 Application of gypsum panel products shall comply with the requirements for System I or System II of Specification C 840, as applicable, based on the specified number of layers; and with the requirements of System XII where floating interior angles are used.

5.5.2 Application of gypsum panel products to steel framing or furring shall comply with System VIII of Specification C 840.

5.5.3 The thickness of a gypsum panel product installed as a facing shall not exceed the thickness specified in the heating system design specification.

NOTE 5—Installing facing thicker than specified can impair heat transfer into the heated area, and may cause overheating of the electrical heat source.

5.5.4 Furring of any material or construction shall not be installed between gypsum panel product facing and flexible radiant heating panels.

NOTE 6—The air gap produced by furring can impair heat transfer into the heated area, and may cause flexible radiant heating panels to overheat.

5.5.5 All joints and heads of fasteners shall be finished in accordance with Specification C 840, to the specified level of finish.

NOTE 7—When repairing an existing surface, the level of finish of the repair should be the same as that of the original surface.

5.5.6 Foil backed gypsum panel products shall not be installed in contact with thin sheet flexible radiant heating panels.

5.6 *Decoration*:

5.6.1 The heating system shall be turned off and allowed to cool before decorating.

5.6.2 Decoration of finished work, including sizing or sealing, shall not proceed until joint compound has dried.

5.6.3 When texture finishes are used, such finishes must be thoroughly dry prior to heating system operation.

Designation: C 1550 – 08

Standard Test Method for Flexural Toughness of Fiber Reinforced Concrete (Using Centrally Loaded Round Panel)[1]

This standard is issued under the fixed designation C 1550; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of flexural toughness of fiber-reinforced concrete expressed as energy absorption in the post-crack range using a round panel supported on three symmetrically arranged pivots and subjected to a central point load. The performance of specimens tested by this method is quantified in terms of the energy absorbed between the onset of loading and selected values of central deflection.

1.2 This test method provides for the scaling of results whenever specimens do not comply with the target thickness and diameter, as long as dimensions do not fall outside of given limits.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Terminology

3.1 *Definitions*—For definitions of terms used in this test method, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *central deflection*—the net deflection at the center of the panel measured relative to a plane defined by the three pivots used to support the panel; this is a conditioned deflection that excludes extraneous deformations of the load train and local crushing of the panel at the point of load application and points of support.

3.2.2 *compliance*—a measure of the tendency of a structure to deflect under load, found as the inverse of stiffness or deflection divided by the corresponding load.

3.2.3 *load train*—those parts of a testing machine that experience load and undergo straining during a mechanical test, including the actuator, frame, support fixtures, load cell, and specimen.

3.2.4 *toughness*—the energy absorbed by the specimen equivalent to the area under the load-deflection curve between the onset of loading and a specified central deflection.

4. Summary of Test Method

4.1 Molded round panels of cast fiber-reinforced concrete or fiber-reinforced shotcrete are subjected to a central point load while supported on three symmetrically arranged pivots. The load is applied through a hemispherical-ended steel piston advanced at a prescribed rate of displacement. Load and deflection are recorded simultaneously up to a specified central deflection. The energy absorbed by the panel up to a specified central deflection is representative of the flexural toughness of the fiber-reinforced concrete panel.

5. Significance and Use

5.1 The post-crack behavior of plate-like, fiber-reinforced concrete structural members is well represented by a centrally loaded round panel test specimen that is simply supported on three pivots symmetrically arranged around its circumference. Such a test panel experiences bi-axial bending in response to a central point load and exhibits a mode of failure related to the *in situ* behavior of structures. The post-crack performance of round panels subject to a central point load can be represented by the energy absorbed by the panel up to a specified central deflection. In this test method, the energy absorbed up to a specified central deflection is taken to represent the ability of a fiber-reinforced concrete to redistribute stress following cracking.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.42 on Fiber-Reinforced Concrete.

Current edition approved Oct. 1, 2008. Published October 2008. Originally approved in 2002. Last previous edition approved in 2005 as C 1550 – 05.

www.technobetar.ir

NOTE 1—The use of three pivoted point supports in the test configuration results in determinate out-of-plane reactions prior to cracking, however the support reactions are indeterminate after cracking due to the unknown distribution of flexural resistance along each crack. There is also a change in the load resistance mechanism in the specimen as the test proceeds, starting with predominantly flexural resistance and progressing to tensile membrane action around the center as the imposed deflection is increased. The energy absorbed up to a specified central deflection is related to the toughness of the material but is specific to this specimen configuration because it is also determined by the support conditions and size of the specimen. Selection of the most appropriate central deflection to specify depends on the intended application for the material. The energy absorbed up to 5 mm central deflection is applicable to situations in which the material is required to hold cracks tightly closed at low levels of deformation. Examples include final linings in underground civil structures such as railway tunnels that may be required to remain water-tight. The energy absorbed up to 40 mm is more applicable to situations in that the material is expected to suffer severe deformation *in situ* (for example, shotcrete linings in mine tunnels and temporary linings in swelling ground). Energy absorption up to intermediate values of central deflection can be specified in situations requiring performance at intermediate levels of deformation.

5.2 The motivation for use of a round panel with three supports is based on the within-batch repeatability found in laboratory[3] and field experience.[4] The consistency of the failure mode that arises through the use of three symmetrically arranged support pivots results in low within-batch variability in the energy absorbed by a set of panels up to a specified central deflection. The use of round panels also eliminates the sawing that is required to prepare shotcrete beam specimens.

5.3 The nominal dimensions of the panel are 75 mm in thickness and 800 mm in diameter. Thickness has been shown to strongly influence panel performance in this test, while variations in diameter have been shown to exert a minor influence on performance.[5] Correction factors are provided to account for actual measured dimensions.

NOTE 2—The target dimensions of the panel specimen used in this test are held constant regardless of the characteristics of aggregate and fibers used in the concrete comprising the specimen. Post-crack performance may be influenced by size and boundary effects if large aggregate particles or long fibers are used in the concrete. These influences are acknowledged and accepted in this test method because issues of size effect and fiber alignment arise in actual structures and no single test specimen can suitably model structures of all sizes. Differences in post-crack behavior exhibited in this test method can be expected relative to cast fiber-reinforced concrete members thicker than 100 mm. Because fiber alignment is pronounced in structures produced by shotcreting, and the maximum aggregate size in shotcrete mixtures is typically 10 mm, post-crack behavior in specimens tested by this method are more representative of *in situ* behavior when they are produced by spraying rather than casting concrete.

[4] Hanke, S. A., Collis, A., and Bernard, E. S., "The M5 Motorway: An Education in Quality Assurance for Fibre Reinforced Shotcrete," *Shotcrete: Engineering Developments*, Bernard (ed.), Swets & Zeitlinger, Lisse, pp. 145-156, 2001.

[5] Bernard, E. S. and Pircher, M., 2001, "The Influence of Thickness on Performance of Fiber-Reinforced Concrete in a Round Determinate Panel Test," *Cement, Concrete, and Aggregates*, CCAGDP, Vol 23, No. 1, pp. 27–33, June 2001 .

6. Apparatus

6.1 *Testing Machine*—A servo-controlled testing machine incorporating an electronic feed-back loop that uses the measured deflection of either the specimen or the loading actuator to control the motion of the actuator shall be used to produce a controlled and constant rate of increase of deflection of the specimen without the intervention of an operator. To avoid unstable behavior after cracking, the system stiffness of the testing machine inclusive of load frame, load cell (if used), and support fixture shall exceed that of the specimen. The system stiffness of the testing machine can be determined in accordance with the procedure described in Annex A1. Load-controlled test machines incorporating one-way hydraulic valves or screw mechanisms lacking an electronic feed-back loop for automatically controlling the rate of increase in displacement shall not be used. The load-sensing device shall have a resolution sufficient to record load to ±50 N.

NOTE 3—Although it is commonly believed that servo-controlled systems, incorporating a feed-back loop in which the measured central displacement of the specimen is used to control the motion of the actuator, are capable of overcoming the disadvantages of a structurally compliant testing machine, this will depend on the speed and sensitivity of the feed-back loop and the mechanical response rate of the loading apparatus. A more reliable configuration comprises a servo-controlled actuator in which the measured displacement of the actuator is used in the feed-back loop to control the motion of the actuator combined with a high load train stiffness. Experience has indicated that the redistribution of stress that occurs in fiber-reinforced concrete panels following cracking of the concrete matrix generally results in stable post-crack behavior provided a testing machine complying with the requirements of this section is used.

6.2 *Support Fixture*—The fixture supporting the panel during testing shall consist of any configuration that includes three symmetrically arranged pivot points on a pitch circle diameter of 750 mm. The supports shall be capable of supporting a load of up to 100 kN applied vertically at the center of the specimen. The supports shall be sufficiently rigid so that they do not displace in the radial direction by more than 0.5 mm between the onset of loading and 40 mm central deflection for a test involving a specimen displaying a peak load capacity of 100 kN. The three supports must also not translate by more than 0.5 mm in the circumferential direction during a test. The pivots shall not restrict rotation of the panel fragments after cracking. The support fixture shall be configured so that the specimen does not come into contact with any portion of the support fixture apart from the three pivots during a test. A photograph of a suggested design is shown in Fig. 1. The contact between the specimen and each pivot shall comprise a steel transfer plate with plan dimensions of approximately 40 × 50 mm with a spherical seat of about 4 mm depth machined into one surface to accept a ball pivot (see Fig. 2). The distance between the surface of the panel and the center of the pivot shall be 20 ± 2 mm. The diameter of the pivot ball shall be 16 ± 2 mm. Grease is permitted to reduce friction in the seat of each pivot, but rollers or grease are not permitted to reduce friction between the transfer plates and specimen.

6.3 *Deflection Measuring Equipment*—Determine the central deflection of the specimen relative to the support points in a manner that excludes extraneous deformations of the testing machine and support fixture. This is achieved by one of two

www.technobetar.ir

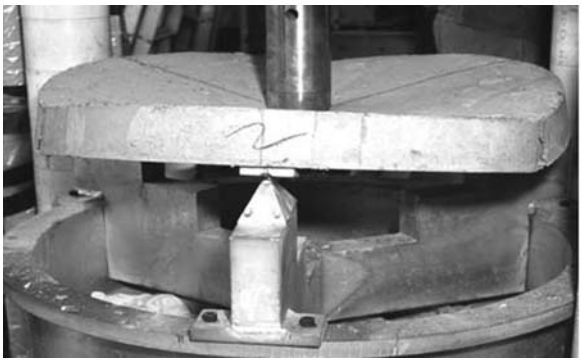

FIG. 1 Photograph of a Suggested Support Fixture

methods. If the displacement of the tensile surface of the panel at the center is measured relative to the pivot supports, then no correction for extraneous deformations of the testing machine and support fixture need be made to the recorded deflections. If the movement of the loading piston relative to the crosshead of the testing machine is used to measure deflection, the deflection record must be adjusted to discount extraneous deformations. A method of adjusting the deflection record to account for extraneous deformations is given in the calculation section. Regardless of the method of deflection measurement selected, use a displacement transducer with a resolution sufficient to record deflection to ±0.05 mm.

NOTE 4—All components of the load train in a test system experience deformation when the specimen is placed under load. If the deflection of the specimen is measured relative to the machine crosshead, then the deformation of the load train is included as extraneous deformations in the deflection record. Additional extraneous deformations may arise from local crushing of concrete under the load point (especially debris on the surface), or from crushing of any debris between the specimen and transfer plates. This second form of extraneous deformation usually results in curvature in the initial portion of the load-deflection curve.

NOTE 5—If the deflection of the center of the tensile surface of the specimen is measured directly with a transducer, an incomplete or erroneous deflection record may occur if a crack opens at the point of measurement. It may be possible to alleviate this problem through the use of a transducer with a probe approximately 20 mm wide. The probe should not exceed this width because off-center cracks may induce exaggerated apparent deflections if they occur adjacent to a wide probe.

6.4 *Data Logging System*—Record the deflection imposed on the panel and corresponding applied load simultaneously at a rate sufficient to record deflection in increments of no more than 0.05 mm if using a digital recording system. For a test up to a specified central deflection of 40 mm, record at least 800 data points. Deflection increments for measurements beyond this point shall be increased to 0.20 mm. For tests in which the assessment deflection is less than 40 mm, applied load and deflection shall be recorded at intervals of no greater than 0.05 mm and at least 100 recorded points shall be used to derive each energy-based assessment parameter. If an analog *X-Y* plotter is used to record behavior, the scales must be chosen so that a 40 mm deflection is reached at not less than 80 % of full-scale deflection in the *X* direction. The peak load capacity of the specimen must be achieved at no less than 50 % of full-scale in the *Y* direction. As a guide, the majority of specimens having standard dimensions and exhibiting normal strength fail at a load of less than 40 kN.

6.5 *Loading Piston*—The load point shall consist of a steel hemispherical piston with the dimensions shown in Fig. 3. The radius of the hemispherical portion of the head shall be 80 ± 5 mm, and that of the piston shaft 50 ± 5 mm.

7. Specimen Preparation and Sampling

7.1 Produce specimens with an overall diameter of 800 ± 10 mm and a thickness of 75 -5/+15 mm. Panels shall not be tested if dimensions are outside of the specified limits. The standard deviation in 10 measures of thickness taken in accordance with the instructions in the procedure section must be less than 3.0 mm. Maintain these dimensions regardless of the size of aggregate or length of fiber used in the concrete or shotcrete. Make the side of the specimen perpendicular relative to the faces.

7.2 Prepare specimens in such a way as to approximate the mode of placement *in situ*. Specimens representing cast concrete shall therefore be cast, while those representing shotcrete shall be sprayed. Specimens shall be screeded to the required thickness before the concrete has hardened (see Appendix X1 for further recommendations regarding specimen production). Remove molds when the concrete has attained sufficient strength so that the specimen can be placed into the testing position without being damaged.

NOTE 6—Grinding or sawing of the surface to reduce an overly thick panel to the required thickness is possible, but may influence the performance of the as-cast or sprayed surface concrete.

7.3 Molds for the production of specimens shall consist of a base and side made of either non-reactive metal or coated plywood. The base and side shall be sufficiently rigid so as not to vibrate or permanently distort during casting or spraying. The interior face of the mold shall be 75 mm deep so that a screed may be run directly across the surface to produce a specimen of correct thickness. See Appendix X1 for recommendations regarding mold design.

7.4 Control the diameter of the mold through careful attention to manufacture. Maintenance of the correct thickness is subject to the skill of personnel charged with finishing the specimens. For normal setting concrete, sufficient time is normally available to screed the surface to obtain a uniform thickness. Accelerated shotcrete may, however, stiffen quickly leaving insufficient time to adequately screed the surface. In such cases, it is necessary to produce several specimens and only retain those that are uniform in thickness.

7.5 *Sampling*—Prepare at least three specimens for each batch of concrete or shotcrete tested. A sample shall consist of at least two successful tests. A successful test involves a failure that includes at least three radial cracks. Specimens occasionally fail in a beam-like mode involving a single crack across the specimen that is characterized by low energy absorption. The result of such a test shall be discarded. Only two specimens need be tested if both specimens fail by the required mode and have a standard deviation in thickness not exceeding 3.0 mm.

8. Conditioning

8.1 The purchaser shall specify the curing and moisture conditioning requirements to be used prior to testing, and the

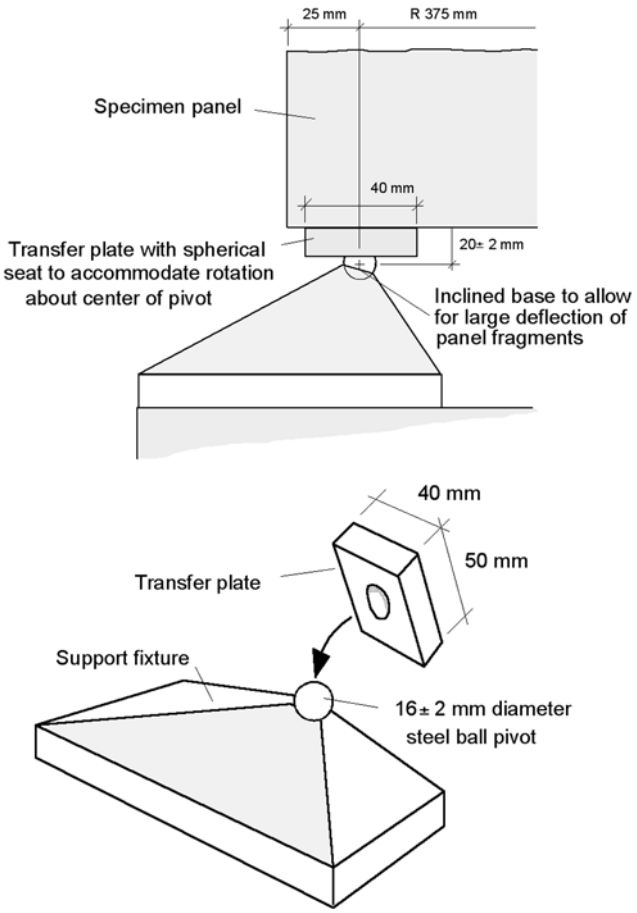

FIG. 2 Detail of Transfer Plate and Pivot Support

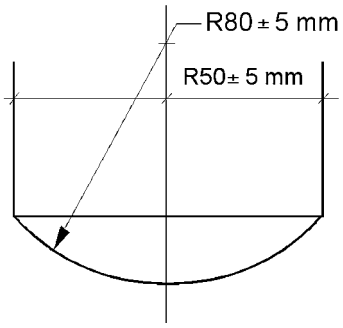

FIG. 3 Hemispherical End of Loading Piston

test age. If the specimens are continuously moist cured and are to be tested in a moist condition, complete testing within 15 min after removal from the moist curing conditions, or apply a curing membrane or wet burlap to control drying from the time of removal until testing is completed.

NOTE 7—Drying shrinkage strains occur in a specimen that is allowed to dry. These strains may result in micro-cracks and may reduce the flexural strength and post-crack energy absorption of the panel.

9. Procedure

9.1 Mount the test specimen in the test apparatus by placing the molded face onto the three transfer plates resting on the pivots. Center the panel with respect to both the supports and loading piston.

9.2 Measure the diameter of the panel to the nearest 2 mm at three places coincident with the intended support locations and calculate the average diameter. If the average diameter of the specimen is less than 790 mm or greater than 810 mm, discard the specimen.

9.3 Operate the testing machine so that the piston advances at a constant rate of 4.0 ± 1.0 mm/min up to a central displacement of at least 45.0 mm.

NOTE 8—The test can be extended to an end-point deflection greater than 45 mm if it is desired to examine behavior at higher levels of deformation.

NOTE 9—The central deflection at which cracking of the concrete matrix first occurs is approximately 0.50 mm for a 75 mm thick concrete specimen of normal strength and composition, exclusive of extraneous displacements. A rate of displacement equal to 4.0 mm/min therefore causes cracking of the concrete matrix in about 8 s. However, if a displacement-controlled testing machine is used and the surface of the

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

specimen is rough, as is often the case with shotcrete specimens, the effective displacement rate of the center of the specimen may be less than 4.0 mm/min at the start of a test. Experience has shown that local crushing of concrete under the load point usually occurs within the first few millimetres of movement. Research has also shown that small changes in the effective rate of central displacement have only a minor influence on energy absorption for displacement rates within the range of 0.5 to 10 mm/min.[6]

9.4 Count the number of radial cracks occurring between the center and the perimeter. Any flexural crack occurring on the tensile face of the panel is counted as a full crack provided its average width exceeds 0.5 mm upon completion of the test and removal of the load.

NOTE 10—Energy is absorbed by fiber-reinforced concrete in this test through a number of processes. Minor amounts of energy are absorbed either through elastic deformation of the specimen or as a result of friction between the underside of the specimen and the transfer plates at the three supports. The majority of energy is absorbed through the process of fiber pull-out and deformation that takes place as each crack opens in response to imposed deformation. Cracks that suffer minimal opening do not absorb significant amounts of energy and thus can be ignored. Given that the average maximum crack opening for each of the three radial cracks in this test is 10 mm at 40 mm central deflection, a crack of less than 0.5 mm width is regarded as insignificant. Laboratory experience has also demonstrated that small cracks appear to have little effect on total energy absorption.

9.5 Remove the failed specimen fragments from the test apparatus, and measure the thickness at three points along each of the cracked surfaces and at the center so that the resulting 10 values provide a representative estimate of the average thickness of the specimen. Measure the thickness to the nearest 1 mm and calculate the average thickness to the nearest 1 mm. If the average thickness is less than 70 mm or greater than 90 mm, discard the specimen. Calculate the standard deviation in thickness. If the standard deviation in thickness exceeds 3.0 mm, discard the specimen.

10. Calculation

10.1 Adjust the load-deflection record by subtracting extraneous deformations associated with compliance of the load train and crushing of concrete under the load point and at the supports. If the load-deflection record was obtained using a transducer that measured the deflection of the tensile surface of the specimen relative to the transfer plates, adjustments need only be made for crushing of concrete at the transfer plates. If the deflection of the specimen was measured through the loading mechanism of the testing machine, this record includes extraneous displacements that must be deleted from the deflection record to reveal the net deflection of the specimen.

NOTE 11—The result of a test is a load-deflection record indicating resistance to load between the onset of loading and a central deflection of at least 40 mm. Depending on the method of deflection measurement used, the load-deflection record may include extraneous deformations associated with load train compliance or crushing of the concrete around the load point or supports, or both. Extraneous deformations associated with load train compliance are regarded as systematic errors. These are discounted by computing the deformation of the load train (which is proportional to the load imposed on the specimen) and subtracting this from the recorded deflection at each deflection increment. The adjusted deflection δ of the specimen at a given load P exclusive of extraneous deformations associated with load train compliance can be calculated as:

$$\delta = \delta_m - PC_{LT} \quad (1)$$

where:

δ_m = the measured deflection including extraneous deformation due to compliance of the load train, and

C_{LT} = the compliance of the load train (see Annex A1).

Extraneous deformations associated with crushing of concrete around the load point or supports are specimen-dependent. These are manifested as offsets between the measured and net deflection of the specimen in the load-deflection record. The offset is determined approximately by linear extrapolation of the portion of the load-deflection curve occurring prior to the first peak to the horizontal (deflection) axis as shown in Fig. 4. Once the offset between the nominal and true origin for the deflection record has

[6] Bernard, E. S., "The Influence of Strain Rate on Performance of Fiber-Reinforced Concrete Loaded in Flexure," *Cement, Concrete, and Aggregates* , CCAGDP, Vol 23, No. 1, pp. 11–18, June 2001.

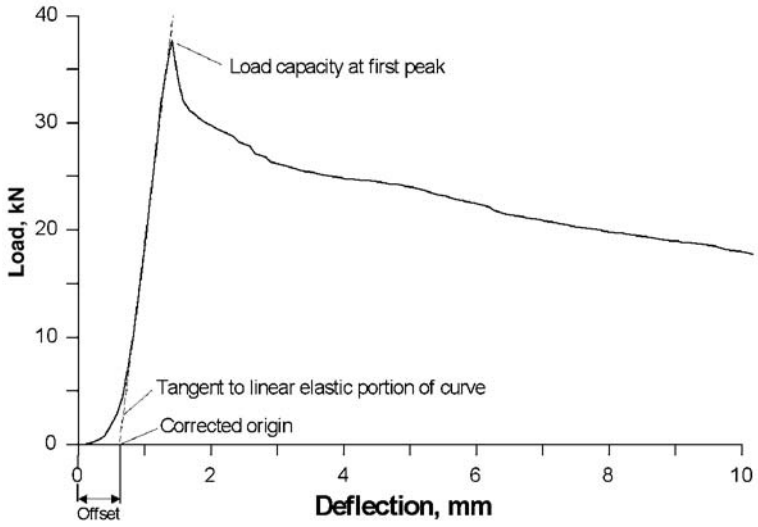

FIG. 4 . Estimation of True Origin of the Load-Deflection Curve

www.technobetar.ir

been determined, the load-deflection curve can be further adjusted by translation to the corrected origin. Because the magnitude of the offset may not become apparent until a test is completed, it is usually necessary to continue a test up to a central deflection that exceeds the specified central deflection by several millimetres.

10.2 Using a load-net deflection curve that has been adjusted so it is free of extraneous deformations, calculate the energy absorption between the onset of loading and the specified central deflection. Determine energy absorption as the area under the load-net deflection curve between the origin and the specified central deflection, as shown in Fig. 5. Toughness in this test is ordinarily defined at central deflections of 5, 10, 20, or 40 mm.

NOTE 12—If the load and net deflection are measured in units of Newtons (N) and metres (m), or kiloNewtons (kN) and millimetres (mm), the resulting measure of energy will be in units of Joules (J).

10.3 Correct the energy absorption using the following equation:

$$W = W'\left(\frac{t_0}{t}\right)^{\beta}\left(\frac{d_0}{d}\right) \quad \text{where } \beta = 2.0 - (\delta - 0.5)/80 \qquad (2)$$

where:

W = the corrected energy absorption,
W' = the measured energy absorption,
t = the average thickness, mm,
t_0 = the nominal thickness of 75 mm,
d = the average diameter, mm,
d_0 = the nominal diameter of 800 mm, and
δ = the specified central deflection at which the capacity to absorb energy is measured, mm.

In Eq 2, the number 0.5 is an estimate of the elastic deflection of the specimen that occurs prior to cracking. If the average dimensions of the specimen lie outside the bounds listed above, discard the specimen and results.

11. Report

11.1 Report the following information:

11.1.1 Type of specimen (cast or sprayed) and specimen identification numbers or symbols,

11.1.2 Type of fiber observed on the cracked surfaces, and dosage rate, if known,

11.1.3 Average thickness of the specimen to the nearest 1 mm, and the standard deviation in thickness to the nearest 0.1 mm,

11.1.4 Average diameter of the specimen to the nearest 5 mm,

11.1.5 The number of radial cracks that occurred in the specimen,

11.1.6 The uncorrected and corrected values of energy absorption between the onset of loading and the specified central deflection, rounded to the nearest Joule.

11.1.7 Age of specimen at test,

11.1.8 Curing history and moisture condition of specimen at test, and

11.1.9 Any defects in specimen prior to test, and abnormalities in specimen behavior during test.

12. Precision and Bias

12.1 *Precision*—Data to establish the precision of this test method in accordance with Practice C 670 have not been determined. Studies of repeatability in energy absorption up to 40 mm central displacement observed within one laboratory indicate single-operator values of the one-sigma within-batch limit (1s %) of 6 %. Therefore, results from two properly conducted tests by the same operator on specimens made from the same batch of concrete are not expected to differ from each other by more than 17 %.

12.2 *Bias*—There is no bias in this test method because the energy absorption of a centrally loaded round panel can only be measured by this method.

13. Keywords

13.1 energy absorption; fiber-reinforced concrete; flexure; post-crack behavior; toughness

ANNEX

(Mandatory Information)

A1. DETERMINATION OF LOAD-TRAIN COMPLIANCE

A1.1 The compliance of the load train is the difference between the apparent compliance of the specimen when deformation of the load train is included and the true compliance of the specimen.

$$C_{LT} = C_{app} - C_{spec} \quad \text{(A1.1)}$$

where:

C_{LT} = the compliance of the load train,
C_{app} = the apparent compliance of the specimen inclusive of load train deformation,
C_{spec} = the true compliance of the specimen.

Compliance shall be measured in units of mm/kN. The term C_{spec} can be determined by dividing the load, P, to cause a given central deflection into the corresponding deflection, Δ_{spec}, measured so as to exclude deformations of the load train and corrected for crushing of concrete. Hence,

$$C_{spec} = \Delta_{spec} / P \quad \text{(A1.2)}$$

The term C_{app} is determined in a similar manner, but the central deflection, Δ_{app}, arising from the load, P, shall include the deformation of the load train.

The use of a large number of data points to determine the compliances C_{app} and C_{spec} is more accurate than the use of a single pair of points. Hence, the inverse of the slope of a line fitted through the straight portion of the load-deflection record prior to cracking is the apparent compliance of the specimen and load train, C_{app}. The inverse of the slope of a line fitted through the straight portion of the load-deflection record obtained by measurement of the deflection of the specimen relative to the support points prior to cracking is the compliance of the specimen, C_{spec}.

A1.2 The deflection of a specimen exclusive of load-train deformation is measured by applying displacement transducers directly to the surface of the specimen during a test so that the deflection of the center of the specimen is measured relative to the supported portions of the specimen. Since local crushing of the surface of the specimen is likely to occur under the load point, it is usually necessary to measure deflection at the center on the tensile face of the specimen relative to the pivot supports by means of a yoke (see Figs. A1.1 and A1.2, and Section 6). The yoke shall be loosely supported at the pivot supported to allow for a slight movement of these during deformation of the specimen. A small extraneous deformation can arise through crushing of concrete at the transfer plates, but this is corrected through attention to the off-set in the load-deflection record shown in Fig. A1.3. A plan view of a suggested test configuration for the measurement of load train compliance is shown in Fig. A1.4.

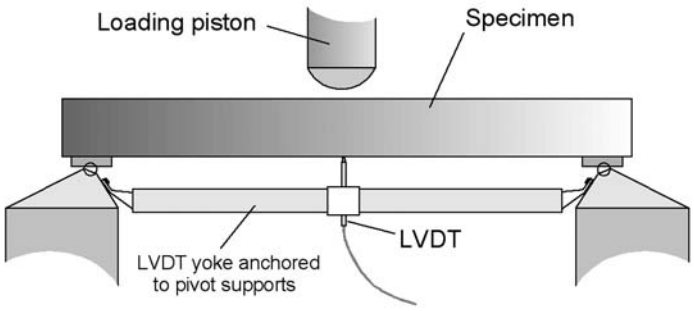

FIG. A1.1 Suggested Method of Deflection Measurement to Exclude Load-Train Deformations and Crushing of Concrete at the Point of Loading Using a Linear Variable Deflection Transducer (LVDT)

www.technobetar.ir

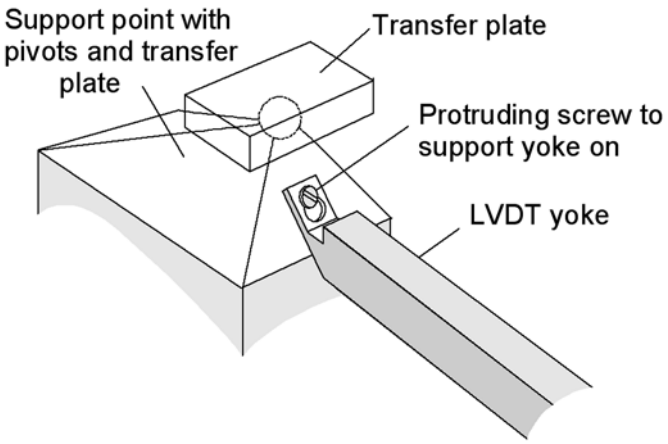

FIG. A1.2 Suggested Method of Connecting LVDT Yoke to Transfer Plates

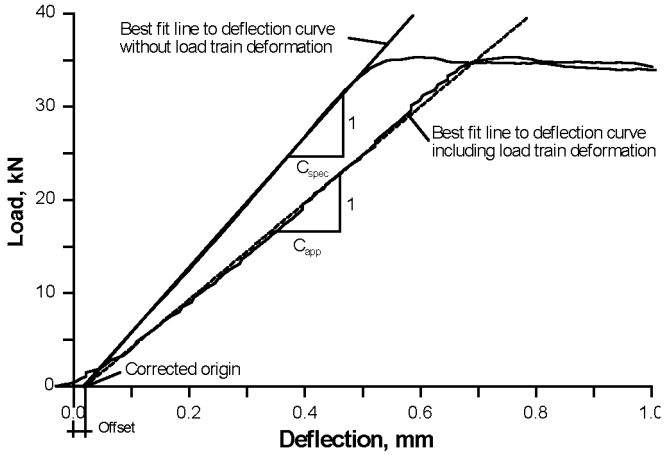

FIG. A1.3 Deflection Record for a Specimen Inclusive and Exclusive of Load Train Deformations

A1.3 The deflection of the specimen inclusive of extraneous deformations is measured by recording the displacement of the actuator relative to its immediate supports during a test. These data are normally measured using a transducer located within the test machine. The displacement of the actuator relative to its immediate supports includes the deformation of the testing machine, load cell, and load transferring fixtures, plus that of the specimen and crushing of concrete at the point of loading. Deformation associated with crushing of concrete around the load point must not be included in the assessment of load train compliance, hence only the portion of the displacement record that displays essentially linear behavior shall be used. A plot of the deflection both inclusive and exclusive of extraneous deformations is shown in Fig. A1.3. The deflection at a given load inclusive of extraneous deformations is always greater than the net deflection of the specimen (hence the magnitude of the compliance will be greater).

A1.4 Determination of the load train compliance using measurements of true and apparent specimen deflection is most reliably undertaken using data from that part of the load-deflection history for a specimen obtained prior to cracking of the concrete matrix.

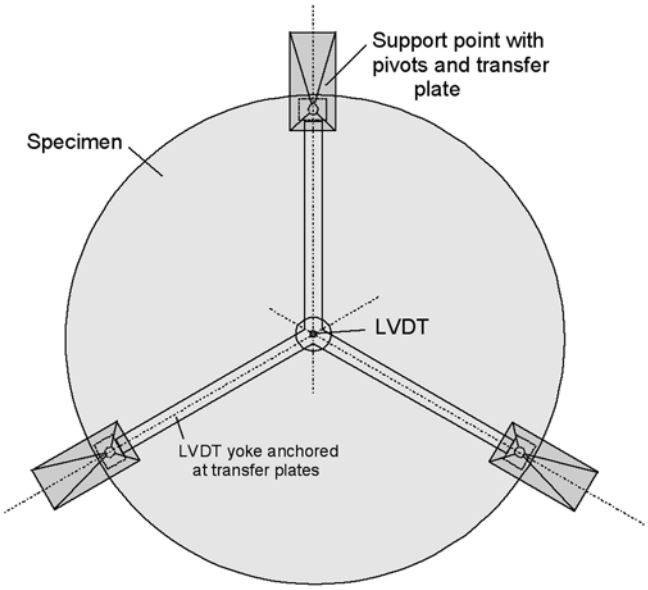

FIG. A1.4 Plan View of Suggested Method of Deflection Measurement

APPENDIX

(Nonmandatory Information)

X1. PREPARING ROUND PANELS FOR TESTING

X1.1 Scope

X1.1.1 This appendix provides recommendations for preparing test panels of concrete or shotcrete intended for testing using Test Method C 1550.

X1.1.2 Round test panels of cast fiber-reinforced concrete or fiber-reinforced shotcrete should be fabricated using the materials and placement equipment, if appropriate, under investigation.

X1.2 Forms for Test Panels

X1.2.1 The form for receiving concrete or shotcrete should be of either wood or steel construction and remain sufficiently rigid to prevent deformation of the form, or dislodging of the concrete or shotcrete through vibration or deformation, during placement. The form shall have an inside diameter of 800 ± 5 mm and an internal depth of 75 ± 2 mm.

X1.2.2 *Wooden Forms*—Wooden forms shall have a backing made of form plywood at least 17-mm thick. Side pieces should be made from a metal, timber, or plastic material having sufficient rigidity to remain in place and maintain the concrete in the form without significant deformation during placement and consolidation operations. The form should be designed in such a way that the filled form can be moved without damaging the specimen. Sheet metal sides can be used if they are stiffened by the base of the form or external stiffeners. Metal sides of at least 3-mm thickness are required if no stiffeners are provided. An acceptable design for a simple wood and sheet metal form is shown in Fig. X1.1.

Concrete will ordinarily bond to timber and metal surfaces during hardening so release oil should be applied prior to placement of concrete. Experience has also shown that wooden forms deteriorate after several cycles of use unless maintained with form oil or a release compound between cycles of use.

X1.2.3 *Steel Forms*—Steel forms should be made using material having a minimum thickness of 3 mm for the flat base of the form. Steel of at least 0.5 mm thickness should be used around the curved side of the form, provided stiffeners are used to limit deformation of the entire form during placement. Steel at least 3 mm thick should be used for the side if no stiffeners are provided to maintain the circular shape of the panel during casting or spraying. Two recommended designs for steel forms are shown in Figs. X1.2 and X1.3. Use of a form with a hoop handle (as depicted in Figs. X1.3 and X1.4) permits the specimen to be moved by a single operator after the specimen has gained sufficient strength to withstand damage due to handling.

X1.3 Filling Mold

X1.3.1 *Cast Concrete*—Prior to casting of panel specimens, the pre-oiled forms should be leveled and checked to ensure that they are flat and free from distortion. The specimens (panels) should be prepared by successively casting fiber reinforced concrete into each of the forms provided for a

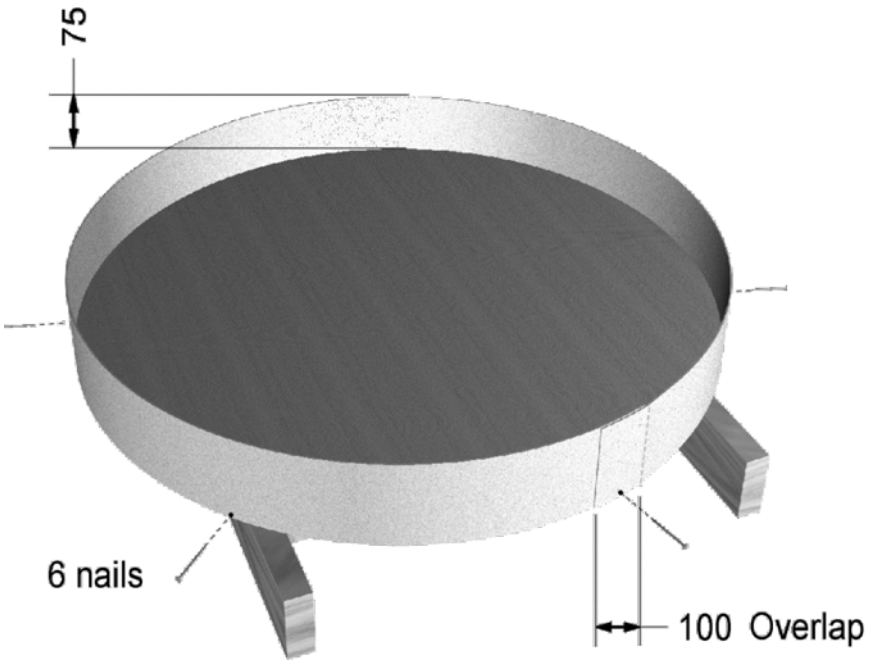

FIG. X1.1 Simple Form Comprising Plywood Base and Sheet or Rolled Steel Side Nailed or Screwed to the Base

FIG. X1.2 Simple Steel Form With Rigid Base and Handles for Transport and Handling

particular job. An amount of concrete sufficient to just fill the form should be placed and then consolidated using a vibrator. The vibrator is to be used to eliminate voids and prevent honey-combing within the specimen, and ensure that no differentiation between successive layers of concrete placed into the form. An external vibrator is recommended, but such a device must be powerful enough to consolidate approximately 100 kg of concrete in a satisfactory period of time. Alternately, an internal vibrator can be used. The internal vibrator should meet the requirements stated in Practice C 31/C 31M with a shaft no greater than 38 mm in diameter. If numerous specimens are produced concurrently, then the same means of vibration and consolidation should be applied to all specimens.

After consolidation has been completed, the surface should be screeded and struck off level with the sides of the form. This should be done by raking a screed in a zig-zagging fashion across the surface of the specimen so that excess concrete above the edge of the form is removed. Care should be taken to ensure that fibers are not withdrawn from within the body of the specimen during this process and that an excessive amount of concrete is not removed during each pass. This can be done

www.technobetar.ir

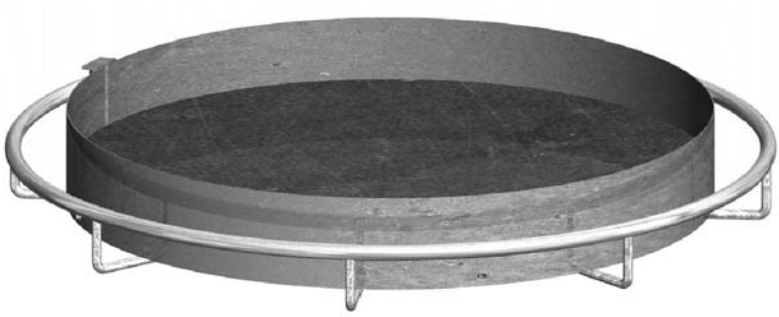

FIG. X1.3 Elaborate Steel Form with Removable Side Allowing a Single Operator to Move the Specimen by Rolling

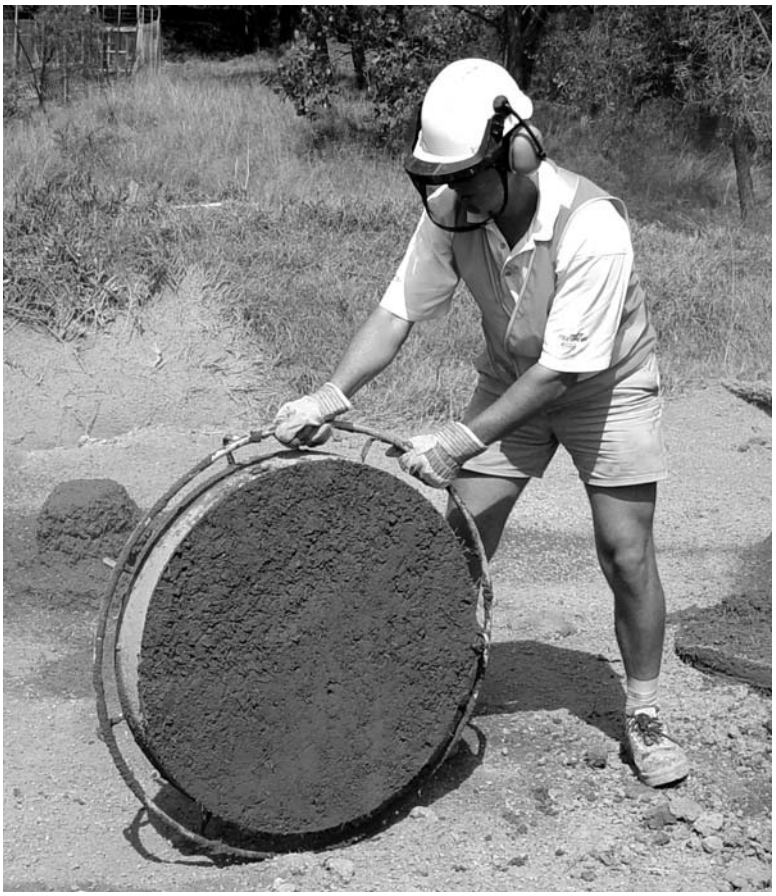

FIG. X1.4 Rolling Steel Form after Specimen Has Gained Sufficient Strength to Withstand Damage

most effectively by screeding the specimen several times, taking about 5 to 10 mm of concrete off during each pass. When the surface of the specimen is level with the side of the form, a final pass of the screed should be carried out with gentle side-to-side motion to leave a relatively smooth surface. A suitable screed will comprise any straight and rigid piece of non-reactive metal, timber, or plastic of sufficient length to bridge the face of the mold.

After screeding is completed, the surface of the panel should be gently floated. It is then to be left undisturbed until bleeding has ceased and initial setting has occurred. A final float should then be performed if required to leave the surface flat and smooth. The specimens should then be subjected to the specified curing condition.

X1.3.2 *Shotcrete*—Prior to production of sprayed specimens, pre-oiled forms should be placed against props and checked to ensure that the bases are flat and free from distortion. The specimens (panels) should then be prepared by successively spraying fiber reinforced shotcrete into each of the forms provided for a particular job until they are full of shotcrete. The specimens should be shot by the same personnel charged with completing the in situ shotcreting required for construction using the same equipment intended for this purpose. An amount of shotcrete sufficient to just over-fill the

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

form should be sprayed in by commencing spraying at the base and moving the nozzle in a circular fashion around the form until full. Spraying should be undertaken by a nozzleman familiar with the requirement to minimize rebound and accumulation of rebound in the corners of the form. Once spraying has been completed, the surface of each specimen should be struck off level with the top of the form to obtain a flat surface and uniform thickness.

Initial spraying of the panels should not be undertaken with the nozzle pointing at the form. Spray the concrete away from the form for several seconds, or until a steady and uniform stream of concrete is emerging from the nozzle, and then commence spraying the panel by moving the nozzle in a circular fashion. The nozzle should never be pointed at the form upon commencement of spraying because set accelerator and concrete seldom emerge at the same time, thus the first concrete introduced into the jetstream will not be representative of concrete that emerges later. The edges should be filled first with concrete to minimize entrapment of rebound and then the remainder of the form should be filled using slow to-and-fro passes of the nozzle until the thickness of concrete slightly exceeds the depth of the form.

The nozzle should at all times be maintained perpendicular to the surface being sprayed and at a consistent distance from the surface. Experience has shown that the superior dexterity possible with manual spraying (Fig. X1.5) results in less rebound, a more uniform thickness, and superior quality for fiber reinforced shotcrete panels than is commonly obtained using remotely-controlled nozzles (Fig. X1.6). Remotely-controlled manipulator arms have fewer degrees of freedom of motion than is possible by manual spraying and this commonly results in the requirement for perpendicularity being violated (see Fig. X1.6).

If the shotcrete is stiff, screeding may be performed with the formwork in a propped position. If the shotcrete is relatively fluid, the forms should be moved and placed on a horizontal surface before screeding can take place. Screeding can be performed by raking the screed in a zig-zagging fashion across the surface of the specimen so that excess shotcrete above the edge of the form is removed. Care should be taken to ensure that fibers are not withdrawn from within the body of the specimen during this process and that an excessive amount of shotcrete is not removed during each pass. This can be done most effectively by screeding the specimen several times, taking about 5 to 10 mm of material off during each pass of the screed. When the surface of the specimen is level with the side of the form, a final pass of the screed should be carried out with gentle side-to-side motion to leave a relatively smooth surface.

After screeding is completed, the surface of the panel may be gently floated. It should then be left undisturbed until bleeding has ceased (if this occurs at all) and initial setting has occurred. A final float should then be performed if required to leave the surface flat and smooth. The specimens should then be subjected to the specified curing condition.

Designation: C 1556 – 04

Standard Test Method for Determining the Apparent Chloride Diffusion Coefficient of Cementitious Mixtures by Bulk Diffusion[1]

This standard is issued under the fixed designation C 1556; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the laboratory determination of the apparent chloride diffusion coefficient for hardened cementitious mixtures.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2 *NORDTEST Standards:*

NT BUILD 443, Approved 1995-11, Concrete, Hardened: Accelerated Chloride Penetration (in English)[3]

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this test method, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *apparent chloride diffusion coefficient, D_a, n*—a chloride transport parameter calculated from acid-soluble chloride profile data obtained from saturated specimens exposed to chloride solutions, without correction for chloride binding, that provides an indication of the ease of chloride penetration into cementitious mixtures.

3.2.2 *chloride binding, v*—the chemical process by which chloride ion is removed from solution and incorporated into cementitious binder hydration products.

3.2.2.1 *Discussion*—Chloride binding is primarily associated with hydration products formed by the aluminate phase of cement and mixtures containing ground granulated blast furnace slag.

3.2.3 *chloride penetration, v*—the ingress of chloride ions due to exposure to external sources.

3.2.4 *exposure liquid, n*—the sodium chloride solution in which test specimens are stored prior to obtaining a chloride profile.

3.2.5 *exposure time, n*—the time that the test specimen is stored in the solution containing chloride ion.

3.2.6 *initial chloride-ion content, C_i, n*—the ratio of the mass of chloride ion to the mass of concrete for a test specimen that has not been exposed to external chloride sources.

3.2.7 *profile grinding, v*—the process of grinding off and collecting a powder sample in thin successive layers from a test specimen using a dry process.

3.2.8 *surface chloride content, C_s, n*—the theoretical ratio of the mass of chloride ion to the mass of concrete at the interface between the exposure liquid and the test specimen.

4. Summary of Test Method

4.1 Obtain a representative sample of the cementitious mixture prior to exposure to chloride ion. Separate each sample into a test specimen and an initial chloride-ion content specimen. Crush the initial chloride-ion content specimen and determine the initial acid-soluble chloride-ion content. Seal all sides of the test specimen, except the finished surface, with a

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.66 on Concrete's Resistance to Fluid Penetration.

Current edition approved June 1, 2004. Published July 2004. Originally approved in 2003. Last previous edition approved in 2003 as C 1556 – 03.

www.technobetar.ir

suitable barrier coating. Saturate the sealed specimen in a calcium hydroxide solution, rinse with tap water, and then place in a sodium chloride solution. After a specified exposure time, the test specimen is removed from the sodium chloride solution and thin layers are ground off parallel to the exposed face of the specimen. The acid-soluble chloride content of each layer is determined. The apparent chloride diffusion coefficient and the projected surface chloride-ion concentration are then calculated using the initial chloride-ion content, and at least six related values for chloride-ion content and depth below the exposed surface.

5. Significance and Use

5.1 This test method is applicable to cementitious mixtures that have not been exposed to external chloride ions, other than the negligible quantity of chloride ion exposure from sample preparation using potable water, prior to the test.

5.2 The calculation procedure described in this test method is applicable only to laboratory test specimens exposed to a sodium chloride solution as described in this test method. This calculation procedure is not applicable to specimens exposed to chloride ions during cyclic wetting and drying.

NOTE 1—The diffusion of ionic species in concrete occurs within the fluid-filled pores, cracks and void spaces. The concentration and valence of other ionic species in the pore fluid also influence the rate of chloride diffusion, and therefore, the apparent diffusion coefficient as determined by this test procedure.

5.3 In most cases, the value of the apparent chloride diffusion coefficient for cementitious mixtures changes over time (See Note 2). Therefore, apparent diffusion coefficients obtained at early ages may not be representative of performance in service.

NOTE 2—The rate of change of the apparent diffusion coefficient for cementitious mixtures containing pozzolans or blast-furnace slag is typically different than that for mixtures containing only portland cement.

5.4 The apparent chloride diffusion coefficient is used in Fick's second law of diffusion to estimate chloride penetration into cementitious mixtures that are in a saturated condition.

5.5 The apparent chloride diffusion coefficient is commonly used in chloride ingress models based on Fick's second law of diffusion. The apparent diffusion coefficient determined by this method includes chemically bound chloride, so proper use of the apparent chloride diffusion coefficient to predict chloride ingress requires consideration of chloride binding.

5.6 The resistance to chloride penetration is affected by such factors as the environment, finishing, mixture composition, workmanship, curing, and age.

6. Apparatus

6.1 *Balance*, accurate to at least ±0.01 g.

6.2 *Thermometer*, accurate to at least ±1.0 °C.

6.3 *Controlled Temperature Laboratory or Chamber*. The laboratory or chamber shall maintain the temperature of a water bath at 23 ± 2 °C.

6.4 *Plastic Container*, with tight-fitting lid. Select a container size in accordance with provisions in 9.1.2.

6.5 Equipment for grinding off and collecting powder from concrete, mortar, or grout specimens in layers of approximately 2 mm thickness. Refer to Figs. 1 and 2 for examples of satisfactory equipment (See Note 3).

NOTE 3—A lathe or milling machine equipped with a short-barrel carbide-tipped, or diamond-tipped, core drill bit has been found satisfactory for profile grinding.

6.6 *Resealable Polyethylene Bags*, 200- to 300-mm wide by 250- to 300-mm long, and sheet thickness not less than 0.1 mm.

6.7 Equipment for crushing concrete, mortar or grout. Suitable equipment is described in Test Method C 1152/C 1152M.

6.8 Equipment for chloride analysis as described in Test Method C 1152/C 1152M.

6.9 *Slide Caliper*, accurate to at least ± 0.1 mm.

7. Reagents and Materials

7.1 *Distilled or De-ionized Water*.

7.2 *Calcium Hydroxide [$Ca(OH)_2$]*, technical grade.

7.3 *Calcium Hydroxide Solution*, saturated, (approx. 3 g/L).

7.4 *Sodium Chloride [NaCl]*, technical grade.

7.5 *Exposure Liquid*—An aqueous NaCl solution prepared with a concentration of 165 ± 1 g NaCl per L of solution.

7.6 *Two-component Polyurethane or Epoxy-resin Based Paint*, capable of forming a barrier membrane that is resistant to chloride ion diffusion.

8. Test Specimens

8.1 Drilled cores, molded cylinders, or molded cubes are acceptable test specimens. One sample consists of at least two test specimens representative of the cementitious mixture under test (See Note 4). Specimens must be free of defects such as voids or cracks visible to the unaided eye (See Note 5). The minimum dimension across the finished surface of each test specimen must be at least 75 mm, but not less than three times the nominal maximum aggregate particle size. The specimen depth must be at least 75 mm.

NOTE 4—The material between the exposed surface and the outermost layer of reinforcement is often of interest because it is here that the protection against chloride penetration is needed. Furthermore, the quality of the material in this particular area can deviate from that in the rest of the system, as this region is often affected by construction practices.

NOTE 5—Specimens with voids deeper than the profile layer thickness can increase the apparent rate of chloride penetration, and increases test variability.

8.2 Unless otherwise specified, provide 28 days of laboratory standard moist curing in accordance with Practice C 31/C 31M or C 192/C 192M prior to sample preparation for immersion in the exposure liquid.

8.2.1 Describe any variance from standard curing practice in the report.

8.3 For drilled cores obtained according to Test Method C 42/C 42M, prepare the test specimen by cutting off the outermost 75 mm of the core. The test specimen thus obtained has one face that is the original finished surface, and the other face that is a sawn surface as shown in Fig. 3.

www.technobetar.ir

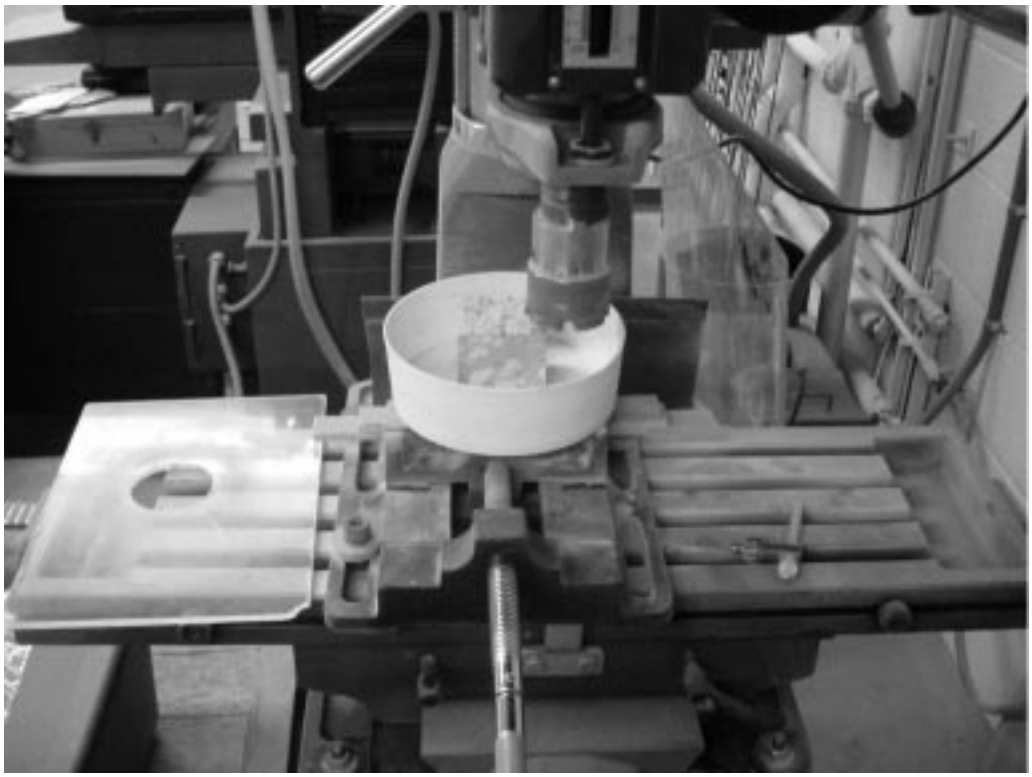

FIG. 1 Profile Grinding Using a Milling Machine

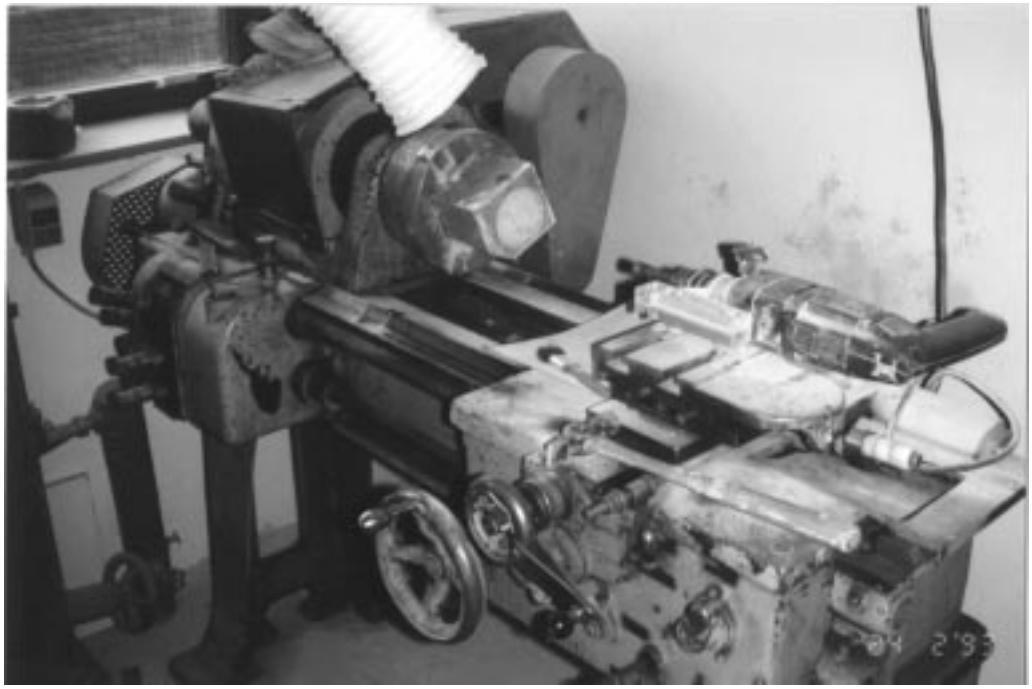

FIG. 2 Profile Grinding Using a Lathe

8.4 For specimens prepared in accordance with Practice C 31/C 31M or C 192/C 192M, the test specimen is prepared by cutting parallel to the finished surface. The top 75 mm is used as the test specimen (see Fig. 3).

8.5 From the remainder of the drilled core, or molded specimen, cut a slice that is at least 20-mm thick. Use this slice to determine the initial chloride-ion content, C_i.

8.6 Rinse the specimens with tap water immediately after cutting. Scrub the surface with a stiff nylon brush, and rinse again. Prior to sealing specimen surfaces, air dry until no moisture can be removed from the surface with a dry paper towel (See Note 6).

8.6.1 Exposure specimens must be surface-dry but internally moist prior to sealing. This condition is satisfied by

www.technobetar.ir

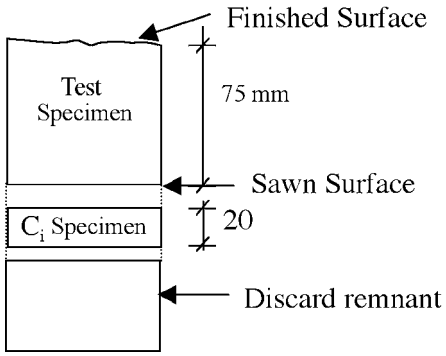

FIG. 3 Sketch of Specimens Obtained from a Typical Sample

standard moist-cured specimens allowed to air dry for no more than 24 h in laboratory air maintained at 23 ± 2 °C and 50 ± 3 % RH.

NOTE 6—Specimens cured in a saturated calcium hydroxide water bath are normally covered by residual lime particles. If this residue is not removed and test specimens are allowed to temporarily dry in air, a calcium carbonate layer can form on the surface of the specimen. This carbonate layer may interfere with the test result, which is why cleansing and rinsing with tap water after cutting or removal from the saturated calcium hydroxide water bath is required.

8.7 Seal all sides of the exposure specimen except for the finished surface following the procedure described in Test Method C 1202.

8.8 Determine the initial mass of the test specimen when the coating has hardened.

8.9 Immerse the test specimen in the saturated calcium hydroxide water bath at 23 ± 2°C in a tightly closed plastic container. The container must be filled to the top to prevent carbonation. After 24 h of immersion, remove the specimen, blot the surface dry with a paper towel, and determine the mass of the specimen in the surface-dry condition.

8.10 The test specimen is immersed in a saturated calcium hydroxide water bath until the mass does not change by more than 0.1 % in 24 h (See Note 7). An acceptable alternative procedure is to vacuum saturate the specimens with saturated calcium hydroxide solution using a vacuum chamber similar to the system described in Test Method C 1202.

NOTE 7—Typically, the mass of moist-cured specimens stabilizes within 48 h.

9. Procedure

9.1 *Exposure*:

9.1.1 Remove the saturated test specimen from the calcium hydroxide water bath, immediately rinse the specimen surface with tap water, place the specimen in the exposure container, fill the container with the exposure liquid, and then seal the container. Place the container in a temperature-controlled chamber or room maintained at 23 ± 2°C. Record the start date and start time to the nearest hour.

9.1.2 It is permitted to place multiple specimens in a single container as long as the specimens are placed in the container such that the entire exposure surface is unobstructed. Maintain the exposed surface area to exposure liquid volume ratio within the range of 50 ± 30 cm^2/L (See Note 8).

NOTE 8—The volume of exposure liquid required for nominal 100-mm diameter cylinder or core exposure specimens is approximately one liter per specimen.

9.1.3 The specimens must remain in the exposure liquid for at least 35 days (See Note 9).

NOTE 9—The exposure time should be extended for mixtures such as those that are more mature, were made with low w/cm, or high-performance mixtures containing supplementary cementitious materials.

9.1.4 If evaporation of water from the exposure liquid or a container leak allows the specimen surface to dry during the exposure time, the test is not valid (See Note 10).

NOTE 10—It is suggested to monitor the mass of the sealed container if evaporation of water from the exposure solution is expected.

9.1.5 Record the exposure time to the nearest hour.

9.2 *Profile Grinding*:

9.2.1 Remove the test specimen from the exposure liquid, rinse with tap water, and dry for at least 24 h in laboratory air maintained at 23 ± 2°C and 50 ± 3 % RH.

9.2.2 When grinding is to be performed longer than 48 h after removal from the exposure solution, store the specimens in watertight resealable polyethylene bags until time of grinding. When grinding is to be performed longer than 7 days after removal from the exposure solution, store the bagged specimens in a freezer maintained at -15 °C (±5 °C) until time of grinding.

9.2.3 Obtain the powder samples by grinding off material in layers parallel to the exposed surface. Do not grind closer than

TABLE 1 Recommended Depth Intervals (in mm) for Powder Grinding[A]

w/cm	0.25	0.30	0.35	0.40	0.50	0.60	0.70
Depth 1	0-1	0-1	0-1	0-1	0-1	0-1	0-1
Depth 2	1-2	1-2	1-2	1-3	1-3	1-3	1-5
Depth 3	2-3	2-3	2-3	3-5	3-5	3-6	5-10

www.technobetar.ir

5 mm from the edge of the specimen to avoid edge effects and disturbances from the coating.

9.2.4 For the minimum exposure time of 35 days, grind off eight layers in accordance with Table 1. For longer exposure times, select depth increments such that a minimum of 6 points span the range from 1 mm below the exposed surface to a depth with a chloride-ion content equal to, or slightly greater than, the initial chloride-ion content.

9.2.5 The following alternate profiling procedure is permitted if the exposure time is sufficient to allow chloride penetration deeper than 40 mm. Slice the test specimen parallel to the exposure surface using a water-cooled diamond saw in 5- to 6-mm increments, minimizing the time specimens are exposed to water. Dry the slices for 24 h in laboratory air, then crush and prepare the powder sample as described in Test Method C 1152/C 1152M.

9.2.6 Obtain a sample of at least 10 g of powder from each layer. Determine the distance from the exposure surface to the mid-depth of each layer. For example, the layer thickness and mid-depth are determined from measurements of the specimen before and after powder sample collection. Calculate the depth below the exposed surface as the average of five uniformly distributed measurements using a slide caliper.

9.3 *Chloride Analysis*:

9.3.1 Determine the acid-soluble chloride-ion content of the powder samples, C_x (mass %), to ±0.001 % according to Test Method C 1152/C 1152M.

9.3.2 Obtain the initial chloride-ion content, C_i (mass %), from the 20-mm thick slice by crushing and prepare a powder sample as described in Test Method C 1152/C 1152M.

9.4 Record any deviations from the requirements of this method.

10. Calculations

10.1 *Test Results*:

10.1.1 Determine the values of surface concentration and apparent chloride diffusion coefficient by fitting Eq 1 to the measured chloride-ion contents by means of a non-linear regression analysis using the method of least squares. Omit the chloride-ion content determined from the exposure surface layer in the regression analysis. All other chloride-ion content measurements are included in the regression analysis.

$$C(x,t) = C_s - (C_s - C_i) \cdot erf\left(\frac{x}{\sqrt{4 \cdot D_a \cdot t}}\right) \quad (1)$$

where:

$C(x,t)$ = chloride concentration, measured at depth x and exposure time t, mass %,
C_s = projected chloride concentration at the interface between the exposure liquid and test specimen that is determined by the regression analysis, mass %,
C_i = initial chloride-ion concentration of the cementitious mixture prior to submersion in the exposure solution, mass %,
x = depth below the exposed surface (to the middle of a layer), m,
D_a = apparent chloride diffusion coefficient, m^2/s,
t = the exposure time, s, and
erf = the error function described in Eq 2.

$$erf(z) = 2 / \sqrt{\pi} \cdot \int_0^z exp(-u^2)du \quad (2)$$

10.1.2 Tables with values of the error function are given in standard mathematical reference books.[4] The error function is also included as a library function in most electronic calculation software.

10.1.3 The test results are:

10.1.3.1 The initial chloride concentration, C_i (mass %), stated to three significant digits.

10.1.3.2 The projected surface chloride concentration at the exposed surface, C_s (mass %), stated to three significant digits.

10.1.3.3 The apparent chloride diffusion coefficient, D_a (m^2/s), stated to 2 significant digits.

10.2 *Non-linear Regression Analysis*—Perform the regression analysis by minimizing the sum given in Eq 3. Refer to Fig. 4 for clarification.

$$S = \sum_{n=2}^{N} \Delta C^2(n) = \sum_{n=2}^{N} (C_m(n) - C_c(n))^2 \quad (3)$$

where:

S = sum of squares to be minimized, (mass %)^2,
N = the number of layers ground off,
$\Delta C(n)$ = difference between the measured and calculated chloride concentration of the nth layer, mass %,
$C_m(n)$ = measured chloride concentration of the nth layer, mass %, and
$C_c(n)$ = calculated chloride concentration in the middle of the nth layer, mass %.

10.3 *Other Calculations*:

10.3.1 Plot the measured chloride contents at all points versus depth below the surface. Plot the best-fit curve on the same graph (see Fig. 4).

11. Report

11.1 Report the following information if known:

11.1.1 Name and address of the laboratory, and the place at which tests were performed, if different from the laboratory address.

11.1.2 Date and identification number of the test report.

11.1.3 Method of sampling and other circumstances (date and person responsible for sampling).

11.1.4 Description of the tested object including specimen type, identification marks, mixture proportions, the date the tested object was cast, curing regimen employed, and age at the start of exposure.

11.1.5 Start date and duration of the exposure time.

11.1.6 Conditioning of the test specimens, and a description of the exposure conditions during the test, such as temperature, evidence of evaporation.

11.1.7 Identification of the test equipment and instruments used.

11.1.8 Any deviation from the test method together with other information of importance for judging the result.

[B] Coefficient of variation.

11.1.11 The measured value of C_i and the values of C_s, and D_a determined from the regression analysis.

11.1.12 Date and signature.

12. Precision and Bias

12.1 *Precision*—There has been no interlaboratory study of this test method. However, there are precision data[5] from an interlaboratory study of NORDTEST NT Build 443, from which this test method was developed. The report includes data from two interlaboratory studies involving three concrete mixtures and three to five laboratories participated, depending on the mixture. Average values of D_a among the mixtures ranged from 2.1 to 14.7 $\times$ (10^{-12}) m^2/s. Average values of C_s among the mixtures ranged from 0.61 to 1.0 %. Table 3 summarizes the single-laboratory and multiple-laboratory coefficient of variation and maximum difference expected between duplicate determinations in 95 % of such comparisons. Therefore, the apparent diffusion coefficient results of two properly conducted tests should not differ by more than 39.8 % of the mean value.

12.2 *Bias*—Since there is no accepted reference material suitable for determining the bias of this test method, no statement on bias is made.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1556 – 03, that may impact the use of this test method. (Approved June 1, 2004)

(*1*) Added Note 1 to Significance and Use, increment reference numbers for all existing notes.

(*2*) Freezing requirement added to 9.2.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1565 – 09

Standard Test Method for Determination of Pack-Set Index of Portland Cement[1]

This standard is issued under the fixed designation C 1565; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of the pack-set index, which provides an indication of the mechanical force needed to overcome the consolidation of portland cement.

1.2 The pack-set index number provides a numerical value useful for manufacturers who desire to measure and control the effect that vibration-induced consolidation has upon the manufactured cement.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard. Values stated in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the rules of Conversion and rounding given in Standard IEEE/ASTM SI 10, of measurements made in other units.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**WARNING**—Fresh hydraulic-cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

IEEE/ASTM SI 10 International System of Units (SI) The Modernized Metric System

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *pack set*, *n*—a condition of hydraulic cement, exhibited in varying degrees, following silo storage or transport in bulk railcars or trucks, that causes the cement to resist flowing until considerable mechanical effort has been applied.

3.1.2 *pack-set index*, *n*—the numerical indication of the degree of pack set a particular cement exhibits when subjected to the procedures of this test method.

3.1.3 *peak voltage*, *n—as pertaining to this method only*, the energy in volts applied to consolidate the sample, which results in the maximum pack-set index for a particular cement and the apparatus used for the measurement.

4. Summary of Test Method

4.1 Portland cement is placed into a flask and then consolidated on a vibrating table by a vibration force controlled by time and volts. The consolidated bed is measured for relative strength by turning the flask to a horizontal position and rotating in 180° increments until the bed collapses from the bottom of the flask. The number of half turns is a relative indication of the force required to overcome the consolidation and is designated the pack-set index, or P.S.I.

5. Significance and Use

5.1 This method is intended to help manufacturers determine the relative pack-set tendency of their cement(s). The test establishes a pack-set index which, when properly correlated with field performance, is useful in predicting or preventing field unloading difficulties.

5.2 The test is an aid to routine control during cement production and is not suitable for specification purposes.

5.3 In general, field performance of cement flowability is satisfactory when the pack-set index as determined on freshly ground cement averages 0 to 15 and is unsatisfactory when the index exceeds 25. Any prediction of field performance of cement flowability measuring 16 to 25 is tenable. These are general ranges and the field performance of individual cements may not necessarily fall within these ranges. Additional conditions, after the cement has left the control of the manufacturing facility, can affect the apparent pack set index as well.

5.4 Any attempt to apply the critical range of pack-set index numbers based on freshly ground cement to job cement without special treatment of the sample would be problematic. The test

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.20 on Additions.

Current edition approved June 1, 2009. Published July 2009. Originally approved in 2003. Last previous edition approved in 2004 as C 1565 – 04.

www.technobetar.ir

is a "GO-NO GO" type of test and should not be used for specification purposes.

5.5 The pack-set index of field cement can be evaluated in terms of the pack-set index ranges of that cement as determined when freshly-ground. This comparison can aid the manufacturer in producing cement that offers the best field performance for pack-set properties.

5.6 Silo storage of cement may result in a greater amount of consolidation than this method is designed to induce, and the resulting forces required to overcome that consolidation are not measured by this test method.

5.7 Pack set is not to be confused with "warehouse set" which results from surface hydration of the cement from adsorbed moisture.

6. Interferences

6.1 Results obtained from the pack-set test are dependent on sample exposure (See Note 1).

NOTE 1—Fresh cement has a greater pack-set tendency. Cement stored in silos for only a day or two will test similar to fresh cement. Cement stored in full silos, where aeration is negligible, may develop lower pack-set indices upon further aging, Even samples in sealed containers may vary.

6.2 Pack-set index determination can be affected by sample temperature (See Note 2).

NOTE 2—Cement with a temperature noticeably hotter than room temperature may produce a different pack-set index number than that same cement cooled to room temperature. Cooling of hot cement samples must be accomplished with minimum aeration to avoid moisture and CO_2 adsorption.

6.3 The testing room humidity can significantly influence the determined pack-set index.

6.4 Keep the apparatus level during the testing procedure.

6.5 The vibration energy transferred to the sample is affected by the support given the apparatus (See Note 3). The determination of pack-set index for unknown samples shall be accomplished on the same physical support that the peak voltage for the test was determined on.

NOTE 3—Apparatus which is not setting firmly on the counter or table may not deliver repeatable results.

6.6 Vibration energy delivered by the table is related to the proper handling and adjustment of the table. See Section 7 for details.

6.7 Vibration energy delivered by the table is related to the frequency of the source voltage. This variation, if present, will result in a poor repeatability and require more frequent determination of the peak voltage.

7. Apparatus

7.1 *Erlenmeyer Flask*, 250 mL capacity, regular wall thickness, fitted with a number 14 (large diameter 32 mm and small diameter 25 mm) cork stopper. Flasks are not interchangeable. Each flask and cork combination must have the peak voltage determined prior to use in the test method (See Note 4).

7.2 *Reference Masses and Devices for Determining Mass* shall conform to the requirements of Specification C 1005 as appropriate for the size of the sample, the mass of which is to be determined, with a sensitivity of no less than 0.1 g and a readability of 0.1 g or less.

NOTE 4—There are enough differences between Erlenmeyer flasks of the same rated capacity to cause significant difference in the pack-set index. It is recommended that several flasks which deliver similar pack-set index numbers for the same cement be kept as spares.

7.3 *Vibrating Table*, (see Fig. 1), capable of generating electromagnetic vibrations at the frequency of 60 Hz, having a wooden or phenolic resin top with dowel pins installed equidistant from each other on the circumference of the circle centered on the table, with a radius slightly greater than the largest radius of the flask (to restrain the flask movement on the table).[4] A device that is capable of stopping any lateral movement of the flask during vibration is required (See Note 5). The air gap setting between the armatures of the vibrating table is critical to the generation of the proper vibrational amplitude and must be adjusted according to the manufacturer's instructions. Manufacturer's recommendations and precautions for proper operation must be followed to assure the accurate determination of the pack set index.

NOTE 5—Three or four dowel pins of 6 to 10 mm diameter and 25 to 30 mm long will be sufficient to restrain the flask. Interconnecting rubber bands or rubber cam-locks can be used to restrain the flask to prevent lateral movement of the flask during vibration.

7.4 *Roto-Tester*, (see Fig. 2), a device on which the Erlenmeyer flask can be mounted in a horizontal position against a vertical, flat, rotating plate that contains frictional hold-down cams to prevent the flask from falling, and capable of smoothly rotating the flask and table while in that horizontal position, in 180° increments at the rate of approximately 40 one-half rotations per minute with a short partial second pause between half-rotations. The device shall be equipped with a counter capable of recording the number of one-half rotations of the table.[5]

7.5 *Voltmeter*, capable of measuring and displaying the voltage delivered to the vibrating table to the nearest 0.5 VAC.

7.6 *Variable-voltage Transformer*, inductance-type, capable of supplying the vibrating table with voltage within the range of 0 v to 100 % of the design voltage of the vibrating table.

7.7 *Automatic Timer*, capable of controlling the "ON" time of the variable-voltage transformer and the vibrating table to 15 ± ½ s.

8. Preparation of Apparatus—Determination of Peak Voltage

8.1 Determine the peak voltage applied to the vibrating table to achieve the maximum pack-set index number for a sample.

8.1.1 Turn the vibrating table ON, and using the voltage adjustment of the variable-transformer, set the voltage so that little or no compaction takes place in the cement sample during the 15 s vibration. Increment the voltage by 2v until the compaction achieved result is a pack-set index value greater

[4] The vibrating table is available from suppliers of the pack set apparatus. A list of suppliers can be obtained from ASTM.

[5] The roto-tester is available from suppliers of the pack set apparatus. A list of suppliers can be obtained from ASTM.

www.technobetar.ir

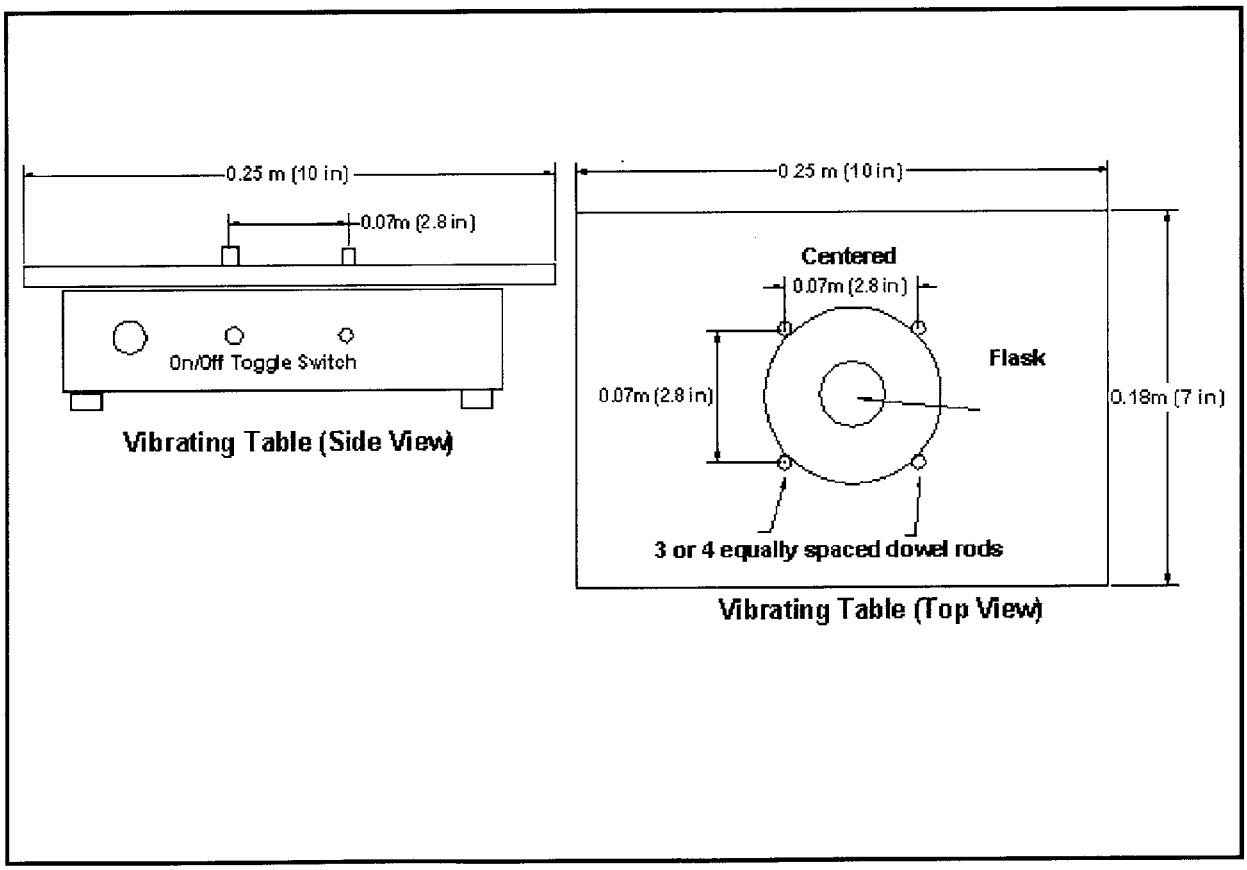

FIG. 1 Vibrating Table

than zero. Continue incrementing the voltage by 2v until a pack-set index is determined that is lower than the index determined using the preceding voltage. The preceding voltage is the peak voltage for that cement and apparatus combination (See Note 6).

NOTE 6—The test method uses the concept of vibration voltage increasing in order to develop cement bed compaction from nearly nothing to that voltage which provides a maximum pack-set index, to that voltage which disrupts the compaction and reduces the pack-set index to below the maximum. A starting voltage somewhere between 40-60 volts will generally satisfy that need.

8.2 Determine the peak voltage for the following conditions:

8.2.1 For each type of cement from a single source.

8.2.2 For samples obtained in the field or for interlaboratory testing.

8.2.3 Whenever the flask or cork is changed.

8.2.4 Whenever the vibrating table, voltmeter, variable-transformer, timer, or Roto-Tester are adjusted or replaced.

8.2.5 No less frequently than every 1 month for any single cement from a single source.

9. Conditioning

9.1 Maintain the temperature of the room and dry materials at 23.0 ± 3.0 °C.

9.2 Maintain the relative humidity of the testing room at a minimum of 50 %.

9.3 Sieve all samples through an 850-µm (No. 20) mesh screen prior to the pack-set determination.

9.4 Prior to each use, clean the inside and outside of the flask, the table top of the vibrating table, and the roto-tester with a dry clean cloth.

10. Procedure

10.1 Place 100.0 ± 0.1 g of cement, or 90.0 ± 0.1 g if Type III cement, into the clean flask. Stopper tightly with the cork stopper to avoid spillage.

10.2 *De-agglomeration*:

10.2.1 Support the flask with the neck maintained in a nearly horizontal position (consider nearly horizontal to be less than 90° but more than 70° from the vertical position of the flask). Rotate the flask one-half turn in the same direction. Continue rotation at the rate of two half-turns per second for a minimum of 10 s (See Note 7).

10.2.2 Level the bed of cement by manually suspending the flask by the neck in an upright position and gently swirling the flask about its longitudinal axis. Avoid excessive shaking or swirling which can cause re-agglomeration of the cement particles.

NOTE 7—Proper and sufficient de-agglomeration is required for acceptable repeatability of the test. Operators should practice the procedure to reduce differences between repeat determinations of the index.

www.technobetar.ir

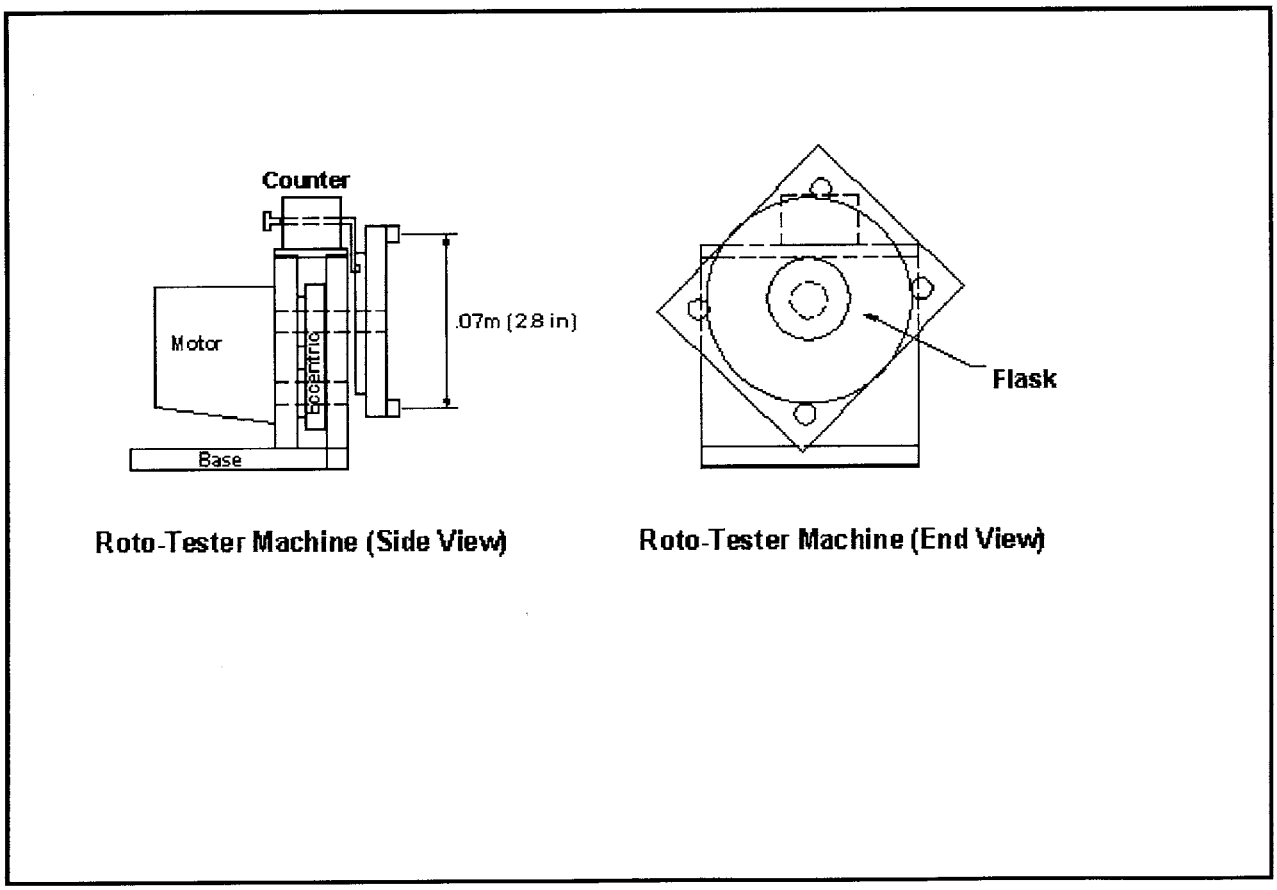

FIG. 2 Roto-Tester

10.3 Insure that the voltage supplied to the vibrating table is set at the predetermined peak voltage. The table must be "ON" for this procedure. Turn the table "OFF" when finished.

10.4 Gently place the flask onto the vibrating table inside of the retaining dowels, engage the restraining device in such a manner as to insure no lateral movement between dowels and flask wall during vibration. Set the timer for 15 s, and operate the vibrating table for the 15 s.

10.5 Remove the flask from the table, gently tip the flask to a horizontal position, place the flask into the roto-tester, carefully fasten the flask into the roto-tester with the friction cam clamps. The bottom of the flask and the roto-tester table must be contacting each other over the entire circumference of the flask. Read the counter on the roto-tester or reset the counter to zero. Operate the roto-tester until the consolidated bed of cement collapses from the bottom of the flask. Turn the roto-tester "off" and read the counter. If the bed only partially collapses, consider the run invalid if the bed does not completely collapse within two additional one-half rotations. Subtract the beginning number from the ending number to determine the number of one-half rotations required to collapse the bed of cement (See Note 8).

10.6 Make five (5) determinations using steps 10.2, 10.4, and 10.5.

NOTE 8—Under some circumstances, the number of half-turns for a single run will go above 50. When the number of turns does go above 50, it is permissible to stop the roto-tester and record the result as "50+."

11. Calculation of Results

11.1 Calculate the pack-set index by averaging the results of the five runs. Round the average to the nearest whole number.

12. Report

12.1 Report the pack-set index as a whole number, abbreviated, if desired, as P.S.I. and the peak voltage used to obtain the result. For example, "P.S.I. = 10 at 56 v."

13. Precision and Bias

13.1 Test data for the determination of pack-set index precision is being evaluated by Subcommittee C01.20. Statements of precision will be included in a later revision of this test method.

13.2 Since there is no accepted reference material suitable for determining any bias that may be associated with this test method, no statement is being made.

14. Keywords

14.1 pack set; pack-set index; peak voltage; portland cement; roto-tester

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 1565 – 04, that may impact the use of this test method. (Approved June 1, 2009)

(*1*) Revised 4.1, 7.3, 10.4, and Footnotes 4 and 5.

(*2*) Replaced the term “maximum voltage” with “peak voltage” throughout the standard.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1567 – 08

Standard Test Method for Determining the Potential Alkali-Silica Reactivity of Combinations of Cementitious Materials and Aggregate (Accelerated Mortar-Bar Method)[1]

This standard is issued under the fixed designation C 1567; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method permits detection within 16 days of the potential for deleterious alkali-silica reaction of combinations of cementitious materials and aggregate in mortar bars. The cementitious materials are composed of various proportions of hydraulic cement, pozzolans and ground granulated blast-furnace slag.

1.2 The test results are only valid for the specific combinations of pozzolan, slag, and reactive aggregates tested.

1.3 This test is not suitable for evaluating the potential for deleterious reaction of combinations of hydraulic cement and aggregate (that is, in the absence of pozzolans or ground granulated blast-furnace slag).

1.4 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. A specific precautionary statement is given in the section on Reagents.*

4. Significance and Use

4.1 This test method provides a means for evaluating the ability of pozzolans and ground granulated blast-furnace slag to control deleterious internal expansion due to alkali-silica reaction when used with an aggregate intended for use in concrete. It is based on the Accelerated Test Method developed at the National Building Research Institute (NBRI) in the Republic of South Africa (**1-4**).[3]

4.2 Results obtained using this test method may overestimate the reactivity of some types of aggregates if used in service with the same pozzolans or slag and hydraulic cement of low alkali content.

4.3 Different levels of pozzolan and ground granulated blast-furnace slag may require testing to determine the amount required to reduce expansion to an acceptable level. Pozzolans and ground granulated blast-furnace slag may be tested separately or in combination.

4.4 It is recommended to test the same aggregate and hydraulic cement (without pozzolans and slag) using Test Method C 1260.

4.5 This test method may underestimate the expansion of cementitious systems containing pozzolans with an alkali content > 4.0 % sodium oxide equivalent (**7-9**). It is recommended that such materials be tested using Test Method C 1293.

5. Apparatus

5.1 The apparatus shall conform to Practice C 490, except as follows:

5.2 *Sieves*—Square hole, woven-wire cloth sieves, shall conform to Specification E 11.

5.3 *Mixer, Paddle, and Mixing Bowl*—Mixer, paddle, and mixing bowl shall conform to the requirements of Practice C 305, except that the clearance between the lower end of the paddle and the bottom of the bowl shall be 5.1 ± 0.3 mm.

5.4 *Tamper and Trowel*—The tamper and trowel shall conform to Test Method C 109/C 109M.

5.5 *Containers*—The containers shall be of such a nature that the bars can be totally immersed in either the water or 1N sodium hydroxide (NaOH) solution. The containers shall be made of material that can withstand prolonged exposure to 80 °C and must be resistant to a 1N NaOH solution (see Note 1). The containers must be so constructed that when used for storing specimens, the loss or gain of moisture is prevented by tight-fitting covers, by sealing, or both (see Note 2). The bars in the solution must be placed and supported so that the solution has access to the entire surface of each bar; therefore, ensure that the specimens do not touch the sides of the container or each other. The specimens, if stood upright in the solution, shall not be supported by the metal gage stud.

NOTE 1—The NaOH solution corrodes glass or metal containers.

NOTE 2—Some microwave-proof food storage containers made of polypropylene or high-density polythylene have been found to be acceptable.

[3] The boldface numbers in parentheses refer to a list of references at the end of the text.

5.6 *Oven, or Water Bath*—A convection oven or water bath with temperature control maintaining 80.0 ± 2.0 °C.

6. Reagents

6.1 *Sodium Hydroxide (NaOH)*—USP or technical grade may be used, provided the Na^+ and OH^- concentrations are shown by chemical analysis to lie between 0.99N and 1.01N.

6.2 *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Type IV of Specification D 1193.

6.3 *Sodium Hydroxide Solution*—Each litre of solution shall contain 40.0 g of NaOH dissolved in 900 mL of water, and shall be diluted with additional distilled or deionized water to obtain 1.0 L of solution. The volume proportion of sodium hydroxide solution to mortar bars in a storage container shall be 4 ± 0.5 volumes of solution to 1 volume of mortar bars. The volume of a mortar bar may be taken as 184 mL. Include sufficient test solution to ensure complete immersion of the mortar bars.

6.3.1 *Warning*—Before using NaOH, review: (1) the safety precautions for using NaOH; (2) first aid for burns; and (3) the emergency response to spills, as described in the manufacturer's Material Safety Data Sheet or other reliable safety literature. NaOH can cause very severe burns and injury to unprotected skin and eyes. Suitable personal protective equipment must always be used. These include full-face shields, rubber aprons, and gloves impervious to NaOH. Gloves must be checked periodically for pinholes.

7. Conditioning

7.1 Maintain the temperature of the molding room and dry materials at not less than 20 °C and not more than 27.5 °C. The temperature of the mixing water, and of the moist closet or moist room, shall not vary from 23 °C by more than 2 °C.

7.2 Maintain the relative humidity of the molding room at not less than 50 %. The moist closet or room shall conform to Specification C 511.

7.3 Maintain the storage oven or water bath in which the specimens are stored at a temperature of 80.0 ± 2.0 °C.

8. Sampling and Preparation of Test Specimens

8.1 *Selection of Aggregate*—Process materials proposed for use as fine aggregate in concrete as described in 8.2 with a minimum of crushing. Process materials proposed for use as coarse aggregate in concrete by crushing to produce as nearly as practical a graded product from which a sample can be obtained. Grade the sample as prescribed in Table 1. The sample shall represent the composition of the coarse aggregate as proposed for use.

TABLE 1 Grading Requirements

Sieve Size		Mass, %
Passing	Retained on	
4.75 mm (No. 4)	2.36 mm (No. 8)	10
2.36 mm (No. 8)	1.18 mm (No. 16)	25
1.18 mm (No. 16)	600 µm (No. 30)	25
600 µm (No. 30)	300 µm (No. 50)	25
300 µm (No. 50)	150 µm (No. 100)	15

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.1.1 When a given quarried material is proposed for use both as coarse and as fine aggregate, test only a selection of the fine aggregate, unless there is reason to expect that the coarse aggregate has a different composition than the fine aggregate. If such a difference is expected and if the differences might significantly affect expansion due to reaction with the alkalies in cement or from the environment of service, test the coarse aggregate in a manner similar to that employed in testing the fine aggregate.

8.2 *Preparation of Aggregate*—Grade aggregates to provide a sample meeting the requirements given in Table 1. Crush aggregates in which sufficient quantities of the sizes specified in Table 1 do not exist until the required material has been produced. In the case of aggregates containing insufficient amounts of one or more of the larger sizes listed in Table 1, and if no larger material is available for crushing, the first size in which sufficient material is available shall contain the cumulative percentage of material down to that size as determined from the grading specified in Table 1. When such procedures are required, make a special note thereof in the test report. After the aggregate has been separated into the various sieve sizes, wash each size with a water spray over the sieve to remove adhering dust and fine particles from the aggregate. Dry the portions retained on the various sieves and, unless used immediately, store each such portion individually in a clean container provided with a tight-fitting cover.

8.3 *Selection and Preparation of Cement*:

8.3.1 *Hydraulic Cement*—Use a hydraulic cement meeting the requirements of Specification C 150 (Note 3). In addition, the autoclave expansion in Test Method C 151 shall be less than 0.20 %.

NOTE 3—The alkali content of the cement has been found to have negligible (**3**) or minor (**6**) effects on expansion in this test.

8.3.2 *Preparation of Cement*—Pass cement for use in this test through an 850-µm (No. 20) sieve to remove lumps before use.

8.4 *Selection of pozzolan or ground granulated blast-furnace slag*—Use one, or a combination, of the following:

8.4.1 Fly ash or natural pozzolan meeting the requirements of Specification C 618.

8.4.2 Silica fume meeting the requirements of Specification C 1240.

8.4.3 Ground granulated blast furnace slag meeting the requirements of Specification C 989.

8.5 *Preparation of Test Specimens*:

8.5.1 *Number of Specimens*—Make at least three test specimens for each cementitious materials-aggregate combination.

8.5.2 *Preparation of Molds*—Prepare the specimen molds in accordance with the requirements of Practice C 490 except, the interior surfaces of the molds shall be covered with a release agent (see Note 4). A release agent is acceptable if it serves as a parting agent without affecting the time of setting of the cement and without leaving any residue that will inhibit the penetration of water into the specimen.

NOTE 4—TFE-fluorocarbon tape complies with the requirements for a mold release agent.

8.5.3 *Proportioning of Mortar*—Proportion the dry materials for the test mortar using 1 part of cementitious materials (hydraulic cement plus pozzolan or ground granulated blast-furnace slag) to 2.25 parts of graded aggregate by mass for aggregates with a relative density (OD) at or above 2.45. For aggregates with a relative density (OD) below 2.45, determine the aggregate proportion as follows:

$$\textit{Aggregate Proportion} = 2.25 \times \frac{D}{2.65}$$

where:

D = relative density (OD) of test aggregate.

8.5.3.1 For aggregates with a relative density (OD) equal to or greater than 2.45, the quantities of dry materials to be mixed at one time in the batch of mortar for making three specimens shall be 440 g of cementitious material and 990 g of aggregate made up by recombining the portions retained on the various sieves in the grading prescribed in Table 1. Use a water-cement ratio equal to 0.47 by mass (see Note 5).

8.5.3.2 For aggregates with a relative density (OD) less than 2.45, the quantities of dry materials to be mixed at one time in the batch of mortar for making three specimens shall be 440 g of cementitious material and mass of aggregate shall be 440 g multiplied by the aggregate proportion determined in 8.5.3. This aggregate mass shall be made up by recombining the portions retained on the various sieves in the grading prescribed in Table 1. Use a water-cementitious material ratio equal to 0.47 by mass (see Note 5).

NOTE 5—Ruggedness tests indicated that mortar bar expansions were less variable at a fixed water-cement ratio than when gauged to a constant flow (**3**).

8.5.3.3 If silica fume or metakaolin are used, a high range water reducer (HRWR), meeting the requirements of Specification C 494/C 494M Type F, shall be used (if necessary) to provide adequate dispersion and workability of the mixture. The water-cementitious material ratio shall remain 0.47 by mass and the amount of HRWR shall be that to obtain a flow of ± 7.5 percentage points of a control mortar without silica fume or metakaolin as determined in accordance with Test Method C 1437 using 10 drops of the flow table. If liquid HRWR is used, the water present in the liquid must be included in the calculation of the water-cementitious material ratio.

8.5.4 *Mixing of Mortar*—Mix the mortar in accordance with the requirements of Practice C 305.

8.5.5 *Molding of Test Specimens*—Mold test specimens within a total elapsed time of not more than 2 min and 15 s after completion of the original mixing of the mortar batch. Fill the molds with two approximately equal layers, each layer being compacted with the tamper. Work the mortar into the corners, around the gage studs, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, cut off the mortar flush with the top of the mold and smooth the surface with a few strokes of the trowel.

9. Procedure

9.1 *Initial Storage and Reading*—Place each mold in the moist cabinet or room immediately after molds have been

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:36:41 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

filled. The specimens shall remain in the molds for 24 ± 2 h. Remove the specimens from the molds and, while they are being protected from loss of moisture, properly identify and make an initial comparator reading. Make and record the initial and all subsequent readings to the nearest 0.002 mm. Place the specimens made with each aggregate sample in a storage container with sufficient tap water to totally immerse them. Seal and place the containers in an oven or water bath at 80.0 ± 2.0 °C for a period of 24 h ± 2 h.

9.2 *Zero Readings*—Remove the containers from the oven or water bath one at a time. Remove other containers only after the bars in the first container have been measured and returned to the oven or water bath. The time elapsed between removal and return of the specimens to the oven or water bath shall not exceed 10 min. Remove the bars one at a time from the water and dry their surface with a towel paying particular attention to the two metal gage studs. Take the zero reading (see Note 6) of each bar immediately after drying, and read as soon as the bar is in position. Complete the process of drying and reading within 15 ± 5 s of removing the specimen from the water. After taking comparator readings, leave the specimen on a towel until comparator readings have been taken on the remainder of the bars. Place all specimens made with each unique cementitous materials-aggregate combination in a separate container with sufficient 1N NaOH, at 80.0 ± 2.0 °C for the specimens to be totally immersed. Seal the container and return it to the oven or water bath.

NOTE 6—The reference bar should be read prior to each set of specimens since the heat from the mortar bars may cause the length of the comparator to change.

9.3 *Subsequent Storage and Measurement*—Make subsequent comparator readings of the specimens periodically, with at least three intermediate readings, for 14 days after the zero reading, at approximately the same time each day. If readings are continued beyond the 14-day period, take at least one reading per week. The procedure is identical to that described in the 9.2, except that the specimens are returned to their own container after measurement.

10. Calculation

10.1 Calculate the difference between the zero comparator reading of the specimen and the reading at each period to the nearest 0.001 % of the effective gage length and record as the expansion of the specimen for that period. Report the average expansion of the three specimens of a given cementitious materials-aggregate combination to the nearest 0.01 % as the expansion for the combination for a given period.

11. Report

11.1 Report the following information:

11.1.1 Type and source of aggregate,

11.1.2 Type and source of hydraulic cement,

11.1.3 Type, source, and proportions of pozzolan

11.1.4 Grade, source, and proportions of ground granulated blast-furnace slag

11.1.5 Autoclave expansion and alkali content of cement as percent potassium oxide (K_2O), sodium oxide (Na_2O), and calculated sodium oxide (Na_2O) equivalent (Na_2O_{eq}= $\%Na_2O + 0.658 \times \%K_2O$),

11.1.6 Average length change in percent at each reading of the specimens,

11.1.7 Any relevant information concerning the preparation of aggregates, including the grading of the aggregate when it differs from that given in 8.2,

11.1.8 Any significant features revealed by examination of the specimens during and after test,

11.1.9 Amount of mixing water expressed as a mass fraction of the total cementitious material,

11.1.10 A graph of the length change data from the time of the zero reading to the end of the 16 day period.

12. Precision and Bias

12.1 The following precision statements are taken from Test Method C 1260, and are based on tests without pozzolans or ground slag.

12.2 *Within-Laboratory Precision*—It has been found that the average within-laboratory coefficient of variation for materials with an average expansion greater than 0.1 % at 14 days is 2.94 % **(5)** (Note 7). Therefore, the results of two properly conducted tests within the same laboratory on specimens of a sample of aggregate should not differ by more than 8.3 % (Note 7) of the mean expansion.

12.3 *Multi-Laboratory Precision*—It has been found that the average multilaboratory coefficient of variation for materials with an average expansion greater than 0.1 % at 14 days is 15.2 % **(5)** (Note 7). Therefore, the results of two properly conducted tests in different laboratories on specimens of a sample of aggregate should not differ by more than 43 % (Note 7) of the mean expansion.

NOTE 7—These numbers represent, respectively, the (1s %) and (d2s %) limits as described in Practice C 670.

12.4 *Bias*—Since there is no accepted reference material for determining the bias of this test method, no statement on bias is being developed.

13. Keywords

13.1 aggregate; alkali-silica reactivity; length change; mortar; pozzolans, slag, sodium hydroxide

APPENDIX

(Nonmandatory Information)

X1. INTERPRETATION OF TEST RESULTS

X1.1 There is good agreement in the published literature (**2, 10-12**) for the following expansion limits:

X1.1.1 Combinations of cement, pozzolan, or ground granulated blast-furnace slag, and aggregate that expand less than 0.10 % at 16 days after casting are likely to produce acceptable expansions when tested in concrete (that is, Test Method C 1293) and to have a low risk of deleterious expansion when used in concrete under field conditions.

X1.1.2 Combinations of cement, pozzolan, or ground granulated blast-furnace slag, and aggregate that expand more than 0.10 % at 16 days after casting are indicative of potentially deleterious expansion. However, the potential for deleterious reaction should be confirmed by testing the same combination of materials in concrete (that is, Test Method C 1293). The expansion may be reduced by retesting the material combination using the pozzolan or ground granulated blast-furnace slag at a higher replacement level.

Designation: C 1579 – 06

Standard Test Method for Evaluating Plastic Shrinkage Cracking of Restrained Fiber Reinforced Concrete (Using a Steel Form Insert)[1]

This standard is issued under the fixed designation C 1579; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method compares the surface cracking of fiber reinforced concrete panels with the surface cracking of control concrete panels subjected to prescribed conditions of restraint and moisture loss that are severe enough to produce cracking before final setting of the concrete.

1.2 This test method can be used to compare the plastic shrinkage cracking behavior of different concrete mixtures containing fiber reinforcement.

1.3 The values stated in SI units are to be regarded as the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. (***Warning**— fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[2]

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 143/C 143M Test Method for Slump of Hydraulic-Cement Concrete

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 403/C 403M Test Method for Time of Setting of Concrete Mixtures by Penetration Resistance

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 995 Test Method for Time of Flow of Fiber-Reinforced Concrete Through Inverted Slump Cone

3. Summary of Test Method

3.1 Panels of control concrete and fiber reinforced concrete are prepared in a prescribed manner and are exposed to controlled drying conditions after finishing. The drying conditions (See Note 1) are intended to be severe enough to induce plastic shrinkage cracking in test panels made of control concrete. The evaporation rate from a free water surface is monitored by pans placed next to the panels in the environmental chamber.

NOTE 1—An important parameter in this method is the rate of evaporative water loss, which is controlled by the atmospheric conditions surrounding the test specimens. Since the concrete specimens will not always have the same rate of water evaporation as the pan of water (due to evaporative and bleeding effects), the rate of evaporation of 1.0 kg/m^2·h from the pan of water represents the minimum evaporation rate that must be attained for this test (**1**).[4] The moisture loss from the concrete test panels can also be monitored and reported, however, the rate of evaporation from the free surface of the water in the pan is the parameter that should be used to quantify the drying environment.

3.2 The test is terminated at the time of final setting of the concrete determined in accordance with Test Method C 403/C 403M. At 24 h from initial mixing, the average crack width is determined.

3.3 A cracking reduction ratio (CRR) is computed from the average crack width for the fiber-reinforced concrete panels and the average crack width for the control concrete panels.

4. Significance and Use

4.1 The test method is intended to evaluate the effects of evaporation, settlement, and early autogenous shrinkage on the plastic shrinkage cracking performance of fiber reinforced concrete up to and for some hours beyond the time of final setting (See Terminology C 125).

4.2 The measured values obtained from this test may be used to compare the performance of concretes with different mixture proportions, concretes with and without fibers, concretes containing various amounts of different types of fibers, and concretes containing various amounts and types of admixtures. For meaningful comparisons, the evaporative conditions during test shall be sufficient to produce an average crack width

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.42 on Fiber-Reinforced Concrete.

www.technobetar.ir

of at least 0.5 mm in the control specimens (**2, 5**) (See Note 2). In addition, the evaporation rate from a free surface of water shall be within ± 5 % for each test.

NOTE 2—To achieve evaporation rates that result in a crack of at least 0.5 mm in the control specimens, it may be necessary to use an evaporation rate higher than that discussed in Note 1.

4.3 This method attempts to control atmospheric variables to quantify the relative performance of a given fresh concrete mixture. Since many other variables such as cement fineness, aggregate gradation, aggregate volume, mixing procedures, slump, air content, concrete temperature and surface finish can also influence potential cracking, attention shall be paid to keep these as consistent as possible from mixture to mixture.

5. Apparatus

5.1 *Molds*:

5.1.1 For maximum coarse aggregate size equal to or less than 19 mm, use a mold with a depth of 100 ± 5 mm and rectangular dimensions of 355 ± 10 mm by 560 ± 15 mm (See Fig. 1). The mold can be fabricated from metal, plastic, or plywood.

NOTE 3—If plywood is used for molds, the plywood should have low moisture absorption. The mold should be constructed to be lightweight and stiff. The molds, when properly constructed, should last for approximately 50 uses.

5.1.2 This test method is designed for aggregate less than or equal to 19 mm. For coarse aggregate greater than 19 mm, the depth of the mold shall be at least 65 mm plus at least 2 times the maximum coarse aggregate size.

5.2 *Stress Riser and Internal Restraints*—The internal restraints and stress riser shall be bent from one piece of sheet metal, as illustrated in Fig. 1, or made from a solid piece of steel. The sheet metal shall have a thickness of 1.2 ± 0.05 mm (18 gauge) (See Fig. 1 and Ref **2**). Two 32 ± 1 mm high restraints are placed 90 ± 2 mm inward from each end of the mold. The central stress riser is 64 ± 2 mm high and serves as

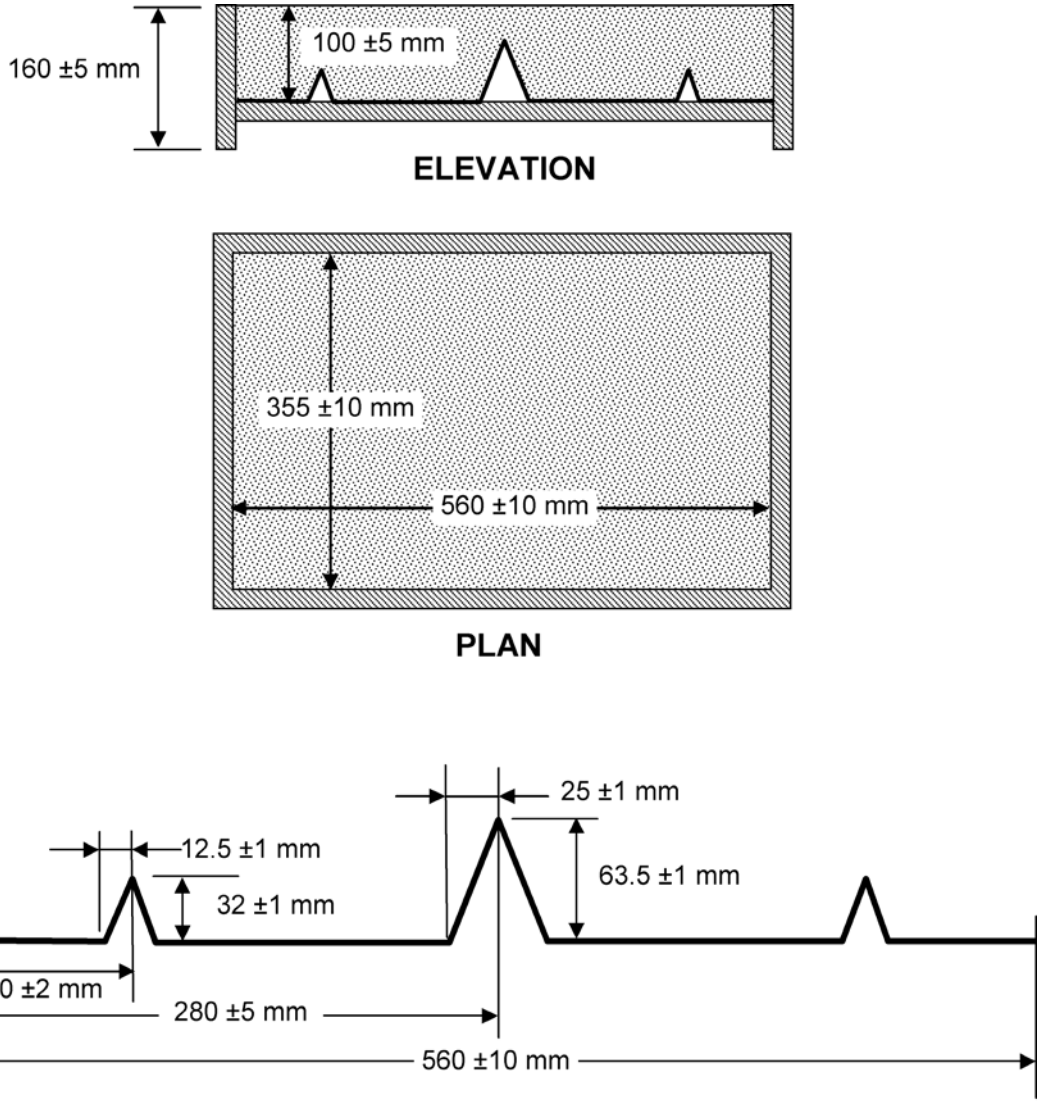

FIG. 1 Specimen and Stress Riser Geometry (4, 5)

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

an initiation point for cracking. This sheet metal stress riser with internal restraints shall fit at the bottom of the mold.

5.2.1 Use form release oil to coat the metal insert and mold sides to reduce bond with concrete. The insert and mold are considered to be properly oiled when the entire surface is coated and excess oil has been removed with a clean, dry rag.

5.3 *Variable Speed Fan(s)*—The fan(s) used shall be capable of achieving a wind speed of more than 4.7 m/s over the entire test panel surface area.

5.4 *Environmental Chamber*—The use of a fan box in an environmental chamber is a method for producing a uniform airflow over the panel surface (See Fig. 2). A clear cover over the panels will aid in obtaining uniform airflow and allow for observation of cracking. Another method of producing uniform airflow is to use a specifically designed environmental chamber as shown in Fig. 3. A commercially available heater, humidifier, and dehumidifier can be used to maintain the specified environmental condition. This test is conducted using either apparatus shown in Fig. 2 or Fig. 3 by exposing the panels to an evaporation rate of at least 1.0 kg/m^2·h (See Note 1). For the standard test, the temperature must be maintained at 36 ± 3 °C, the relative humidity must be 30 ± 10 %, and the wind velocity must be sufficient to maintain the minimum evaporation rate during the test.

NOTE 4—Before casting the concrete panels, atmospheric variables in the environmental facility should be checked to determine that the necessary evaporative conditions can be achieved. A wind velocity of 4.7 m/s should be sufficient to achieve the minimum specified evaporation rate, but a higher wind velocity may be needed to obtain sufficient average crack width in some control panels.

5.5 *Sensors*—Use temperature, humidity, and wind velocity sensors to measure ambient air and concrete surface temperature to the nearest 0.5 °C, relative humidity to the nearest 1 %, and air speed to the nearest 0.1 m/s.

5.6 *Vibrating Platform*—Any device that can fully consolidate the test panel that meets minimum frequency requirements as stated in Practice C 192/C 192M for an external vibrator is suitable.

5.7 *Surface Finishing Equipment*—An angle iron screed shall be used for the concrete after vibration. A magnesium, steel, or wood trowel shall be used for finishing the surface of the specimen after screeding.

5.8 *Monitoring Pan*—A pan suitable for exposing water to the air stream for each concrete test panel is required. The sides of the pan shall be vertical. The pan shall be of sufficient size to expose at least 0.1 ± 0.01 m^2 of water to the air stream. The exposed lip of the pan shall not extend more than 5 mm above the water level at the start of the test.

NOTE 5—The test panels and monitoring pans can be placed in an environmental chamber designed for this test method (See Fig. 3) or the pans can be placed downstream from panels in a fan box (See Fig. 2).

5.9 *Scale*—If the rate of moisture loss from test panels is required by the specifier of tests, weigh test panels with a scale having a capacity of at least 100 kg and accurate to within 0.1 % of the test load. Weigh the evaporation rate monitoring pans with a balance or scale having a capacity of at least 3 kg and accurate to within 5 g.

5.10 *Crack Measurement Tool*—Optical hand-held microscope, crack comparator, or image analysis system can be used. The measurement tool should be capable of measuring crack width to at least the nearest 0.05 mm. If an automated image analysis system is used, it should be demonstrated to provide an accurate measurement. To demonstrate the accuracy of the measurement, the system shall be used to measure a 0.5 mm notch that is machined into a piece of steel and the reported notch width shall be within ± 0.05 mm of the machined width.

6. Sampling, Test Specimens, and Test Units

6.1 *Test Panels*—Cast test panels in accordance with the applicable provisions of Practice C 192/C 192M, using the same source of materials, preparation, mixing and finishing procedures.

6.2 *Test Unit*—A test unit is comprised of at least two control specimens and at least two fiber reinforced concrete specimens with the same mixture proportions. A group of two control specimens has to be tested each time in order to determine the plastic shrinkage crack reduction of fiber reinforced concrete.

7. Procedure

7.1 Determine the slump of each mixture in accordance with Test Method C 143/C 143M. If the slump is too low for a concrete mixture containing fibers, use the time of flow through an inverted slump cone to measure workability in accordance with Test Method C 995.

7.2 Fabricate specimens for setting time determination in accordance with Test Method C 403/C 403M. If fiber reinforced concrete cannot be wet sieved readily, use the control concrete specimen to measure time of final setting of both the control and the fiber-reinforced mixtures. Place the time of setting specimens in the air stream so that they are exposed to the same environmental conditions as the plastic shrinkage panels.

7.3 Fill the panel molds using one layer. Consolidate the concrete with external vibration until the concrete is approximately level with the top of the mold. Screed each specimen perpendicular to the stress riser three times.

7.4 After screeding, trowel specimens using a predetermined number of passes. If moisture loss from the panel is to be determined, remove any waste concrete adhering to the outside of the mold and weigh each panel while in the mold.

7.5 Place a fiber reinforced concrete mixture panel and control mixture panel in the environmental chamber downstream from the fan(s) (See arrangements in Figs. 2 and 3).

7.6 Turn on the fan(s), which have been preset to achieve the air speed to obtain the required evaporative conditions (See Note 4). The evaluation of cracking commences at this time.

7.7 At the start of the test and at 30-min intervals, record air temperature, relative humidity, and air flow speed at a location 100 ± 5 mm above each panel surface. If required by the specifier of tests, record the time at which cracking is first observed for each panel surface. Perform penetration tests at regular time intervals according to Test Method C 403/C 403M. Continue recording the environmental variables until the time of final setting.

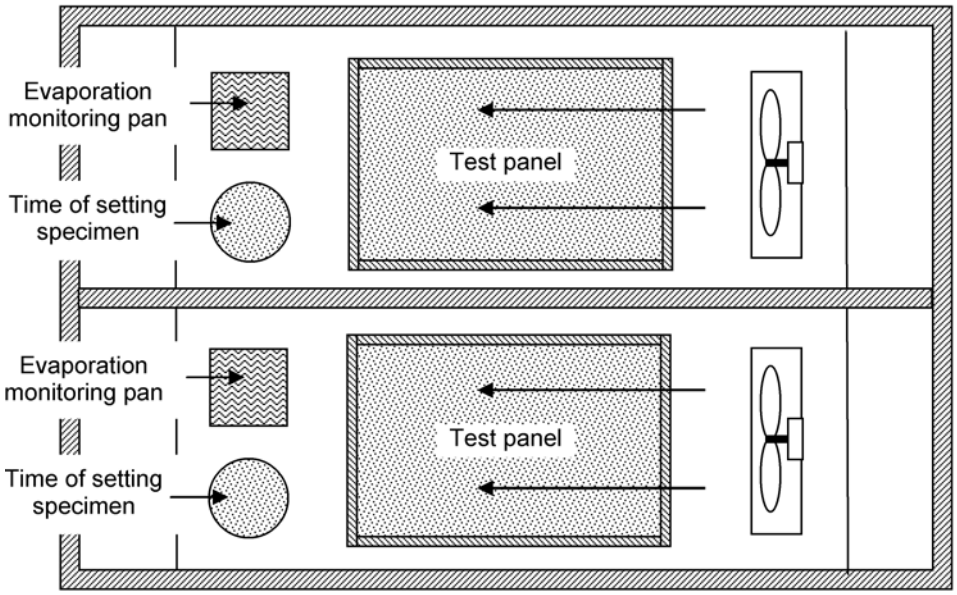
ELEVATION



PLAN

FIG. 3 Example of Chamber to Maintain Environmental Conditions (4)

7.8 The evaporation rate is determined by initially weighing the full monitoring pans at the start of the test and at 30-min intervals thereafter (**3**). Record the mass loss to the nearest 5 g at each weighing. To determine the evaporation rate during each time interval, divide the mass loss between successive weighings by the surface area of the water in the weighing pan and the time interval between successive weighings (See Note 6). The test is not valid if the average evaporation rate is less than 1.0 kg/m^2·h.

NOTE 6—Adjustments to wind velocity should be made if necessary to maintain the evaporation rate at the required level. It is suggested that the monitoring pans be placed on scales in the air stream for continuous monitoring without periodic removal during testing. If this is not possible, the monitoring pan should be removed from the air stream, weighed, and returned to the air stream within 15 seconds.

7.9 After final setting occurs (use the later of the measured time of setting in the two specimens), record the atmospheric variables, stop the fans, record the time, and determine the total water loss from the monitoring pans. If panel moisture loss is to be determined, weigh the test panels in their molds. Store the

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

panels in the laboratory at 23 ± 2 °C and under plastic sheets to minimize evaporation until time of crack width measurement.

8. Quantification of Cracking

8.1 Quantify the amount of cracking by measuring crack widths at the surface of the panels 24 ± 2 h after mixing.

NOTE 7—Studies have shown that, when panels are covered with plastic, there is no appreciable change in average crack width from a time of six hours to 24 h after mixing (**5**).

8.2 To avoid possible effects of panel boundaries on crack width, do not measure crack widths within 25 mm of test panel boundaries.

8.3 Measure the width of each crack along the cracking path over the stress riser in a progressive order from one side of the panel to the other. If a manual crack width measuring procedure is used, use a crack comparator or crack microscope to measure crack widths. Measure crack width to the nearest 0.1 mm at 10 ± 1 mm intervals along the length of the crack. Repeat the above procedure until all cracks have been measured. If an imaging analysis procedure is used for crack width measurement, record crack widths over the same measuring distance (See Note 8). Overlap between adjacent images shall be cut off to avoid duplicated measurements (**4**). Record all crack widths to calculate average crack width.

NOTE 8—A grid mask can be used to sample crack widths at predetermined locations (**4**).

8.4 Calculate the average crack width to the nearest 0.05 mm. If an average crack width of at least 0.5 mm is not observed on the control panels (average of at least two panels), with no single control panel under 0.4 mm average crack width, the test is not valid. Increase the evaporation rate to achieve this minimal average crack width, and repeat the test (See Note 10).

NOTE 9—Requiring a minimum crack width of the control panel will help to prevent marginal modifications to the concrete mixture from showing a statistically significant performance improvement, which may not be sufficient to control cracking under field conditions.

NOTE 10—Refer to ACI 305R (**1**) for guidance on how wind speed affects evaporation rate.

8.5 Calculate the crack reduction ratio (CRR) using the following equation:

$$CRR = \left[1 - \frac{\text{Average Crack Width of Fiber Reinforced Concrete Mixture}}{\text{Average Crack Width of Control Concrete Mixture}}\right] \times 100\ \% \quad (1)$$

9. Report

9.1 Report the following for each mixture tested:

9.1.1 The mixture proportions in kg/m^3 of water, cement (or cementitious materials): aggregates; admixtures in L/m^3; water-cement ratio (w/c) to the nearest 0.01; and slump in mm (or time of flow in seconds when used for fiber-reinforced concrete mixtures).

9.1.2 The fiber characteristics (if available) including fiber material, length, cross-sectional area, fiber shape, and addition rate in kg/m^3.

9.1.3 Length, depth, and width of panels in mm.

9.1.4 Cracking value of each panel as the average crack width to the nearest 0.05 mm.

9.1.5 The temperature, relative humidity, wind velocity, and measured evaporation rate during the test.

9.1.6 If required, the moisture loss of each panel in kilograms of water per square meter of surface (kg/m^2). Report the time interval between panel weighings.

9.1.7 The cracking reduction ratio (CRR) to the nearest percent (%).

10. Precision and Bias

10.1 *Precision*—A multi-laboratory study of precision has not been completed. Information on repeatability of this test method was derived from within-laboratory testing using a single operator and replicate panels (**5**) (See Practices C 670). Table 1 shows the number of replicate panels, average of the average crack width, and standard deviation of the average crack width for control panels and panels made with concretes having different amounts of fiber. The standard deviation appears to be constant and is used as the measure of repeatability. When three panels were used to determine the Crack Reduction Ratio (CRR), the value of the single operator standard deviation was 4.6 %.

10.2 *Bias*—The procedure for measuring the cracking value has no bias because the cracking value is defined only in terms of this test method.

TABLE 1 Single-Operator Average Crack Width Repeatability (22 Crack Width Measurements per Panel Using Manual Measurement Procedure)

NOTE—The results in this table correspond with the behavior of a mixture using a single type of fiber as described in Ref **5**.

Mixture Identification	Fiber Volume	Number of Panels	Average Crack Width (mm)	Standard Deviation of Average Crack Width (mm)
A	0 % Fiber	6	0.67	0.04
B	0.05 % Fiber	4	0.44	0.05
C	0.10 % Fiber	4	0.33	0.05
D	0.15 % Fiber	4	0.08	0.04
E	0.20 % Fiber	2	0.03	0.02

11. Keywords

11.1 crack width; evaporation; fiber-reinforced concrete; plastic shrinkage cracking; restrained shrinkage cracking

Designation: C 1580 – 09

Standard Test Method for Water-Soluble Sulfate in Soil[1]

This standard is issued under the fixed designation C 1580; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method is for the determination of water-soluble sulfate in soils.

1.2 This test method was developed for concentrations of water-soluble sulfate in soils between 0.02 and 3.33 % sulfate by mass.

1.3 This test method does not determine sulfur in any form except as sulfate.

1.4 Some governing bodies regulate the movement of soils from one area to another. It is up to the sampler and laboratory to comply with all regulations.

1.5 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 114 Test Methods for Chemical Analysis of Hydraulic Cement

D 1193 Specification for Reagent Water

E 60 Practice for Analysis of Metals, Ores, and Related Materials by Molecular Absorption Spectrometry

E 275 Practice for Describing and Measuring Performance of Ultraviolet and Visible Spectrophotometers

3. Significance and Use

3.1 This test method can be used to determine if soils could have an adverse reaction with hydraulic cement concrete.

4. Apparatus

4.1 *Photometer*—One of the following, given in order of preference:

4.1.1 Nephelometer or turbidimeter,

4.1.2 Spectrophotometer for use at 420 nm with light path of 4 to 5 cm, and

4.1.3 Filter photometer with a violet filter having a maximum near 420 nm and a light path of 4 to 5 cm. Filter photometers and photometric practices prescribed in this test method shall conform to Practice E 60; spectrophotometer practices shall conform to Practice E 275.

4.2 *Stopwatch*, readable to 0.1 minutes.

4.3 *Measuring Spoon*, capacity 0.2 to 0.3 mL.

4.4 *Drying oven*, capable of continuously heating at 110 ± 5 ºC.

4.5 *Balance*, shall be capable of reproducing results within 0.0002 g with an accuracy of ±0.0002 g. Direct-reading balances shall have a sensitivity not exceeding 0.0001 g. Conventional two-pan balances shall have a maximum sensibility reciprocal of 0.0003 g. Any rapid weighing device that may be provided, such as a chain, damped motion, or heavy riders, shall not increase the basic inaccuracy by more than 0.0001 g at any reading and with any load within the rated capacity of the balance.

4.6 *Stirrer*, magnetic variable speed, with a TFE-fluorocarbon coated magnetic stirring rod or an overhead stirrer with a propeller.

5. Reagents and Materials

5.1 *Purity of Reagents*—All reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society.[3]

5.2 *Purity of Water*—Unless otherwise indicated, reference to water shall be understood to mean reagent water conforming to Specification D 1193, Type I. Other reagent water types (See Note 1) may be used, provided it is first ascertained that the

www.technobetar.ir

water is of sufficiently high purity to permit its use without adversely affecting the precision and bias of the test method.

NOTE 1—Type II water was specified at the time of round robin testing of this test method.

5.3 *Barium Chloride*—Crystals of barium chloride ($BaCl_2 \cdot 2H_2O$) screened to 850 to 600 µm. To prepare in the laboratory, spread crystals over a large watch glass, desiccate for 24 h, screen to remove any crystals that are not 850 to 600 µm, and store in a clean, dry jar.

5.4 *Conditioning Reagent*—Place 30 mL of concentrated hydrochloric acid (HCl, sp gr 1.19), 300 mL reagent water, 100 mL 95 % ethanol or isopropanol and 75 g sodium chloride (NaCl) in a container. Add 50 mL glycerol and mix.

5.5 *Sulfate Solution, Standard* (1 mL = 0.100 mg SO_4)—Dissolve 0.1479 g of anhydrous sodium sulfate (Na_2SO_4) in water, and dilute with water to 1 L in a volumetric flask.

5.6 *pH paper*, readable to at least 0.5 pH units.

5.7 *Sodium Hydroxide, (0.1N)*—Dissolve 4 g of sodium hydroxide (NaOH) in water and dilute with water to 1L

5.8 *Hydrochloric Acid (0.1N)*—Dilute 8.6 mL of concentrated hydrochloric acid (HCl sp gr 1.19) to 1L with water

6. Permissible Variations

6.1 Both the referee method and qualified methods as described in Test Methods C 114 are permissible as alternatives to the turbidimetric procedure.

7. Calibration and Standardization

7.1 Prepare standards by diluting 0.0, 2.0, 5.0, 10.0, 15.0, 20.0, 30.0, and 40.0 mL of standard sulfate solution with water to 100-mL volumes in volumetric flasks. These solutions will have sulfate ion concentrations of 0.0, 2.0, 5.0, 10.0, 15.0, 20.0, 30.0, and 40.0 mg/L, respectively. Follow the procedure given in Section 8 using appropriate amounts of the standard sulfate solution prepared in accordance with 5.5 and prepare a calibration curve showing sulfate ion content in mg/L plotted against the corresponding photometer readings.

7.2 A separate calibration curve must be prepared for each photometer and a new curve must be prepared if it is necessary to change the cell, lamp, or filter, or if any other alterations of instrument or reagents are made. Check the curve with each series of tests by running two or more solutions of known sulfate concentrations in the range of 5 to 40 mg SO_4/L.

NOTE 2—The slope of the curve may not be linear below 5 or above 40 mg SO_4/L for this method.

8. Procedure

8.1 Collect at least 100 g of representative soil for analysis. Dry the sample for 18 to 24 h at 110 °C. Crush to pass a 600 µm sieve. In a 400 mL beaker labeled Sample A, put a sample consisting of approximately 30 g. In a second 400 mL beaker labeled Sample B, place a sample of approximately 3 g. Record the mass of each sample to the nearest 0.001 g. Add 250 mL of deionized water to each beaker, and stir on a magnetic stirrer for at least 1.0 h but no more than 1.2 h. Filter the extraction through two dry medium texture filter papers under suction. Do not wash the residue. Repeat the filtration if solution is not clear. Check the pH of the filtrate using pH paper and, if needed, neutralize each filtrate to pH of 7 ± 1 using either 0.1N HCl or 0.1N NaOH.

8.2 Adjust the temperature of the solution in the volumetric flasks to between 20 and 25 °C [68 to 77 °F].

8.3 Use an aliquot of 10 mL for specimen A1, 20 mL for specimen A2, 10 mL for specimen B1, and 20 mL for specimen B2. Dilute to a volume of 100 mL in a volumetric flask and follow the procedure below or Test Methods C 114. Pour the 100 mL into a 250 mL beaker. Add 5.0 mL of conditioning reagent. Mix by stirring with a stir bar and magnetic stirrer. Add 0.3 g of the prepared $BaCl_2$ crystals using a measuring spoon and start the timer.

8.4 Stir exactly 1.0 min, at the same constant speed for all determinations.

8.5 Remove the beaker from the stirrer, pour solution into the cell, and put the cell into the photometer. Record the turbidity at 4.0 min after pouring the solution into the cell.

8.6 Determine the mg of SO_4 from the calibration curve.

9. Calculation or Interpretation of Results

9.1 Calculate the sulfate content (% by mass) for each specimen as follows:

.

$$P = \frac{2.5*M}{A*W} \quad (1)$$

Where:

P = % SO_4 in dried soil
M = mg/L of SO_4 calculated from calibration curve
W = mass of soil placed into 400 mL beaker, in g
A = volume of aliquot specimen, in mL

9.2 Limits of values for results to be valid. (See Note 3)

Specimen	Lower Limit	Upper Limit
A1	0.04%	0.33%
A2	0.02%	0.17%
B1	0.41%	3.33%
B2	0.21%	1.67%

1. Determine which results fall within the above limits
2. Discard those that do not
3. Average all results that comply

NOTE 3—These values were derived from the limits on the sulfate test of 5 to 40 mg/L, and a solubility of sulfate of 1.6 g/L at pH 7 when calcium sulfate is present. The method is not applicable for soils outside this range. For those samples, see the Annex.

10. Report

10.1 Report the average obtained as % sulfate by mass of sample. If milligrams sulfate in kilograms of soil (mg SO_4/kg soil) is desired, multiply % sulfate by 10 000. Report results to nearest 0.01 % or 100 mg/kg.

11. Precision and Bias

11.1 *Precision*—The standard deviation was found to vary with concentration, so therefore, a coefficient of variation was used for the precision statement. The single operator coefficient of variation was found to be 4.4 %. Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 12.4 % of their average. The multilaboratory coefficient of variation was found

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:36:44 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

to be 21.2 %. Therefore, results of two different laboratories on identical samples of a material should not differ from each other by more than 60 % of their average.

11.2 *Bias*—Since there is no accepted reference material suitable for determining bias, bias can not be determined.

12. Keywords

12.1 hydraulic cement; soil; Sulfate; turbidimeter

ANNEX

(Mandatory Information)

A1. REDUCING THE NUMBER OF SUB-SAMPLES AND SAMPLES OUT OF COMPLIANCE

A1.1 This procedure was written to accommodate laboratories that are not familiar with the soil under test. If prior knowledge is available, a lesser number of sub-samples, and/or dilutions may be used.

A1.2 If a sample falls above 3.33 % sulfate, then different sample masses and/or dilutions can be used. If this procedure is followed, then the mg SO_4 from the turbidimeter reading shall be maintained within 5 to 40 mg/L. If another procedure is used, then validation shall be provided showing that the results are within the linear range of the calibration.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1580 – 05, that may impact the use of this test method. (Approved April 1, 2009)

(*1*) Revised 8.1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Designation: C 1581 – 04

Standard Test Method for Determining Age at Cracking and Induced Tensile Stress Characteristics of Mortar and Concrete under Restrained Shrinkage[1]

This standard is issued under the fixed designation C 1581; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the laboratory determination of the age at cracking and induced tensile stress characteristics of mortar or concrete specimens under restrained shrinkage. The procedure can be used to determine the effects of variations in the proportions and material properties of mortar or concrete on cracking due to both drying shrinkage and deformations caused by autogenous shrinkage and heat of hydration.

1.2 This test method is not intended for expansive materials.

1.3 The values stated in inch-pound units are to be regarded as standard. The values shown in parenthesis are in SI units and are given for information only.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)

2.2 *ASME Standards:*[3]

B 46.1 Surface Texture (Surface Roughness, Waviness and Lay)

3. Summary of Test Method

3.1 A sample of freshly mixed mortar or concrete is compacted in a circular mold around an instrumented steel ring. The compressive strain developed in the steel ring caused by the restrained shrinkage of the mortar or concrete specimen is measured from the time of casting **(1-6)**[4]. Cracking of the test specimen is indicated by a sudden decrease in the steel ring strain. The age at cracking and the rate of tensile stress development in the test specimen are indicators of the material's resistance to cracking under restrained shrinkage.

4. Significance and Use

4.1 This test method is for relative comparison of materials and is not intended to determine the age at cracking of mortar or concrete in any specific type of structure, configuration, or exposure.

4.2 This test method is applicable to mixtures with aggregates of 0.5-in. (13-mm) maximum nominal size or less.

4.3 This test method is useful for determining the relative likelihood of early-age cracking of different cementitious mixtures and for aiding in the selection of cement-based materials that are less likely to crack under retrained shrinkage. Actual cracking tendency in service depends on many variables

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.68 on Volume Change.

Current edition approved July 1, 2004. Published August 2004.

www.technobetar.ir

including type of structure, degree of restraint, rate of property development, construction and curing methods, and environmental conditions.

4.4 This test method can be used to determine the relative effects of material variations on induced tensile stresses and cracking potential. These variations can include, but are not limited to, aggregate source, aggregate gradation, cement type, cement content, water content, supplementary cementing materials, or chemical admixtures.

4.5 For materials that have not cracked during the test, the rate of tensile stress development at the time the test is terminated provides a basis for comparison of the materials.

5. Apparatus

5.1 *Steel ring*—Structural steel pipe with a wall thickness of 0.50 ± 0.05 in. (13 ± 0.12 mm), an outside diameter of 13.0 ± 0.12 in. (330 ± 3.3 mm) and a height of 6.0 ± 0.25 in. (152 ± 6 mm) (see Fig. 1). Machine the inner and outer faces to produce smooth surfaces with a texture of 63 microinches (1.6 micrometres) or finer, as defined in ASME B 46.1.

5.2 *Strain gages*—As a minimum, use two electrical resistance strain gages to monitor the strain development in the steel ring. Each strain gage shall be wired in a quarter-bridge configuration (that is, one leg of a full Wheatstone bridge). See Note 1 for additional information.

5.3 *Data acquisition system*—The data acquisition system shall be compatible with the strain instrumentation and automatically record each strain gage independently. The resolution of the system shall be ±0.0000005 in./in. (m/m). The system shall be capable of recording strain data at intervals not to exceed 30 minutes.

NOTE 1—Use of a precision resistor, to balance the leg of the bridge, a strain conditioner input module, to complete the other half of the bridge, and a 16-channel interface board has been found to adequately provide the required resolution of the system.

5.4 *Base*—Epoxy-coated plywood or other non-absorptive and non-reactive surface.

5.5 *Outer ring*—Use one of the following alternative materials as the outer ring.

5.5.1 *PVC pipe*—Schedule 80-18 PVC pipe, in accordance with Specification F 441, with a 16.0 ± 0.12-in. (406 ± 3-mm) inside diameter and 6.0 ± 0.25-in. (152 ± 6-mm) height (see Fig. 1).

5.5.2 *Steel outer ring*—0.125-in. (3-mm) thick steel sheeting formed to obtain a 16.0 ± 0.12-in. (406 ± 3-mm) inside diameter and 6.0 ± 0.25-in. (152 ± 6-mm) height.

5.5.3 *Other materials*—Other suitable non-absorptive and non-reactive materials formed to obtain a 16.0 ± 0.12-in. (406 ± 3-mm) inside diameter and 6.0 ± 0.25-in. (152 ± 6-mm) height.

5.6 *Testing environment*—Store the specimens in an environmentally controlled room with constant air temperature of 73.5 ± 3.5 °F (23.0 ± 2.0 °C) and relative humidity of 50 ± 4 %.

6. Materials and Mixing

6.1 *Materials*:

6.1.1 *Cement*—Cement shall conform to Specifications C 150, C 595, or C 1157.

6.1.2 *Aggregates*—Aggregates shall conform to Specification C 33. The maximum nominal size of the coarse aggregate shall be 0.5-in. (13-mm) or less.

6.2 *Mixing*:

6.2.1 *Concrete mixtures*—Machine mix the concrete as prescribed in Practice C 192/C 192M.

6.2.2 *Mortar mixtures*—Mix the mortar as prescribed in Specification C 387.

7. Properties of Fresh Mixtures

7.1 *Concrete mixtures*—Samples of freshly mixed concrete shall be tested in accordance with the following methods:

7.1.1 *Density (unit weight) and air content*—Test Method C 138/C 138M.

7.1.2 *Slump*—Test Method C 143/C 143M.

7.2 *Mortar mixtures*—Samples of freshly mixed mortar shall be tested in accordance with the following methods:

7.2.1 *Density*—Specification C 387.

7.2.2 *Flow*—Test Method C 1437.

8. Specimen Fabrication and Test Setup

8.1 Bond two strain gages at midheight locations on the interior surface of the steel ring along a diameter; that is, mount the second gage diametrically opposite the first gage. Orient the gages to measure strain in the circumferential direction. Follow the manufacturer's procedures for mounting and waterproofing the gages on the steel ring and connecting leadwires to the strain gage tabs.

8.2 *Test specimen mold*—The test specimen mold consists of a base, an inner steel ring and an outer ring.

8.2.1 Fabricate a base for each test specimen as described in Section 5.4. The top surface of each base shall minimize frictional restraint of the specimen.

NOTE 2—Use of an epoxy coating or a Mylar sheet covering has been found to provide a suitable surface between the test specimen and the base.

8.2.2 Secure the steel ring to the base before casting using bolts with eccentric washers (see Fig. 1).

8.2.2.1 Coat the outer surface of the steel ring with a release agent.

8.2.3 Coat the inner surface of the outer ring with a release agent.

8.2.4 Secure the outer ring to the base to complete the test specimen mold using bolts with eccentric washers. Maintain a 1.50 ± 0.12-in. (38 ± 3-mm) space between the inner steel ring and the outer ring (see Fig. 1).

8.3 Make and cure at least three test specimens for each material and test condition following the applicable requirements of Practice C 192/C 192 M. In making a specimen, place the test specimen mold on a vibrating table, fill the mold in two approximately equal layers, rod each layer 75 times using a ⅜-in. (10-mm) diameter rod, and vibrate each layer to consolidate the mixture.

8.4 Strike-off the test specimen surface after consolidation. Finish with the minimum manipulation necessary to achieve a flat surface. Remove any fresh concrete or mortar that has spilled inside the steel ring or outside the outer ring so that the

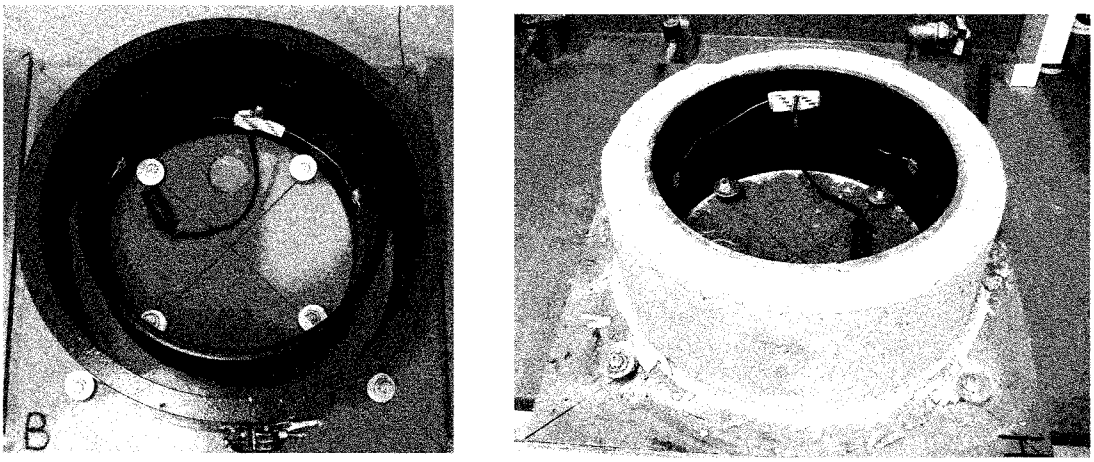

FIG. 1 Test specimen dimensions (top), specimen mold (bottom left), and specimen (bottom right).

base is clean. Transfer the test specimens to the testing environment within 10 minutes after completion of casting.

8.5 Upon transfer of the test specimens to the testing environment, immediately loosen the bolts with eccentric washers and rotate the washers so they are not in contact with the steel ring and outer ring. Within 2 minutes after loosening the bolts with eccentric washers, connect the strain gage lead-wires to the data acquisition system, record the time, and begin monitoring the strain gages at intervals not greater than 30 minutes. Ensure that the strain gage connecting wires are

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

clean of loose material before making the connections. The time of the first strain measurement is taken as zero age of the specimen.

NOTE 3—Monitoring the strain gages soon after casting provides information on the internal deformations caused by autogenous shrinkage and heat of hydration **(4)**.

8.6 *Curing*—Unless otherwise specified, test specimens shall be moist cured in the molds for 24 h at 73.5 ± 3.5 °F (23.0 ± 2.0 °C) using wet burlap covered with polyethylene film meeting the requirements of Specification C 171. Begin the curing process within 5 minutes after the first strain reading. If the curing period is longer than 24 h, remove the outer ring at 24 h and continue the curing process.

8.7 At the end of curing and between strain measurements, prepare the test specimens for drying as follows. Complete the test specimen preparation within 15 minutes.

8.7.1 Remove the outer ring, if it is still in place, and/or remove the polyethylene film and burlap.

8.7.2 Gently remove loose material, if present, from the top surface of the test specimen.

8.7.3 Seal the top surface of the test specimen using one of the following alternative procedures.

NOTE 4—With the top surface sealed, and the specimen resting on its base, the test specimen dries from the outer circumferential surface only.

8.7.3.1 *Paraffin wax*—Coat the top surface of the test specimen with molten paraffin wax. Take precautions to ensure that the outer circumference of the test specimen is not coated with the paraffin wax.

NOTE 5—Use of a 1.5-in. (38-mm) wide brush has been found to be an appropriate means of applying the paraffin wax to the top surface of the test specimens.

8.7.3.2 *Adhesive aluminum-foil tape*—Seal the top surface of the test specimen with adhesive aluminum-foil tape.

8.7.4 For the calculations outlined subsequently, the age when drying is initiated is the time when the first strain reading is made after the test specimens have been sealed.

9. Measurement Procedure

9.1 Record the time at the start of strain monitoring as stated in Section 8.5.

9.2 Record ambient temperature and relative humidity of the testing environment every day.

9.3 Monitor the strains in the steel rings at intervals not to exceed 30 minutes, recording the output of each strain gage separately with the data acquisition system. Record both the time and the strain at each measurement. A sudden decrease in compressive strain in one or both strain gages indicates cracking (see Note 6) **(1-5)**. Review the strain measurements and visually inspect the specimens for cracking at time intervals not greater than 3 days.

NOTE 6—The sudden decrease in compressive strain at cracking is usually greater than 30 microstrains (see Fig. 2).

9.4 Monitor and record the strain in the steel rings for at least 28 days after initiation of drying, unless cracking occurs prior to 28 days.

9.5 Plot the steel ring strain for each strain gage against specimen age (see Fig. 2).

10. Calculation

10.1 *Age at cracking*—Determine the age at cracking as the age of each test specimen (measured from the time of casting) when a sudden decrease in strain occurs. Report the age at cracking to the nearest 0.25 day. If a test specimen does not crack within the duration of the test, report the result as “no cracking” and record the age when the test was terminated.

10.1.1 *Average age at cracking*—Calculate the average age at cracking for the test specimens to the nearest day.

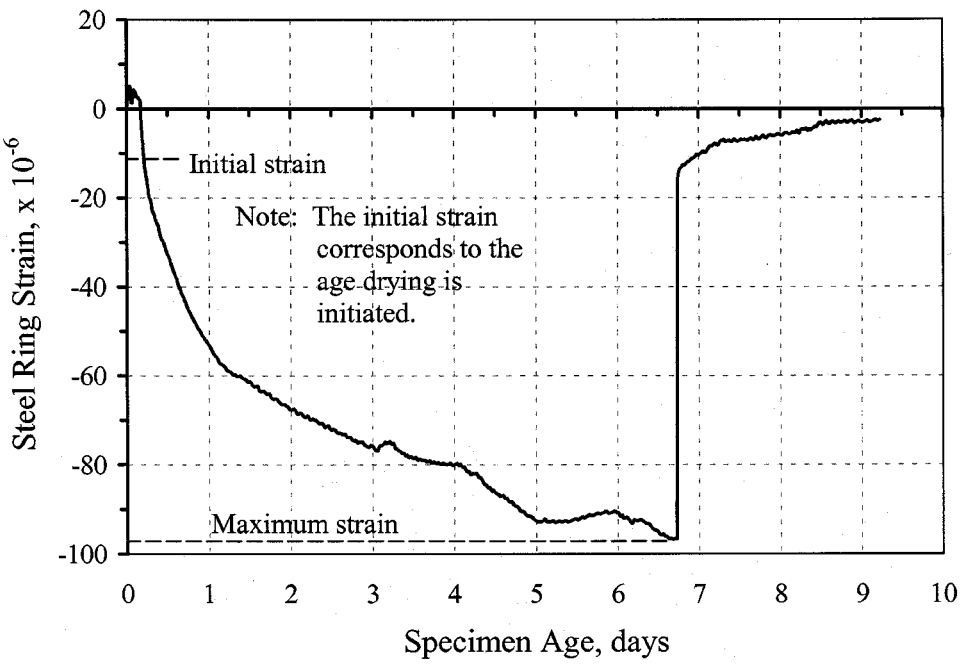

FIG. 2 Steel ring strain versus specimen age.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:36:46 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.2 *Initial strain*—From the time-strain data for each strain gage, record the initial strain as the strain corresponding to the age when drying was initiated (see Fig. 2).

10.2.1 *Average initial strain*—Calculate the average initial strain for the test specimens.

NOTE 7—The average initial strain indicates the net effect of deformations caused by early-age autogenous shrinkage and heat of hydration under the restrained conditions **(4)**.

10.3 *Maximum strain*—From the time-strain data for each strain gage on each test specimen, record the maximum strain as the strain corresponding to the age at cracking or the age when the test is terminated.

10.3.1 When cracking occurs, the maximum strain is the strain value just prior to the sudden decrease in strain (see Fig. 2).

10.4 *Average maximum strain,* ϵ_{max}—Calculate the average maximum strain for the test specimens.

NOTE 8—The average maximum strain relates to the magnitude of stress buildup in the material under the conditions of restraint provided in this test method.

10.5 *Stress rate, S*—For the test material, use the following procedure to calculate the rate of tensile stress development that corresponds to the age at cracking or the age when the test is terminated (see Section 4.5).

10.5.1 *Elapsed time, t*—Calculate the elapsed time for each test specimen as the difference between each recorded time and the age drying was initiated.

10.5.2 *Net strain*—For each strain gage on the test specimen, calculate the net strain at each recorded time, starting from the age drying was initiated, as the difference between the strain in the steel ring at each recorded time and the initial strain.

10.5.3 *Strain rate factor,* α—Plot the net strain against the square root of elapsed time for each strain gage on the test specimen and use linear regression analysis to fit a straight line through the data. The strain rate factor is the slope of the line (see Eq 1):

$$\epsilon_{net} = \alpha \sqrt{t} + k \quad (1)$$

where:

ϵ_{net} = net strain, in./in. (m/m),
α = strain rate factor for each strain gage on the test specimen (in./in.)/day$^{1/2}$ ((m/m)/day$^{1/2}$),
t = elapsed time, days, and
k = regression constant

NOTE 9—The square root function has been found to consistently provide a good fit to the test data **(3)**.

10.5.4 *Average strain rate factor,* α_{avg}—Calculate the average strain rate factor for each test specimen.

10.5.5 *Stress rate, q*—Calculate the stress rate in each test specimen at cracking or at the time the test is terminated **(3)**:

$$q = \frac{G\,|\alpha_{avg}|}{2\sqrt{t_r}} \quad (2)$$

where:

q = stress rate in each test specimen, psi/day (MPa/day),
G = 10.47×10^6 psi (72.2 GPa),
$|\alpha_{avg}|$ = absolute value of the average strain rate factor for each test specimen, (in./in.)/day$^{1/2}$ ((m/m)/day$^{1/2}$), and
t_r = elapsed time at cracking or elapsed time when the test is terminated for each test specimen, days

NOTE 10—G in Eq 2 is a constant based on the ring dimensions used in this test method **(1-4)**.

10.5.6 *Average stress rate, S*—Calculate the average stress rate for the test specimens to the nearest psi/day (0.01 MPa/day).

11. Report

Record in the report the following data as pertinent to the variables studied:

11.1 Properties of the material being tested: mixture proportions, air content, slump and density of concrete mixtures, and mixture proportions, flow, and density of mortar mixtures.

11.2 Type and duration of curing;

11.3 Daily ambient temperature and relative humidity data for the test environment;

11.4 Plots of steel ring strain vs. specimen age for each test specimen;

11.5 Average age at cracking;

11.6 Age when the test was terminated for specimens that have not cracked during the test;

11.7 Average initial strain;

11.8 Average maximum strain;

11.9 Plots of net strain vs. square root of elapsed time for each specimen; and

11.10 Average stress rate at cracking or at the time the test was terminated.

12. Precision and Bias

12.1 *Precision*—The precision of this test method has not been determined. The single laboratory repeatability standard deviation of the age at cracking is 2 days. The single laboratory repeatability standard deviation of the stress rate at cracking is 4 psi/day (0.03 MPa/day) for materials with an average stress rate equal to or less than 40 psi/day (0.28 MPa/day). The single laboratory repeatability standard deviation of the stress rate at cracking is 11 psi/day (0.08 MPa/day) for materials with an average stress rate greater than 40 psi/day (0.28 MPa/day) **(3)**.

12.2 *Bias*—No statement on bias is being made since there is no accepted reference material suitable for determining the bias of these procedures.

13. Keywords

13.1 Cracking; restrained shrinkage; ring test; shrinkage; tensile stress.

APPENDIX

(Nonmandatory Information)

X1. Interpretation of Results

TABLE X1.1 Potential for cracking classification

Net Time-to-Cracking, t_{cr}, days	Average Stress Rate, S (psi/day)	Average Stress Rate, S (MPa/day)	Potential for Cracking
$0 < t_{cr} \leq 7$	$S \geq 50$	$S \geq 0.34$	High
$7 < t_{cr} \leq 14$	$25 \leq S < 50$	$0.17 \leq S < 0.34$	Moderate-High
$14\ t_{cr} \leq 28$	$15 \leq S < 25$	$0.10 \leq S < 0.17$	Moderate-Low
$t_{cr} > 28$	$S < 15$	$S < 0.10$	Low

X1.1 *Net Time-to-cracking, t_{cr}*—Calculate the net time-to-cracking for the material as the difference between the age at cracking and the age drying was initiated. Note that if a test material cracks during the period of curing (that is, before drying is initiated), the net time-to-cracking is zero.

X1.2 *Potential for cracking*—A classification table for cracking potential based on the net time-to-cracking and the average stress rate at cracking or at the time the test is terminated is provided to aid in the comparison of materials **(3)**.

X1.2.1 The net time-to-cracking classification in Table X1.1 can be used to assess the relative performance of materials that crack during the test.

X1.2.2 For materials with average stress rates lower than 15 psi/day (0.10 MPa/day) that have not cracked during the test, the magnitudes of average stress rate can be compared to assess the relative potential for cracking. This allows for an appropriate comparison of materials where time constraint does not permit testing to be carried out until cracking occurs.

Designation: C 1582/C 1582M – 04

Standard Specification for Admixtures to Inhibit Chloride-Induced Corrosion of Reinforcing Steel in Concrete[1]

This standard is issued under the fixed designation C 1582/C 1582M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers material for use as chloride-corrosion-inhibiting admixtures for concrete.

1.2 Results of the tests conducted to meet this specification are not to be used to rank the expected field performance of various chloride-corrosion-inhibiting admixtures.

1.3 The values stated in either inch-pound or SI units shall be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system must be used independently of the other without combining values in any way.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory requirements prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

C 260 Specification for Air-Entraining Admixtures for Concrete

C 403/C 403M Test Method for Time of Setting of Concrete Mixtures by Penetration Resistance

C 494/C 494M Specification for Chemical Admixtures for Concrete

C 666 Test Method for Resistance of Concrete to Rapid Freezing and Thawing

C 1152/C 1152M Test Method for Acid-Soluble Chloride in Mortar and Concrete

G 15 Terminology Relating to Corrosion and Corrosion Testing

G 109 Test Method for Determining the Effects of Chemical Admixtures on the Corrosion of Embedded Steel Reinforcing in Concrete Exposed to Chloride Environments

2.2 *American Concrete Institute Standard:*

ACI 211.1 Practice for Selecting Proportions of Normal, Heavyweight, and Mass Concrete[4]

3. Terminology

3.1 *Definitions*—Refer to Terminologies C 125 and G 15 for definitions of terms used in this specification.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *chloride-ion content*—the acid-soluble chloride-ion content, measured according to Test Method C 1152/C 1152M, of a powder sample taken at a depth equal to the depth of reinforcement.

3.2.2 *completion of testing*—when the following conditions are satisfied: *(1)* the mean integrated macrocell current in the control beams is greater than or equal to 150 coulombs (C); and *(2)* the mean chloride-ion content of the test beams is greater than or equal to the critical chloride-ion content.

3.2.2.1 *Discussion*—Refer to the Appendix for additional explanation of the methodology used to evaluate the performance of a chloride-corrosion-inhibiting admixture.

3.2.3 *control beams*—beams subjected to the treatment in Test Method G 109 that are made from concrete without the chloride-corrosion-inhibiting admixture.

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.23 on Chemical Admixtures.

www.technobetar.ir

3.2.4 *critical chloride-ion content*—the mean chloride-ion content in the unreinforced control beams at t_{50} plus the standard deviation.

3.2.5 *reinforced beams*—beams used to measure macrocell corrosion current according to Test Method G 109.

3.2.6 t_{50}—time when the mean integrated macrocell current of the control beams reaches 50 C.

3.2.7 t_{150}—time when the mean integrated macrocell current of the control beams reaches 150 C.

3.2.8 *test beams*—beams subjected to the treatment in Test Method G 109 that are made from concrete with the chloride-corrosion-inhibiting admixture.

3.2.9 *unreinforced beams*—beams without reinforcement that are subjected to the cyclic ponding and drying treatment in Test Method G 109 and used to determine chloride-ion content.

4. General Requirements

4.1 For initial compliance with this specification, test-concrete made with the chloride-corrosion-inhibiting admixture shall conform to the requirements prescribed in Table 1.

4.2 The purchaser is allowed to require a limited retesting to confirm current compliance of the admixture to specification requirements. The limited retesting covers physical and chemical properties and performance of the admixture.

4.2.1 The physical properties retesting shall consist of uniformity and equivalence tests for infrared analysis, residue by oven drying, and specific gravity as described in Specification C 494/C 494M.

TABLE 1 Physical Requirements of Concrete Containing a Chloride-Corrosion-Inhibiting Admixture

Time of setting, allowable deviation from control, h:min		
Initial: not more than 3:30 earlier or later		
Final: not more than 3:30 earlier or later		
Strength:		
Age	Compressive strength, min. % of control:[A,B]	Flexural strength, min. % of control:[A,B]
3 days	80	80
7 days	80	80
28 days	80	80
6 months	80	
1 year	80	
Length change, max. shrinkage (alternative requirements)[C]		
Percent of control: 135		
Increase over control, percentage points: 0.010		
Relative durability factor, minimum %: 80		

[A] The values in the table include allowance for normal variation in test results. The objective of the 80 % relative strength is to require a level of performance comparable to that of the control concrete. Reinforced concrete, subjected to brackish water, salt spray and/or deicers, requires a water-cement ratio of 0.40 or less for long-term durability. This durability requirement results typically in compressive strengths in excess of what is required structurally. If high-strength concrete is needed for structural purposes, mixture proportions may need to be adjusted when using a chloride-corrosion-inhibiting admixture.

[B] The compressive and flexural strength of the concrete containing the admixture under test at any test age shall not be less than 90 % of that attained at any previous test age. The objective of this limit is to require that the compressive or flexural strength of the concrete containing the admixture under test shall not decrease with age.

[C] For the alternative requirements (see Specification C 494/C 494M), the percent of control limit applies when length change of the control concrete is 0.030 % or greater, and the increase over control limit applies when length change of the control concrete is less than 0.030 %.

4.2.2 The performance property retesting shall consist of time of setting and compressive strength at 3, 7, and 28 days. Purchasers having special requirements are allowed to require additional tests currently in this standard.

4.3 At the request of the purchaser, the manufacturer shall state in writing that the admixture supplied for use in the project is identical in all essential respects, including concentration, to the admixture tested under this specification and found to comply therewith.

4.4 Tests for uniformity and equivalence shall be made on the initial sample in accordance with Specification C 494/C 494M, and the results retained for reference and comparison with the results of tests of samples taken from elsewhere within the lot or subsequent lots of admixture supplied for use in the project.

5. Corrosion-Inhibiting Performance

5.1 In addition to producing concrete that meets the requirements in Table 1, the test admixture must show corrosion-inhibiting performance as summarized in Table 2 when tested in accordance with Test Method G 109 with reinforcing bar depths and mixture proportions as specified in Sections 10 and 11 of this specification. The following requirements must be attained.

5.2 At completion of testing (see 3.2.2), the mean integrated macrocell current of the test beams must be less than or equal to 50 C.

5.3 At completion of testing, the mean corroded area of the top reinforcing steel in the test beams must be less than or equal to ⅓ of the mean corroded area of the top steel in the control beams.

5.4 At the completion of testing, the mean chloride-ion content of the test beams must be greater than or equal to the critical chloride-ion content.

6. Packaging and Package Marking

6.1 When the admixture is delivered in packages or containers, the proprietary name of the admixture and the net mass or volume shall be plainly marked thereon. Similar information shall be provided in the shipping information accompanying packaged or bulk shipments of admixtures.

7. Storage

7.1 Store the admixture so as to permit easy access for proper inspection and identification of each shipment, and in a suitable weather-tight building that will protect the admixture from dampness and freezing.

8. Sampling and Inspection

8.1 Sampling and inspection shall be in accordance with Specification C 494/C 494M.

TABLE 2 Corrosion Inhibiting Requirements

Mean integrated macrocell current of test beams, C[A]	≤ 50
Mean corroded area of test beams, fraction of control[A]	≤ ⅓

[A] At completion of testing using Test Method G 109 and based on a minimum of three specimens of control and test concrete, and discarded specimens are not included.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9. Rejection

9.1 For initial compliance testing, the purchaser is allowed to reject the admixture if it fails to meet any of the applicable requirements for this specification.

9.2 For limited retesting, the purchaser is allowed to reject the admixture if it fails to meet any of the requirements of the Uniformity and Equivalence Section of Specification C 494/C 494M and of the applicable parts of Table 1 of this standard.

9.3 An admixture stored at the point of manufacture, for more than 6 months prior to shipment, or an admixture in local storage in the hands of a vendor for more than 6 months, after completion of tests, shall be retested before use when requested by the purchaser and is allowed to be rejected if it fails to conform to any of the applicable requirements of this specification.

9.4 Packages or containers varying more than 5 % from the specified mass or volume are allowed to be rejected. If the average mass or volume of 50 packages taken at random is less than that specified, the entire shipment is allowed to be rejected.

9.5 When the admixture is to be used in non-air-entrained concrete, it shall be rejected when the purchaser desires if the test concrete containing it has an air content greater than 3.5 %; when the admixture is to be used in air-entrained concrete, it shall be rejected when the purchaser desires if the test concrete containing it has an air content greater than 7.0 %.

TEST METHODS

NOTE 1—These tests are based on arbitrary stipulations which make possible highly standardized testing in the laboratory and are not intended to simulate actual job conditions.

10. Test Specimens

10.1 Two types of concrete are used to make test specimens. One, the control concrete, is made without the chloride-corrosion-inhibiting admixture. The other concrete, the test concrete, is made with the chloride-corrosion-inhibiting admixture. Do not use cement that causes the air content of the control concrete made without the subject admixture to exceed 3.0 %.

10.2 Make specimens for measuring compressive strength, flexural strength, resistance to freezing and thawing, and length change in accordance with Specification C 494/C 494M. Prepare three separate batches of each concrete mixture in accordance with Specification C 494/C 494M, and report the mean test results from the three batches.

10.3 Make specimens for corrosion testing and chloride-ion analysis from a separate batch of each concrete. For each concrete mixture, make at least three beams with steel reinforcement in accordance with Test Method G 109, and make at least three beams of the same size without reinforcement (Note 2). The reinforcement shall be deformed bars designation No. 4 [13] with a nominal diameter of ½ in. [12.7 mm] and the cover depth shall be 1.0 ± 0.1 in. [25 ± 3 mm]. Subject all beams to the same cyclic ponding and drying treatment described in Test Method G 109.

NOTE 2—The reinforced beams are used to determine the macrocell corrosion current as a function of time, and the unreinforced beams are used to determine the chloride-ion content at specified times.

11. Specimen Preparation

11.1 *Mixture Proportions*—Proportion all concrete mixtures to conform to the requirements described in 11.1.1 through 11.1.5. Unless otherwise specified, include the chloride-corrosion-inhibiting admixture with the first increment of mixing water that is added to the mixer.

11.1.1 The water-cement ratio shall be 0.50 ± 0.01 and the cement content shall be between 550 and 650 lb/yd^3 [325 and 385 kg/m^3]. The test and control mixtures are to have water and cement contents equivalent to within ± 1 % by mass.

11.1.2 Cement shall meet the requirements of a Type II cement according to Specification C 150.

NOTE 3—Type II cement is used to limit the tricalcium aluminate (C_3A) content and is not intended as design guidance for specific projects.

11.1.3 The grading of the coarse aggregate shall comply with size number 7 or 8 of Specification C 33, that is, the nominal maximum size is ½ in. [12.5 mm] or ⅜ in. [9.5 mm]. For the first trial mixture, refer to ACI 211.1 for guidance on the amount of coarse aggregate to use based on the fineness modulus of the fine aggregate.

NOTE 4—Tabulated values of coarse aggregate content given in ACI 211.1 are intended to ensure workable mixtures with the least favorable combinations of aggregate likely to be used. It is suggested, therefore, that for a closer approximation of the required proportions, the volume of coarse aggregate (in the dry-rodded condition) per unit volume of concrete selected from ACI 211.1 be increased by about 0.07 for the first trial mixture.

11.1.4 For air-entrained concrete, the air content of the fresh concrete shall be 6 ± 1 % as measured according to Test Method C 231. For concrete that is not air-entrained, the air content of the fresh concrete shall be less than 3.5 % as measured according to Test Method C 231.

11.1.5 The slump shall be greater than or equal to 3 in. [75 mm] and less than or equal to 8 in. [200 mm] as measured according to Test Method C 143/C 143M. The use of a water-reducing admixture is not prohibited to obtain the required slump, but the same quantity must be used in the control concrete and in the test concrete.

11.2 *Quantity of Concrete*—Prepare concrete mixtures with and without the chloride-corrosion-inhibiting admixture in sufficient volume to produce specimens needed for performing the tests listed in Table 1 and for corrosion testing.

NOTE 5—The required quantity of concrete for each batch depends on the number of extra specimens that are cast. It is recommended that more than the required minimum number of specimens be cast in case some of them are faulty. If one time of setting specimen and the minimum number of 6- by 12-in. [150- by 300-mm] cylinders, 3- by 4- by 16-in. [75- by 100- by 410-mm] freezing and thawing prisms, 6- by 6- by 21-in. [150- by 150- by 535-mm] flexural beams, and 3- by 3- by 11.25-in. [75- by 75- by 285-mm] length-change prisms are made, the required volume of concrete is 3.1 ft^3 [0.087 m^3]. Twice this amount is used typically to allow for extra specimens. The minimum of three reinforced beams and three unreinforced beams for corrosion testing requires about 1.1 ft^3 [0.029 m^3] of concrete. Additional unreinforced beams are recommended for chloride ion analysis in the event that specimens are faulty, and additional reinforced beams are recommended to ensure that the criterion in 14.6.3 is satisfied at the completion of testing. Each additional beam requires about 0.2 ft^3 [0.005 m^3] of concrete.

11.3 *Admixture Dosage*—Add the chloride-corrosion-inhibiting admixture at the dosage recommended by the manufacturer.

11.4 *Specimen Fabrication and Curing*—Make and cure test specimens for measuring strength, resistance to freezing and thawing, and length change in accordance with Specification C 494/C 494M. Make and cure specimens for corrosion testing and chloride-ion determination in accordance with Test Method G 109.

12. Tests of Freshly Mixed Concrete

12.1 *Slump*—Test Method C 143/C 143M.

12.2 *Air Content*—Test Method C 231.

12.3 *Time of Setting*—Test Method C 403/C 403M. Store the time-of-setting specimens at 73.5 ± 3.5 °F [23.0 ± 2.0 °C] during the test period.

13. Tests of Hardened Concrete

13.1 *Compressive Strength*—Test Method C 39/C 39M. Measure compressive strength at ages of 3 days, 7 days, 28 days, 6 months, and 1 year. For each test age, divide the mean strength of the test concrete specimens by the mean strength of the control concrete specimens and multiply the quotient by 100.

13.2 *Flexural Strength*—Test Method C 78. Measure flexural strength at ages of 3, 7, and 28 days. For each test age, divide the mean strength of the test concrete specimens by the mean strength of the control concrete specimens and multiply the quotient by 100.

13.3 *Resistance to Freezing and Thawing*—Test Method C 666, Procedure A. Calculate the relative durability factor in accordance with Specification C 260.

13.4 *Length Change*—Test Method C 157/C 157M as modified by Specification C 494/C 494M.

14. Corrosion Testing

14.1 *General*—Test the corrosion performance of the reinforced control beams and the reinforced test beams according to Test Method G 109, except as noted in this specification. Subject the reinforced and unreinforced beams to the same cyclic ponding and drying process that is described in Test Method G 109. Chloride-ion content measurements are made when the mean integrated macrocell current in the control beams reaches 50 C and 150 C. The criteria for completion of testing are specified in 3.2.2.

NOTE 6—Appendix X1 provides a flowchart to explain further the corrosion testing procedure. The flowchart includes references to the corresponding section numbers in this specification.

14.2 *Tests at* t_{50}—Measure the integrated macrocell current in the reinforced beams as specified in Test Method G 109. When the mean integrated macrocell current of the reinforced control beams reaches 50 C, determine the mean chloride-ion content of the companion unreinforced control beams in accordance with 14.2.1 and 14.2.2.

14.2.1 Obtain powder samples for chloride-ion content analysis by drilling into the sides of three unreinforced control beams at the level of the reinforcing steel in the reinforced beams. For each beam, drill holes at three locations directly below the plastic dam (see Fig. 1(a)). Use a ½-in. [13-mm] drill bit, and locate the center of each hole so that it coincides with the depth of the center of the bar in the reinforced beams. Discard the powder obtained from the outermost 1.0 ± 0.1 in. [25 ± 3 mm] of each hole, clean powder from the drill bit, and collect at least a 10-g powder sample from each hole. Discontinue cyclic ponding of the tested unreinforced control beam after chloride-ion content sampling.

14.2.2 Measure the acid-soluble chloride-ion content of each powder sample in accordance with Test Method C 1152/C 1152M. Compute the mean and standard deviation of the nine chloride-ion measurements. Calculate the critical chloride-ion content as the mean plus the standard deviation of the nine measurements.

14.3 *Tests at* t_{150}—Continue the cyclic ponding and drying process and measurement of the integrated macrocell current in accordance with Test Method G 109. When the mean integrated macrocell current of the reinforced control beams reaches 150 C, determine the mean chloride-ion content of the unreinforced test beams in accordance with 14.3.1 and 14.3.2.

14.3.1 Obtain one 10-g powder sample from each of three unreinforced test beams using the sampling procedure in 14.2.1. Drill the hole in each beam so that it is below the dam and near one end (see Fig. 1(b)). If additional cyclic ponding and drying is required in accordance with 14.5, fill the holes with the epoxy of the kind that was used to seal the beams. Ensure that surfaces surrounding the holes are sealed.

14.3.2 Measure the acid-soluble chloride-ion content of each powder sample in accordance with Test Method C 1152/C 1152M. Calculate the mean chloride-ion content of the three samples from the test beams.

14.4 *Completion of Testing*—If the mean chloride-ion content of the test beams at t_{150} is greater than the critical chloride-ion content, testing is completed. Perform a destructive examination of the control and test beams as described in 14.6.

14.5 *Additional Testing*—If the mean chloride-ion content of the test beams at t_{150} is less than the critical chloride-ion content and the mean integrated macrocell current of the test beams is less than 50 C, continue corrosion testing according to Test Method G 109 for the additional number of cycles determined in 14.5.1. If the mean integrated macrocell current of the test beams at t_{150} is more than 50 C, the admixture fails to meet this specification.

14.5.1 Based on the mean chloride-ion content of the test beams determined at t_{150} and assumed chloride-ion content of zero at start of testing, estimate the additional cyclic ponding time required to obtain a chloride-ion content equal to or greater than the critical chloride-ion content. Use linear extrapolation for this estimate. If the estimated time is more than 12 cycles of ponding and drying, obtain powder samples according to 14.5.2 after an additional testing time of 12 cycles. If one or more of the control beams crack before reaching the planned additional cycles of ponding and drying, stop testing, obtain powder samples from the unreinforced test beams according to 14.5.2, and perform a destructive examination of the control and test beams as described in 14.6.

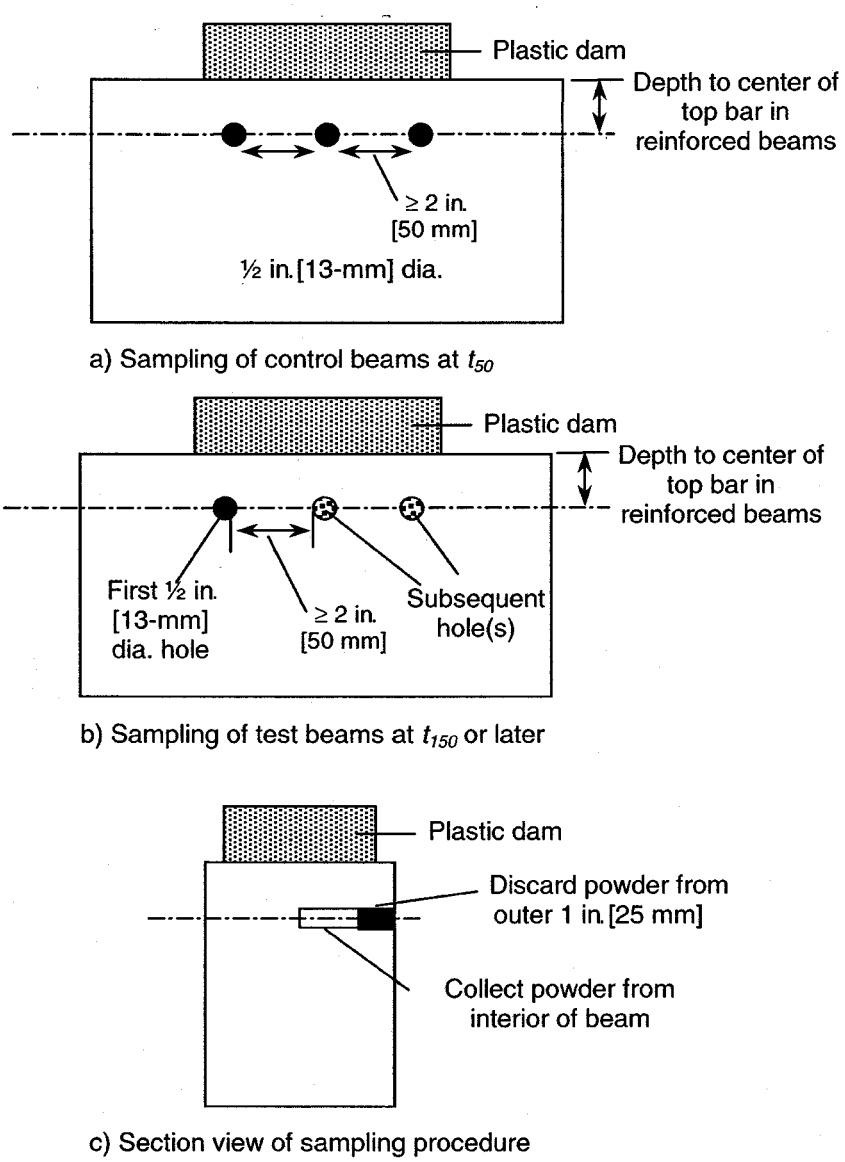

FIG. 1 Sampling of Unreinforced Beams for Chloride-Ion Content Determination

14.5.2 After additional cyclic ponding and drying, determine the chloride-ion content in the test beams by sampling from one drill hole in each of three unreinforced test beams as described in 14.2.1. Locate the center of the new hole in each beam so that it is below the dam but no closer than 2 in. [50 mm] to the hole drilled previously (see Fig. 1(b)). If additional cyclic ponding and drying is required in accordance with 14.5.6, fill the holes with epoxy, and ensure that surfaces surrounding the holes are sealed.

14.5.3 Measure the acid soluble chloride-ion content of each powder sample in accordance with Test Method C 1152/C 1152M. Calculate the mean chloride-ion content of the three samples from the test beams.

14.5.4 If the mean chloride-ion content calculated in 14.5.3 is equal to or greater than the critical chloride-ion content, testing is completed. Perform a destructive evaluation of the control and test beams in accordance with 14.6.

14.5.5 If the mean chloride-ion content is less than the critical chloride-ion content and the control beams are not cracked, make a new estimate of the time to reach the critical chloride-ion content. Repeat the procedure starting at 14.5.2 until the mean chloride-ion content is equal to or greater than the critical chloride-ion content, or the total time of corrosion testing exceeds five years.

14.5.6 If testing is stopped because of cracking in control beams and the mean chloride-ion content of the test beams is equal to or greater than the critical chloride-ion content, perform a destructive evaluation in accordance with 14.6.

14.6 *Destructive Examination*—Cut each reinforced beam longitudinally above and below the top reinforcing bar using a water-cooled diamond tipped concrete saw. Use care not to cut the bar. Break the test beam in half and extract the top reinforcing bar. Avoid wetting the top bar during extraction. If

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the bar is wetted, dry immediately and store in an environment at less than 50 % relative humidity until inspection according to 14.6.2.

14.6.1 Make additional saw cuts, and extract the bottom bars from each beam. If the bars are wetted, dry immediately and store in an environment at less than 50 % relative humidity until inspection according to 14.6.2.

14.6.2 Visually inspect the top- and bottom-reinforcing bars, photograph the bars, and estimate the percentage of corroded area on each bar as instructed in Test Method G 109.

14.6.3 If the corroded area on the bottom bars from any test beam is greater than 1 % of the exposed area, the test results from that beam are invalid. Substitute the results of a valid backup beam if available.

NOTE 7—Bottom bar corrosion can occur in situations such as: when an aggressive agent is present in the concrete; the exterior coating does not properly seal around the bottom bars; or the bottom of the test specimen is cracked.

14.7 *Evaluation of Results*—At completion of testing, evaluate whether the test concrete satisfies the performance criteria.

14.7.1 If the mean integrated macrocell current of the test beams is less than 50 C, the performance criterion in 5.2 is satisfied.

14.7.2 If the mean percentage of corroded area of the top reinforcing bars extracted from the test beams is less than ⅓ the mean percentage of corroded area of the control beams, the performance criterion in 5.3 is satisfied.

14.7.3 If after five years of corrosion testing, the chloride-ion content in the test beams is less than the critical chloride-ion content, the admixture does not qualify as a chloride-corrosion-inhibiting admixture under this specification.

14.7.4 If one or more of the control beams crack and the mean chloride-ion content of the test beams is less than the critical chloride-ion content, the admixture does not qualify as a chloride-corrosion-inhibiting admixture under this specification.

15. Report

15.1 For each mixture, report:

15.1.1 The mixture proportions, cement content, water-cement ratio, quantities of admixtures, slump, and air content.

15.1.2 The mean values of the tests listed in Table 1.

15.1.3 Corrosion data including individual macrocell current values for all beams as described in Test Method G 109.

15.1.4 The times in weeks from start of cyclic ponding and drying for control beams to reach an integrated macrocell current of 50 C and 150 C (t_{50} and t_{150}, respectively) and the total time at completion of testing, if longer than t_{150}.

15.1.5 The mean integrated macrocell current of the reinforced control and test beams at completion of testing calculated according to Test Method G 109.

15.1.6 The percentage of corroded area for all reinforcing bars, and include photographs of the extracted reinforcing bars.

15.1.7 The average percentage of corroded area for the control beams and the test beams.

15.1.8 The acid-soluble chloride-ion content values, the calculated mean, and standard deviation from the unreinforced control beams sampled at t_{50}.

15.1.9 The acid-soluble chloride-ion content values and the calculated mean from unreinforced test beams at t_{150}, any intermediate sampling time, and the completion of testing.

16. Keywords

16.1 admixture; chloride; corrosion inhibitor; corrosion testing; macrocell current

APPENDIX

(Nonmandatory Information)

X1. TEST PROTOCOL FOR EVALUATING CHLORIDE-CORROSION-INHIBITING ADMIXTURES

X1.1 General

X1.1.1 The testing procedure used to evaluate a chloride-corrosion-inhibiting admixture is complex. This appendix provides supplementary information to explain the process.

X1.1.2 When reinforced concrete is exposed to chloride ions, the reinforcement is vulnerable to corrosion if the chloride-ion content exceeds a threshold value. For the same exposure, the onset of corrosion can be delayed by restricting the penetration of chloride ions or by altering the electrochemical reactions at the surface of the steel bars so that higher chloride-ion content is needed to initiate corrosion. The latter condition is the basis of a chloride-corrosion-inhibiting admixture covered by this specification. An admixture that only restricts chloride-ion penetration, under the prescribed testing conditions, is not classified as a chloride-corrosion-inhibiting admixture.

X1.1.3 Performance of chloride-corrosion-inhibiting admixtures is evaluated by means of Test Method G 109. Beams are made with a top reinforcing bar and two bottom reinforcing bars. The top bar is connected to the bottom bars by an external circuit. Under the conditions of test, a corrosion macrocell is created in which the top bar (the anode) undergoes corrosion. The rate of corrosion is evaluated by measuring the current between the top bar and the bottom bars. Corrosion is induced by subjecting the beams to a cyclic treatment composed of ponding with a salt solution and air drying. At the middle of the ponding cycle, the corrosion current is measured. From the history of current versus time, the total charge is calculated (integrated macrocell current), and this quantity (measured in coulombs) is indicative of the amount of corrosion that has occurred from the start of the cyclic ponding and drying treatment.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X1.1.4 The corrosion performance of the test concrete containing the chloride-corrosion-inhibiting admixture is compared with that of the control concrete. The two mixtures are similar in all respects, except for the presences of chloride-corrosion-inhibiting admixture. For each mixture, two types of beams are used: one is reinforced in accordance with Test Method G 109 and the other is made without reinforcement. The reinforced beams are used to evaluate the corrosion activity, and the unreinforced beams are used to evaluate the chloride-ion content at a depth corresponding to the depth of the top reinforcement. Both types of beams are subjected to the same ponding and drying treatment. At least three replicate beams of each type are used for each measurement, but it is recommended that more beams be made in case specimens have to be discarded. The evaluation can be time-consuming and costly. Therefore, it is wise to have back up specimens rather than having to repeat the entire evaluation.

X1.2 Completion of Testing

X1.2.1 The cyclic ponding and drying procedure is continued and corrosion current is measured according to Test Method G 109 until the mean integrated macrocell current in the reinforced control beams reaches 50 coulombs (C). The time when this occurs is called t_{50}, and at this time the chloride-ion content is measured in the unreinforced control beams. Powder samples are obtained by drilling holes in the sides of the unreinforced control beams at a depth corresponding to the depth of the steel reinforcement in the test beams. The three powder samples from each beam are tested for acid-soluble chloride ion according to Test Method C 1152/C 1152M. The average and standard deviation(s) of the nine chloride-ion determinations are calculated. The standard deviation of these determinations is used to establish the critical chloride-ion content in the test beams (see the definitions in 3.2).

X1.2.2 The cyclic ponding and drying treatment is continued until the mean integrated macrocell current in the control beams reaches 150 C, and this time is called t_{150}. At t_{150} the chloride-ion contents of the test beams are measured and the mean integrated macrocell current of the test beams is determined. One powder sample is taken from each of three beams. The average chloride-ion content in the unreinforced test beams determines whether corrosion testing is completed. If the mean chloride-ion content in the test beams exceeds the critical chloride-ion content, testing is completed and the corrosion performance of the test concrete is evaluated. This situation is indicated as Case 1 on the left side of Fig. X1.1. The top graph is a schematic plot of the integrated macrocell current versus time, and the lower graph is a schematic of the chloride-ion content. The bottom graph shows that at time t_{150} the chloride-ion content in the test beams exceeds the critical value.

X1.2.3 If at t_{150} the mean chloride-ion content in the test beams is less than the critical value, the cyclic-ponding drying treatment is continued until the chloride-ion content exceeds the critical value. This condition is indicated as Case 2 on the right side of Fig. X1.1. When the chloride-ion content in the unreinforced test beams exceeds the critical value, the corrosion performance of the test concrete is evaluated. If one or more control beams crack, testing is stopped and the chloride-ion content of the test beams is evaluated. If the chloride-ion content is less that the critical value, the admixture is not classified as a chloride-corrosion-inhibiting admixture. In addition, if after 5 years of corrosion testing, the chloride-ion content of the test beams is less than the critical value, the admixture is not classified as a chloride-corrosion-inhibiting admixture.

X1.3 Chloride-Corrosion-Inhibiting Criteria

X1.3.1 At the completion of testing, the mean chloride-ion content of the test beams has to be equal to or greater than the critical value. The integrated macrocell current of the test beams is calculated and the corrosion area of the top steel is compared with the control beams. To satisfy this specification, two conditions have to be satisfied:

X1.3.1.1 The integrated macrocell current of the test beams has to be less than or equal to 50 C; and

X1.3.1.2 The mean percentage of corroded area of the top bar has to be less than ⅓ of the mean percentage of corroded area in the control beams.

X1.4 Flowchart

X1.4.1 Fig. X1.2 is a flow chart to summarize the corrosion testing process used to evaluate a chloride-corrosion-inhibiting admixture. The numbers within the boxes refer to the sections within the text.

Designation: C 1583/C 1583M – 04ε1

Standard Test Method for Tensile Strength of Concrete Surfaces and the Bond Strength or Tensile Strength of Concrete Repair and Overlay Materials by Direct Tension (Pull-off Method)[1]

This standard is issued under the fixed designation C 1583/C 1583M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—The designation was changed editorially to agree with the existing values statement in the Scope in March 2008.

1. Scope

1.1 This test method is suitable for both field and laboratory use to determine one or more of the following:

1.1.1 The near-surface tensile strength of the substrate as an indicator of the adequacy of surface preparation before application of a repair or overlay material.

1.1.2 The bond strength of a repair or an overlay material to the substrate.

1.1.3 The tensile strength of a repair or overlay material, or an adhesive used in repairs, after the material has been applied to a surface.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 125 Terminology Relating to Concrete and Aggregates

C 881/C 881M Specification for Epoxy-Resin Base Bonding Systems for Concrete

C 900 Test Method for Pullout Strength of Hardened Concrete

3. Terminology

3.1 *Definitions*—For definitions of terms used in this test method refer to Terminology C 125 and ACI 503R[3].

4. Summary of Test Method

4.1 This test is performed on the surface of a prepared concrete base before application of a concrete repair or overlay material, or on the surface of a concrete repair or overlay material after the material has been applied to the prepared concrete surface.

4.2 The test specimen is formed by drilling a shallow core into and perpendicular to the surface of the substrate, and leaving the intact core attached to the concrete. A steel disk is bonded to the top surface of the test specimen.

4.3 A tensile load is applied to the steel disk until failure occurs. The failure load and the failure mode are recorded and the nominal tensile stress at failure is calculated.

5. Significance and Use

5.1 This test method determines the tensile strength of concrete near to the prepared surface, which can be used as an indicator of the adequacy of surface preparation before applying a repair or an overlay material.

5.2 When the test is performed on the surface of a repair or an overlay material, it determines the bond strength to the substrate or the tensile strength of either the overlay or substrate, whichever is weaker.

5.3 The method may also be used to evaluate the adhesive strength of bonding agents.

5.4 When the test is performed on the surface of a material applied to the substrate, the measured strength is controlled by the failure mechanism requiring the least stress. Thus it is not possible to know beforehand which strength will be measured by the test. For this reason, the failure mode has to be reported

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.25 on Organic Materials for Bonding.

Current edition approved Feb. 1, 2004. Published March 2004.

for each individual test result, and tests results are averaged only if the same failure mode occurs.

6. Apparatus

6.1 *Core Drill*, for preparing test specimen.

6.2 *Core Barrel*, with diamond impregnated bits - nominally 50 mm [2.0 in.] inside diameter.

6.3 *Steel Disk*, nominally 50 mm [2.0 in.] diameter and at least 25 mm [1.0 in.] thick.

6.4 *Tensile Loading Device*, with a load-indicating system and nominal capacity of 22 k N (5,000 lbf) and capable of applying load at the specified rate. The loading device includes a tripod or bearing ring for distributing the force to the supporting surface.

6.4.1 Within the operating range, the indicated tensile force shall be within ± 2 % of the force measured by a calibrated testing machine or load cell. Verify the tensile loading device at least once a year and after repairs and adjustments.

NOTE 1—See Test Method C 900 for suitable verification schemes.

6.4.2 A coupling device shall be used to connect the steel disk to the tensile loading device. The coupling device shall be designed to withstand the tensile load capacity without yielding, and to transmit the tensile force parallel to and in line with the axis of the cylindrical test specimen without imparting torsion or bending to the test specimen.

7. Materials

7.1 Epoxy adhesive material for bonding the steel disk to the test specimen. It shall be a fast-curing paste or gel meeting the requirements of Specification C 881/C 881M for Type IV, Grade 3, except that a shorter gel time is permitted.

8. Sampling

8.1 Three individual test results with similar failure modes shall be obtained for each test site.

8.2 The field test site shall be large enough so that all methods to be used in the full-scale repair or overlay operation, including surface preparation, are used for preparing test specimens. The test site shall be at least 1 by 1 m [3 by 3 ft]. It shall be selected to be representative of actual field conditions.

8.3 If concrete cover is less than 20 mm [¾ in.], do not locate test specimens directly over bars in the layer of reinforcement nearest to the surface.

NOTE 2—The location of reinforcement may be established using reinforcement locators or metal detectors. Follow the manufacturer's recommendations for proper operation of such devices.

8.4 The center-to-center distance of adjacent test specimens shall be at least two disk diameters. The distance from the center of a test specimen and a free edge of the test object shall be at least one disk diameter.

9. Preparation of Surface

9.1 *Preparation to Determine Tensile Strength of Substrate*:

9.1.1 Remove all surface contaminants and loose or deteriorated concrete to obtain a clean, undamaged surface.

9.1.2 Prepare the surface using the same method to be used in the full-scale repair or overlay.

9.1.3 The surface must be in the same condition regarding dryness and cleanliness as specified for the actual work.

9.2 *Preparation to Determine Bond or Tensile Strength of the Repair or Overlay Material*:

9.2.1 Prepare the surface in accordance with 9.1.

9.2.2 Apply and cure the repair or overlay material in accordance with specifications for the repair or overlay operation.

10. Preparation of Test Specimen

10.1 Using the coring equipment, drill a circular cut perpendicular to the surface. For tests of substrate concrete, drill to a depth of at least 10 mm [0.5 in.]. For tests of repair or overlay materials, drill to at least 10 mm [0.5 in.] below the concrete-overlay interface. The test specimen is left intact, attached to the substrate. Measure the diameter of the test specimen in two directions at right angles to each other. Record the average diameter to the nearest 0.2 mm [0.01 in.].

10.2 Remove any standing water; clean the surface of any debris from the drilling operation and allow to dry.

10.3 Attach the steel disk to the top of the test specimen using the epoxy adhesive. Ensure that the disk is centered with the test specimen and that the axis of the disk is parallel to the axis of the test specimen. Cure the epoxy adhesive following manufacturer's instructions (see Note 4). Do not allow the adhesive to run down the side of the test specimen into the annular cut; if this occurs, the specimen is not tested and another is prepared. At temperatures below 20°C [70°F], it is permitted to gently heat the steel disk to no more than 50°C [120°F] to facilitate spreading of the adhesive and to accelerate curing. The test specimen shall not be heated with a direct flame.

NOTE 3—Figs. 1 and 2 are schematics of the tests for determining tensile strength of the substrate and bond or tensile strength of the repair or overlay material, respectively. These schematics are not intended to indicate specific equipment designs.

NOTE 4—Guidance on applying and curing the epoxy adhesive may be found in ACI 503R.

11. Test Procedure

11.1 Attach the tensile loading device to the steel disk using the coupling device.

11.2 Apply the tensile load to the test specimen so that the force is parallel to and coincident with the axis of the specimen.

11.3 Apply the tensile load at a constant rate so that the tensile stress increases at a rate of 35 ± 15 kPa/s [5 ± 2 psi/s].

11.4 Record the failure load and the failure mode. Record the failure mode as *(a)* in the substrate, *(b)* at the bond line between the substrate and the repair or overlay material, *(c)* in the repair or overlay material, or *(d)* at the bond line between the repair or overlay material and the epoxy adhesive used to bond the steel disk. If failure occurs at the bond line between the steel disk and the epoxy adhesive, discard the test result and perform another test. Refer to Fig. 3 for schematics of the different failure modes.

11.5 Report results as bond strength when failure occurs in the bond line between the substrate and the repair or overlay material. Report results as tensile strength when the failure

www.technobetar.ir

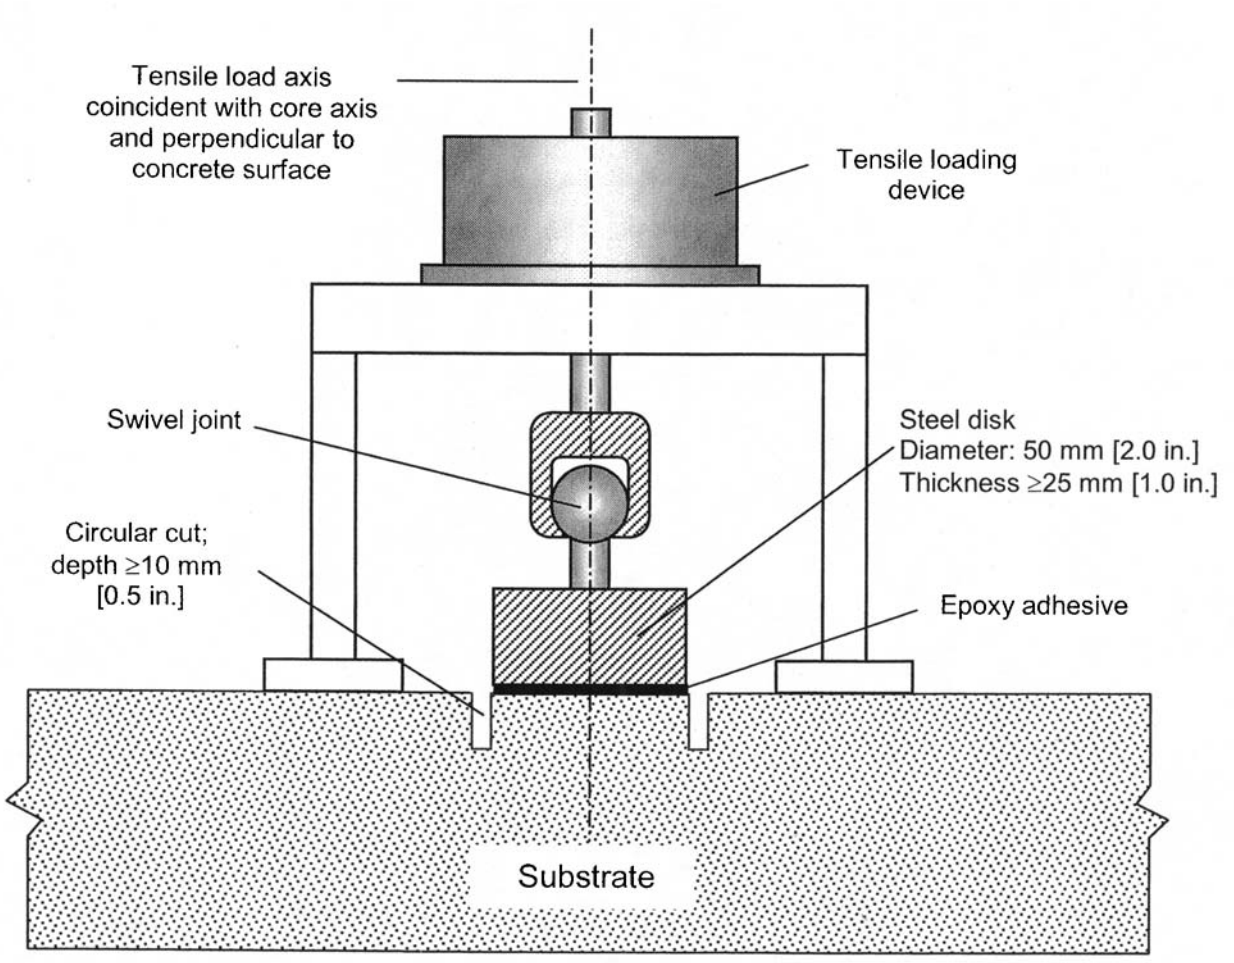

FIG. 1 Schematic of Setup to Test Substrate

occurs in the substrate or the repair or overlay material. Calculate the bond strength or tensile strength by dividing the tensile load at failure by the area of the test specimen:

$$\text{Bond or Tensile Strength (MPa [psi])} = \frac{\text{Tensile load (N [lbf])}}{\text{Area of test specimen (mm}^2\text{ [in.}^2\text{])}} \quad (1)$$

11.6 Record the individual strengths to the nearest 0.01 MPa [1 psi].

11.7 Record ambient weather conditions and surface temperatures during testing.

12. Report

12.1 The test report shall contain the following:

12.1.1 Purpose of the test:

12.1.1.1 To assess the substrate before application of repair or overlay material with regards to the adequacy of surface preparation and the strength of the near-surface region of the substrate;

12.1.1.2 To determine the controlling failure mode and corresponding strength when a repair or an overlay material is bonded to the substrate; or

12.1.1.3 To determine the controlling failure mode and corresponding strength when an adhesive is bonded to the substrate.

12.1.2 Identification of all materials used in the test,

12.1.3 Test conditions—location of test, weather conditions, and surface temperatures, and

12.1.4 The failure mode and the tensile or bond strength for each individual test reported to the nearest 0.01 MPa [1 psi].

13. Precision and Bias

13.1 *Precision*—An interlaboratory testing program to determine the precision of this test method has not yet been carried out. There are, however, published data[4] to provide an estimate of within-test repeatability. The referenced study involved pull-off tests of repair materials applied to concrete substrates. Three replicate tests were conducted for each condition, and the mean pull-off strength ranged from 0.41 to 3.44 MPa [60 to 500 psi]. Two instruments were used with disk diameters of 75 mm [3 in.] and 50 mm [2 in.]. Replicate tests with the same failure modes were used to determine the within-test standard deviations for each condition. There was no statistically significant difference in repeatability for failures

Designation: C 1585 – 04$^{\epsilon 1}$

Standard Test Method for Measurement of Rate of Absorption of Water by Hydraulic-Cement Concretes[1]

This standard is issued under the fixed designation C 1585; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—A typo in Eq 1 was corrected editorially in December 2007.

1. Scope

1.1 This test method is used to determine the rate of absorption (sorptivity) of water by hydraulic cement concrete by measuring the increase in the mass of a specimen resulting from absorption of water as a function of time when only one surface of the specimen is exposed to water. The exposed surface of the specimen is immersed in water and water ingress of unsaturated concrete dominated by capillary suction during initial contact with water.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 31/C 31M Practice for Making and Curing Concrete Test Specimens in the Field

C 42/C 42M Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 642 Test Method for Density, Absorption, and Voids in Hardened Concrete

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

3. Terminology

3.1 For definitions of terms used in this standard, refer to Terminology C 125.

4. Significance and Use

4.1 The performance of concrete subjected to many aggressive environments is a function, to a large extent, of the penetrability of the pore system. In unsaturated concrete, the rate of ingress of water or other liquids is largely controlled by absorption due to capillary rise. This test method is based on that developed by Hall[3] who called the phenomenon "water sorptivity."

4.2 The water absorption of a concrete surface depends on many factors including: *(a)* concrete mixture proportions; *(b)* the presence of chemical admixtures and supplementary cementitious materials; *(c)* the composition and physical characteristics of the cementitious component and of the aggregates; *(d)* the entrained air content; *(e)* the type and duration of curing; *(f)* the degree of hydration or age; *(g)* the presence of microcracks; *(h)* the presence of surface treatments such as sealers or form oil; and *(i)* placement method including consolidation and finishing. Water absorption is also strongly affected by the moisture condition of the concrete at the time of testing.

4.3 This method is intended to determine the susceptibility of an unsaturated concrete to the penetration of water. In general, the rate of absorption of concrete at the surface differs from the rate of absorption of a sample taken from the interior. The exterior surface is often subjected to less than intended curing and is exposed to the most potentially adverse conditions. This test method is used to measure the water absorption rate of both the concrete surface and interior concrete. By drilling a core and cutting it transversely at selected depths, the absorption can be evaluated at different distances from the exposed surface. The core is drilled vertically or horizontally.

4.4 This test method differs from Test Method C 642 in which the specimens are oven dried, immersed completely in

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.66 on Concrete's Resistance to Fluid Penetration.

Current edition approved Feb. 1, 2004. Published March 2004.

www.technobetar.ir

water at 21°C, and then boiled under water for 5 h. In this test method, only one surface is exposed to water at room temperature while the other surfaces are sealed simulating water absorption in a member that is in contact with water on one side only. Test Method C 642, on the other hand, is used to estimate the maximum amount of water that can be absorbed by a dry specimen and therefore provides a measure of the total, water permeable pore space.

5. Apparatus

5.1 *Pan*, a watertight polyethylene or other corrosion-resistant pan large enough to accommodate the test specimens with the surfaces to be tested exposed to water.

5.2 *Support Device*, rods, pins, or other devices, which are made of materials resistant to corrosion by water or alkaline solutions, and which allow free access of water to the exposed surface of the specimen during testing. Alternatively, the specimens can be supported on several layers of blotting paper or filter papers with a total thickness of at least 1 mm.

5.3 *Top-pan Balance*, complying with Specification C 1005 and with sufficient capacity for the test specimens and accurate to at least ± 0.01 g.

5.4 *Timing Device*, stop watch or other suitable timing device accurate to ± 1 s.

5.5 *Paper Towel or Cloth*, for wiping excess water from specimen surfaces.

5.6 *Water-Cooled Saw*, with diamond impregnated blade to cut test specimens from larger samples.

5.7 *Environmental Chamber*, a chamber allowing for air circulation and able to maintain a temperature of 50 ± 2°C and a relative humidity at 80 ± 3 %. Alternatively, an oven able to maintain a temperature of 50 ± 2°C and a dessicator large enough to contain the specimens to be tested is permitted. The relative humidity (RH) is controlled in the dessicator at 80 ± 0.5 % by a saturated solution of potassium bromide. The solubility of potassium bromide is 80.2 g/100 g of water at 50°C. The solution shall be maintained at the saturation point for the duration of the test. The presence of visible crystals in the solution provides acceptable evidence of saturation.

5.8 *Polyethylene Storage Containers*, with sealable lids, large enough to contain at least one test specimen but not larger than 5 times the specimen volume.

5.9 *Caliper*, to measure the specimen dimensions to the nearest 0.1 mm.

6. Reagents and Materials

6.1 *Potassium Bromide, Reagent Grade*, required if the oven and dessicator system described in 5.7 is used.

6.2 *Sealing Material*, strips of low permeability adhesive sheets, epoxy paint, vinyl electrician's tape, duct tape, or aluminium tape. The material shall not require a curing time longer than 10 minutes.

6.3 *Plastic Bag or Sheeting*, any plastic bag or sheeting that could be attached to the specimen to control evaporation from the surface not exposed to water. An elastic band is required to keep the bag or sheeting in place during the measurements.

7. Test Specimens

7.1 The standard test specimen is a 100 ± 6 mm diameter disc, with a length of 50 ± 3 mm. Specimens are obtained from either molded cylinders according to Practices C 31/C 31M or C 192/C 192M or drilled cores according to Test Method C 42/C 42M. The cross sectional area of a specimen shall not vary more than 1 % from the top to the bottom of the specimen. When cores are taken, they should be marked (see Note 1) so that the surface to be tested relative to the original location in the structure is clearly indicated.

NOTE 1—The surface to be exposed during testing shall not be marked or otherwise disturbed in such a manner as may modify the absorption rate of the specimen.

7.2 The average test results on at least 2 specimens (Note 2) shall constitute the test result. The test surfaces shall be at the same distance from the original exposed surface of the concrete.

NOTE 2—Concrete is not a homogeneous material. Also, an exterior surface of a concrete specimen seldom has the same porosity as the interior concrete. Therefore, replicate measurements are taken on specimens from the same depth to reduce the scatter of the data.

8. Sample Conditioning

8.1 Place test specimens in the environmental chamber at a temperature of 50 ± 2°C and RH of 80 ± 3 % for 3 days. Alternatively, place test specimens in a dessicator inside an oven at a temperature of 50 ± 2°C for 3 days. If the dessicator is used, control the relative humidity in the dessicator with a saturated solution of potassium bromide (see 5.7), but do not allow test specimens to contact the solution.

NOTE 3—To control the RH using the potassium bromide solution, the solution should be placed in the bottom of the dessicator, to ensure the largest surface of evaporation possible.

8.2 After the 3 days, place each specimen inside a sealable container (as defined in 5.8). Use a separate container for each specimen. Precautions must be taken to allow free flow of air around the specimen by ensuring minimal contact of the specimen with the walls of the container.

8.3 Store the container at 23 ± 2°C for at least 15 days before the start of the absorption procedure.

NOTE 4—Storage in the sealed container for at least 15 days results in equilibration of the moisture distribution within the test specimens and has been found[4] to provide internal relative humidities of 50 to 70 %. This is similar to the relative humidities found near the surface in some field structures.[5,6]

9. Procedure

9.1 Remove the specimen from the storage container and record the mass of the conditioned specimen to the nearest 0.01 g before sealing of side surfaces.

9.2 Measure at least four diameters of the specimen at the surface to be exposed to water. Measure the diameters to the nearest 0.1 mm and calculate the average diameter to the nearest 0.1 mm.

9.3 Seal the side surface of each specimen with a suitable sealing material. Seal the end of the specimen that will not be exposed to water using a loosely attached plastic sheet (see 6.2). The plastic sheet can be secured using an elastic band or other equivalent system (see Fig. 1).

9.4 Use the procedure below to determine water absorption as a function of time. Conduct the absorption procedure at 23 ± 2°C with tap water conditioned to the same temperature.

9.5 *Absorption Procedure*:

9.5.1 Measure the mass of the sealed specimen to the nearest 0.01 g and record it as the initial mass for water absorption calculations.

9.5.2 Place the support device at the bottom of the pan and fill the pan with tap water so that the water level is 1 to 3 mm above the top of the support device. Maintain the water level 1 to 3 mm above the top of the support device for the duration of the tests.

NOTE 5—One method for keeping the water level constant is to install a water-filled bottle upside down such that the bottle opening is in contact with the water at the desired level.

9.5.3 Start the timing device and immediately place the test surface of the specimen on the support device (see Fig. 1). Record the time and date of initial contact with water.

9.5.4 Record the mass at the intervals shown in Table 1 after first contact with water. Using the procedure in 9.5.5, the first point shall be at 60 ± 2 s and the second point at 5 min ± 10 s. Subsequent measurements shall be within ± 2 min of 10 min, 20 min, 30 min, and 60 min. The actual time shall be recorded to within ± 10 s. Continue the measurements every hour, ± 5 min, up to 6 h, from the first contact of the specimen with water and record the time within ± 1 min. After the initial 6 h, take measurements once a day up to 3 days, followed by 3 measurements at least 24 h apart during days 4 to 7; take a final measurement that is at least 24 h after the measurement at 7 days. The actual time of measurements shall be recorded within ± 1 min. This will result in seven data points for contact time during days 2 through 8. Table 1 gives the target times of measurements and the tolerances for the times.

9.5.5 For each mass determination, remove the test specimen from the pan, stop the timing device if the contact time is less than 10 min, and blot off any surface water with a dampened paper towel or cloth. After blotting to remove excess water, invert the specimen so that the wet surface does not come in contact with the balance pan (to avoid having to dry the balance pan). Within 15 s of removal from the pan, measure the mass to the nearest 0.01 g. Immediately replace the specimen on the support device and restart the timing device.

10. Calculations

10.1 The absorption, I, is the change in mass divided by the product of the cross-sectional area of the test specimen and the density of water. For the purpose of this test, the temperature dependence of the density of water is neglected and a value of 0.001 g/mm^3 is used. The units of I are mm.

$$I = \frac{m_t}{a*d} , \quad (1)$$

where:

I = the absorption,
m_t = the change in specimen mass in grams, at the time t,
a = the exposed area of the specimen, in mm^2, and
d = the density of the water in g/mm^3.

10.2 The initial rate of water absorption (mm/s$^{1/2}$) is defined as the slope of the line that is the best fit to I plotted against the square root of time (s$^{1/2}$). Obtain this slope by using least-squares, linear regression analysis of the plot of I versus time$^{1/2}$. For the regression analysis, use all the points from 1 min to 6 h, excluding points for times after the plot shows a clear change of slope. If the data between 1 min and 6 h do not follow a linear relationship (a correlation coefficient of less

TABLE 1 Times and Tolernaces for the Measurements Schedule

Time	60 s	5 min	10 min	20 min	30 min	60 min	Every hour up to 6 h	Once a day up to 3 days	Day 4 to 7 3 measurements 24 h apart	Day 7 to 9 1 (one) measurement
Tolerance	2 s	10 s	2 min	2 min	2 min	2 min	5 min	2 h	2 h	2 h

than 0.98) and show a systematic curvature, the initial rate of absorption cannot be determined.

NOTE 6—Appendix X1 gives an example of absorption data and the results of regression analysis.

10.3 The secondary rate of water absorption ($mm/s^{1/2}$) is defined as the slope of the line that is the best fit to *I* plotted against the square root of time ($s^{1/2}$) using all the points from 1 *d* to 7 *d*. Use least-square linear regression to determine the slope. If the data between 1 *d* and 7 *d* do not follow a linear relationship (a correlation coefficient of less than 0.98) and show a systematic curvature, the secondary rate of water absorption cannot be determined.

11. Report

11.1 Report the following:

11.1.1 Date when concrete was sampled or cast,

11.1.2 Source of sample,

11.1.3 Relevant background information on sample such as mixture proportions, curing history, type of finishing, and age, if available,

11.1.4 Dimensions of specimen before sealing,

11.1.5 Mass of specimen before and after sealing,

11.1.6 A plot of absorption, *I*, in mm versus square root of time in $s^{1/2}$,

11.1.7 The average initial rate of water absorption calculated to the nearest 0.1×10^{-4} $mm/s^{1/2}$ and the individual initial absorption rates for the two or more specimens, and

11.1.8 The average secondary rate of water absorption calculated to the nearest 0.1×10^{-4} $mm/s^{1/2}$ and the individual absorption rates of the two or more specimens tested.

12. Precision and Bias

12.1 *Precision*—The repeatability coefficient of variation has been determined to be 6.0 % in preliminary measurements for the absorption as measured by this test method for a single laboratory and single operator. An interlaboratory program is being organized to develop the repeatability and reproducibility values.

12.2 *Bias*—The test method has no bias because the rate of water absorption determined can only be defined in terms of the test method.

13. Keywords

13.1 concrete; initial rate of water absorption; mortar; rate of absorption; secondary rate of water absorption

Calculations:

Initial Absorption:
$I = S_i \sqrt{t} + b$ (points measured up to 6 h are used)
The initial rate of absorption is: $S_i = 3.5 \times 10^{-4}$ mm/√s $r = 0.99$

Secondary Absorption:
$I = S_s \sqrt{t} + b$ (points measured after the first day are used)
The secondary rate of absorption is: $S_s = 1.1 \times 10^{-4}$ mm/√s

Designation: C 1597M – 04 (Reapproved 2009)ε1

Standard Specification for Gypsum Wallboard (Hard Metric Sizes)[1]

This standard is issued under the fixed designation C 1597M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

ε[1] NOTE—Specification C 36/C 36M was replaced with Specification C 1396/C 1396M editorially in 1.2 and Referenced Documents in September 2009.

1. Scope

1.1 This specification covers gypsum wallboard which is designed to be used for walls, ceilings, or partitions and affords a surface suitable to receive decoration.

NOTE 1—Specification C 840 contains application procedures for gypsum wallboard.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard. For gypsum wallboard produced to inch-pound units see Specification C 1396/C 1396M.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. Referenced Documents

C 1264 Specification for Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage of Gypsum Panel Products

C 1396/C 1396M Specification for Gypsum Board

E 84 Test Method for Surface Burning Characteristics of Building Materials

E 96/E 96M Test Methods for Water Vapor Transmission of Materials

E 119 Test Methods for Fire Tests of Building Construction and Materials

3. Terminology

3.1 Definitions of terms shall be in accordance with Terminology C 11.

4. Materials and Manufacture

4.1 Gypsum wallboard shall consist of a noncombustible core, essentially gypsum, surfaced with paper bonded to the core.

4.2 Foil backed gypsum wallboard shall consist of gypsum wallboard with a layer of aluminum foil laminated to the back surface.

4.3 Gypsum wallboard, type X (special fire resistant) designates gypsum wallboard complying with this specification that provides not less than 1 hour fire-resistance for boards 16 mm thick or ¾ hour fire-resistance for boards 13 mm thick, applied parallel with and on each side of load bearing 2 × 4 wood studs spaced 400 mm o.c. with coated nails, 50 mm long, 2.0 mm diameter shank, 6.0 mm diameter heads, spaced 200 mm o.c. with wallboard joints staggered 400 mm on each side of the partition and tested in accordance with the requirements of Test Methods E 119.

NOTE 2—Consult producers for independent test data on assembly details and fire resistance classifications for other types of construction. See fire test reports or listings from recognized fire testing laboratories for assembly particulars, materials, and classifications.

4.4 Gypsum wallboard shall have a flame spread index of not more than 25 when tested in accordance with Test Method E 84.

5. Physical Properties

5.1 Specimens shall be taken from the samples obtained in accordance with Specification C 1264.

5.2 Specimens shall be tested in accordance with Test Methods C 473.

5.2.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

[1] This specification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Sept. 1, 2009. Published September 2009. Originally approved in 2004. Last previous edition approved in 2004 as C 1597M – 04.

Thickness, in. [mm]	Method A Load, N Bearing Edges Across Fiber of Surfacing	Method A Load, N Bearing Edges Parallel to Fiber of Surfacing	Method B Load, N Bearing Edges Across Fiber of Surfacing	Method B Load, N Bearing Edges Parallel to Fiber of Surfacing
6.5	220	90	200	70
10.0	360	140	340	120
13.0	500	180	480	160
16.0	660	220	640	200
20.0	760	260	740	240

5.2.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, mm	Humidified Deflection, mm
6.5	not required
10.0	40
13.0	30
16.0	15
20.0	15

5.2.3 *Core, End, and Edge Hardness*—The specimens shall have an average hardness of not less than 60 N when tested by Method A and 50 N when tested by Method B.

5.2.4 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, mm	Method A Nail Pull Resistance, N	Method B Nail Pull Resistance, N
6.5	180	160
10.0	280	260
13.0	360	340
16.0	400	390
20.0	440	430

5.3 *Foil Backed Gypsum Wallboard*

5.3.1 Foil-backed gypsum wallboard shall meet all of the requirements for gypsum wallboard.

5.3.2 When tested in accordance with Test Methods E 96/E 96M, the permeance of foil-backed gypsum wallboard shall be not more than 20 ng/Pa·s·m^2 (Desiccant Method) for the condition of 50 % relative humidity on the face of the board and 0 % relative humidity on the foil-covered back side of the board.

6. Dimensions and Tolerances

6.1 Specimens shall be taken from the samples obtained in accordance with Specification C 1264.

6.2 Thickness, width, length, and end squareness shall be determined in accordance with Test Methods C 473.

6.2.1 *Thickness*—The thickness shall be 6.5, 10.0, 13.0, 16.0, 20.0 mm with tolerances in the nominal thickness of ± 0.5 mm with local variations of ± 1.0 mm from the nominal thickness.

6.2.2 *Width*—The width shall be up to 1400 mm, with a tolerance of 3 mm under the specified width.

6.2.3 *Length*—The length and tolerance shall be as follows:

Thickness mm	Length mm	Variation mm
6.5	1200 to 4000	± 6
10.0	1200 to 5000	± 6
13.0	1200 to 5000	± 6
16.0	1200 to 5000	± 6
20.0	1200 to 5000	± 6

6.2.4 *Tapered Edge Depth*—The average thickness of the edge of recessed or tapered edge shall be not less than 0.50 mm but not more than 2.5 mm less than the average thickness of the gypsum wallboard.

6.2.5 *End Squareness*—Corners shall be square with a tolerance of ± 3 mm in the full width of the board.

6.3 *Edges and Ends*—The edges and ends shall be straight and either square, beveled, featured, tapered, or featured and tapered.

7. Finish and Appearance

7.1 The surfaces of gypsum wallboard shall be true and free from imperfections that render the gypsum wallboard unfit for use with or without decoration.

8. Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling and Storage

8.1 Shall be in accordance with Specification C 1264.

9. Keywords

9.1 ceiling; foil-backed; gypsum; gypsum wallboard; gypsum wallboard, type X; metric units; partitions; wall

APPENDIX

(Nonmandatory Information)

X1. ALTERNATE DEFINITION FOR TYPE X

INTRODUCTION

This Appendix gives general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this specification.

The definition of type X as given in 4.3 and the alternate definition given in this appendix, are intended only as a test to define the gypsum wallboard as meeting the requirements of type X. These tests do not indicate a preferred application nor do they limit the use of the product in other fire rated assemblies.

All gypsum panel products, except lath, shaftliner, and coreboard, use the same test for type X products, therefore the type X designation indicates a consistent level of fire resistance.

X1.1 Gypsum wallboard, type X (special fire-resistant) designates gypsum wallboard providing a greater fire resistance than regular gypsum wallboard of the same thickness. Type X (special fire-resistant) gypsum wallboard, when tested in accordance with Test Methods E 119, shall provide the following minimum fire resistance for the assemblies described:

X1.1.1 One hour for a 16.0 mm thickness applied to a partition in a single layer application on each side of 90 mm deep non-loadbearing galvanized steel studs complying with Specification C 645, spaced 600 mm on center. The 16.0 mm thick gypsum wallboard 1200 mm wide shall be attached using 25 mm long drywall screws spaced 200 mm on center along the edges and ends, and 300 mm along intermediate studs. All joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly, and

X1.1.2 Two hours for a 13.0 mm thickness applied to a partition in a double layer application on each side of 65 mm deep non-loadbearing galvanized steel studs complying with Specification C 645, spaced 600 mm on center. The 1200 mm wide base layer shall be attached using 25 mm long drywall screws spaced 300 mm on center along board edges, ends, and along intermediate studs. Joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly. The 1200 mm wide face layer shall be attached using 40 mm long drywall screws spaced 300 mm along board edges, ends, and along intermediate studs. Joints shall be oriented parallel to and located over studs, offset 600 mm from the base layer joints, and staggered on opposite sides of the assembly.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1600/C 1600M – 08

Standard Specification for Rapid Hardening Hydraulic Cement[1]

This standard is issued under the fixed designation C 1600/C 1600M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification is for rapid hardening hydraulic cements. This is a specification giving performance requirements. There are no restrictions on the composition of the cement or its constituents.

1.2 The specification classifies cements by type based on specific requirements for very early compressive strength development.

1.3 The values stated in either SI units or inch-pound units shall be regarded separately as standard. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.4 The text of this standard refers to notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) are not requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 109/C 109M Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)

C 114 Test Methods for Chemical Analysis of Hydraulic Cement

C 151 Test Method for Autoclave Expansion of Hydraulic Cement

C 183 Practice for Sampling and the Amount of Testing of Hydraulic Cement

C 186 Test Method for Heat of Hydration of Hydraulic Cement

C 191 Test Methods for Time of Setting of Hydraulic Cement by Vicat Needle

C 219 Terminology Relating to Hydraulic Cement

C 227 Test Method for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar-Bar Method)

C 441 Test Method for Effectiveness of Pozzolans or Ground Blast-Furnace Slag in Preventing Excessive Expansion of Concrete Due to the Alkali-Silica Reaction

C 596 Test Method for Drying Shrinkage of Mortar Containing Hydraulic Cement

C 1012 Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution

C 1038 Test Method for Expansion of Hydraulic Cement Mortar Bars Stored in Water

C 1437 Test Method for Flow of Hydraulic Cement Mortar

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this specification, see Terminology C 219.

3.2 *Definitions of Terms Specific to This Standard:*

3.3 *Rapid Hardening Hydraulic Cement*, *n*—a hydraulic or blended hydraulic cement which exhibits rapid strength gain during the first 24 h of hydration, with or without other constituents, processing additions, and functional additions.

4. Nomenclature, Classifications and Use

4.1 Cements conforming to this specification shall be designated "Rapid Hardening Hydraulic Cement" with the high early strength gain characteristic indicated by type in accordance with the types described in section 4.2. When the type is not specified, the requirement of Type GRH shall apply.

4.2 The specification is for four types of rapid hardening cement as follows:

4.2.1 *Type URH*—Ultra Rapid Hardening For use where *ultra high* early strength is desired (See Table 1).

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.13 on Special Cements.

Current edition approved Sept. 1, 2008. Published October 2008. Originally approved in 2007. Last previous edition approved in 2007 as C 1600/C 1600M – 07.

[2] See the section on Safety, Manual of Cement Testing, *Annual Book of ASTM Standards*, Vol 04.01.

TABLE 1 Standard Physical Requirements

(must be reported on manufacturer's certification)

	Cement Type			
	URH	VRH	MRH	GRH
Compressive Strength (See Section 9 for procedures), min, MPa [psi]				
1½ h	21 [3000]	12 [1700]	. . .	. . .
3 h	28 [4100]	15 [2200]	10 [1500]	7 [1000]
6 h	. . .	. . .	14 [2000]	10 [1500]
1 day	35 [5100]	24 [3500]	17 [2500]	14 [2000]
7 days	41 [6000]	28 [4100]	28 [4100]	24 [3500]
28 days	57 [8300]	35 [5100]	31 [4500]	28 [4100]
Drying Shrinkage, max %				
7 days	0.06	0.06	0.08	0.10
28 days, air storage	0.07	0.07	0.09	0.12
Min Time of Final Set C 191 apparatus Minutes[A]	10	10	10	10
Autoclave, max expansion %	0.8	0.8	0.8	0.8

[A]The initial setting time typically ranges from 10 to 45 min for rapid hardening cements of various types and composition.

4.2.2 *Type VRH*—Very Rapid Hardening For use where *very high* early strength is desired (See Table 1).

4.2.3 *Type MRH*—Medium Rapid Hardening for use where *mid-range* rapid hardening high early strength is desired (See Table 1).

4.2.4 *Type GRH*—General Rapid Hardening for use when the higher strength properties of a Type VRH or a Type MRH cement is not required (See Table 1).

5. Ordering Information

5.1 Orders for cement meeting the requirements of this specification shall include the following:

5.1.1 This specification designation and date.

5.1.2 The quantity of cement desired.

5.1.3 The type of cement desired.

5.1.4 A request for the manufacturer's certification, if desired.

6. 6. Chemical Composition

6.1 The chemical composition for the cement is not specified. However, the purchaser shall have the option to request the cement composition from the producer. If analyzed, the procedure used shall be Test Methods C 114.

7. Physical Properties

7.1 Cement of the type specified shall conform to all of the applicable standard physical requirements in Table 1.

7.2 The water/cement ratio used to determine strength requirement compliance shall be reported in the manufacturer's certification.

7.3 The density for the cement is not specified. However, the density shall be determined by the manufacturer and reported in the manufacturer's certification.

8. Sampling

8.1 When the purchaser desires that the cement be sampled and tested to verify compliance with this specification, the finished cement shall be sampled in accordance with Practice C 183 at the mill or at the job site in accordance with the purchaser's requirements (See Note 1).

NOTE 1—Practice C 183 is not designed for manufacturing quality control and is not required for manufacturer's certification.

9. Test Methods

9.1 When testing cement for compliance with this specification, use the following methods, with modifications or exceptions as indicated:

9.1.1 *Autoclave Expansion*—Determine autoclave expansion by Test Method C 151 as specified in Table 1.

9.1.2 *Time of Setting*—Determine the time of setting using Test Method C 191 as specified in Table 1. Immediately after molding the test specimen in the conical ring, determine the penetration of the needle at this time and every 3 min. until the needle no longer penetrates to the bottom of the specimen, then every 1 min. until final set is determined.

9.1.3 *Compressive Strength*—Determine compressive strength using Test Method C 109/C 109M as modified herein. Tests shall be run at each age specified in Table 1. The mixing water requirement in Test Method C 109/C 109M shall be adjusted to produce a flow of 110 ± 5 as determined using Test Method C 1437.

9.1.4 *Drying Shrinkage of Mortar*—Determine drying shrinkage of mortar as specified in Table 1 using Test Method C 596.

9.1.5 *Heat of Hydration*—Determine heat of hydration using Test Method C 186 (See Table 2).

9.1.6 *Sulfate Resistance*—Determine sulfate resistance using Test Method C 1012 (See Table 2).

9.1.7 *Alkali Silica Reactivity*—Determine reactivity of cement with alkali-reactive aggregate (Option R) using Test Method C 227 using crushed borosilicate glass, as described in Test Method C 441, as aggregate (See Table 2).

9.1.8 *Expansion in Water*—Determine expansion of hydraulic cement mortar bars stored in water by Test Method C 1038 (See Table 2).

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

TABLE 2 Optional Requirements

Sulfate expansion[A] (C 1012)				
6 months, max %	0.05	0.05	0.05	0.05
1 year, max %	0.10	0.10	0.10	0.10
ASR Expansion[B] (C 441)				
14 days, max %	0.020	0.020	0.020	0.020
56 days, max %	0.060	0.060	0.060	0.060
Heat of Hydration (C 186)				
7 days, max, kJ/kg (kcal/kg)	250 [60]	250 [60]	250 [60]	250 [60]
28 days, max, kJ/kg (kcal/kg)	290 [70]	290 [70]	290 [70]	290 [70]
Expansion in Water (C 1038)				
14 days, max %	0.10	0.10	0.10	0.10

[A] In the testing of these cements, testing at one year shall not be required when the cement meets the 6-month limit. Cement failing the 6-month limit shall not be rejected unless it also fails the one-year limit.

[B] The test for mortar expansion is an optional requirement to be applied only at the purchaser's request and is not required unless the cement will be used with alkali-reactive aggregate.

10. Testing Time

10.1 The age of the specimens is to be determined from the time when the cement contacts the mixing water.

10.2 Specimens to be tested at 1½ , 3, and 6 h shall be removed from the molds a maximum of 10 min. prior to time of test. After the specimens are removed from the molds, keep them covered with a damp towel until time to be tested. The cubes must be tested within 10 min. of the time specified.

10.3 All other specimens shall be removed from the molds at 22 h, ± 2 h. If the specimens are removed from the molds before 24 h, keep them on the shelves of the moist closet or moist room until they are 24 h old, and then immerse the specimens except for the 24-h test, in saturated limewater for storage.

10.4 The 24-h, 7-d, and 28-d test specimens shall be broken within the permissible time tolerances prescribed in Test Method C 109/C 109M.

10.5 Record and calculate the compressive strength in accordance with the Calculation Section of Test Method C 109/C 109M.

10.6 Apply the sampling and testing requirements of Practice C 183.

10.7 For testing of samples taken subsequent to shipment, the purchaser shall make necessary arrangements for shipment of samples to the testing laboratory. Add the time required for transport to the laboratory to the minimum time intervals allowed from receipt of the samples by the testing laboratory.

10.8 The minimum time allowed from receipt of samples by the testing laboratory to the report of test results shall be determined by the required age of specimen at the time of testing plus seven days.

10.9 A written report of results of applicable tests shall be available within not more than three days after the interval specified in 10.8.

10.10 These time limits do not apply to retesting or additional testing (See Note 2).

NOTE 2—Aging effects on small samples or quantities of cement stored for long periods of time can produce test results that are not representative of the fresh cement nor of cement stored in large quantity for equal periods of time.

11. Testing by the Manufacturer

11.1 Secure representative samples of cement during production or transfer and test them for compliance with this specification. Location and frequency of sampling are at the discretion of the manufacturer. Sampling and testing shall be either part of, or in addition to, the manufacturer's normal quality control.

12. Inspection

12.1 Inspection of the material shall be as agreed upon between the purchaser and the seller as part of the purchase contract.

12.2 All packages shall be in good condition at the time of inspection.

13. Certification

13.1 When specified in the purchase order or contract, furnish the manufacturer's certification at the time of shipment stating the results of tests made on cement sampled during production or transfer and certifying that the applicable requirements of this specification have been met.

14. Package Marking

14.1 When the cement is delivered in packages, the words "Rapid Hardening Hydraulic Cement," the type of cement, the specification designation, the name and brand of manufacturer and the mass of cement contained therein shall be plainly marked on each package. Similar information shall be provided in the manufacturer's certification accompanying the shipment of packaged or bulk cement.

15. Storage

15.1 The cement shall be stored in such a manner as to permit reasonable access for proper inspection and identification of each shipment and in a suitable weather-tight building, container, or package that will protect the cement from dampness and minimize warehouse set.

16. Keywords

16.1 blended hydraulic cement; high early strength; hydraulic cement; rapid hardening hydraulic cements

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this specification since the last issue, C 1600/C 1600M – 07, that may impact the use of this specification. (Approved September 1, 2008)

(*1*) Revised Table 1.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1602/C 1602M – 06

Standard Specification for Mixing Water Used in the Production of Hydraulic Cement Concrete[1]

This standard is issued under the fixed designation C 1602/C 1602M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers the compositional and performance requirements for water used as mixing water in hydraulic cement concrete. It defines sources of water and provides requirements and testing frequencies for qualifying individual or combined water sources. In any case where the requirements of the purchaser differ from these in this specification, the purchaser's specification shall govern.

1.2 This specification does not purport to cover methods of storage, transportation, or blending of water, or to address the development and maintenance of quality control programs sponsored or managed by the manufacturer.

1.3 The values stated in either SI units, shown in brackets, or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.4 The text of this specification references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2.2 *ACI Documents:*[3]

ACI 318 Building Code Requirements for Structural Concrete and Commentary

3. Terminology

3.1 *Definitions:* For definitions of terms used in this specification, refer to Terminology C 125

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *combined water*—a mixture of two or more sources of water blended together, before or during introduction into the mixture, for use as mixing water in the production of concrete.

3.2.2 *hydration stabilizing admixtures*—extended set retarding admixtures that control the hydration of cement in applications of managing returned concrete and water from concrete production

3.2.3 *non-potable*—water sources that are not fit for human consumption, or if it contains quantities of substances that discolor it or make it smell or have objectionable taste but does not contain water from concrete production operations.

3.2.4 *potable water*—water suitable for human consumption

3.2.5 *water from concrete production operations*—water recovered from processes of hydraulic cement concrete production that includes wash water from mixers or that was a part of a concrete mixture; water collected in a basin as a result of storm water runoff at a concrete production facility; or water that contains quantities of concrete ingredients.

4. Requirements for Use

4.1 Mixing water shall consist of:

[1] This specification is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.40 on Ready-Mixed Concrete.

Current edition approved Feb. 15, 2006. Published March 2006. Originally approved in 2004. Last previous edition approved in 2005 as C 1602/C 1602M – 05.

4.1.1 Batch water (water weighed or metered through the batch plant),

4.1.2 Ice,

4.1.3 Water added by truck operator,

4.1.4 Free moisture on the aggregates, and

4.1.5 Water introduced in the form of admixtures when this water increases the water-cementitious materials ratio by more than 0.01.

4.2 Potable water is permitted to be used as mixing water in concrete without testing for conformance with the requirements of this specification.

4.3 Mixing water that is wholly or partially composed of sources of water that are non-potable or from concrete production operations are permitted to be used in any proportions to the limits qualified to meet the requirements of Table 1. At the option of the purchaser and when appropriate for the construction, any of the optional limits found within Table 2 shall be specified at the time of concrete ordering according to the section on *Ordering Information* of Specification C 94/C 94M.

4.3.1 Non-potable sources of water shall be qualified for use in accordance with 5.1. When the non-potable water source is blended with a potable source, the qualification of the mixing water shall be at the highest percentage of the non-potable source in the combined mixing water anticipated during production.

4.3.2 Combined water blended from two or more sources, where one of the sources includes that from concrete production, shall be qualified for use in accordance with 5.2. The combined water shall be qualified at the highest solids content in the total mixing water anticipated during production. Mixing water containing total solids equal to or less than the level qualified by testing shall be permitted.

5. Testing and Requirements

5.1 For sources of non-potable mixing water (as defined in 3.2.3) proposed for use as total mixing water or in the combined mixing water (as defined in 3.2.1), the following shall apply to the total combined mixing water:

5.1.1 Water shall be tested for compliance with Table 1 before first use and thereafter every three months or more often when there is reason to believe that a change has occurred in the characteristics of the source. Testing is permitted to be at a lower frequency, but not less than annually when results from four consecutive tests indicate compliance with Table 1.

5.1.2 The manufacturer shall maintain documented evidence that the characteristics of the combined mixing water are in compliance with Table 2. These tests shall be conducted before first use and thereafter every 6 months or more often when there is reason to believe that a change has occurred in the characteristics of the source. These records shall be provided to the purchaser on request.

TABLE 1 Concrete Performance Requirements for Mixing Water

	Limits	Test Methods
Compressive strength, min % control at 7 days[A,B]	90	C 31/C 31M, C 39/C 39M
Time of set, deviation from control, h: min[A]	From 1:00 early to 1:30 later	C 403/C 403M

[A] Comparisons shall be based on fixed proportions for a concrete mix design representative of questionable water supply and a control mix using 100 % potable water or distilled water. (See Annex A1).

[B] Compressive strength results shall be based on at least two standard test specimens made from a composite sample.

5.2 For sources of water from concrete production operations (as defined in 3.2.5) proposed for use as the total mixing water or in the combined mixing water (as defined in 3.2.1), the following shall apply to the total combined mixing water:

5.2.1 The density of the source of water from ready mixed concrete shall be tested at least on a daily basis in accordance with Test Method C 1603 or monitored with a hydrometer that has been verified in accordance with Test Method C 1603. Manufacturers that use automated devices shall maintain at the production facility documentation on the procedures and calibration of systems, as needed (See Note 1).

NOTE 1—Blending proportions of water sources can be determined in accordance with Appendix A1 of Test Method C 1603 for achieving a target solids content.

5.2.2 Combined water shall be tested for compliance with the requirements of Table 1 at the highest solids content anticipated to be used during production in accordance with the following testing frequencies:

5.2.2.1 When the density of the combined water is less than 1.01 g/mL, the water shall be tested before first use and thereafter once every six months. Testing frequency is permitted to be reduced to once every 12 months when the results of two consecutive tests indicate compliance with the requirements of Table 1 (See Note 2).

NOTE 2—This condition is intended to cover the use of clarified wash water that has been passed through a settling pond system.

5.2.2.2 When the density of the combined water is between 1.01 and 1.03, the water shall be tested before first use and thereafter monthly. Testing frequency is permitted to be reduced to once every three months when the results of 4 consecutive tests indicate compliance with the requirements of Table 1 (See Note 3).

NOTE 3—Water density of 1.03 approximately represents a total solids content of 50,000 ppm.

5.2.2.3 When the density of the combined water exceeds 1.03, the water shall be tested weekly or more often when there is reason to believe that there is a change in the water characteristics for compliance with the requirements of Table 1. Testing frequency is permitted to be reduced to once every month when the results of two months of consecutive tests indicate compliance with the requirements of Table 1.

5.2.2.4 Testing for water with density exceeding 1.05 shall be the same as that of 5.2.2.3 whether the water includes or does not include a set stabilizing admixture (See Note 4).

NOTE 4—Water density exceeding approximately 1.05, where the solids are essentially composed of cementitious materials, may require the use of hydration stabilizing admixtures to maintain compliance with the requirements of Table 1. The producer should have a documented process in place to verify the effectiveness of the admixtures and dosages employed.

5.2.3 The manufacturer shall maintain documentation on the characteristics of the water in compliance with the requirements of Table 2, other than the total solids requirement. These requirements shall apply to the combined water at the highest

www.technobetar.ir

TABLE 2 Optional Chemical Limits for Combined Mixing Water[A]

	Limits	Test Method
Maximum concentration in combined mixing water, ppm[B]		
A. Chloride as Cl^-, ppm		
1 in prestressed concrete, bridge decks, or otherwise designated	500[C]	C 114
2 other reinforced concrete in moist environments or containing aluminum embedments or dissimilar metals or with stay-in-place galvanized metal forms	1000[C]	C 114
B. Sulfate as SO_4, ppm	3000	C 114
C. Alkalies as (Na_2O + 0.658 K_2O), ppm	600	C 114
D. Total solids by mass, ppm	50 000	C 1603

[A]Specification limits from this table are not prohibited from being specified as individual items or as a whole per paragraph 4.1.6 of Specification C 94/C 94M.
[B]ppm is the abbreviation for parts per million
[C]The requirements for concrete in ACI 318 shall govern when the manufacturer can demonstrate that these limits for mixing water can be exceeded. For conditions allowing the use of calcium chloride ($CaCl_2$) accelerator as an admixture, the chloride limitation is permitted to be waived by the purchaser.

solids content anticipated for use. These tests shall be conducted before first use and thereafter once every 6 months. These records shall be provided to the purchaser on request (See Note 5).

5.3 Concrete testing to verify compliance with the requirements of Table 1 shall be conducted on concrete samples obtained from production batches or in laboratory batches in accordance with Practice C 192/C 192M (See Note 5).

NOTE 5—The sampling of total combined water in its final form from either the batch plant or transportation unit is impractical. Therefore, for the purposes of testing for compliance to the requirements of Table 1 and Table 2, it is acceptable to sample, proportion, and combine the individual sources of water to produce a test sample that is representative of the actual combined mixing water used in production.

6. Keywords

6.1 combined water; density; hydration stabilizing admixture; mixing water; recycled water

ANNEX

(Mandatory Information)

A1. GUIDE FOR THE COMPARISON BETWEEN TWO CONCRETE MIXTURES NECESSARY FOR COMPLIANCE WITH Table 1

INTRODUCTION

To comply with the performance requirements in Table 1, comparison between two concrete mixtures is required: one as a control batch using a potable water source, and a second as a test batch using the water source(s) proposed for use. The following shall apply:

A1.1 Water for the test batch as defined in 3.2 with a density greater than 1.01 g/mL, or as close in approximation to density as used during actual production.

A1.2 Water for the test batch as defined in 3.2 shall be as close as possible to the actual age of water used during actual production.

A1.3 Air entraining and water reducing admixtures are permitted in test and control batches. The air-entraining admixture shall be adjusted to produce the target air content with a tolerance of ±1.5 %. The dosage of water reducing admixture shall be the same in both batches.

A1.4 Hydration stabilizing admixtures are permitted for use in the mixing water for the test batch. No other set controlling admixtures are permitted.

A1.5 Mixing water content of the test batch shall not be less than the mixing water content of the control batch.

A1.6 Mixture proportions shall be made available upon request.

A1.7 Each batch for concrete comparison purposes to determine compliance with Table 1 shall be within ± 1 °C at the time of mixing and shall be conditioned the same for the duration of the test.

APPENDIX

(Nonmandatory Information)

X1. GUIDE FOR TESTING FREQUENCY AS RELATED TO WATER SOURCE USED IN MIXING WATER.

Water Sources	Combined Water Density (g/mL)	Testing Frequency		
		Density, C 1603	Table 1	Table 2
Potable	N/A	N/A	N/A	N/A
Non-Potable[A]	N/A	N/A	3 months; after 4 tests annually (5.1.1)	6 months (5.1.2)
Concrete	<1.01	Daily (5.2.1)	6 months; annually after 2 tests (5.2.2.1)	6 months (5.2.3)
Production[A]	1.01 – 1.03		Monthly; 3 months after 4 tests (5.2.2.2)	
	> 1.03		Weekly; monthly after 8 tests (5.2.2.3)	

[A]Testing frequencies apply to the combined mixing water when it is wholly or partially composed of the listed source as defined in Section 3.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C 1602/C 1602M – 05, that may impact the use of this specification. (Approved February 15, 2006)

(*1*) Added new footnote A in Table 2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1603 – 05a

Standard Test Method for Measurement of Solids in Water[1]

This standard is issued under the fixed designation C 1603; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the measurement of the solids content in water for use as mixing water in ready-mixed concrete and the measurement of its density. Solids content is expressed in terms of parts per million (ppm) or in terms of percent by mass of the water sample.

1.2 The values stated in SI units are to be regarded as standard; inch-pound units are shown in parenthesis for information only.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 29/ C 29M Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 1602/C 1602M Standard Specification for Mixing Water Used in the Production of Hydraulic Cement Concrete

3. Significance and Use

3.1 This test method is used to determine the solids content of mixing water used to produce concrete when one or more of the water sources is wash water from concrete production operations or water that contains solids when batched as mixing water in concrete.

3.2 The test method provides a means to determine the relationship between the density and solids content of water for compliance with solids content limits of mixing water such as in Specification C 1602/C 1602M.

3.3 During production of concrete, the water property measured is its density, which can then be used to estimate the solids content from procedures described in this test method.

3.4 To develop a correlation between the density and solids content of water, water samples should be tested that cover the range of solids concentrations anticipated during production.

4. Apparatus

4.1 Density Measure: A cylindrical container (Note 1) with a volume of 200 ± 25 mL (7 ± 1 fl. oz.) with a glass or hard plastic plate that is placed over it. The glass or plastic plate shall be at least 6 mm (¼ in.) thick and 40 mm (1½-in.) larger than the outer diameter of the measure. The top of the density measure shall be flat such that it does not leak when the plate is placed over it.

NOTE 1—A commonly available smaller size mason jar with top ground smooth is acceptable.

4.2 The volume of the density measure shall be determined to nearest 0.1 mL in accordance with procedures used for calibrating air or density measures, as in Test Method C 29/ C 29M.

4.3 A microwave oven with at least 900 W of power capacity.

4.4 A microwave-safe glass dish large enough to contain the water sample and fiberglass cloth (See Note 2).

NOTE 2—A 450 × 450 × 25 mm (9 × 9 × 1 in.) dish is acceptable. Fiberglass cloth commonly used with fiberglass resin for boat or auto body repair is found in most hardware stores.

4.5 A balance or scale with a minimum capacity of 2000 g accurate to 0.1 g

4.6 A rubber syringe

5. Measurement of Density

5.1 Obtain the mass of the empty density measure and plate to the nearest 0.1g.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.40 on Ready-Mixed Concrete.

Current edition approved July 1, 2005. Published August 2005. Originally approved in 2004. Last previous edition approved in 2005 as C 1603 – 05.

[2] For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

5.2 If the water contains solids in suspension, ensure that the water is sampled while the water source is being agitated. Take a representative sample of water and fill the density measure to overflowing. Slide the cover plate over the measure ensuring that there are no air bubbles. Wipe the outside of the plate and measure dry and obtain the mass of the filled density measure covered with the plate.

5.3 Calculate the density of the water sample to 0.001 g/mL

$$D_W = \frac{M_W}{V} \quad (1)$$

Where:
D_W = Density of the water, g/mL,
M_W = Net mass of water in the density measure, g, and
V = Volume of the density measure, mL.

6. Measurement of Solids Content

6.1 Obtain the mass of the empty dish and a piece of fiber glass cloth about 500 mm (20 in.) square to the nearest 0.1 g.

6.2 Keep the glass plate over the density measure and shake the water suspension. Pour the water sample into the glass dish. Using the rubber syringe, wash solids adhered in the measure into the dish using a minimum amount of water. Cover the water with the fiberglass cloth to prevent loss of solids during drying.

6.3 Place the dish in a microwave oven and heat it for approximately 20 min or until the water has evaporated. Determine the mass of the dish and place it back in the microwave oven for 2 min increments until the mass determined in two subsequent determinations do not differ by more than 0.5 g.

6.4 Determine the mass of the dish and cloth with the dried solids.

6.5 Calculate the percent solids in terms of percent by mass to the nearest 0.1 % and in ppm to the nearest 1000 ppm.

$$S_W,\% = \frac{M_s}{M_W} \times 100 \quad (2)$$

$$S_{ppm} = S_W \times 10\,000 \quad (3)$$

Where:
M_s = Mass of dry solids,
M_W = Mass of water with solids,
S_W = Solids content in water, in percent, and
S_{ppm} = Solids content in water, in ppm.

6.6 Repeat these measurements for water with different solids content. Test water at 4 or more different levels of solids content.

7. Relationship Between Density and Solids Content

7.1 Establish a relationship using linear regression analysis (See Note 3) between the measured density and solids content of water sample measurements for a range of solid concentrations that cover the anticipated range in the production facility.

NOTE 3—The linear regression analysis can be performed using spreadsheet software.

7.1.1 Express the relationship between the density of the water and the solids content as follows, such that the measured density on a particular production day can be used to determine the solids content of the water.

$$S_{ppm} = A + B \times D_W \quad (4)$$

Where: A and B are regression constants

NOTE 4—Eq 4 provides an approximate linear relationship between solids content and measured density. The relationship between solids content and density is non-linear (see Eq 5) and Eq 4 should not be used to estimate the solids content of water outside the range of values used to establish the relationship in Eq 4.

NOTE 5—During concrete production, a producer might choose to monitor the density of a water source using a hydrometer. It is recommended that the density of the water using a hydrometer be determined on the water at the time of this density measurement to obtain a relationship, if needed, or to calibrate the hydrometer. The water sample should be placed in a transparent volumetric measuring flask. The hydrometer measurement should be taken within 10 s after filling the water in the flask. This is to ensure that significant settlement of solids has not occurred before the measurement is taken as that will affect the measured density.

7.2 When the relationship between density and solids content is not determined by testing, calculate the solids content of the water in ppm from the measured density using the following:

$$S_{ppm} = \left(\frac{D_W - 1}{D_S - 1}\right) \times \frac{D_S}{D_W} \times 1\,000\,000 \quad (5)$$

where:
D_S = Density of solids in the water, g/mL

7.2.1 When the density of solids in the water is unknown, assume it to be 2.6 g/mL, and determine the solids content of the water in ppm from the measured density using the simplified form of Eq 5 as follows:

$$S_{ppm} = 1\,625\,000 \times \left(1 - \frac{1}{D_W}\right) \quad (6)$$

NOTE 6—Guidance for blending two sources of water with different solids content is provided in Appendix X1.

8. Report

8.1 For the water samples tested to establish the relationship of water density to solids content, maintain a record of the density of water to the nearest 0.001 g/mL; and the solids content of the same water sample in ppm to the nearest 1000 ppm or percent by mass of water to the nearest 0.1 %. Include the dates of these tests and maintain a record of the regression equation used to establish the relationship of water density to solids content.

8.2 For tests of water samples during production of concrete or to calibrate automated measuring devices, maintain a record of water density tests to the nearest 0.001 g/mL or solids content to the nearest 1000 ppm. Include the date and time of these tests. Record the calculated solids content of the tested water sample and the method (7.1 or 7.2) used to determine the solids content.

9. Precision and Bias

9.1 *Precision*—The estimates of precision for this test method are based on results from tests on wash water samples with a range of solids content between 25 000 and 140 000 ppm. Four operators tested the same water samples in triplicate for the density and in duplicate for solids content.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:30:31 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.1.1 *Single Operator Precision*—The single-operator standard deviation (1s) is shown in Table 1 by average density and solids content; therefore, results of two properly conducted tests on the same sample by the same operator are not expected to differ by more than the d2s values listed in Table 1.

9.1.2 *Multi-Operator Precision*—The multi-operator standard deviation (1s) is shown in Table 1 by average density and solids content; therefore, results of two properly conducted tests on the same sample by two different operators are not expected to differ by more than the d2s values listed in Table 1.

9.2 *Bias*—Since there is no accepted reference material for determining the bias of the results from this test method, no statement on bias is made.

10. Keywords

10.1 concrete mixing water; density; recycled water; solids

TABLE 1 *Table Precision*

	Standard Deviation (1s)[A]	Acceptable Range of Two Results (d2s)[A]

APPENDIX

(Nonmandatory Information)

X1. Determination of Blending Percentages of Combined Water

X1.1 Use the following relationships to determine the mixing percentage (Note X1.1) of each of two water sources to be blended to ensure that the added mixing water to concrete is at a target limit of solids content or the respective target density.

X1.1.1 When the solids content of the two sources of water is known and water is batched by mass or by volume, use Eq X1.1:

$$P_1 = \frac{S_T - S_2}{S_1 - S_2} \times 100 \quad \text{(X1.1)}$$

X1.1.2 When the density of the two sources of water is known, use Eq X1.2 when water is batched by mass and Eq X1.3 when water is batched by volume:

$$P_1 = \frac{D_T - D_2}{D_1 - D_2} \times \frac{D_1}{D_T} \times 100 \quad \text{(X1.2)}$$

$$P_1 = \frac{D_T - D_2}{D_1 - D_2} \times 100 \quad \text{(X1.3)}$$

Where:

P_1 = Percentage of water from source 1 in the blended mixing water,

S_T *and* D_T = Target solids content in ppm and density in g/mL of the blended mixing water,

S_1 *and* D_1 = Solids content in ppm and density in g/mL of the water from source 1, and

S_2 *and* D_2 = Solids content in ppm and density in g/mL of the water from source 2.

NOTE X1.1—The target solids content may be a limit established in a specification or one that the quality control function of the ready mixed concrete producer establishes. The solids content, typically dissolved, of municipal water may be considered to be 0 ppm and the density may be considered to be 1.0 g/mL, to simplify this calculation.

X1.2 When wash water from concrete production is used at a higher percentage of solids content, there will be necessary corrections in the quantity of mixing water and the volume of solids to account for the solids content in the total mixing water.

Designation: C 1604/C 1604M – 05

Standard Test Method for Obtaining and Testing Drilled Cores of Shotcrete[1]

This standard is issued under the fixed designation C 1604/C 1604M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers obtaining, preparing, and testing cores drilled from shotcrete for length, compressive strength, or splitting tensile strength determinations.

1.2 The values stated in either inch-pound units or SI units shall be regarded separately as standard. SI units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 *This standard does not purport to address the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 For definitions of terms used in this standard, refer to Terminology C 125.

4. Significance and Use

4.1 This test method provides standardized procedures for obtaining cored specimens to determine the compressive strength and splitting tensile strength of shotcrete during pre-construction, during construction, and from older shotcrete structures.

4.2 Generally, test specimens are obtained *in situ* when doubt exists about the in-place shotcrete quality due either to low strength test results during construction or signs of distress in the structure. Other uses of this method are to provide specimens for acceptance testing, construction control and to assess the condition, quality and uniformity of the shotcrete in accordance with Practice C 823 (see Note 1).

4.3 Specimens obtained by this method are used to verify the thickness of shotcrete and aid in the visual assessment of the shotcrete quality, workmanship, defects, shotcrete-to-substrate bond and the condition of any reinforcement used in the shotcrete[4].

4.4 Shotcrete strength is affected by the location of the shotcrete in a structure. Vertical, sub-horizontal and overhead elements of the shotcrete structure may show variability. Core strength is affected by core orientation relative to direction of shotcrete application. These factors shall be considered in

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.46 Shotcrete.

planning the locations for obtaining shotcrete samples and in interpreting strength test results.

4.5 Shotcrete is applied in single or multiple layers, as plain shotcrete, reinforced shotcrete, or fiber-reinforced shotcrete. Core samples containing wire-mesh and reinforcing bars shall not be used for compressive strength testing.

4.6 The strength of shotcrete is affected by moisture content, the specified moisture conditioning procedure for cores is intended to provide test specimens with reproducible moisture contents that minimize within-laboratory and between-laboratory variations.

4.7 Sample acquisition may require a combination of core-drilling, sawing, and grinding that may have the potential to adversely affect the sample condition if care is not taken during sampling and testing.

4.8 A sampling plan shall be established that indicates the number of samples and their locations (see Note 1). The acceptance criteria for shotcrete core strengths shall be established by the specifier of tests (see Note 2).

NOTE 1—Practice C 823 provides guidance on the development of a sampling plan for concrete in constructions. A number of methods that supplement the examination of hardened shotcrete by means of representative core samples and testing are discussed in ACI 506.4R.

NOTE 2—The core strength acceptance criteria cited in ACI 318 are based on a comparison of molded cylinder specimens and cores. Shotcrete strengths are always based on core specimens, therefore the 85 % factor used in core to cylinder comparisons is not relevant to the evaluation of shotcrete core strengths. A typical shotcrete specification reflecting standard industry practice is contained in ACI 506.2.

5. Apparatus

5.1 *Core Drill*, for obtaining cylindrical core specimens with diamond impregnated bits attached to a core barrel. The core drill shall have a rigid mounting base and be capable of being operated in any orientation normal to the shotcrete structure that is being sampled. The core drill shall be free from excessive vibration when in operation and shall have sufficient torque and consistent rotational speed to sustain uniform rates of penetration of the core drill. The core barrel shall be cooled and core cuttings flushed with water during operation.

5.2 *Saw*, for cutting core specimens to size for compressive strength. The saw shall have a diamond or silicon carbide cutting edge and shall be capable of cutting plain and reinforced specimens in a single pass that conform with the prescribed dimensions, without excessive heating or shock.

5.3 *Grinding wheel*, to trim and clean plain and fiber-reinforced shotcrete specimens that conform to prescribed tolerances without significantly disturbing the aggregates, matrix or fiber-reinforcement.

6. Sampling

6.1 *General*:

6.1.1 Sampling shall be planned in accordance with the applicable provisions of Practice C 823. The number of samples, sample locations and sampling procedures shall be established in the plan.

6.1.2 Shotcrete samples obtained from test panels shall be in accordance with the applicable provisions of Practice C 1140.

6.1.3 Samples of hardened shotcrete for use in the preparation of strength test specimens shall not be taken until the shotcrete is strong enough to permit sample removal without disturbing the bond between the mortar, coarse aggregate (see Note 3) and fiber-reinforcement. When preparing strength test specimens from samples of hardened shotcrete, samples that have been damaged in the process of removal shall not be used. Specimens of defective shotcrete that cannot be tested shall be reported as such if the defects are representative of the in-place condition of the shotcrete (see ACI 506.4R).

NOTE 3—It is not possible to specify a minimum age when shotcrete is strong enough to withstand damage during removal, because the strength at any age depends on the strength grade and curing of the shotcrete. If accelerating admixtures are used during shotcrete application, core specimens may be obtained for testing at approximately 6 h. If this is not practical, removal of shotcrete can proceed if cored or cut surfaces do not display erosion of the mortar and the exposed coarse aggregate particles are embedded firmly in the mortar. Nondestructive test methods may be used to estimate level of in-place strength development prior to attempting removal of shotcrete core samples (see ACI 506.4R).

6.1.4 Specimens containing embedded reinforcement shall not be used for determining compressive or splitting tensile strength.

6.2 *Core Drilling*—Drill core specimens perpendicular to the surface and avoid drilling near formed joints or edge placement. Record the approximate angle between the drilled core axis and the plane of the shotcrete as placed.

7. Measuring the Length of Drilled Cores

7.1 Cores for determining the thickness of shotcrete layers or other structural elements shall have a diameter of at least 3.0 in.. [75 mm] when the lengths of such cores are to be measured in accordance with Test Method C 174/C 174M.

7.2 For cores that are not intended for determining structural dimensions, measure the longest and shortest lengths on the cut surface along lines parallel to the core axis. Record the average length to the nearest ¼ in. [5 mm].

8. Cores for Compressive Strength

8.1 *Diameter*—The diameter of core specimens for the determination of compressive strength in load bearing structural members shall be at least 3.0 in. [75 mm] (see Note 4). Core diameters less than 3.0 in. [75 mm] shall be permitted as directed by the specifier of the tests.

NOTE 4—The compressive strengths of 2-in [50-mm] diameter cores are known to be somewhat lower and more variable than those of 3-in. [75-mm] diameter cores. In addition, smaller diameter cores appear to be more sensitive to the effect of the length-diameter ratio[4].

8.2 *Length*—The preferred length of the capped or ground specimen is nominally two times the diameter.

8.2.1 If the ratio of the length to the diameter (L/D) of the core exceeds 2.1, reduce the length of the core so that the ratio of the capped or ground specimen is between 1.9 and 2.1. Core specimens with length-diameter ratios equal to or less than 1.75 require corrections to the measured compressive strength (see. 8.8.1). A strength correction factor is not required for L/D greater than 1.75. A core having a length of less than 95 % of its diameter before capping or a length less than its diameter after capping or end grinding shall not be tested unless so directed by the specifyer of the tests.

www.technobetar.ir

8.2.2 For non-load bearing structural members or when it is impossible to obtain shotcrete cores with length-diameter ratio (L/D) greater than or equal to 1.0, core specimens shall be subject to the approval of the specifier of the tests.

8.3 *Moisture Conditioning*—The following procedure is intended to preserve the moisture of the drilled core and to provide a reproducible moisture condition that minimizes the effects of moisture gradients introduced by wetting during drilling and specimen preparation.

8.3.1 The following procedure is used to obtain cores having a moisture condition that is representative of the in-place shotcrete. After cores have been drilled, wipe off surface water on the drilled core with a dry cloth and allow remaining surface moisture to evaporate. When surfaces appear dry, but not later than 1 h after drilling, place cores in separate plastic bags or nonabsorbent containers and seal to prevent moisture loss. Maintain cores at ambient temperature, and protect cores from exposure to direct sunlight. Transport the cores to the testing laboratory as soon as practicable. Keep cores in the sealed plastic bags or nonabsorbent containers at all times except during end preparation and for a maximum time of 2 h to permit capping before testing.

8.3.2 If water is used during sawing or grinding of core ends, complete these operations as soon as practicable, but no later than 2 days after drilling of cores. After completing end preparation, use a dry cloth to remove surface moisture, allow the surfaces to dry, and place the cores in sealed plastic bags or nonabsorbent containers. Minimize the duration of exposure to water during end preparation.

8.3.3 Allow cores aged 28 days or more to remain in the sealed plastic bags or nonabsorbent containers for at least 5 days after last being wetted and before testing (See Note 5). For early strength testing of specimens aged 28 days or less, test specimens as directed by the specifier of the tests.

NOTE 5—The waiting period of at least 5 days is intended to reduce moisture gradients introduced when the core is drilled or wetted during sawing or grinding.

8.3.4 When the specifier of the tests so directs, test cores in a moisture condition other than achieved by conditioning according to 8.3.3. Report the alternative moisture conditioning procedure.

8.4 *Sawing of Ends*—The ends of core specimens to be tested in compression shall be flat, and perpendicular to the longitudinal axis. If necessary, saw the ends of cores that will be capped so that the following requirements are met:

8.4.1 Projections, if any, shall not extend more than 0.2 in. [5 mm] above the end surfaces.

8.4.2 The end surfaces shall not depart from perpendicularity to the longitudinal axis by a slope of more than 1:8*d* [or 1:0.3*d*], where *d* is the average core diameter in inches [or mm].

NOTE 6—This limitation is intended to avoid cap thicknesses that exceed the requirements of Practice C 617.

8.5 *Capping*—If the ends of the cores do not conform to the perpendicularity and planeness requirements of Test Method C 39/C 39M, they shall be sawn or ground to meet those requirements or capped in accordance with Practice C 617. If cores are capped in accordance with Practice C 617, the capping device shall accommodate actual core diameters and produce caps that are concentric with the core ends. Measure core lengths to the nearest 0.1 in. [2 mm] before capping. Unbonded caps in accordance with Practice C 1231 are not permitted.

NOTE 7—Before capping, the density of a core may be estimated by weighing it and dividing the mass by the volume calculated from the average diameter and length.

8.6 *Measurement*—Before testing, measure the length of the capped or ground specimen to the nearest 0.1 in. [2 mm] and use this length to compute the length-diameter (L/D) ratio. Determine the average diameter by averaging two measurements taken at right angles to each other at the mid-height of the specimen. Measure core diameters to the nearest 0.01 in. [0.2 mm] when the difference in core diameters does not exceed 2 % of their average; otherwise, measure to the nearest 0.1 in. [2 mm]. Do not test cores if the difference between the largest and smallest diameter exceeds 5 % of their average.

8.7 *Testing*—Test the specimens in accordance with Test Method C 39/C 39M. Test the specimens within 7 days after coring, unless so directed by the specifier of the tests.

8.8 *Calculation*—Calculate the compressive strength of each specimen using the computed cross-sectional area based on the average diameter of the specimen.

8.8.1 If the ratio of the core length to diameter (L/D) of the specimen is 1.75 or less, correct the results obtained in 8.8 by multiplying by the appropriate correction factor shown in the following table (see Note 8).

Ratio of Length to Diameter (L/D)	Strength Correction Factor
1.75	0.98
1.50	0.96
1.25	0.93
1.00	0.87

Use interpolation to determine correction factors for L/D values not given in the table.

NOTE 8—Correction factors depend on various conditions such as moisture condition, strength level, and elastic modulus. Average values are given in the table. These correction factors apply to normal density shotcrete. They are applicable to both dry and wet shotcrete for nominal concrete strengths between 2000 psi and 6000 psi [14 MPa and 42 MPa]. For strengths above 10 000 psi [70 MPa], test data on concrete cores show that the correction factors may be larger than the values listed above[5].

8.9 *Report*—Report the results as required by Test Method C 39/C 39M with the addition of the following information:

8.9.1 Length of core as drilled to the nearest ¼ in. [5 mm],

8.9.2 Length of test specimen before and after capping or end grinding to the nearest 0.1 in. [2 mm], and average diameter of core to the nearest 0.01 in. [0.2 mm] or 0.1 in. [2 mm],

8.9.3 Compressive strength to the nearest 10 psi [0.1 MPa] when the diameter is measured to the nearest 0.01 in. [0.2 mm]

[5] Bartlett, F.M. and MacGregor, J.G, "Effect of Core Length-to-Diameter Ratio on Concrete Core Strengths," *ACI Materials Journal*, Vol. 91, No. 4, July-August 1994, pp. 339-348.

www.technobetar.ir

and to the nearest 50 psi [0.5 MPa] when the diameter is measured to the nearest 0.1 in. [2 mm], after correction for length-diameter ratio when required,

8.9.4 Direction of application of the load on the specimen with respect to the horizontal plane of the shotcrete as placed,

8.9.5 The moisture conditioning history:

8.9.5.1 The date and time core was obtained and first placed in sealed bag or nonabsorbent container;

8.9.5.2 If water was used during end preparation, the date and time end preparation was completed and core placed in sealed bag or nonabsorbent container,

8.9.6 The date and time when tested,

8.9.7 Nominal maximum size of shotcrete aggregate,

8.9.8 If determined, the estimated density,

8.9.9 If applicable, description of defects in cores that could not be tested, and

8.9.10 If any deviation from this test method was required, describe the deviation and explain why it was necessary.

8.10 *Precision*

8.10.1 The precision of compressive strength of shotcrete cores measured by this test method has not been established, but is believed to be similar to that of concrete cores[6]. Therefore, the following provisional statements taken from the Test Method C 42/C 42M are provided until an inter-laboratory study of shotcrete cores are completed.

8.10.2 The single-operator coefficient of variation on concrete cores has been found to be 3.2 %[7] for a range of compressive strength between 4500 psi [32.0 MPa] and 7000 psi [48.3 MPa]. Therefore, results of two properly conducted tests of single cores by the same operator on the same sample of material should not differ from each other by more than 9 %[7] of their average.

8.10.3 The multi-laboratory coefficient of variation on cores has been found to be 4.7 %[7] for a range of compressive strength between 4500 psi [32.0 MPa] and 7000 psi [48.3 MPa]. Therefore, results of two properly conducted tests on cores sampled from the same hardened concrete (where a single test is defined as the average of two observations (cores), each made on separate adjacent drilled 4-in. [100-mm] diameter cores) and tested by two different laboratories should not differ from each other by more than 13 %[7] of their average.

8.11 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

9. Cores for Splitting Tensile Strength

9.1 *Test Specimens*—The specimens shall conform to the dimensional requirements in 8.1, 8.2, 8.4.1, and 8.4.2. Ends are not to be capped.

9.2 *Moisture Conditioning*—Condition the specimens as described in 8.3, or as directed by the specifier of the tests.

9.3 *Bearing Surfaces*—The line of contact between the specimen and each bearing strip shall be straight and free of any projections or depressions higher or deeper than 0.01 in. [0.2 mm]. When the line of contact is not straight or contains projections or depressions having heights or depths greater than 0.01 in [0.2 mm], grind or cap the specimen so as to produce bearing lines meeting these requirements. Do not test specimens with projections or depressions greater than 0.1 in. [2 mm]. When capping is employed, the caps shall be as thin as practicable and shall be formed of high-strength gypsum cement.

NOTE 9—Fig. 1 illustrates a device suitable for applying caps to the bearing surfaces of core specimens.

9.4 *Testing*—Test the specimens in accordance with Test Method C 496/C 496M.

9.5 *Calculation and Report*—Calculate the splitting tensile strength and report the results as required in Test Method C 496/C 496M. When grinding or capping of the bearing surfaces is required, measure the diameter between the finished surfaces. Indicate that the specimen was a core and provide the moisture conditioning history as in 8.9.5.

9.6 *Precision*

9.6.1 The precision of splitting tensile strength of shotcrete cores measured by this test method has not been established, but is believed to be similar to that of concrete cores[8]. Therefore, the following provisional statements taken from the Test Method C 42/C 42M are provided until an inter-laboratory study of shotcrete cores is completed.

9.6.2 The within-laboratory single operator coefficient of variation for splitting tensile strength between 520 psi [3.6 MPa] and 590 psi [4.1 MPa] of cores has been found to be 5.3 %[9]. Therefore, results of two properly conducted tests by the same operator in the same laboratory on the same sample of material should not differ by more than 14.9 %[9] of their average.

9.6.3 The multi-laboratory coefficient of variation for splitting tensile strength between 520 psi [3.6 MPa] and 590 psi [4.1 MPa] of cores has been found to be 15 %.[9] Therefore, results of two properly conducted tests on the same sample of material of hardened concrete and tested by two different laboratories should not differ from each other by more than 42.3 %[9] of their average.

9.7 *Bias*—Since there is no accepted reference material suitable for determining the bias of the procedure in this test method, no statement on bias is being made.

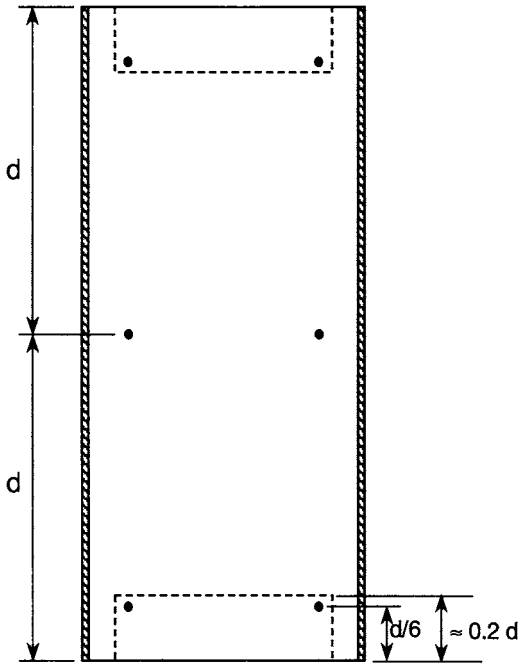

FIG. 1 Suitable Capping Device for Splitting Tensile Strength Test

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1608 – 07

Standard Test Method for Chemical Shrinkage of Hydraulic Cement Paste[1]

This standard is issued under the fixed designation C 1608; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method measures the internal (absolute) volume change of hydraulic cement paste that results from the hydration of the cementitious materials. This volume change is known as *chemical shrinkage*.

1.1.1 Procedure A, volumetric method.

1.1.2 Procedure B, the density method.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 186 Test Method for Heat of Hydration of Hydraulic Cement

C 188 Test Method for Density of Hydraulic Cement

C 219 Terminology Relating to Hydraulic Cement

C 670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C 1005 Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

3. Terminology

3.1 *Definitions:*

3.1.1 *chemical shrinkage*, *n*—the absolute (internal) volume change accompanying the hydration of cement, due to the fact that the cement hydration products occupy less physical volume than the reactants.

3.1.2 All other terms are as defined in Terminology C 219.

4. Significance and Use

Numerous properties of cementitious materials are controlled by their initial hydration rate. Examples include early-age strength development, heat release, and crack resistance. One direct and convenient measure of this initial hydration rate is provided by the measurement of the chemical shrinkage of the cement paste during its hydration. As cement hydrates, the hydration products occupy less volume than the initial reacting materials (cement and water). Due to this volume change, a hydrating cement paste will sorb water from its immediate surroundings, when available. At early times, this sorption is in direct proportion to the amount of hydration that has occurred.[4] This method is based on the one developed by Geiker.[5] The results are relevant to understanding the hydration behavior of cements. This method does not measure the bulk volume changes (autogenous shrinkage) associated with chemical shrinkage nor the cracking potential of concretes produced with the evaluated cement.

5. Apparatus

5.1 *Devices for Determining Mass*, conforming to the requirements of Specification C 1005 and evaluated for precision and accuracy at a total load of 100 g.

5.2 *Constant Temperature Water Bath*—a water bath capable of maintaining a temperature of 23.0 ± 0.5 °C, with a

www.technobetar.ir

sufficient capacity to hold the specimens being evaluated. To avoid evaporative cooling, the surface of the water in the bath shall be covered with floating plastic balls or fitted with an insulated lid.

5.3 *Timing Device*—Clock that can measure time to the nearest minute.

5.4 For procedure A

5.4.1 *Capillary Tube*—A graduated glass capillary tube with graduations of 0.01 mL or smaller, and typically a capacity of 1.0 mL.

5.4.2 *Small Glass Vials (e.g., 22-mm diameter and 55-mm height) with Rubber Stoppers* that fit tightly into the glass vials and have a hole placed in each stopper with the graduated capillary tube inserted through the hole (as shown in Fig. 1). Fix the capillary tube in the stopper using a two-component epoxy or other suitable adhesive applied at the stopper's top and bottom surfaces.

5.5 For Procedure B

5.5.1 *Density bottle*, glass, capacity approximately 20 ml with internally conical glass stopper as shown in Fig. 2.

6. Reagents and Materials

6.1 Paraffin oil.

6.2 De-aerated water (prepared by boiling water and sealing it in a closed container before it has cooled.)

7. Procedure

7.1 *Preparation of Cement Paste*—Prepare the cement paste in accordance with the proportions and procedure described in Test Method C 186 (Note 1). The pastes shall be prepared in a mixing room meeting the temperature and humidity requirements outlined in Specification C 511. Record to the nearest minute the time when the water first contacts the dry cement powder.

NOTE 1—Other mixing procedures such as mixing in a Hobart mixer (see Practice C 305) or kneading by hand in a sealed plastic bag may be used. The standard paste mixture uses 150 g of cement and 60 ml of water (water-cement ratio of 0.40). Adjust the volume of paste mixed to match the mixing equipment used. Other water-cement ratios may be used as long as they are stated in the test report; higher water-cement ratios may produce significant bleeding of the cement paste which will influence the results (by changing the effective water-cement ratio, etc.); lower water-cement ratios may lead to difficulties in preparing a fully compacted, homogeneous paste for subsequent evaluation and self-desiccation may occur.

7.2 Prepare a minimum of two replicate specimens as described below for either Procedure A or Procedure B.

7.3 Procedure A

7.3.1 Determine the mass of each empty glass vial to the nearest 0.01 g.

7.3.2 Carefully place the prepared cement paste into the glass vial to achieve a paste height between 5 mm and 10 mm in the vial. Consolidate the paste in the vial by tapping the vial on a laboratory countertop, or placing it on a vibrating table, or some similar procedure.

7.3.3 Determine the mass of each glass vial with the cement paste to the nearest 0.01 g.

7.3.4 Carefully, without disturbing the cement paste, add clean, de-aerated water to fill the glass vial to the top.

7.3.5 Place the rubber stopper with the inserted capillary tube tightly into the glass vial. Be careful to avoid the entrapment of air bubbles when the bottom rubber stopper surface encounters the water in the glass vial. As the rubber stopper is inserted, the water level in the graduated capillary tube will rise. Optimally, the water level should rise near to but not beyond the top mark of the graduations on the capillary tube. If the water level is not near enough to the top mark, clean, de-aerated water can be added via the top of the capillary

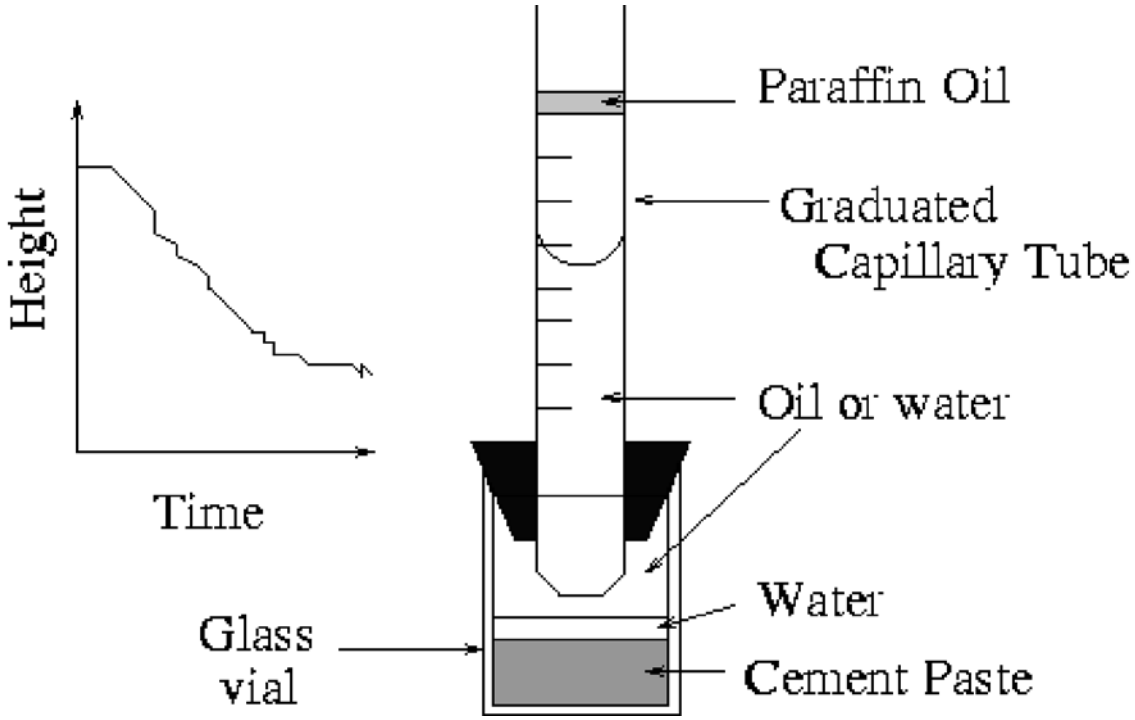

FIG. 1 Illustration of One Experimental Setup for Monitoring Chemical Shrinkage of Hydrating Cement Paste Using Procedure A.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

tube to achieve the desired initial water height. Once the rubber stopper has been fitted to the vial, the completed assembly shall be handled only by the vial (not by the capillary tube) to avoid loosening of the rubber stopper which will result in an apparent volume change of the specimen.

7.3.6 Place a drop of paraffin oil in the top of the graduated capillary tube to minimize water evaporation from the tube during the testing period.

7.3.7 Place the prepared specimens in the constant temperature water bath at 23 °C such that the tops of the glass vials are just above the water level in the bath. Maintain the temperature of the laboratory at 23 ± 2 °C. Record the time and initial level (height) of water, to the nearest 0.0025 mL, in the capillary tubes.

7.3.8 Periodically (every 30 min or every hour, as convenient) record the time to the nearest minute and water level in the capillary tubes to the nearest 0.0025 mL for a total period of at least 24 h. After the first 8 h, the recording intervals can be lengthened to 8 h or more to avoid taking readings during the night, as long as a 24 h reading is obtained the following day. Be sure to take a reading 1 h after the paste was first mixed to use as a zero point in all calculations (this allows time for the specimen to achieve temperature equilibrium within the water bath).

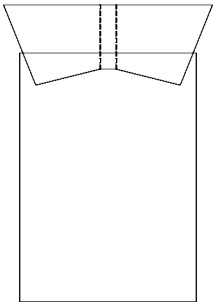

FIG. 2 Illustration of a Density Bottle for Use in Procedure B.

7.4 Procedure B

7.4.1 Determine the mass of each empty density bottle to the nearest 0.0001 g.

7.4.2 Carefully place the prepared cement paste into the density bottle to achieve a paste height between 5 mm and 10 mm in the bottle. Consolidate the paste in the bottle by tapping the bottle on a laboratory countertop, or placing it on a vibrating table or some similar procedure. Determine the mass of the density bottle with the consolidated cement paste to the nearest 0.0001 g.

7.4.3 Carefully, without disturbing the cement paste, add clean, de-aerated water to fill the bottle to the top.

7.4.4 Place the stopper tightly into the bottle. Be careful to remove any entrapped air bubbles when the bottom of the stopper encounters the water in the bottle. Add clean, de-aerated water via the perforated stopper to fill the bottle and stopper to excess (leave a bead of water on the top of the stopper to overfill the capillary tube). The filled assembly shall be handled only by the bottle (not by the stopper) to avoid loosening the stopper, which will result in an apparent change in the specimen, and not with bare fingers (e.g., wear latex gloves) which will cause an increase in mass due to transfer of oil.

7.4.5 Remove the excess water from the top of the stopper using absorbent paper, wiping quickly to avoid sucking water out of the capillary tube.

7.4.6 Immediately determine the mass of the density bottle filled with water to the top of the capillary tube. Determine the mass to the nearest 0.0001 g.

7.4.7 Place the filled density bottles in the constant temperature water bath at 23 °C such that the tops of the stoppers are just above the water level in the bath.

7.4.8 At 1 h after the paste was first mixed, remove the density bottle from the water bath and wipe dry, fill to excess with water, remove the excess and determine the mass to the nearest 0.0001 g.

7.4.9 Periodically (every 30 or 60 min, as convenient) for a period of at least 24 h, remove the density bottle from the water bath and wipe dry, fill to excess with water, remove the excess and determine the mass to the nearest 0.0001 g. After the first eight hours, the recording intervals can be lengthened to 8 h or more to avoid taking readings during the night, as long as a 24 h reading is obtained the following day.

8. Calculation

8.1 The chemical shrinkage is computed as the measured mL of sorbed water per gram of cement in the paste specimen. The mass of cement powder in the vial is given by:

$$M_{cement} = \frac{(M_{vial+paste} - M_{vialempty})}{\left(1.0 + \frac{w}{c}\right)} \quad (1)$$

where

M_{cement} = mass of cement in the vial (g),
$M_{vial+paste}$ = mass of the glass vial with the added cement paste (g),
$M_{vialempty}$ = mass of the empty vial (g),
w/c = water-cement ratio by mass of the prepared paste (e.g., 0.40) and a density of 1000 kg/m^3 is assumed for water.

8.2 Procedure A

8.2.1 The chemical shrinkage per unit mass of cement at time t is computed as:

$$CS(t) = \frac{[h(t) - h(60\text{min})]}{M_{cement}} \quad (2)$$

where

$CS(t)$ = chemical shrinkage at time t (mL/g cement) (Note 2).
$h(t)$ = water level in capillary tube at time t (mL)

NOTE 2—If it is desired to report the chemical shrinkage per unit volume of cement powder, the values from Eq 2 can be converted to mL/mL cement using the density of the cement powder determined using Test Method C 188.

8.3 Procedure B

8.3.1 The chemical shrinkage per unit mass of cement at time t is computed as:

$$CS(t) = \left(\frac{[M(t) - M(60\text{min})]}{M_{cement}}\right)/\rho W \quad (3)$$

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

where:
$CS(t)$ = chemical shrinkage at time t (mL/g cement)
$M(t)$ = mass of filled density bottle at time t (g)
ρW = density of water (mL/g) (0.99754 at 23 °C)

9. Report

9.1 Report the following:

9.1.1 Date and time paste specimen is prepared;

9.1.2 Cementitious material sources and names;

9.1.3 Mixing and compaction procedure employed and water-cement ratio by mass;

9.1.4 Mass of each empty vial and mass of each vial with cement paste;

9.1.5 A table of the water level in each capillary tube or the mass of each filled density bottle vs. time;

9.1.6 A table and/or plot of the chemical shrinkage per gram of cement (reported to the nearest 0.0001 mL/g) vs. time.

10. Precision and Bias

10.1 *Precision*—The precision statements for this test method are listed in Table 1 and are based on the results obtained in an interlaboratory study described in Research Report C01-1010.[6]

10.2 *Bias*—Since there is no accepted reference material suitable for determining the bias of this procedure, no statement on bias is made.

11. Keywords

11.1 chemical shrinkage; hydration.

[6] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C01-1010.

TABLE 1 Precision

	Standard Deviation 1s[A]	Acceptable Range of Test Results d2s[A]
Measurements made between 4 and 8 h after mixing		
Repeatability	0.00084	0.00236
Reproducibility	0.00090	0.00253
Measurements made 24 h after mixing		
Repeatability	0.00193	0.00541
Reproducibility	0.00240	0.00672

[A] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

SUMMARY OF CHANGES

Committee C01 has identified the location of selected changes to this test method since the last issue, C 1608 – 06, that may impact the use of this test method. (Approved June 15, 2007)

(*1*) Revised 10.1 and added new Table 1.

Committee C01 has identified the location of selected changes to this test method since the last issue, C 1608 – 05, that may impact the use of this test method. (Approved November 1, 2006)

(*1*) Revised 7.3.4 and 7.4.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1609/C 1609M – 07

Standard Test Method for Flexural Performance of Fiber-Reinforced Concrete (Using Beam With Third-Point Loading)[1]

This standard is issued under the fixed designation C 1609/C 1609M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method evaluates the flexural performance of fiber-reinforced concrete using parameters derived from the load-deflection curve obtained by testing a simply supported beam under third-point loading using a closed-loop, servo-controlled testing system.

1.2 This test method provides for the determination of first-peak and peak loads and the corresponding stresses calculated by inserting them in the formula for modulus of rupture given in Eq 1. It also requires determination of residual loads at specified deflections, and the corresponding residual strengths calculated by inserting them in the formula for modulus of rupture given in Eq 1 (see Note 1). At the option of the specifier of tests, it provides for determination of specimen toughness based on the area under the load-deflection curve up to a prescribed deflection (see Note 2).

NOTE 1—Residual strength is not a true stress but an engineering stress computed using simple engineering bending theory for linear elastic materials and gross (uncracked) section properties.

NOTE 2—Specimen toughness expressed in terms of the area under the load-deflection curve is an indication of the energy absorption capability of the particular test specimen, and its magnitude depends directly on the geometry of the test specimen and the loading configuration.

1.3 This test method utilizes two preferred specimen sizes of 100 by 100 by 350 mm [4 by 4 by 14 in.] tested on a 300 mm [12 in.] span, or 150 by 150 by 500 mm [6 by 6 by 20 in.] tested on a 450 mm [18 in.] span. A specimen size different from the two preferred specimen sizes is permissible.

1.4 *Units*—The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—The terms used in this test method are defined in Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *end-point deflection*—the deflection value on the load-deflection curve equal to 1/150 of the span length, or a larger value as specified at the option of the specifier of tests.

3.2.2 *first-peak load, P_1*—the load value at the first point on the load-deflection curve where the slope is zero.

3.2.3 *first-peak deflection, δ_1*—the net deflection value on the load-deflection curve at first-peak load.

3.2.4 *first-peak strength f_1*—the stress value obtained when the first-peak load is inserted in the formula for modulus of rupture given in Eq 1.

3.2.5 *load-deflection curve*—the plot of load versus net deflection of a flexural beam specimen loaded to the end-point deflection.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.42 on Fiber-Reinforced Concrete.

Current edition approved Dec. 15, 2007. Published January 2008. Originally approved in 2005. Last previous edition approved in 2006 as C 1609/C 1609M – 06.

www.technobetar.ir

3.2.6 *net deflection*—the deflection measured at mid-span of a flexural beam specimen exclusive of any extraneous effects due to seating or twisting of the specimen on its supports or deformation of the support and loading system.

3.2.7 *peak load,* P_P—the maximum load on the load-deflection curve.

3.2.8 *peak-load deflection,* δ_P—the net deflection value on the load-deflection curve at peak load.

3.2.9 *peak strength,* f_P—the stress value obtained when the peak load is inserted in the formula for modulus of rupture given by Eq 1.

3.2.10 *D*—nominal depth of the beam specimen in mm.

NOTE 3—To simplify nomenclature, the nominal beam depth is shown in units of mm for both the SI and inch-pound version of this test method.

3.2.11 *L*—span length or distance between the supports.

3.2.12 *residual load,* P^D_{600} —the load value corresponding to a net deflection of L/600 for a beam of nominal depth D.

3.2.13 *residual load,* P^D_{150} —the load value corresponding to a net deflection of L/150 for a beam of nominal depth D.

3.2.14 *residual strength,* f^D_{600} —the stress value obtained when the residual load P^D_{600} is inserted in the formula for modulus of rupture given in Eq 1.

3.2.15 *residual strength,* f^D_{150} —the stress value obtained when the residual load P^D_{150} is inserted in the formula for modulus of rupture given in Eq 1.

3.2.16 *specimen toughness,* T^D_{150} —toughness of beam specimen of nominal depth D at a net deflection of L/150.

4. Summary of Test Method

4.1 Molded or sawn beam specimens having a square cross-section of fiber-reinforced concrete are tested in flexure using a third-point loading arrangement similar to that specified in Test Method C 78 but incorporating a closed-loop, servo-controlled testing system and roller supports that are free to rotate on their axes. Load and net deflection are monitored and recorded to an end-point deflection of at least 1/150 of the span. Data are recorded and plotted by means of an X-Y plotter, or they are recorded digitally and subsequently used to plot a load-deflection curve. Points termed first-peak, peak, and residual loads at specified deflections are identified on the curve, and are used to calculate flexural performance parameters.

5. Significance and Use

5.1 The first-peak strength characterizes the flexural behavior of the fiber-reinforced concrete up to the onset of cracking, while residual strengths at specified deflections characterize the residual capacity after cracking. Specimen toughness is a measure of the energy absorption capacity of the test specimen. The appropriateness of each parameter depends on the nature of the proposed application and the level of acceptable cracking and deflection serviceability. Fiber-reinforced concrete is influenced in different ways by the amount and type of fibers in the concrete. In some cases, fibers may increase the residual load and toughness capacity at specified deflections while producing a first-peak strength equal to or only slightly greater than the flexural strength of the concrete without fibers. In other cases, fibers may significantly increase the first-peak and peak strengths while affecting a relatively small increase in residual load capacity and specimen toughness at specified deflections.

5.2 The first-peak strength, peak strength, and residual strengths determined by this test method reflect the behavior of fiber-reinforced concrete under static flexural loading. The absolute values of energy absorption obtained in this test are of little direct relevance to the performance of fiber-reinforced concrete structures since they depend directly on the size and shape of the specimen and the loading arrangement.

5.3 The results of this test method may be used for comparing the performance of various fiber-reinforced concrete mixtures or in research and development work. They may also be used to monitor concrete quality, to verify compliance with construction specifications, obtain flexural strength data on fiber-reinforced concrete members subject to pure bending, or to evaluate the quality of concrete in service.

5.4 The results of this standard test method are dependent on the size of the specimen.

NOTE 4—The results obtained using one size molded specimen may not correspond to the performance of larger or smaller molded specimens, concrete in large structural units, or specimens sawn from such units. This difference may occur because the degree of preferential fiber alignment becomes more pronounced in molded specimens containing fibers that are relatively long compared with the cross-sectional dimensions of the mold. Moreover, structural members of significantly different thickness experience different maximum crack widths for a given mid-span deflection with the result that fibers undergo different degrees of pull-out and extension.

6. Apparatus

6.1 *Testing Machine*—The testing machine shall be capable of servo-controlled operation where the net deflection of the center of the beam is measured and used to control the rate of increase of deflection. Testing machines that use stroke displacement control or load control are not suitable for establishing the portion of the load-deflection curve immediately after first-peak. The loading and specimen support system shall be capable of applying third-point loading to the specimen without eccentricity or torque. The fixtures specified in Test Method C 78 are suitable with the qualification that supporting rollers shall be able to rotate on their axes and shall not be placed in grooves or have other restraints that prevent their free rotation.

6.2 *Deflection-Measuring Equipment*—Devices such as electronic transducers or electronic deflection gages shall be located in a manner that ensures accurate determination of the net deflection at the mid-span exclusive of the effects of seating or twisting of the specimen on its supports. One acceptable arrangement employs a rectangular jig, which surrounds the specimen and is clamped to it at mid-depth directly over the supports (Figs. 1 and 2). Two electronic displacement transducers or similar digital or analog devices mounted on the jig at mid-span, one on each side, measure deflection through contact with appropriate brackets attached to the specimen. The average of the measurements represents the net deflection.

6.3 *Data Recording System*—An X-Y plotter coupled directly to electronic outputs of load and deflection is an acceptable means of obtaining the relationship between load and net deflection—that is, the load-deflection curve. A data

FIG. 1 Arrangement to Obtain Net Deflection by Using Two Transducers Mounted on Rectangular Jig Clamped to Specimen Directly Above Supports

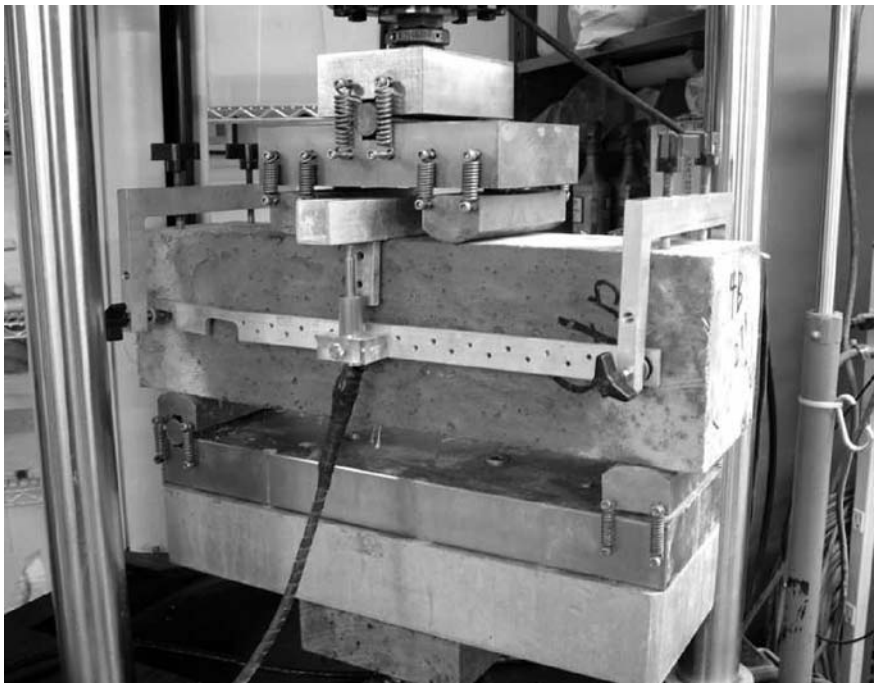

FIG. 2 Arrangement to Obtain Net Deflection by Using Two Transducers Mounted on Jig Secured to Specimen Directly Above Supports

acquisition system capable of digitally recording and storing load and deflection data at a sampling frequency of at least 2.5 Hz is an acceptable alternative. After a net deflection of L/600 has been exceeded, it is permissible to decrease the data acquisition sampling and recording frequency to 1 Hz.

NOTE 5—For X-Y plotters, accurate determination of the area under the load-deflection curve and the loads corresponding to specified deflections is only possible when the scales chosen for load and deflection are reasonably large. A load scale chosen such that 25 mm [1 in.] corresponds to a flexural stress of the order of 1 MPa [150 psi], or no more than 20 % of the estimated first-peak strength, is recommended. A recommended deflection scale is to use 25 mm [1 in.] to represent about 10 % of the end-point deflection of $\frac{1}{150}$ of the span, which is 2 mm [0.08 in.] for a 350 by 100 by 100 mm [14 by 4 by 4 in.] specimen size, and 3 mm [0.12 in.] for a 500 by 150 by 150 mm [20 by 6 by 6 in.] specimen size. When data are digitally stored, the test parameters may be determined directly from the stored data or from a plot of the data. In the latter case, use a plot scale similar to that recommended for an X-Y plotter.

7. Sampling, Test Specimens, and Test Units

7.1 *General Requirements*—The nominal maximum size of aggregate and cross-sectional dimensions of test specimens shall be in accordance with Practice C 31/C 31M or Practice C 192/C 192M when using molded specimens, or in accordance with Test Method C 42/C 42M when using sawn specimens, provided that the following requirements are satisfied:

7.1.1 The length of test specimens shall be at least 50 mm [2 in.] greater than three times the depth, and in any case not less than 350 mm [14 in.]. The length of the test specimen shall not be more than two times the depth greater than the span.

7.1.2 The tolerances on the cross-section of the test specimens shall be within ± 2 %. The test specimens shall have a square cross-section within these tolerances.

7.1.3 The width and depth of test specimens shall be at least three times the maximum fiber length.

7.1.4 When the specimen size is not large enough to meet all the requirements of 7.1-7.1.3, specimens of square cross-section large enough to meet the requirements shall be used. The three times maximum fiber length requirement for width and depth may be waived at the option of the specifier of tests to permit specimens with a width and depth of 150 mm [6 in.] when using fibers of length 50 to 75 mm [2 to 3 in.].

NOTE 6—The results of tests on beams with relatively stiff fibers, such as steel fibers, longer than one-third the width and depth of the beam may not be comparable with test results of similar-sized beams with fibers shorter than one-third the width and depth because of preferential fiber alignment, and different size beams may not be comparable because of size effects. The degree of preferential fiber alignment may be less for fibers that are flexible enough to be bent by contact with aggregate particles or mold surfaces than for rigid fibers that remain straight during mixing and specimen preparation.

7.2 *Freshly Mixed Concrete*—Obtain samples of freshly mixed fiber-reinforced concrete for the preparation of test specimens in accordance with Practice C 172.

7.2.1 Mold specimens in accordance with Practice C 31/C 31M or Practice C 192/C 192M, except that consolidation shall be by external vibration. Consolidation may be considered to be adequate when entrapped air voids are no longer observed rising to the surface of the specimen. Fill the mold in one layer by using a wide shovel or scoop parallel to the length of the mold to place the layer uniformly along the length of the mold.

NOTE 7—Make sure that the time of vibration is sufficient to ensure adequate consolidation, as fiber-reinforced concrete requires a longer vibration time than concrete without fibers, especially when the fiber concentration is relatively high.

7.2.2 When filling the mold, attempt to add an amount of concrete that will exactly fill the mold after consolidation. When screeding the top surface, continue external vibration to ensure that fibers do not protrude from the finished surface.

7.2.3 Curing shall be in accordance with Practice C 31/C 31M or Practice C 192/C 192M.

7.3 *Hardened Concrete*—Select samples of hardened fiber-reinforced concrete from structures in accordance with Practice C 823.

7.3.1 Prepare and condition sawn specimens in accordance with Test Method C 42/C 42M.

7.4 Prepare specimens from shotcrete panels in accordance with Practice C 1140.

7.5 *Test Unit*—Prepare and test at least three specimens from each sample of fresh or hardened concrete.

8. Evaporation Control

8.1 When the time between removal of test specimens from a moist curing environment and the start of testing is likely to exceed 15 min, minimize drying by covering with wet burlap, applying a curing compound, or by other appropriate techniques.

9. Procedure

9.1 Molded or sawn specimens shall be turned on their side with respect to the position as cast before placing on the support system. Specimens representing shotcrete shall be loaded in the same direction as the specimen was shot.

9.2 Arrange the specimen and the loading system so that the specimen is loaded at the third points in accordance with Test Method C 78. The span length shall be three times the specimen depth or 300 mm [12 in.], whichever is greater.

NOTE 8—If full contact cannot be reasonably assured between the specimen, the load-applying devices, and the supports before loading, grind the contact surfaces of the specimen so that full contact is achieved. Alternatively, use capping materials at the load or support points.

9.3 Operate the testing machine so that the net deflection of the specimen increases at a constant rate. For a 350 by 100 by 100 mm [14 by 4 by 4 in.] specimen size, the rate of increase of net deflection shall be within the range 0.05 to 0.10 mm/min [0.002 to 0.004 in./min] until a net deflection of L/600 is reached. After that, the rate of increase of net deflection shall be within the range 0.05 to 0.20 mm/min [0.002 to 0.008 in./min] until the specified end-point deflection is reached. For a 500 by 150 by 150 mm [20 by 6 by 6 in.] specimen size, the rate of increase of net deflection shall be within the range 0.06 to 0.12 mm/min [0.002 to 0.005 in./min] until a net deflection of L/600 is reached. After that, the rate of increase of net deflection shall be within the range 0.06 to 0.24 mm/min [0.002 to 0.010 in./min] until the specified end-point deflection is reached. The corresponding rate for other sizes and shapes of specimens shall be based on reaching the first-peak deflection 30 to 60 s after the start of the test.

NOTE 9—First-peak deflection for third-point loading is estimated assuming linear-elastic behavior up to first peak from the equation:

$$\delta_1 = \frac{23P_1L^3}{1296EI}\left[1 + \frac{216d^2(1+\mu)}{115L^2}\right]$$

where:

δ_1 = the first peak deflection, mm [in.]
P_1 = the first-peak load, N [lbf]
L = the span length, mm [in.]
E = the estimated modulus of elasticity of the concrete, MPa [psi]
I = the cross-sectional moment of inertia, mm^4 [$in.^4$]
d = the average depth of specimen at the fracture, as oriented for testing, mm [in.] and
μ = Poisson's ratio

For a Poisson's ratio of 0.20 and a d to L ratio of 1/3, the value of the portion of the equation in brackets is 1.25.

NOTE 10—For a 350 by 100 by 100 mm [14 by 4 by 4 in.] specimen

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

size, the net deflection at first-peak load is approximately 0.04 mm [0.0016 in.], and for a 500 by 150 by 150 mm [20 by 6 by 6 in.] specimen size, it is approximately 0.05 mm [0.002].

9.4 When using deflection-measuring equipment for the first time, or after alterations or maintenance, confirm the reliability of the measured net deflection by comparing the measured deflection at first-peak load with the value estimated from the formula in Note 9.

9.5 Unless otherwise required by the specifier of tests, terminate the test at a net deflection of 1/150 of the span.

9.6 Further testing to a greater end-point deflection shall be specified at the option of the specifier of tests, and shall be specified as the span divided by some whole number less than 150.

9.7 Make two measurements of the specimen depth and width adjacent to the fracture (one on each face of the specimen) to the nearest 1 mm [0.05 in.] to determine the average depth and width.

9.8 Determine the position of the fracture by measuring the distance along the middle of the tension face from the fracture to the nearest point of support.

9.9 When the fracture occurs outside the middle third of the span, discard the results.

10. Calculation

10.1 Values of load and deflection used in subsequent calculations shall be obtained from the load-deflection curve, or from stored digital data.

10.2 Determine the first-peak load as that value of load corresponding to the first point on the load-deflection curve where the slope is zero, that is, the load is a local maximum value. Determine the corresponding deflection value. See Figs. 3 and 4.

NOTE 11—Small ripples or fluctuations in the load-deflection curve due to electronic noise or mechanical vibration should not be confused with a definite change in the slope of the load-deflection curve in the vicinity of first peak load, particularly when the portion of the curve in question is magnified.

10.3 Calculate the first-peak strength using the first-peak load determined in 10.2, the average specimen dimensions determined in 9.7, and the following formula for modulus of rupture:

$$f = \frac{PL}{bd^2} \quad (1)$$

where:

f = the strength, MPa [psi],
P = the load, N [lbf],
L = the span length, mm [in.],
b = the average width of the specimen at the fracture, as oriented for testing, mm [in.], and
d = the average depth of the specimen at the fracture, as oriented for testing, mm [in.].

10.3.1 Record the number rounded to the nearest 0.05 MPa [5 psi] as the first-peak strength, f_1.

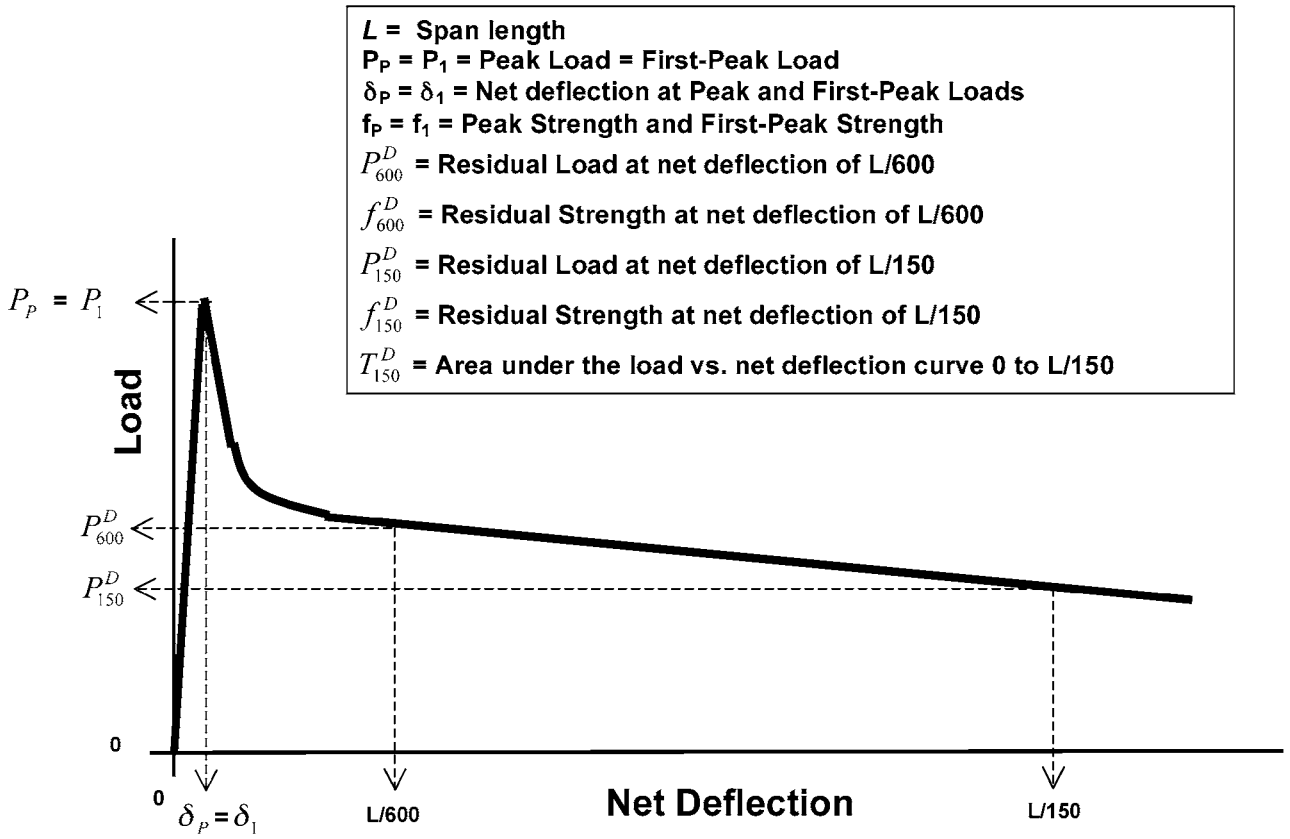

FIG. 3 Example of Parameter Calculations for First-Peak Load Equal to Peak Load (Not to Scale)

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

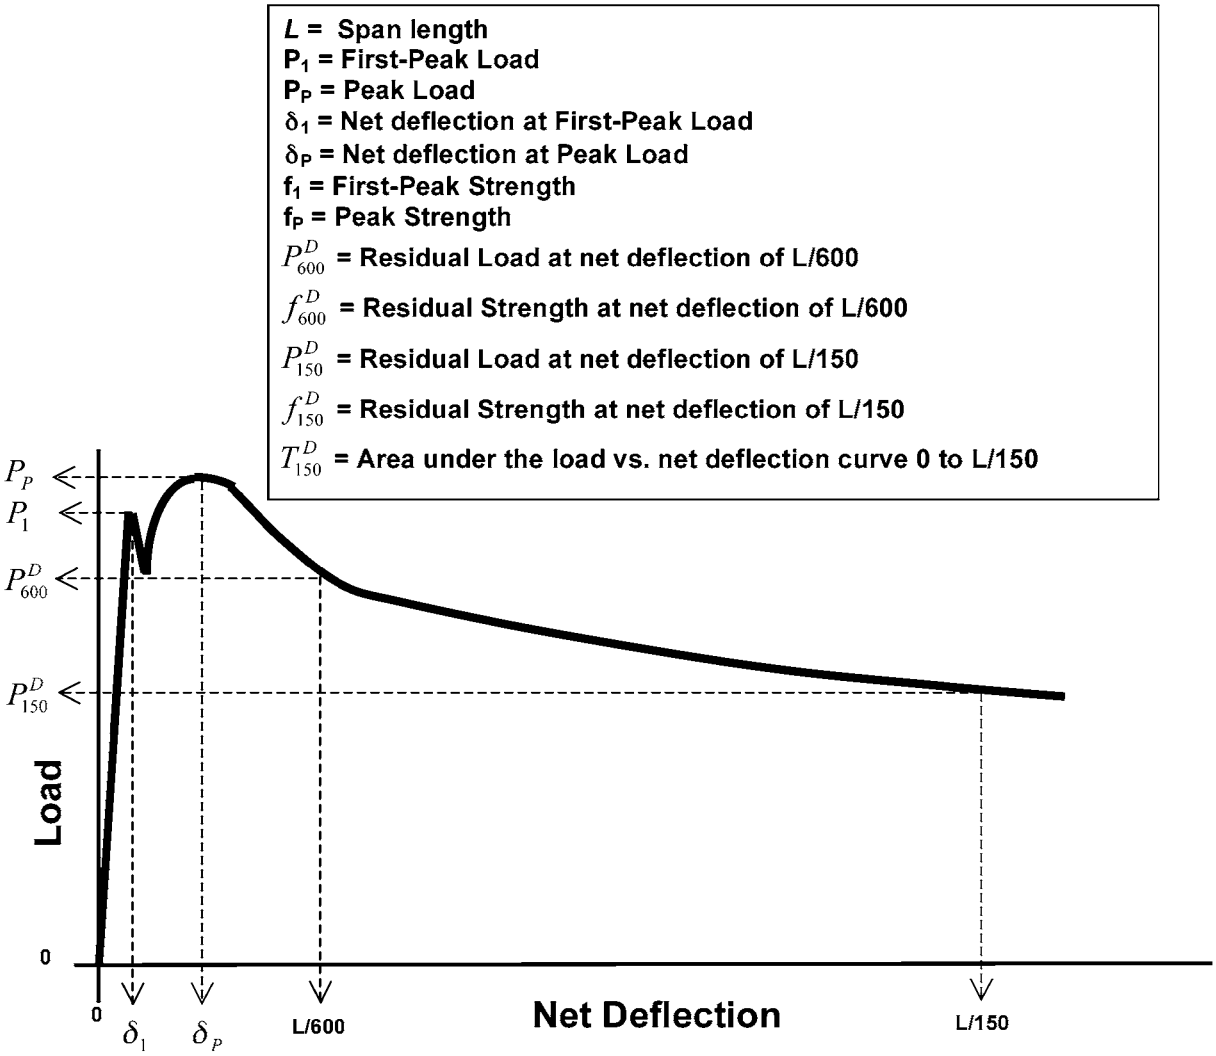

FIG. 4 Example of Parameter Calculations when Peak Load is Greater than First-Peak Load (Not to Scale)

10.4 Determine the peak load as that value of load corresponding to the point on the load-deflection curve that corresponds to the greatest value of load obtained prior to reaching the end-point deflection. Determine the corresponding deflection value.

10.5 Calculate the peak strength using the peak load determined in 10.4, the average specimen dimensions determined in 9.7, and Eq 1. Record the number rounded to the nearest 0.05 MPa [5 psi] as the peak strength, f_P.

10.6 Determine the residual load values, P^D_{600} and P^D_{150} as appropriate for the specimen depth, corresponding to net deflection values of 1/600 and 1/150 of the span length.

10.7 Calculate the residual strengths, f^D_{600} and f^D_{150} using the residual loads determined in 10.6, the average specimen dimensions determined in 9.7, and Eq 1. Record the numbers rounded to the nearest 0.05 MPa [5 psi] as the residual strengths, f^D_{600} and f^D_{150} as appropriate for the specimen depth.

10.8 When required by the specifier of tests, determine the residual load(s) and calculate the residual strength(s) at the values of net deflection required by the specifier of tests at value(s) greater than 1/600 of the span length using the procedures in this section. Record the calculated value(s) rounded to the nearest 0.05 MPa [5 psi] using the appropriate superscript and subscript(s) to indicate the specimen depth and net deflection(s) selected.

For a specified net deflection δ the subscript XXX is calculated as:

$$XXX = \frac{L}{\delta} \quad (2)$$

10.9 When required by the specifier of tests, calculate the total area under the load-deflection curve up to a net deflection of 1/150 of the span length. Record the number rounded to the nearest Joule [10 in.-lb] as toughness, T^D_{150} as appropriate for the specimen depth.

NOTE 12—If the load and deflection are measured in consistent units, such as Newtons (N) and metres (m), or kilonewtons (kN) and millimetres (mm), the resulting measure of energy will be in units known as Joules (J).

11. Report

11.1 Report the following information:

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

11.1.1 Type of specimen (molded or sawn) and specimen identification numbers or symbols,

11.1.2 Average width and depth of specimen at the point of fracture to the nearest 1 mm [0.05 in.],

11.1.3 Span length to the nearest 2 mm [0.1 in.],

11.1.4 First-peak load, P_1, rounded to the nearest N (lbf), first-peak strength, f_1, to the nearest 0.05 MPa [5 psi], and first-peak deflection, δ_1, to the nearest 0.01 mm [0.0005 in.],

11.1.5 Peak load, P_P, rounded to the nearest N [lbf], peak strength, f_P, to the nearest 0.05 MPa [5 psi], and peak-load deflection, δ_P, to the nearest 0.01 mm [0.0005 in.],

11.1.6 Residual loads, P^D_{600} and P^D_{150} rounded to the nearest N [lbf],

11.1.7 Residual strengths, f^D_{600} and f^D_{150} rounded to the nearest 0.05 MPa [5 psi],

11.1.8 When required by the specifier of tests, toughness, T^D_{150} to the nearest Joule [10 in.-lb],

11.1.9 When required by the specifier of tests, the residual load(s), P^D_{XXX} and corresponding residual strength(s), f^D_{XXX}, rounded to the nearest N [lbf] and 0.05 MPa [5 psi],

11.1.10 Age of the specimens at the time of testing, in days,

11.1.11 Curing history and moisture condition of specimen at test,

11.1.12 Whether the specimen contact surfaces were ground or capped,

11.1.13 Defects in specimen prior to test and abnormalities in specimen behavior during test, and

11.1.14 The load-deflection curve.

12. Precision and Bias

12.1 *Precision*—Tables 1 and 2 provide the repeatability standard deviations for the various parameters measured in this test method (see Note 13). The reproducibility of this test method is being determined.

NOTE 13—The repeatability standard deviations were developed from analysis of a database composed of 26 sets of three or four replicate test specimens that were tested by one operator using a closed-loop, servo-controlled hydraulic universal-testing machine. A test result is the mean value for each set of replicate test specimens. The concrete mixtures tested contained various steel fibers (10 sets) or synthetic fibers (16 sets) at different fiber contents. All test specimens had nominal dimensions of 102 mm by 102 mm by 356 mm [4 in. by 4 in. by 14 in.] and were tested on a 305 mm [12 in.] span. The test specimens for each set were either molded beams (19 sets) or beams cut from shotcrete panels (7 sets).

12.2 *Bias*—This test method has no bias since the properties determined can only be defined in terms of this test method.

13. Keywords

13.1 fiber-reinforced concrete; first-peak strength; flexural toughness; peak strength; residual load; residual strength

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1609/C 1609M – 06, that may impact the use of this test method. (Approved December 15, 2007)

(*1*) Simplified nomenclature (deleted old 3.2.10–3.2.19 and replaced it with new 3.2.10-3.2.16).

(*2*) Added new Note 3.

(*3*) Added new Eq 2.

(*4*) Updated residual load(s), residual strength(s), and toughness parameters according to new nomenclature throughout the standard (including Figs. 3 and 4 and Tables 1 and 2).

(*5*) Changed "D" to "d" in new Note 9 and Eq 1.

(*6*) Changed "(in-lb units)" to "[in-lb units]" throughout the standard.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1609/C 1609M – 05, that may impact the use of this test method. (Approved December 15, 2006)

(*1*) Added new 1.3.
(*2*) Revised 4.1.
(*3*) Added new 5.4.
(*4*) Revised 6.3.
(*5*) Added new 7.1.2.
(*6*) Revised Section 9.
(*7*) Revised 10.3.
(*8*) Revised Section 11.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Designation: C 1610/C 1610M – 06a

Standard Test Method for Static Segregation of Self-Consolidating Concrete Using Column Technique[1]

This standard is issued under the fixed designation C 1610/C 1610M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of static segregation of self-consolidating concrete by measuring the coarse aggregate content in the top and bottom portions of a cylindrical specimen (or column).

1.2 This test method is not applicable to self-consolidating concrete containing lightweight aggregate.

1.3 The values stated in either inch-pounds or SI units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.4 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:* [3]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 127 Test Method for Density, Relative Density (Specific Gravity), and Absorption of Coarse Aggregate

C 173/C 173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method

D 1785 Specification for Poly(Vinyl Chloride) (PVC) Plastic Pipe, Schedules 40, 80, and 120

3. Terminology

3.1 *Definitions:*

3.1.1 For definitions of terms used in this test method, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *Static Segregation*, *n*—settlement of coarse aggregate particles in an undisturbed mass of fresh concrete.

4. Summary of Test Method

4.1 A sample of freshly-mixed self-consolidating concrete is placed in a cylindrical mold without tamping or vibration. The mold is separated into three sections representing different levels of the cylindrical specimen (or column). Portions of concrete from the top and bottom section are washed on a 4.75 mm [No. 4] sieve, leaving the coarse aggregate on the sieve. The masses of coarse aggregate in the top and the bottom sections are determined and the percent static segregation is calculated.

5. Significance and Use

5.1 This test method provides users with a laboratory procedure to determine the potential static segregation of self-consolidating concrete.

5.2 This test method shall be used to develop self-consolidating concrete mixtures with segregation not exceeding specified limits. Self-consolidating concrete is a fluid concrete that can be prone to segregation if not proportioned to be cohesive. A cohesive self-consolidating concrete is important for all applications but is especially critical for deep-section applications such as walls or columns. Therefore, the degree of segregation can indicate if a mixture is suitable for the application.

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.47 on Self-Consolidating Concrete.

Current edition approved Dec. 15, 2006. Published January 2007. Originally approved in 2006. Last previous edition approved in 2006 as C 1610/C 1610M – 06.

www.technobetar.ir

NOTE 1—Some level of segregation is tolerable as long as the desired strength and durability performance is achieved.

6. Apparatus

6.1 *Balance*—as described in Test Method C 127.

6.2 *Column Mold*—The column portion of the mold shall be poly(vinyl chloride) (PVC) plastic pipe Schedule 40 meeting the requirements of Specification D 1785. The column shall be 8 in. [200 mm] in diameter × 26 in. [660 mm] in height and separated into 3 sections. The top section shall be 6.5 in. [165 mm] in height, the middle section 13 in. [330 mm] in height, and the bottom section 6.5 in. [165 mm] in height, as shown in Fig. 1. Each section shall have its ends flat and plane and be marked as "Top", " Middle", or "Bottom" relative to its location in the column. Couplers, brackets, clamps, or other equivalent fastening systems shall be used for securing the column sections together to form a mortar-tight joint and to secure the column to the base plate. The column mold shall be securely attached to a non-absorbent, rigid base plate measuring at least 12 in. [300 mm] × 12 in. [300 mm] square.

NOTE 2—Experience has shown that a base plate made from sealed or laminated plywood at least 0.75 in. [20 mm] thick is suitable for securing the column.

6.3 *Collector Plate*—The collector plate, used to obtain concrete from the top section of the column, shall be made of any nonabsorbent, rigid material measuring at least 20 in. [510 mm] × 20 in. [510 mm] square. The plate shall contain a cut out section in the center measuring 8.5 in. [215 mm] across and it shall contain a rigid lip that is at least 2 in. [50 mm] high running around three sides of the perimeter of the plate, as shown in Fig. 2.

NOTE 3—To facilitate the ease with which the test can be performed, the collector plate may contain legs or another support system so that only one person is needed to perform the concrete collection process from the top section.

6.4 *Strike-off Bar*—As described in Test Method C 173/C 173M or Test Method C 231.

6.5 *Sieve*—A 4.75 mm [No. 4] rectangular sieve with minimum dimensions of 13 in. [330 mm] × 25 in. [630 mm].

6.6 *Sample Receptacle*—The receptacle shall be a heavy-gage metal pan, wheelbarrow, or flat, clean nonabsorbent board of sufficient capacity to allow easy remixing of the entire sample with a shovel, trowel, or scoop.

6.7 *Small Tools*—Tools and items such as shovels, plastic pails, trowels, scoops and rubber gloves shall be provided.

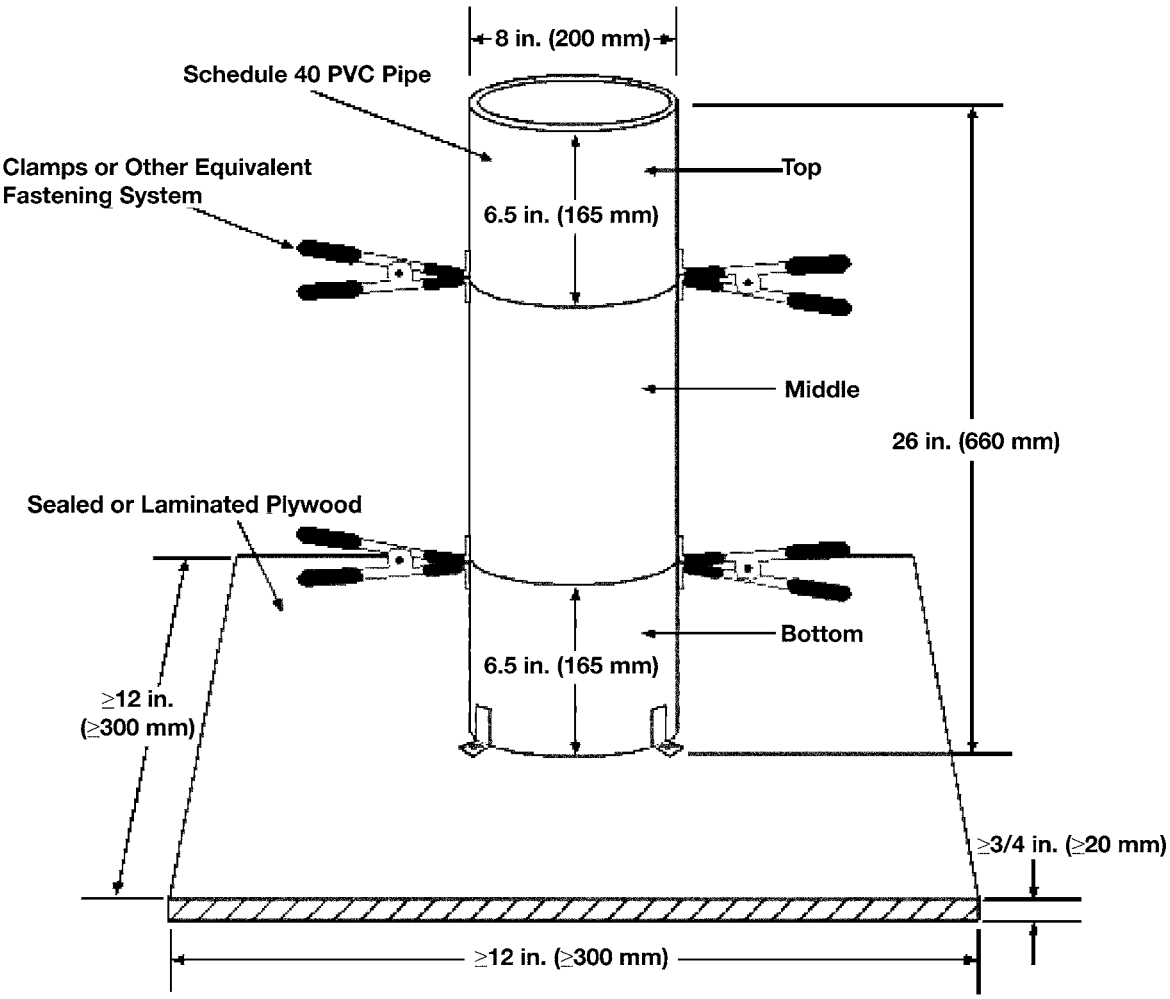

FIG. 1 Detail of Column Mold

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

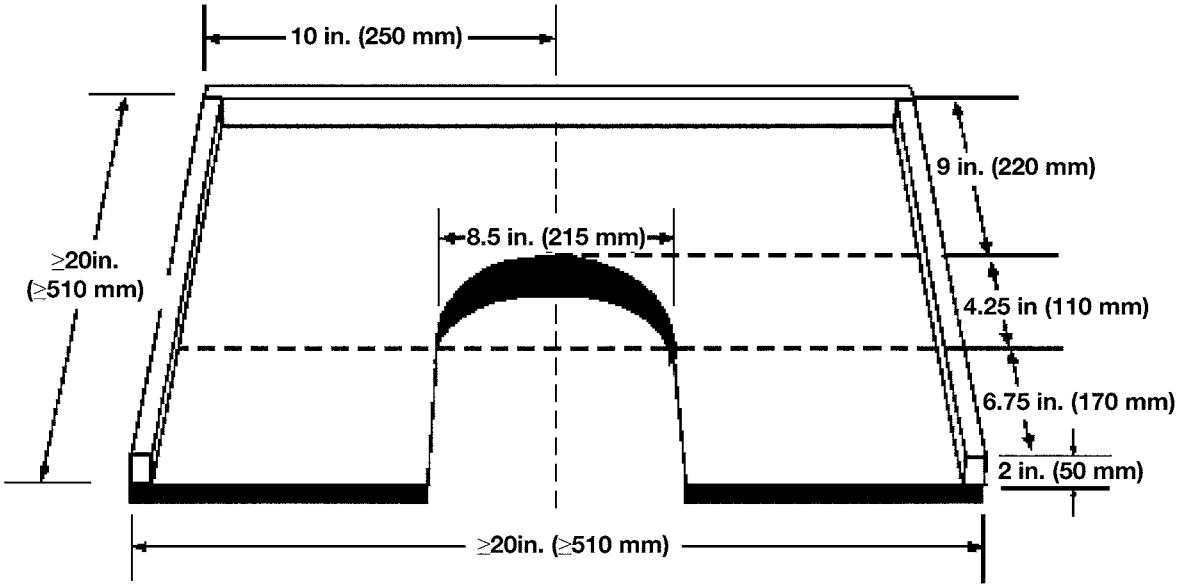

FIG. 2 Detail of Collector Plate

7. Sample

7.1 Obtain a sample of freshly-mixed self-consolidating concrete in accordance with Practice C 192/C 192M and place it in the sample receptacle.

8. Procedure

8.1 Perform the column segregation test on a flat, level surface. Do not subject the testing surface and the column mold to any vibration or disturbance.

8.2 *Remixing of Sample:* Remix the sample obtained in accordance with Section 7.1 in the sample receptacle using a shovel or scoop so that the concrete is homogeneous.

8.3 *Filling Procedure:* Using a shovel, scoop, or plastic pail, immediately fill the column mold with concrete completely and above the rim, within 2 min.

8.4 After filling the mold, strike off the top surface by sliding the strike-off bar across the top rim of the mold with a sawing motion until the concrete surface is level with the top of the mold.

8.5 Allow the concrete to stand undisturbed in the column mold for 15 ± 1 min.

8.6 Immediately following the standing period, securely hold the top section of the mold and remove the fastening system. Complete Steps 8.7 – 8.14 within 20 min thereafter.

8.7 Place the cut out section of the collector plate around the column just below the joint between the "Top" and "Middle" sections to catch and collect concrete.

8.8 Grasp the upper section of the column mold and, using a horizontal rotating motion, screed the concrete from the top section of the column on to the collector plate and then deposit it into a plastic pail.

8.9 Repeat Steps 8.6 – 8.8 to remove the concrete from the middle section of the column mold and discard the concrete.

8.10 Place the concrete sample collected from the upper section of the column onto the 4.75 mm [No. 4] sieve.

8.11 Wash the concrete on the 4.75 mm [No. 4] sieve so that only coarse aggregate remains on the sieve and then deposit the coarse aggregate into a clean plastic pail.

8.12 Repeat Steps 8.10 – 8.11 for the concrete retained in the bottom section of the mold.

8.13 Bring the coarse aggregate obtained from both the top and bottom sections of the column to a surface-dry condition by rolling it in a large absorbent cloth until all visible films of water are removed.

8.14 Determine the mass of coarse aggregate from the top and bottom sections of the column to the nearest 0.1 lb [50 g].

9. Calculation

9.1 Calculate the percent static segregation using the following equation:

$$S = 2\left[\frac{(CA_B - CA_T)}{(CA_B + CA_T)}\right] * 100, \quad if\ CA_B > CA_T$$

$$S = 0, \quad if\ CA_B \le CA_T$$

where:

S = static segregation, percent
CA_T = mass of coarse aggregate in the top section of the column
CA_B = mass of coarse aggregate in the bottom section of the column

10. Report

10.1 Mixture designation.

10.2 The mass of coarse aggregate obtained from the top and bottom sections of the column separately to the nearest 0.1 lb [0.05 kg].

10.3 The static segregation to the nearest 0.1 percent.

11. Precision and Bias

11.1 *Precision*—The estimate of the precision of this test method is provisional. A repeatability standard deviation of

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:42 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

0.2 % was obtained from a study (1) involving five replicate batches of a concrete mixture with a mean static segregation of 3.8 %.

11.2 *Bias*—The procedure used in this test method has no bias since coarse aggregate segregation of self-consolidating concrete is defined only in terms of this method.

12. Keywords

12.1 coarse aggregate; self-consolidating concrete; stability; static segregation

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1610/C 1610M – 06, that may impact the use of this test method. (Approved December 15, 2006)

(*1*) Revised the definition of *static segregation*.
(*2*) Revised 1.2.
(*3*) Replaced reference to Practice C 172 with Test Method C 231.

3.1 For definitions of terms used in this test method, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *halo*, *n*—an observed cement paste or mortar ring that has clearly separated from the coarse aggregate, around the outside circumference of concrete after flowing from the mold.

3.2.2 *spread*, *n*—the distance of lateral flow of concrete during the slump-flow test.

3.2.3 *stability*, *n*—the ability of a concrete mixture to resist segregation of the paste from the aggregates.

3.2.4 *viscosity*, *n*—resistance of a material to flow under an applied shearing stress.

4. Summary of Test Method

4.1 A sample of freshly mixed concrete is placed in a mold either in the upright or inverted position. The concrete is placed in one lift without tamping or vibration. The mold is raised, and the concrete is allowed to spread. After spreading ceases, two diameters of the concrete mass are measured in approximately orthogonal directions. Slump flow is the average of the two diameters.

5. Significance and Use

5.1 This test method provides a procedure to determine the slump flow of self-consolidating concrete in the laboratory or the field.

5.2 This test method is used to monitor the consistency of fresh, unhardened self-consolidating concrete and its unconfined flow potential.

5.3 It is difficult to produce self-consolidating concrete that is both flowable and nonsegregating using coarse aggregates larger than 25 mm [1 in.]. Therefore, this test method is considered applicable to self-consolidating concrete having coarse aggregate up to 25 mm [1 in.] in size. Appendix X1 provides non-mandatory visual rating criteria that may be used

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.47 on Self-Consolidating Concrete.

Current edition approved Aug. 1, 2009. Published September 2009. Originally approved in 2009. Last previous edition approved in 2009 as C 1611/C 1611M – 09a.

[2] Section on Safety Precautions, Manual of Aggregate and Concrete Testing, *Annual Book of ASTM Standards*, Vol. 04.02.

www.technobetar.ir

to classify the ability of a self-consolidating concrete mixture to resist segregation (stability).

5.4 The rate at which the concrete spreads is related to its viscosity. Appendix X1 provides a non-mandatory procedure that may be used to provide an indication of relative viscosity of self-consolidating concrete mixtures.

6. Apparatus

6.1 *Mold*—The mold used in this test method shall conform to that described in Test Method C 143/C 143M.

6.2 *Base Plate*—A nonabsorbent, smooth, rigid plate having a minimum diameter of 915 mm [36 in.] (See Note 1).

NOTE 1—*Field experience and results from the round robin test program have shown that base plates made from sealed/laminated plywood, acrylic plastic, or steel are suitable for performing this test.*

6.3 *Strike-off Bar*—As described in Test Method C 173/C 173M.

6.4 *Measuring Device*—A ruler, metal roll-up measuring tape, or similar rigid or semi-rigid measuring instrument marked in increments of 5 mm [¼ in.] or less.

7. Sample

7.1 The sample of concrete from which test specimens are made shall be representative of the entire batch. It shall be obtained in accordance with Practice C 172.

8. Procedure

8.1 Perform the test on a flat, level, nonabsorbent surface such as a concrete floor or a base plate. Use the base plate in conditions where a flat, level surface is not available, such as on a construction site. When the base plate is used, position and shim the base plate so that it is fully supported, flat, and level. Pre-moisten the work surface or base plate with a damp towel, rag, or sponge.

8.1.1 When performing the slump flow test for a given study or project, do not change the base plate surface type for the duration of the study or project.

8.2 *Filling the Mold:* Fill the mold by following either Procedure A or Procedure B (See Note 2).

8.2.1 *Filling Procedure A (Upright Mold):* Dampen the mold and place it on the work surface, or centered on the base plate, with the larger opening facing down. Hold the mold firmly in place during filling by standing on the two foot pieces. Fill the mold in a continuous manner (See Note 3). Overfill the mold slightly above its top.

8.2.2 *Filling Procedure B (Inverted Mold):* Dampen the mold and place it on the work surface, or centered on the base plate, with the smaller opening facing down (See Note 4). Fill the mold in a continuous manner (See Note 3). Overfill the mold slightly above its top.

NOTE 2—*During the development of this test method, it was found that some of the users preferred to perform the test with the large opening of the mold facing down as is performed in Test Method C 143/C 143M. The provision of a collar to the top of the mold is useful to reduce the probability of concrete spilling over the mold and on to the base plate. Other users preferred to place the mold with the smaller opening face down, which facilitates the ease of filling. Both filling procedures have been found to be suitable when performing this test. The precision statement in Section 10 reflects the use of both procedures. Test data using the two filling procedures can be obtained in the round robin test report available from ASTM headquarters.*

NOTE 3—Filling the mold with concrete by using multiple scoops or by pouring from a bucket or similar container has been found to be acceptable.

NOTE 4—*As a precaution, when filling the mold in the inverted position, the mold may be supported to prevent accidental movement or tipping. Experienced users of this test method have found that it is not necessary to support the mold.*

8.3 Strike off the surface of the concrete level with the top of the mold by a sawing motion of the strike-off bar. Remove concrete from the area surrounding the base of the mold to preclude interference with the movement of the flowing concrete. Remove the mold from the concrete by raising it vertically. Raise the mold a distance of 225 ± 75 mm [9 ± 3 in.] in 3 ± 1 s by a steady upward lift with no lateral or torsional motion. Complete the entire test from the start of filling through removal of the mold without interruption within an elapsed time of 2 ½ min.

8.4 Wait for the concrete to stop flowing and then measure the largest diameter (d_1) of the resulting circular spread of concrete. When a halo is observed in the resulting circular spread of concrete, it shall be included as part of the diameter of the concrete. Measure a second diameter (d_2) of the circular spread at an angle approximately perpendicular to the first measured diameter (d_1). Measure the diameters to the nearest 5 mm [¼ in.]. Determine the Slump flow in accordance with Section 9.

8.5 If the measurement of the two diameters differs by more than 50 mm [2 in.], the test is invalid and shall be repeated.

9. Calculation

9.1 Calculate the slump flow using Eq 1:

$$\text{Slump flow} = (d_1 + d_2)/2 \quad (1)$$

where:

d_1 = the largest diameter of the circular spread of the concrete, and

d_2 = the circular spread of the concrete at an angle approximately perpendicular to d_1

9.2 Record the average of the two diameters to the nearest 10 mm [½ in.].

10. Report

10.1 Report the filling procedure (A or B) used.

10.2 Report the slump flow to the nearest 10 mm [½ in.].

11. Precision and Bias

11.1 The precision of this test method was determined based on the results obtained from a round robin test program conducted by members of the ASTM C09.47 subcommittee on January 9, 2003. The round robin test program consisted of using single and multiple operators performing 3 replicas of the test using the mold in both the upright and inverted positions. The tests were performed using self-consolidating concrete with high and low levels of slump flow and on stable and unstable mixes. Complete details of the round robin test program are available from ASTM headquarters in a report entitled "Report on Development of a Precision Statement for the Slump Flow Test Method for Self-Consolidating Concrete."

www.technobetar.ir

11.2 *Single-Operator Precision*—The single-operator precision statement reflects the use of both procedures A and B. The single-operator standard deviation for slump flow has been found to be 27 mm [1.1 in.] (See Note 5) for mixtures having slump flow values between approximately 480 and 680 mm [19 and 27 in.]. Therefore, results of two properly conducted tests by the same operator on the same batch of concrete should not differ by more than 75 mm [3.0 in.] (See Note 5).

11.3 *Multi-Operator Precision*—The multi-operator precision statement reflects the use of both procedures A and B. The multi-operator standard deviation for slump flow has been found to be 27 mm [1.1 in.] (See Note 5) for mixtures with slump flow values between approximately 530 and 740 mm [21 and 29 in.]. Therefore, the results of properly conducted tests by two operators on the same batch of concrete should not differ by more than 75 mm [3.0 in.] (See Note 5).

NOTE 5—*These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.*

11.4 *Bias*—The procedure used in this test method has no bias since slump flow is defined only in terms of this test method.

12. Keywords

12.1 halo; self-consolidating concrete; slump flow; spread; stability; viscosity; visual stability index

APPENDIX

(Nonmandatory Information)

X1. RELATIVE MEASURE OF FLOW RATE, VISCOSITY, AND STABILITY

X1.1 The flow rate of a self-consolidating concrete mixture is influenced by its viscosity. Hence, for the purpose of developing a self-consolidating concrete mixture in the laboratory, a relative measure of viscosity is useful. When performing the slump flow test, the time it takes for the outer edge of the concrete mass, to reach a diameter of 500 mm [20 in.] from the time the mold is first raised, provides a relative measure of the unconfined flow rate of the concrete mixture. For similar materials, this time period, termed T_{50}, gives an indication of the relative viscosity of the self-consolidating concrete mixture.

NOTE X1.1—The T_{50} value can provide information on the flow properties of the self-consolidating concrete mixture, whereby longer values normally correspond to increased viscosity. Special high-range water-reducing admixtures are typically used to modify the flow properties of the self-consolidating concrete mixture. In addition, viscosity-modifying admixtures and other changes in mixture proportions and materials can also influence flow properties and resistance to segregation.

X1.2 The stability of self-consolidating concrete can be observed visually by examining the concrete mass and therefore can be used for quality control of self-consolidating concrete mixtures. Table X1.1 contains Visual Stability Index (VSI) values with corresponding criteria to qualitatively assess the stability of self-consolidating concrete. However, these values do not quantify a concrete property.

X1.3 *Apparatus:*

X1.3.1 *Inscribed base plate* - a base plate as described in 6.2, with a circular mark centrally located for the placement of mold, and a further concentric circle at 500 mm [20 in.].

TABLE X1.1 Visual Stability Index Values

VSI Value	Criteria
0 = Highly Stable	No evidence of segregation or bleeding.
1 = Stable	No evidence of segregation and slight bleeding observed as a sheen on the concrete mass.
2 = Unstable	A slight mortar halo ≤ 10 mm [≤ 0.5 in.] and/or aggregate pile in the of the concrete mass.
3 = Highly Unstable	Clearly segregating by evidence of a large mortar halo > 10 mm [> 0.5 in.] and/or a large aggregate pile in the center of the concrete mass.

NOTE X1.2—The centrally located circular mark made at the 500 mm [20 in.] location on the base plate will assist the user in determining the T_{50} value.

X1.3.2 *Stop watch* – least reading of not more than 0.01 s.

X1.4 *Procedure:*

X1.4.1 To determine T_{50}, use a stopwatch to measure the time in seconds it takes any part of the outer edge of the spreading concrete to reach the inscribed mark on the base plate from the time the mold is first lifted.

X1.4.2 After spreading of the concrete has stopped, visually inspect the concrete mixture by observing the distribution of the coarse aggregate within the concrete mass the distribution of the mortar fraction particularly along the perimeter, and the bleeding characteristics. Assign a Visual Stability Index (VSI) value to the concrete spread using the criteria shown in Table X1.1 and illustrated in Figs. X1.1-X1.4.

X1.5 *Recording:*

X1.5.1 Record T_{50} to the nearest 0. 2 second.

X1.5.2 Record the VSI value.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1611/C 1611M – 09a, that may impact the use of this test method. (Approved August 1, 2009)

(*1*) Revised 4.1 for harmony with Test Method C 1621/C 1621M.

(*2*) Revised 6.2 for harmony with Test Method C 1621/C 1621M. Added a "measuring device" to the list of apparatus in new 6.4.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1611/C 1611M – 09, that may impact the use of this test method. (Approved June 1, 2009)

(*1*) Revised Section 8, including the addition of Notes 3 and 4.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1611/C 1611M – 05, that may impact the use of this test method. (Approved May 1, 2009)

(*1*) Revised the Scope to harmonize the test method with Test Method C 1621/C 1621M.

(*2*) Added reference to Terminology C 125 in new 3.1 to harmonize the test method with Test Method C 1621/C 1621M and renumbered subsequent paragraphs.

(*3*) Revised 10.1 to harmonize the test method with Test Method C 1621/C 1621M.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1621/C 1621M – 09b

Standard Test Method for Passing Ability of Self-Consolidating Concrete by J-Ring[1]

This standard is issued under the fixed designation C 1621/C 1621M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers determination of the passing ability of self-consolidating concrete by using the J-Ring in combination with a mold.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. (***Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 143/C 143M Test Method for Slump of Hydraulic-Cement Concrete

C 172 Practice for Sampling Freshly Mixed Concrete

C 173/C 173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C 1611/C 1611M Test Method for Slump Flow of Self-Consolidating Concrete

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this test method, refer to Terminology C 125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *halo*, *n*—an observed cement paste or mortar ring that has clearly separated from the coarse aggregate, around the outside circumference of concrete after flowing from the mold.

3.2.2 *J-ring*, *n*—an apparatus consisting of a rigid ring supported on sixteen 16 mm [⅝ in.] diameter rods equally spaced on a 300 mm [12 in.] diameter circle 100 mm [4 in.] above a flat surface as shown in Fig. 1.

3.2.3 *J-ring flow*, *n*—the distance of lateral flow of concrete using the J-Ring in combination with a mold.

3.2.4 *passing ability*, *n*—the ability of self-consolidating concrete to flow under its own weight (without vibration) and fill completely all spaces within intricate formwork, containing obstacles, such as reinforcement.

4. Summary of Test Method

4.1 A sample of freshly mixed concrete is placed in a mold, either in the upright or inverted position, that is concentric with the J-Ring (Fig. 2). The concrete is placed in one lift without tamping or vibration. The mold is raised, and the concrete is allowed to spread through the J-Ring (Fig. 3). After spreading ceases, two diameters of the concrete mass are measured in approximately orthogonal directions. J-Ring flow is the average of the two diameters. The test is repeated without the J-Ring to obtain the slump flow. The difference between the slump flow and J-Ring flow is an indicator of the passing ability of the concrete.

5. Significance and Use

5.1 This test method provides a procedure to determine the passing ability of self-consolidating concrete. This test method is applicable for laboratory use in comparing the passing ability

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.47 on Self-Consolidating Concrete.

Current edition approved July 1, 2009. Published August 2009. Originally approved in 2006. Last previous edition approved in 2009 as C 1621/C 1621M – 09a.

Dimension	in.	mm
A	12.0 +/- 0.13	300 +/- 3.3
B	1.5 +/- 0.06	38 +/- 1.5
C	0.625 +/- 0.13	16 +/- 3.3
D	2.36 +/- 0.06	58.9 +/- 1.5
E	1.0 +/- 0.06	25 +/- 1.5
F	4.0 +/- 0.06	100 +/- 1.5

FIG. 1 J-Ring Apparatus

of different concrete mixtures. It is also applicable in the field as a quality control test.

5.2 The difference between the slump flow and J-Ring flow is an indication of the passing ability of the concrete. A difference less than 25 mm [1 in.] indicates good passing ability and a difference greater than 50 mm [2 in.] indicates poor passing ability. The orientation of the mold for the J-Ring test and for the slump flow test without the J-Ring shall be the same.

5.3 This test method is limited to self-consolidating concrete with nominal maximum size of aggregate of up to 25 mm [1 in.].

6. Apparatus

6.1 *J-Ring*—The apparatus shall consist of a steel (or equivalent nonabsorbent, rigid material) ring measuring 300 mm [12 in.] in diameter at the center of the ring and 25 mm [1 in.] in thickness, and sixteen 16 mm [⅝ in.] diameter smooth steel rods spaced evenly around the ring measuring 100 mm [4 in.] in length (see Fig. 1).

6.2 *Mold*—The mold used in this test method shall conform to that described in Test Method C 143/C 143M, except that the foot pieces are removed when the test is performed with the mold in the upright position (Procedure A).

6.3 *Base Plate*—A nonabsorbent, smooth, rigid plate having a minimum diameter of 915 mm [36 in.].

NOTE 1—Field experience has shown that base plates made from sealed or laminated plywood, rigid plastic, or steel are suitable for performing this test.

6.4 *Strike-off Bar*—As described in Test Method C 173/C 173M.

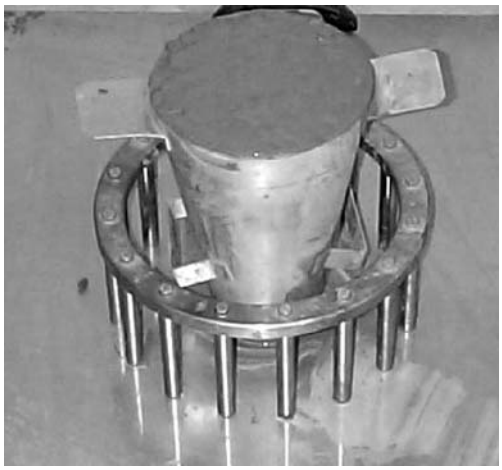

FIG. 2 J-Ring Setup with Inverted Mold Filled with Concrete

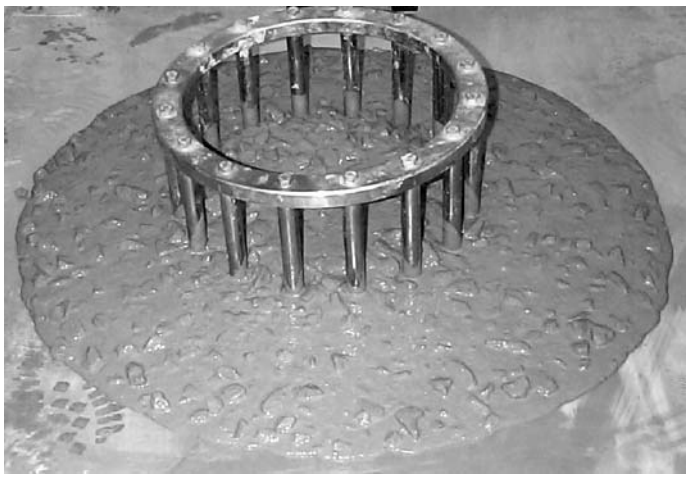

FIG. 3 J-Ring Flow

6.5 *Measuring Device*—A ruler, metal roll-up measuring tape, or similar rigid or semi-rigid measuring instrument marked in increments of 5 mm [¼ in.] or less.

7. Sample

7.1 The sample of concrete from which test specimens are made shall be representative of the entire batch. It shall be obtained in accordance with Practice C 172.

8. Procedure

8.1 Perform the test on a flat, level, nonabsorbent surface such as a concrete floor or a base plate. Use the base plate in conditions where a flat, level surface is not available, such as on a construction site. When the base plate is used, position and shim the base plate so that it is fully supported, flat, and level. Pre-moisten the work surface or base-plate with a damp towel, rag, or sponge. Rest the J-Ring on the work surface or at the center of the base plate.

8.1.1 When performing the slump flow test for a given study or project, do not change the base plate type for the duration of the study or project.

8.2 *Filling the Mold*—Fill the mold by following either Procedure A or Procedure B.

8.2.1 *Filling Procedure A (Upright Mold)*—Dampen the mold and place it on the work surface or base plate with the larger opening facing down and concentric with the JRing. Hold the mold firmly in place during filling. Fill the mold in a continuous manner. Overfill the mold slightly above its top.

8.2.2 *Filling Procedure B (Inverted Mold)*—Dampen the mold and place it on the work surface or base plate with the smaller opening facing down and concentric with the JRing. Support the mold during filling. Fill the mold in a continuous manner. Overfill the mold slightly above its top.

NOTE 2—As a precaution, when filling the mold in the inverted position, the mold may be supported to prevent accidental movement or tipping. Experienced users of this test method have found that it is not necessary to support the mold.

NOTE 3—Filling the mold with concrete by using multiple scoops or by pouring from a bucket or similar container has been found to be acceptable.

8.3 Strike off the surface of the concrete level with the top of the mold by a sawing motion of the strike-off bar. Remove concrete from the area surrounding the base of the mold to preclude interference with the movement of the flowing concrete. Remove the mold from the concrete by raising it vertically. Raise the mold a distance of 225 ± 75 mm [9 ± 3 in.] in 3 ± 1 s by a steady upward lift with no lateral or torsional motion. Complete the entire test from the start of filling through removal of the mold without interruption within an elapsed time of 2 ½ min.

8.4 Wait for the concrete to stop flowing and then measure the largest diameter (j_1) of the resulting circular spread of concrete. When a halo is observed in the resulting circular spread of concrete, it shall be included as part of the diameter of the concrete. Measure a second diameter (j_2) of the circular spread at an angle approximately perpendicular to the first measured diameter (j_1). Measure the diameters to the nearest 5 mm [¼ in.]. Determine the J-Ring flow in accordance with Section 9.

8.5 If the measurement of the two diameters differs by more than 50 mm [2 in.], the test is invalid and shall be repeated.

8.6 Conduct a slump flow test without the J-Ring in accordance with Test Method C 1611/C 1611M. Use the same filling procedure as used with the J-Ring. Complete the tests with and without the J-Ring within 6 min.

9. Calculation

9.1 Calculate J-Ring flow according to the following equation:

$$\text{J}-\text{Ring flow} = \frac{(j_1 + j_2)}{2} \quad (1)$$

where:

j_1 = the largest diameter of the circular spread of the concrete from the J-Ring test, and

j_2 = the circular spread of the concrete at an angle approximately perpendicular to j_1.

9.2 Calculate the slump flow according to the following equation:

$$\text{Slump flow} = \frac{(d_1 + d_2)}{2} \quad (2)$$

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:38 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

where:

d_1 = the largest diameter of the circular spread of the concrete from the slump flow test, and

d_2 = the circular spread of the concrete at an angle approximately perpendicular to d_1.

9.3 Calculate the difference between slump flow and J-Ring flow to the nearest 10 mm [½ in.]. This number represents the passing ability of the concrete.

10. Blocking Assessment

10.1 Identify blocking assessment according to Table 1.

11. Report

11.1 Report the filling procedure (A or B) used.

11.2 Report the J-Ring flow to the nearest 10 mm [½ in.].

TABLE 1 Blocking Assessment

Difference Between Slump Flow and J-Ring Flow	Blocking Assessment
0 to 25 mm [0 to 1 in.]	No visible blocking
>25 to 50 mm [>1 to 2 in.]	Minimal to noticeable blocking
>50 mm [>2 in.]	Noticeable to extreme blocking

11.3 Report the slump flow (without the J-Ring) to the nearest 10 mm [½ in.].

11.4 Report the passing ability as the difference between the slump flow and J-Ring flow to the nearest 10 mm [½ in.]. Identify the blocking assessment.

12. Precision and Bias

12.1 *Precision*—An interlaboratory study of this test method has not been carried out. In a study involving two operators who performed three replicate tests on 30 batches of the same concrete mixture during normal production at a precast plant, the within-test standard deviation (repeatability) for passing ability was 5.8 mm [0.23 in.]. The average passing ability in these tests was 20.5 mm [0.81 in.] for slump-flow values ranging from about 480 to 740 mm [19 to 29 in.]. Measurements were done in the inch-pound system and the SI values are conversion of the inch-pound values.

12.2 *Bias*—The procedure used in this test method has no bias since passing ability based on the J-Ring flow is defined only in terms of this test method.

13. Keywords

13.1 halo; j-ring; j-ring flow; passing ability self-consolidating concrete; slump flow; spread

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1621/C 1621M – 09a, that may impact the use of this test method. (Approved July 1, 2009)

(*1*) Reworded the Scope, Section 5, Section 6, and Section 8 to be in harmony with Test Method C 1611/C 1611M.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1621/C 1621M – 09, that may impact the use of this test method. (Approved June 1, 2009)

(*1*) Revised Section 8. Added new Notes 2 and 3 and renumbered subsequent notes.

(*2*) Revised Section 9 to be in harmony with Test Method C 1611/C 1611M and to comply with ASTM's Form and Style.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1621/C 1621M – 08, that may impact the use of this test method. (Approved May 1, 2009)

(*1*) Added a noun designation to the terms in Section 3.

(*2*) Revised 4.1 and Section 11 to be in harmony with Test Method C 1611/C 1611M.

Committee C09 has identified the location of selected changes to this test method since the last issue, C 1621/C 1621M – 06, that may impact the use of this test method. (Approved June 1, 2008)

(*1*) Revised 1.1 to clarify the scope of this test method.

(*2*) Corrected a value in the dimension table of Fig. 1.

Designation: C1622/C1622M – 09

Standard Specification for Cold-Weather Admixture Systems[1]

This standard is issued under the fixed designation C1622/C1622M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This specification covers cold-weather admixture systems to be added to hydraulic-cement concrete when the temperature of the concrete immediately after placement will be as low as -5.0 °C [23.0 °F].

1.2 This specification stipulates tests of the cold-weather admixture system with suitable materials as described in 11.1-11.3 or with materials proposed for specific work (See 11.5). Unless otherwise requested by the purchaser, tests shall be made using suitable concreting materials as described in 11.1-11.3.

NOTE 1—Whenever practicable, tests should be made using the concreting materials, the mixture proportions, and batching sequence proposed for the specific work (See 11.5) because the time of setting, compressive strength gain, and other properties may vary.

1.3 This specification provides three levels of testing.

1.3.1 *Level 1*—During the initial approval stage, proof of compliance with the performance requirements defined in Table 1 demonstrates that the cold-weather admixture system meets the requirements of this specification. Uniformity and equivalence tests (See Section 6) shall be carried out to provide results against which later comparisons can be made.

1.3.2 *Level 2*—Limited retesting is described in 5.2, 5.2.1, and 5.2.2. Proof of compliance with the requirements of Table 1 demonstrates conformity of the admixture system with the requirements of this specification.

1.3.3 *Level 3*—For acceptance of a lot or for measuring uniformity within or between lots, when specified by the purchaser, uniformity and equivalence tests (See Section 6) shall be used.

1.4 The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.5 The text of this standard references notes and footnotes, which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.6 The following precautionary caveat pertains to the test methods portion, Sections 11-18, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* **WARNING**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2]

TABLE 1 Performance Requirements for Cold-Weather Admixture[A]

Time of Initial Setting, maximum % of control[B]	200
Compressive Strength. minimum % of control[C]	
7 days[D]	40
28 days	80
90 days	90
Length Change, Maximum Shrinkage (alternative requirements)[E]	
Percent of Control[B]	135
Increase over control, percentage points	0.010
Relative Durability Factor, Minimum % of control[F]	80

[A]The values in the table include allowance for normal variation in test results

[B]As an example, in the case of initial time of setting, if the control mixture has a set time of 4.0 hrs, the test specimens can have a set time up to 8.0 hrs. For length change, if the control specimen shrinks X units, the test specimen is allowed to shrink up to 1.35X.

[C]The compressive strength of the concrete containing the cold-weather admixture shall not be less than 90 % of that attained at the previous test age. The objective of this limit is to require that the compressive strength of the cold-weather admixture concrete shall not decrease with age.

[D]Because the test specimens will be cool and damp for the 7d compressive test, it will be necessary to use unbonded caps as described in Practice C1231/C1231M.

[E]Alternative requirements, see 17.1.2: Percent of control applies when shrinkage of control concrete is 0.030 % or greater; the increase over control limit applies when shrinkage of control concrete is 0.030 % or less.

[F]This requirement is applicable only when the cold-weather admixture is to be used in air-entrained concrete that may be exposed to freezing and thawing while wet.

D1193 Specification for Reagent Water

2.2 *American Concrete Institute Standard:*[4]

ACI 211.1 Practice for Selecting Proportions for Normal, Heavyweight, and Mass Concrete

3. Terminology

3.1 *Definitions of Terms:*

3.1.1 For definitions of terms used in this specification, refer to Terminology C125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *cold-weather admixture system*, *n*—an admixture or group of admixtures that depresses the freezing point of mixing water and increases the hydration rate of cement in concrete.

3.2.2 *control concrete mixture*, *n*—a concrete mixture without the cold-weather admixture system.

3.2.3 *dummy concrete specimen*, *n*—additional concrete specimen instrumented with a temperature sensing device to estimate the temperature of test concrete specimens.

3.2.4 *replicate concrete specimen*, *n*—additional time-of-setting specimen exposed to the same temperature regimen as the test concrete specimen.

3.2.5 *test concrete mixture*, *n*—a concrete mixture with the cold weather admixture system.

4. Apparatus

4.1 *Low Temperature Environment*—A chamber of sufficient size to subject the test specimens to the specified low temperature and that allows access for laboratory personnel to conduct appropriate tests. The chamber or chambers shall be capable of cooling numerous specimens from their initial temperature to -5.0 ± 1 °C [23.0 ± 2.0 °F] within the specified elapsed time and maintain them at that temperature for the specified time period.

4.2 *Temperature Measuring Equipment*—The temperature measuring equipment shall be capable of measuring and recording the temperature at the center of the dummy specimens to ± 1.0 °C [± 2.0 °F] at least every ½ h for 7 days.

4.3 *Tools*—Molds and tools for preparing test specimens as described in Practice C192/C192M. Molds shall have lids to provide for sealed conditions.

5. General Requirements

5.1 For initial compliance with this specification, the concrete shall be tested with the cold-weather admixture system for conformance with the requirements in Table 1.

5.2 The purchaser is permitted to require limited retesting to confirm current compliance of the admixture system to specification requirements. The limited retesting includes measurements of physical and performance properties of the admixture system as described in 5.2.1 and 5.2.2.

5.2.1 The physical properties retesting consists of uniformity and equivalence tests of the admixture system for infrared absorption spectrum and relative density.

5.2.2 The performance properties retesting consists of time of initial setting and compressive strength of concrete at 7 and 28 days. Purchasers having special requirements are permitted to require additional tests.

5.3 At the request of the purchaser, the manufacturer shall state in writing that the admixture system supplied for use in the work is equivalent in all essential respects, including concentration, to the admixture system tested under this specification.

5.4 At the request of the purchaser, the manufacturer shall state in writing the chloride content of the admixture system.

5.5 Tests for uniformity and equivalence, as indicated in Section 6, shall be made on the initial sample and the results retained for reference and comparison with the results of samples taken elsewhere within the lot or subsequent lots of admixture supplied to the work.

6. Uniformity and Equivalence Tests

6.1 When specified by the purchaser, the uniformity of a lot, or equivalence of multiple lots from the same source shall be established by the following requirements:

[4] Available from American Concrete Institute (ACI), P.O. Box 9094, Farmington Hills, MI 48333-9094, http://www.aci-int.org.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:36 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.1.1 *Infrared Analysis*—The absorption spectra of the initial sample and the test sample, obtained as specified in Section 18, shall exhibit the same pattern of absorption bands in terms of frequency and intensity.

6.1.2 *Relative Density (Liquid Admixture)*—When tested as specified in Section 18, the relative density (specific gravity) of subsequent test samples shall not differ from the relative density of the initial sample by more than 10 % of the difference between the relative density of the initial sample and reagent water at the same temperature. Reagent water conforming to Specification D1193, Type III or IV, and prepared by distillation, ion exchange, reverse osmosis, or a combination of these procedures, is acceptable (See Note 2).

6.2 When the nature of the admixture system or analytical capability of the purchaser make these procedures unsuitable, other requirements for uniformity and equivalence from lot to lot or within a lot shall be established by agreement between the purchaser and the manufacturer.

NOTE 2—Oven drying methods are not appropriate for measuring the oven-dried residue content for cold-weather admixture system because water, present in the form of bound water of hydration, is released slowly upon drying, and can often lead to highly variable results. Relative density is an acceptable indication of lot-to-lot uniformity.

7. Packaging and Marking

7.1 When the cold-weather admixture system is delivered in packages or containers, the proprietary name of the individual admixtures in the system, the designation of this specification, and the net mass or volume shall be plainly marked thereon. Similar information shall be provided in the shipping information accompanying packages or bulk shipments of admixture.

8. Storage

8.1 Store the cold-weather admixture system to permit easy access for proper inspection and identification of each shipment, and in a suitable building that will protect the admixture from moisture absorption if it is a dry admixture or from freezing if it is a liquid admixture.

9. Sampling and Testing

9.1 Every facility shall be provided to the purchaser for sampling and inspection, either at the point of manufacture or at the site of the work, as specified by the purchaser.

9.2 Samples shall be either “grab” or “composite” samples as specified by this specification. A grab sample is one obtained in a single operation. A composite sample is one obtained by combining three or more grab samples.

9.3 For the purpose of this specification, it is recognized that samples will be taken for two reasons:

9.3.1 *Compliance Tests*—A sample taken for evaluating compliance of a source or lot of cold-weather admixture system shall meet the applicable requirements of this specification. Samples used to determine conformance with this specification shall be composites of grab samples taken from different locations so that the composite sample will be representative of the lot.

9.3.2 *Uniformity and Equivalence Tests*—When specified by the purchaser, a sample taken for evaluating the uniformity of a single lot or equivalence of multiple lots from one source shall be tested as provided in Section 6. When uniformity of a single lot is being determined, grab samples shall be used. When uniformity of multiple lots from the same source is being determined, composite samples from individual lots shall be used.

9.4 *Liquid Admixtures*—Liquid admixtures shall be agitated immediately prior to sampling. Grab samples taken for quality or uniformity tests shall represent a unit shipment or a single production lot. Each grab sample shall be at least 1 L [1 qt]. At least three grab samples of equal portions shall be taken. Composite samples shall be prepared by mixing the grab samples and the resultant mixture shall provide at least 3 L [3 qt] for compliance tests. Grab samples shall be taken from different locations distributed throughout the quantity to be represented.

9.4.1 Admixtures in bulk storage tanks shall be sampled equally from the upper, intermediate, and lower levels by means of drain cocks in the sides of the tanks or a weighted sampling bottle fitted with a stopper that can be removed after the bottle is lowered to the desired depth.

9.4.2 Samples shall be stored in impermeable containers that are resistant to attack by the admixture.

9.5 *Nonliquid Admixtures*—Grab samples taken for compliance or uniformity tests shall be at least 1kg [2 lb]. At least four grab samples of equal portions shall be taken from not more than 2 Mg [2 tons] of admixture. Prepare composite samples by mixing the grab samples and sampling the resultant mixture to provide at least 2.5 kg [5 lb] for the composite sample. Take grab samples from different locations distributed throughout the quantity to be represented.

9.5.1 Obtain samples of packaged admixtures by means of a sampler as described in Practice C183.

9.5.2 Samples shall be stored in moisture-proof, airtight containers.

9.6 Mix samples before testing to ensure uniformity. When recommended by the manufacturer, dissolve the entire sample of non-liquid admixture in water prior to testing.

10. Rejection

10.1 For initial compliance testing, the purchaser is permitted to reject the cold-weather admixture system if it fails to meet any of the requirements of this specification.

10.2 For the initial retesting, the purchaser is permitted to reject the admixture if it fails to meet any of the requirements of Section 6 and applicable parts of Table 1, as defined in 5.2.2.

10.3 If, after completion of tests, an admixture has been stored at the point of manufacture for more than 6 months prior to shipment, or an admixture has been in local storage in the hands of a vendor for more than 6 months, it shall be retested before use when requested by the purchaser and is permitted to be rejected if it fails to conform to this specification.

10.4 Packages and containers varying more than 5 % from the specified mass or volume are permitted to be rejected. If the average mass or volume of 50 packages taken at random is less than that specified, the entire shipment is permitted to be rejected.

10.5 When the admixture is for a specific use in non-air-entrained concrete, it is permitted to be rejected if the test concrete containing it has an air content greater than 3.5 % at

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:36 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

the dosage used to meet this specification. When the admixture is to be used in air-entrained concrete, it is permitted to be rejected if the test concrete containing it has an air content greater than 7.5 % at the dosage used to meet this specification.

11. Materials

11.1 *Concrete Not for Specific Use*—The materials in 11.2-11.4 are for compliance testing using a concrete mixture not for a specific use.

11.2 *Cementitious Materials*—The cementitious materials shall be a Type I or Type II portland cement conforming to Specification C150, or a blend of two or more of these cements from different sources.

11.3 *Aggregates*—Except when tests are made in accordance with 11.4 using the aggregates for a specific use, the fine and coarse aggregates used in any series of tests shall come from single lots of materials that conform to the requirement of Specification C33, except that the grading shall conform to the following requirements:

11.3.1 *Fine Aggregate Grading:*

Sieve	Percent Passing by Mass
4.75 mm (No. 4)	100
1.18 mm (No. 16)	65 to 75
300 µm (No. 50)	12 to 20
150 µm (No. 100)	2 to 5

11.3.2 *Coarse Aggregate Grading*—The coarse aggregate grading shall meet the Size 57 grading requirements of Specification C33. Take care in loading and delivery to avoid segregation.

11.3.3 Coarse aggregate used for control concrete and test concrete shall be essentially the same. Provide sufficient coarse aggregate for the control concrete, the test concrete, and for grading analysis.

11.3.3.1 Prepare required quantities of coarse aggregate (See Note 3) as follows: Fill tared containers, one for sieve analysis, one for a batch of control concrete, and one for a batch of test concrete, to the required mass from the aggregate stockpile. Accomplish this by placing equal quantities into each container, successively, and repeat the procedure until all the containers have their required mass.

NOTE 3—Refer to the section on Sampling Aggregates in the Manual of Aggregate and Concrete Testing for guidance on sampling from stockpiles.

11.3.4 Perform sieve analyses on the coarse aggregate prepared in 11.3.3.1 by Test Method C136. Discard any prepared quantity of aggregate that deviates from the specified percent passing by more than the amount shown in column 3 below.

Sieve	Specification C33, No. 57 Percent Passing by Mass	Maximum Variation from Percent Passing
37.5 mm (1 ½ in.)	100	0.0
25.0 mm (1 in.)	95 to 100	1.0
12.5 mm (½ in.)	25 to 60	4.0
4.75 mm (No. 4)	0 to 10	4.0
2.36 mm (No. 8)	0 to 5	1.0

11.4 *Air-Entraining Admixture*—Except when tests are made in accordance with 11.5 using an air-entraining admixture proposed for specific work, the air-entraining admixture used in the concrete mixtures specified in Section 12 shall be a material such that, when used to entrain the specified amount of air in the concrete mixture, will give concrete of satisfactory resistance to freezing and thawing. The air-entraining admixture shall conform to Specification C260.

11.5 *Concrete for Specific Use*—The materials in this section are for specific use, such as for testing the cold-weather admixture system in simulated job concrete mixtures. To test the cold-weather admixture system for use in specific work, the cementitious materials, aggregates (See 11.3), other chemical admixtures, and air-entraining admixture used shall be representative of those used in the work. Add the cold-weather admixture system in the same manner and at the same time during the batching and mixing sequence as it will be added on the job. Proportion the concrete mixture to be similar to that used in the work. If the maximum size of coarse aggregate in the job concrete is greater than 25.0 mm [1 in.], screen the fresh concrete over a 25.0 mm (1 in.) sieve prior to fabricating the specimens to be tested.

12. Proportioning Concrete Mixtures

12.1 *Preparation and Batching*—Prepare all materials and make all weighing as prescribed in Practice C192/C192M. Prepare all materials so that the test concrete temperature, at the time of specimen casting, shall be 14 ± 2 °C [57 ± 3 °F]. Prepare all control concrete materials according to 14.6.2.

12.2 *Proportions*—Concrete mixtures not for specific uses shall be proportioned using ACI 211.1 (See Note 4). After evaluation of trial mixtures, aggregate proportions shall be adjusted as needed to obtain workable, cohesive mixtures with the correct yield. Unless otherwise specified, the cold-weather admixture system shall be added with the second increment of mixing water added to the mixer.

12.2.1 The cementitious materials content shall be 357 ± 3 kg/m^3[600 ± 5 lb/yd^3].

12.2.2 For the first trial mixture, refer to the table on volume of coarse aggregate in ACI 211.1 for guidance on amount of coarse aggregate to use for the fineness modulus of the fine aggregate being used.

NOTE 4—Values in the referenced table of ACI 211.1 are intended to ensure workable mixtures with the least favorable combinations of aggregates used. It is suggested, therefore, that for a closer approximation of the proportions required for this test, the volume of coarse aggregate (in the dry-rodded condition) per unit volume of concrete selected from ACI 211.1 be increased by about 0.07 for the first trial mixture.

12.2.3 The target air content of air-entrained concrete shall be 6 %.

12.2.4 Adjust the water content to obtain a slump of 150 ± 15 mm [6 ± ½ in.].

The workability of the control concrete mixture shall be suitable for consolidation by hand rodding and the concrete mixture shall have the lowest water content possible. Achieve these conditions by final adjustment in the amount of fine aggregate or in the amount of total aggregate, or both, while maintaining yield and slump.

12.3 *Specimens*—Prepare concrete mixtures with and without the cold-weather admixture system. Control concrete specimens shall be cured in above-freezing conditions and test concrete specimens in below-freezing conditions as specified

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:36 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

in Section 14 and Section 16. Add the cold-weather admixture system in a manner recommended by the manufacturer and in an amount necessary to comply with Table 1.

12.4 *Non-Air-Entrained Concrete*—When the cold-weather admixture system is to be tested in non-air-entrained concrete, the air content of both the control and test mixtures shall be 3.5 % or less, and the difference between the air contents of the two mixtures shall not exceed 1.0 percentage point. If necessary, air-entraining admixture shall be added to the control mixture to achieve the same air content as the test concrete. Tests for freezing and thawing are not required.

12.5 *Air-Entrained Concrete*—When the cold-weather admixture system is to be tested in air-entrained concrete, the air-entraining admixture shall be added to the control concrete and, if necessary, to the test concrete mixtures in sufficient amounts to produce air contents of 6 ± 1.5 % when measured according to Test Method C231. The difference between the air content of the control concrete mixture and that of the test concrete mixture shall not exceed 0.5 percentage point. Tests for freezing and thawing are required.

13. Mixing

13.1 Machine mix the concrete as prescribed in Practice C192/C192M.

NOTE 5—Tests in Sections 14-18 are based on arbitrary stipulations, which make possible highly standardized testing in the laboratory, and are not intended to simulate actual job conditions.

14. Test and Properties of Freshly Mixed Concrete

14.1 Samples of freshly mixed concrete from at least three separate batches for each control and test concrete mixture shall be tested according to 14.2-14.6.

14.2 *Slump*—Test Method C143/C143M.

14.3 *Density*—Test Method C138/C138M

14.4 *Air Content*—Test Method C231.

14.5 *Temperature of Freshly Mixed Concrete*—Test Method C1064/C1064M.

14.6 *Time of Initial Setting*—Test Method C403/C403M with the following exceptions:

14.6.1 Quantity of mortar used in each container for determining initial setting shall not exceed 5.7 L [350 $in.^3$].

14.6.2 *Control Concrete:* Condition concrete ingredients at 20 to 25 °C [68 to 77 °F] prior to mixing. Mix the concrete, prepare test specimens, and measure penetration resistance at this temperature. Make the initial penetration measurement 3 to 4 h after initial contact of the cement with the water.

14.6.3 *Test Concrete:* Measurements are made in a low-temperature environment. Unless otherwise specified, make the initial penetration measurement 3 to 5 h after initial contact of the cement with the water. Prepare three specimens: one for measuring setting time at low temperature; a dummy specimen for measuring temperature history; and a replicate specimen for verifying that freezing did not occur. Place the specimens into the low temperature environment within 40 min after the start of mixing. The temperature at the center of the specimen shall reach -5 ± 1 °C [23 ± 2 °F] not sooner than 6 h and not later than 8 h after placement into the cold temperature environment (See Note 6). Record the initial temperature of the dummy specimen, its temperature history every ½ h while in the low-temperature environment, and the time required to cool it from its initial temperature to the required temperature range.

NOTE 6—It may be desirable to use a series of baths, each at a different temperature, for cooling specimens to target temperature within the specified period.

14.6.3.1 To make certain that the test specimen did not freeze during the test, a replicate specimen (See Table 2) shall be removed from the low-temperature room and placed at 20 to 25 °C [68 to 77 °F] at the time the test specimen reaches initial setting. Penetration readings shall be made on the replicate specimen every 15 min for 2 h. If the penetration resistance continues to increase, the test specimen is considered not to have frozen. Conversely, if a decrease in penetration resistance is observed during the 2 h period, the test specimen is considered to have frozen and the admixture system fails to meet this specification. The results of this testing of the replicate specimen, including the thermal history of the dummy specimen recorded every ½ h, shall be included in the final report.

14.6.4 Calculate the average time of initial setting from the results of each batch of concrete. Calculate relative initial setting time by dividing the average time of initial setting of the test concrete by the average time of initial setting of the control concrete and multiplying by 100.

14.7 *Water-Cementitious Materials Ratio and Water Content*:

14.7.1 Determine the water-cementitious materials ratio of concrete as follows: Determine the amount of total water in the batch as the mass of water added to the batch, water occurring as free moisture on the aggregates, and water introduced by the admixtures. Determine the water-cementitious materials ratio as the mass of the total water divided by the mass of the

TABLE 2 Minimum Number of Specimens for each test.

cementitious materials. Calculate the volume of concrete from the total batch quantities and density in accordance with Test Method C138/C138M. Determine the water content as the mass of total water divided by the volume of the concrete batch. Determine the cementitious materials content as mass of cementitious materials divided by the volume of the concrete batch.

14.7.2 Calculate the relative water content of the test concrete as follows: Divide the average water content of all batches of test concrete by the average water content of all batches of the control concrete and multiply the quotient by 100.

15. Preparation of Test Specimens

15.1 Make sufficient number of specimens representing each test from at least three separate batches. The minimum numbers of specimens are shown in Table 2 (See Note 7). It is permitted to complete specimen fabrication in one, two, or three days of mixing provided control concrete specimens are made each day.

NOTE 7—It is recommended that more than the minimum number of specimens be prepared so that replacements are available in case some specimens are faulty.

15.2 *Manifestly Faulty Specimens*—Visually examine each test specimen before testing and discard any specimen found to be manifestly faulty. Visually examine each test specimen after testing and discard any test result associated with a specimen found to be manifestly faulty. If there are not enough replacement specimens to provide at least two valid results for each test, the entire test shall be disregarded and repeated. The test report shall be the average of the individual test results of the specimens tested or, in the event that one specimen or one result has been discarded, it shall be the average of the remaining test specimens.

16. Test Specimens for Hardened Concrete

16.1 *Number of Specimens*—The minimum number of specimens and the number of test ages are shown in Table 2.

16.2 *Types of Specimens*—Specimens made from control concrete and test concrete shall be prepared in accordance with the following:

16.2.1 *Compressive Strength*—Make specimens in accordance with Practice C192/C192M. Specimen size shall be 100- by 200-mm [4- by 8-in.] cylinders to facilitate adequate cooling rates using readily available cooling equipment. All specimens shall be cured in a sealed condition.

NOTE 8—Typically, plastic cylindrical molds are sealed with plastic caps. Alternately, a plastic bag may be placed over the top of a mold and held snugly to the side of the mold with a rubber band.

16.2.1.1 *Control Concrete:* Specimens shall be stored in a 23 ± 2 °C [73.5 ± 3.5 °F] environment within 40 min of initial contact of cement and water until time of testing.

16.2.1.2 *Test Concrete:* Specimens shall be stored in the low-temperature curing environment within 40 min after the start of mixing. Specimens shall be exposed to the same environment as the time of setting specimens as specified in 14.6.3. Use the dummy specimen to record the maximum initial starting temperature of one batch of test specimens, their temperature history while in the low-temperature environment, and the time required to cool the test specimens to the required temperature range. Test concrete specimens shall be stored in a sealed condition so that their internal temperatures are maintained at -5 ± 1 °C [23 ± 2 °F] until an age of 7 days from initial contact of cement and water. After 7 days, cure the test concrete in accordance with Practice C192/C192M until the 28-day test. After 28 days, cure the remaining test specimens at not less than 95 % relative humidity until time of test. The thermal history of the dummy specimen shall be included in the test report.

16.2.2 *Resistance to Freezing and Thawing*—Concrete specimens shall be prisms made in accordance with Practice C192/C192M, and having dimensions in accordance with Test Method C666/C666M. Make one set of two specimens from each batch of the control concrete and one set of two specimens from each batch of the test concrete. The air content of each mixture shall be as specified in 12.4 and 12.5. The control and test concrete specimens shall be cured in accordance with Practice C192/C192M. Test the specimens in accordance with Test Method C666/C666M, Procedure A, unless specified otherwise.

16.2.3 *Length Change*—Concrete specimens shall be made in accordance with Test Method C157/C157M, except for the following curing conditions. Make one specimen from each batch of the control concrete and one specimen from each batch of the test concrete. Remove the molds at 24 h and store all specimens in lime-saturated water at 23.0 ± 1.0 °C [73.5 ± 2.0 °F] until age of 28 days. At 28 days, remove all specimens from water bath and store in accordance with the air storage procedure in Test Method C157/C157M for an additional 28 days.

17. Tests on Hardened Concrete

17.1 *Compressive Strength*—Test in accordance with Test Method C39/C39M at 7, 28 and 90 days. For the 7-day tests, the test concrete specimens shall be moved from the low-temperature environment to a 23 ± 2 °C [73.5 ± 3.5 °F] environment for no less than 2 h and no more than 4 h before testing (See Note 9). The test concrete specimens shall be spaced at least 50 mm [2 in.] apart during this warming period. Record the temperature history of the dummy specimen from the time of removal from the low-temperature environment until testing. Compute the average compressive strength from the separate batches of test concrete and control concrete. Divide the average strength of the test concrete by the average strength of the control concrete at each test age and multiply by 100 to obtain relative strength. Report the results to the nearest 1 %.

NOTE 9—The intent is to have the center of the test concrete specimens at 4 and 7 °C [40 to 45 °F] at the time of testing to avoid possible influence of ice crystals inside the specimens.

17.1.1 *Resistance to Freezing and Thawing*—Comparison of the test concrete with the control concrete shall be made in accordance with Test Method C666/C666M, Procedure A, unless specified otherwise. Calculate the relative durability factor in accordance with Specification C260, where DF is the durability factor of the control concrete.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:36 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

17.1.2 *Length Change*—Measure the initial length at 28 days within 5 min of removing the specimen from curing water. After 28 days of air drying, determine the length in accordance with Test Method C157/C157M. The drying shrinkage is the length change during the 28-day drying period, based on the initial length at the time of removal of the specimen from the curing water, expressed as a percentage of the initial length to the nearest 0.001 %. Calculate the relative shrinkage by dividing the average shrinkage of the test concrete by the average shrinkage of the control concrete and multiplying by 100. If the shrinkage of the control concrete after 28 days is 0.030 % or greater, the relative shrinkage of the test concrete shall not exceed 135 %. If the shrinkage of the control concrete at 28 days is less than 0.030 %, the test concrete shrinkage shall be not more than 0.010 percentage points greater than the control concrete.

NOTE 10—Since the specific effects produced by a cold-weather admixture system may vary with the properties of other ingredients of the concrete, results of length change tests using aggregates of such a nature that the shrinkage on drying is low may not accurately indicate relative performance to be expected with other aggregates having properties such as to produce concrete of high shrinkage on drying.

18. Uniformity and Equivalence Tests

18.1 Perform the infrared analysis and relative density (specific gravity) procedures in accordance with Specification C494/C494M Section on Uniformity and Equivalence Tests.

19. Report

19.1 Report the following:

19.1.1 Results of tests specified in Section 14 and Sections 16-18 and the relevant specification requirements, with which they are compared,

19.1.2 Brand name, manufacturer's name, lot number, and the quantity represented by the sample of cold-weather admixture system under test,

19.1.3 Brand name, manufacturer's name and specification conformance for air entraining admixture and any other admixtures used,

19.1.4 Brand name, manufacturer's name, type, and specification conformance for cementitious materials used,

19.1.5 Producer's name, description, and specification conformance for fine and coarse aggregates,

19.1.6 Data on concrete mixtures used, including amounts and dosages of admixtures, cementitious materials content, water-cementitious materials ratios, water content, ratio of fine to coarse aggregates, slumps, total air contents, initial setting times, and temperature history of the dummy specimens stored at low-temperature conditions.

19.1.7 In the event that some of the tests have been waived, the circumstances under which such action was taken shall be stated.

20. Keywords

20.1 chemical admixture; cold-weather admixture; concrete; performance requirements

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this specification since the last issue, C1622/C1622M–06, that may impact the use of this specification. (Approved December 15, 2009)

(*1*) Added new 14.6.1 to restrict the size of specimen used for measuring time of setting and renumbered subsequent paragraphs.
(*2*) Revised 14.6.3 by specifying a range of time for the time of setting specimens to reach the target temperature.
(*3*) Revised 16.2.1.2 by requiring compressive strength specimens to be exposed to the same environment as the time of setting specimens.
(*4*) Revised 16.2.2 by reducing the number of speciments for testing resistance to freezing and thawing from three specimens per batch to two specimens per batch.
(*5*) Revised 16.2.3 by reducing the number of speciments for testing length change from three specimens per batch to one specimen per batch.
(*6*) Revised Table 2 for consistency with changes in 16.2.2 and 16.2.3.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1629/C 1629M – 06

Standard Classification for Abuse-Resistant Nondecorated Interior Gypsum Panel Products and Fiber-Reinforced Cement Panels[1]

This standard is issued under the fixed designation C 1629/C 1629M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This standard establishes classifications of abuse resistance based on minimum abuse-resistance performance of nondecorated interior gypsum panel products and fiber-reinforced cement panels (abuse resistant wall panels).

1.2 The values stated in inch-pound and SI (metric) units are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be used independent of the other. Values from the two systems shall not be combined.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 1154 Terminology for Non-Asbestos Fiber-Reinforced Cement Products

D 4977 Test Method for Granule Adhesion to Mineral Surfaced Roofing by Abrasion

D 5420 Test Method for Impact Resistance of Flat, Rigid Plastic Specimen by Means of a Striker Impacted by a Falling Weight (Gardner Impact)

E 695 Test Method of Measuring Relative Resistance of Wall, Floor, and Roof Construction to Impact Loading

2.2 *ISO Documents:*

ISO 6707-1 Building and Civil Engineering -- Vocabulary -- Part 1: General Terms

3. Terminology

3.1 Definitions of terms shall be in accordance with Terminologies C 11 and C 1154.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *failure (hard body impact), n*—test result constituted either by the penetration of the wall cavity by the impacting head of the impacting arm or the denting of the panel resulting in an indentation of a depth that exceeds the thickness of the test panel.

3.2.1.1 *Discussion*—Depth of the indentation on the test panel is measured from the face side.

3.2.2 *failure (soft body impact), n*—a test result constituted either by the breaking of the wall cavity by the soft body impactor or the residual deflection of any area on the test panel that exceeds the thickness of the test panel.

3.2.2.1 *Discussion*—Deformation of the test panel in the form of residual deflection is measured from the face side.

3.2.2.2 *deformation, n*—change of shape or dimension or both. **ISO 6707-1**

3.2.2.3 *surface damage, n*—pulverization of the core of the test panel at the point of impact, which is evidenced by cracking, creasing, or other visible damage short of failure as defined in 3.2.2.

3.2.3 *residual deflection, n*—permanent deformation of a building element, component, or structure after removal of applied force.

3.2.3.1 *Discussion*—Also called permanent set or residual deformation.

4. Significance and Use

4.1 Each abuse/impact property of abuse resistant wall panels is divided into three classification levels. The three levels of classification are: Level I, Level II, and Level III, with Level I representing the lowest rating for any given property. The test methods specified are utilized to establish the abuse-resistance classification of an abuse resistant wall panel. Each

[1] This classification is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Nov. 1, 2006. Published November 2006. Originally approved in 2005. Last previous edition approved in 2005 as C 1629/C 1629M – 05.

www.technobetar.ir

classification level requires a minimum overall specified performance. Any classified abuse resistant wall panel can be used at a classification level which is rated lower than the highest level qualified.

5. Basis of Classification

5.1 Abuse resistant wall panels are classified into one of three levels of abuse resistance based on minimum performance when tested in accordance with test methods that evaluate surface abrasion, indentation, soft body impact, and hard body impact as specified in 6.1 through 6.4.

5.2 Minimum requirements for each level are as shown in Tables 1-4.

6. Test Methods

6.1 *Surface Abrasion Test*—This test is conducted in accordance with Test Method D 4977 using a total load of 25.0 lb. The specimen is conditioned to constant weight at 70F and 50 % relative humidity and subjected to 50 abrasion cycles. The abrasive motion on the specimen creates measurable surface wear or indentation which is measured to determine the level of surface abrasion resistance.

NOTE 1—It is especially important to prepare the apparatus and condition the brush as specified in Test Method D 4977.

6.2 *Indentation Test*—This test, conducted in accordance with Test Method D 5420 (Gardner Impact), utilizes procedure GC, with a ⅝ in. hemispherical head and a 72 in.-lb. [12.6 J] impact energy. The depth of the indentation is measured to determine the level of indentation resistance.

6.3 *Soft Body Impact Test*—This test, conducted in accordance with Method E 695, is performed with the use of the standard leather bag filled with steel pellets to a weight of 60.0 lb [27.2 kg] and dropped through an angular distance until the specimen is impacted.

6.3.1 The specimen is mounted on nominal 2-by-4 wood studs 16 in. [400 mm] o.c. Point of impact is midway between studs at the mid-height of the test panel.

6.3.2 A single specimen is repeatedly impacted at a single point of impact in one cavity with the drop height being increased by 6 in. with each successive drop until structural failure as defined in 3.2.2 is achieved.

6.3.2.1 Surface damage and deformation are recorded following each impact, and the level of impact energy applied is calculated. The residual deflection shall be measured from the face side of the panel.

TABLE 1 Performance Requirements Surface Abrasion Resistance

Classification Level	Abraded Depth Maximum in. [mm]
1	0.126 [3.2]
2	0.059 [1.5]
3	0.010 [0.3]

TABLE 2 Performance Requirements Indentation Resistance

Classification Level	Indentation Maximum in. [mm]
1	0.150 [3.8]
2	0.100 [2.5]
3	0.050 [1.3]

TABLE 3 Performance Requirements Soft Body Impact Test

Classification Level	Soft Body Minimum ft-lbf [J]
1	90 [122]
2	195 [265]
3	300 [408]

TABLE 4 Performance Requirements Hard Body Impact

Classification Level	Hard Body Minimum ft-lbf [J]
1	50 [68]
2	100 [136]
3	150 [204]

NOTE 2—Surface damage and deformation, which do not constitute structural failure, may compound the results.

6.3.3 Following structural failure in the initial cavity, the procedure described in 6.3.2 is repeated on the next cavity, beginning with a drop height of 6 in. higher than the drop height causing structural failure in 6.3.2.

6.3.3.1 If structural failure in the second cavity occurs with the first drop, the test is terminated and the level of energy required to cause the single impact penetration or excessive deformation is calculated to determine the soft body impact resistance.

6.3.3.2 If structural failure in the second cavity occurs on the second or subsequent drop, repeat the procedure described in 6.3.3 in the next cavity, beginning with a drop height 6 in. higher than the drop height causing structural failure in the second cavity.

6.3.4 Repeat the procedures in 6.3.2 through 6.3.3.2 until structural failure occurs on a single drop in a fresh cavity, at which time the test is terminated and the level of energy required to cause the single impact penetration or excessive deformation is calculated to determine the soft body impact resistance.

6.4 *Hard Body Impact Test*—This test is conducted in accordance with the method described in Annex A1 or with another apparatus equipped with an equivalent impact head that is capable of delivering equivalent impact loads.

ANNEX

(Mandatory Information)

A1. HARD BODY IMPACT TEST

A1.1 Scope

A1.1.1 The hard body impact test measures resistance to penetration of a wall panel when impacted by a rigid body. Failure in the hard body impact test is achieved when the impacting head completely penetrates through the test panel, or the depth of the indentation exceeds the thickness of the product being tested when measured from the face side following impact, or both.

A1.2 Summary of Test Method

A1.2.1 A nominal 2 by 2 ft [610 by 610 mm] specimen is mounted to the apparatus frame. A ramming arm impactor strikes the wall specimen while swinging in an arc. The impactor is dropped from a fixed height to impart specific design energy to the wall specimen. Weights are progressively added to the impactor to increase the design impact energy until specimen failure occurs. For each impact, a new test specimen is used.

A1.3 Significance and Use

A1.3.1 The test method measures relative performance of interior wall panel materials. Although the test panel is mounted on framing and tested vertically as a wall assembly, the impact damage is normally limited to a small area.

A1.4 Apparatus

A1.4.1 The apparatus consists of a rigid frame with a ramming arm pinned to swing in an arc. See Figs. A1.1 and A1.2. The frame is constructed of 14 ga, 1 5⁄8 by 1 5⁄8 in. [41.3 by 41.3 mm] B-Line B24 Regular Framing Channels.

A1.4.1.1 The dimensions and details of the ramming arm impactor are shown in Fig. A1.3. The ramming arm impactor consists of a cylindrical steel impact head (made by milling a round steel bar), a structural steel tubing with square cross-section, two square steel plates (front and rear end plates of the structural steel tubing), a steel plate pivot arm, a round steel bar (to add weights), and a rectangular steel plate attached to the bottom of the structural steel tubing. The total weight of the components of the ramming arm impactor is 20.0 lb [9.07 kg] ± 0.5 %, as shown in Table A1.1. The center of mass of the ramming arm impactor coincides with the location of the steel round bar (that is, the weight bar). Additional weights are attached to the weight bar to increase the impacting energy.

TABLE A1.1 Weight (Mass) Schedule for the Components of the Ramming Arm Impactor

Component	Weight lb, ± 0.5 %	Mass kg, ± 0.5 %
Structural Steel Tubing (square cross-section)	8.10	3.67
Steel Plate Pivot Arm	1.10	0.50
Front Square Steel Plate (end plate attached to the front of the structural steel tubing)	0.90	0.41
Rear Square Steel Plate (end plate attached to the back of the structural steel tubing)	0.90	0.41
Cylindrical Steel Impact Head	1.90	0.86
Steel Round Bar (Weight Bar)	2.60	1.18
Bottom Rectangular Steel Plate (attached to the bottom of the structural steel tubing)	4.50	2.04

A1.4.1.2 The ramming arm impactor shall have a suitable mechanism to secure it at the top of the swing. An example of such a mechanism is a small eyebolt attached to the back of the impactor. When released from the top of the swing, the drop height of the center of mass of the ramming arm impactor shall be 12.0 in. [305 mm].

A1.4.1.3 The ramming arm is located such that the face of the impactor head, when hanging free at the bottom of the arc, is in the same plane as the surface of the test specimen so that, when dropped, the impactor head strikes the surface of the specimen at the bottom of the arc.

A1.5 Test Specimen

A1.5.1 The test wall assembly shall be constructed by attaching a 2 by 2 ft [610 by 610 mm] specimen of the interior wall panel material to a frame of 3 5⁄8 in. [92 mm] deep 20 ga steel studs with Type S-12 bugle head screws spaced 8 in. [200 mm] o.c. as shown in Fig. A1.4. The length of the screws shall be 1 1⁄4 in. [32 mm] for panels up to 5⁄8 in. [15.9 mm] in thickness. For panels with thickness greater than 5⁄8 in. [15.9 mm], the length of the screws shall be at least 5⁄8 in. [16 mm] longer than the panel thickness.

A1.6 Preparation of Apparatus

A1.6.1 The apparatus shall be securely anchored to a level floor to prevent sliding or rocking of the apparatus during impact.

A1.7 Procedure

A1.7.1 The test wall assembly shall be securely clamped to the face of the apparatus so that the surface of the test specimen is in the same plane as the face of the impact head.

A1.7.1.1 A new test wall assembly shall be used for each impact.

A1.7.2 The ramming arm is raised to the top or the arc and secured with a pin.

A1.7.3 The pin is removed, allowing the arm to swing freely and strike the test specimen.

A1.7.4 A new test wall assembly is mounted to the apparatus and the weight on the impactor is increased by adding 2.50 lb [1.10 kg] to the weight bar and the test repeated.

A1.7.5 The test shall be performed by incrementally increasing the barbell free weights on the impactor until a failure impact energy is achieved.

A1.7.5.1 The failure impact energy is defined as the minimum energy required for the impactor to penetrate through the face of the panel into the stud cavity, or when the depth of the indentation exceeds the thickness of the product being tested when measured from the face side.

H	24	609.6			

NOTE—All framing members shall be B-Line B24 Regular Framing Channels cut to the specified dimensions in this sketch. These channels are 14 gauge and have an outside dimension of 1 5/8 by 1 5/8 in. (41.3 by 41.3 mm).

FIG. A1.1 Axonometric of Hard Body Apparatus Framing Members (not to scale)

A1.7.6 Testing shall continue until the failure impact energy is confirmed on three identical assemblies for each wall panel material being tested.

A1.7.7 Impact energy and damage at each test shall be recorded.

A1.8 Calculation of Energy Impact

A1.8.1 Impact energy in ft-lb units is calculated as the product of the weight of the impacting instrument and the drop height:

$$E = (w \times h) \quad \text{(A1.1)}$$

where:
E = impact energy, ft-lb,
w = weight of impactor, lb, and
h = drop height of the center of mass of the impactor, ft.

A1.8.2 Impact energy in SI units is calculated as the product of the mass of the following three quantities—the mass of the impactor, gravitational acceleration, and the drop height of the center of mass of the impactor:

$$E = (m \times g \times h) \quad \text{(A1.2)}$$

where:
E = impact energy, J,
m = mass of impactor, kg,
g = gravitational acceleration, 9.81 ms^{-2}, and
h = drop height of the center of mass of the impactor, m.

A1.9 Precision and Bias

A1.9.1 The precision and bias of this test method has not been determined.

SUMMARY OF CHANGES

Committee C11 has identified the location of selected changes to this classification since the last issue, C 1629/C 1629M – 05, that may impact the use of this classification. (Approved November 1, 2006)

(*1*) Revised the titles of Tables 1-4.
(*2*) Revised Section 3.
(*3*) Revised Section 6.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM International, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: C 1646/C 1646M – 08a

Standard Practice for Making and Curing Test Specimens for Evaluating Resistance of Coarse Aggregate to Freezing and Thawing in Air-Entrained Concrete[1]

This standard is issued under the fixed designation C 1646/C 1646M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice covers procedures for making and curing test specimens for evaluating resistance of normal-weight coarse aggregates to freezing and thawing in air-entrained concrete in accordance with Test Method C 666/C 666M, Procedure A or B.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This practice does not purport to address all the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged use.[2])

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 143/C 143M Test Method for Slump of Hydraulic-Cement Concrete

C 150 Specification for Portland Cement

C 173/C 173M Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

C 231 Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method

C 490 Practice for Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

C 494/C 494M Specification for Chemical Admixtures for Concrete

C 666/C 666M Test Method for Resistance of Concrete to Rapid Freezing and Thawing

D 75 Practice for Sampling Aggregates

2.2 *ACI Standard:*[4]

211.1 Practice for Selecting Proportions for Normal, Heavyweight, and Mass Concrete

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this specification, refer to Terminology C 125.

4. Significance and Use

4.1 This practice provides standard requirements for evaluating coarse aggregate in air-entrained concrete subjected to freezing and thawing in accordance with Test Method C 666/C 666M.

4.2 Concrete having an adequate air-void system may not be resistant to freezing and thawing if it contains coarse aggregate that becomes critically saturated. An aggregate particle is considered to be critically saturated when there is insufficient

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.67 on Resistance to the Environment.

Current edition approved Dec. 15, 2008. Published January 2009. Originally approved in 2007. Last previous edition approved in 2008 as C 1646/C 1646M – 08.

www.technobetar.ir

unfilled pore space to accommodate the expansion of water that accompanies the freezing.

4.3 The potential of the coarse aggregate to cause damage due to cycles of freezing and thawing is evaluated by Test Method C 666/C 666M.

5. Apparatus

5.1 Equipment for mixing concrete and procedures for making and curing test specimens shall be in accordance with Practice C 192/C 192M.

6. Coarse Aggregate Preparation

6.1 *Sampling*—Sample in accordance with Practice D 75.

6.2 *Grading*—When coarse aggregates are to be compared using this practice, standardize the coarse aggregate gradings by recombining individual size fractions in accordance with Table 1 for the appropriate size aggregate being tested. Bring the as-received sample to a saturated-surface-dry (SSD) condition or drier prior to sieving. Do not oven-dry the coarse aggregate sample. If necessary, air drying of the sample to achieve this condition is permitted. The nominal-maximum-aggregate size shall not exceed one-third the least dimension of the test specimen to be used. Fine aggregate shall meet the requirements of Specification C 33 and the grading shall conform to Table 1.

6.3 *Conditioning*—Condition fine and coarse aggregates as follows:

6.3.1 *Fine Aggregate*—Uniformly wet the fine aggregate 24 h prior to mixing of concrete so that the moisture content exceeds the saturated-surface-dry condition but there is no tendency for loss of surface water by draining. Keep the fine aggregate covered to prevent evaporation prior to use.

6.3.2 *Coarse Aggregate*—Immerse the coarse aggregate in water 24 h prior to mixing of concrete. On the day of mixing, decant the water from the coarse aggregate.

7. Concrete Mixture

7.1 *Ingredients*—The portland cement shall meet the requirements of Specification C 150, Type I or Type II. Batches for a particular test series shall use cement, fine aggregate, and air-entraining admixture taken from the same lot.

7.2 *Air-entraining admixture*—As described in Specification C 494/C 494M, section on Air-Entraining Admixture (See Note 1).

NOTE 1—As stated in Specification C 494/C 494M, note that "neutralized Vinsol resin" is required if no material is designated by the person or agency for whom the testing is being performed.

7.3 *Proportions*—Except when tests are being made where mixture proportions are those proposed for the work, proportion all concrete using ACI 211.1 conforming to the following requirements:

7.3.1 The cement content shall be 307 ± 3 kg/m^3 [517 ± 5 lb/yd^3]

7.3.2 The air content used in the computation of mixture proportions shall be in accordance with Table 2. The amount of air-entraining admixture used shall be such as to give an air content as prescribed in Table 2, ± 1 %, when tested according to Test Method C 231 or Test Method C 173/C 173M.

7.3.3 The mixture shall contain the amount of coarse aggregate shown in the "Volume of Coarse Aggregate Per Unit of Volume of Concrete" table of ACI 211.1 for the nominal-maximum size of aggregate and for the fineness modulus of the fine aggregate being used.

7.3.4 Adjust the water content and fine aggregate content to obtain a slump of 75 ± 25 mm [3 ± 1 in.] when tested in accordance with Test Method C 143/C 143M.

7.4 *Mixing*—Machine mix the concrete as prescribed in Practice C 192/C 192M.

8. Specimen Preparation and Conditioning

8.1 *Specimen Preparation*—The type and size of the test specimen and the method for molding shall be in accordance with the Test Specimen section of Test Method C 666/C 666M, unless otherwise specified. If length change testing is to be performed as a permitted option in Test Method C 666/C 666M, fit the specimens with axially centered stainless steel gauge studs in accordance with Practice C 490.

8.2 *Number of Specimens*—Make at least three freezing-and-thawing test specimens from each batch. In addition, make at least three cylindrical specimens from each batch for strength verification. The cylindrical specimens shall be made in accordance with Practice C 192/C 192M and tested in accordance with Test Method C 39/C 39M.

8.3 *Curing*—Complete initial storage and remove from molds in accordance with Practice C 192/C 192M. After removal from the molds, inspect for defects and store in saturated limewater at 23.0 ± 2.0 °C [73.5 ± 3.5 °F] to an age of 14 days.

10.1 aggregate; coarse aggregate; freezing and thawing

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1646/C 1646M – 08, that may impact the use of this practice. (Approved December 15, 2008)

(*1*) Revised the title, 1.1, 4.1, 4.2, and Keywords to replace the term “frost” with “freezing and thawing.”

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1646/C 1646M – 07, that may impact the use of this practice. (Approved August 1, 2008)

(*1*) Revised 1.2 and put SI units first throughout the standard to comply with C09’s policy addressing SI units.
(*2*) Added new Section 3 Terminology and renumbered subsequent sections.
(*3*) Added new Note 1 after 7.2.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1658/C 1658M – 06

Standard Specification for Glass Mat Gypsum Panels[1]

This standard is issued under the fixed designation C 1658/C 1658M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the glass mat gypsum panels described in 1.1.1-1.1.3.

1.1.1 *Glass mat interior gypsum panel*, designed for use on walls, ceilings, or partitions and that affords a surface suitable to receive decoration.

1.1.2 *Glass mat coreboard gypsum panel, and glass mat shaftliner gypsum panel*, designed for use as a base in multilayer systems or as gypsum studs or cores in semisolid or solid gypsum board partitions, or in shaftwall assemblies.

1.1.3 *Glass mat water-resistant gypsum panel*, designed to be used as a base for the application of ceramic or plastic tile on walls or ceilings. This product is also suitable for decoration. (*This is distinct from a coated glass mat water-resistant gypsum panel ASTM C 1178.*)

1.2 Specifications applicable to all glass mat gypsum panels are located in Sections 1-4 and 8-10. Specifications applicable to specific glass mat gypsum panels are located in the following sections:

	Section
Glass mat interior gypsum panel	5
Glass mat coreboard gypsum panel, and glass mat shaftliner gypsum panel	6
Glass mat water-resistant gypsum panel	7

1.3 The values stated in either inch-pound units or SI (metric) are to be regarded separately as standard. Within the text, the SI units are shown in brackets. The values stated in each system shall be used independent of the other. Values from the two systems shall not be combined.

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 11 Terminology Relating to Gypsum and Related Building Materials and Systems

C 473 Test Methods for Physical Testing of Gypsum Panel Products

C 645 Specification for Nonstructural Steel Framing Members

C 1264 Specification for Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage of Gypsum Panel Products

E 84 Test Method for Surface Burning Characteristics of Building Materials

E 119 Test Methods for Fire Tests of Building Construction and Materials

3. Terminology

3.1 Definitions used in this specification shall be in accordance with Terminology C 11.

3.2 *Definitions of Terms Specific to This Standard:*

3.3 *glass mat*, *n*—a mat of glass fibers with or without a binder.

4. Materials and Manufacture

4.1 Glass mat gypsum panel shall consist of a noncombustible core, essentially gypsum, surfaced with glass mat partially or completely embedded in the core.

4.1.1 Glass mat interior gypsum panel shall consist of a noncombustible core, essentially gypsum, surfaced on both the face and back with glass mat partially or completely embedded into the core.

4.1.2 Glass mat coreboard gypsum panel, and glass mat shaftliner gypsum panel shall be either a single panel or composed of two factory-laminated gypsum panels to provide up to 1 in. [25.4 mm] total nominal thickness, surfaced on both face and back with glass mat partially or completely embedded into the core.

4.1.3 Glass mat gypsum water-resistant panel shall consist of a noncombustible water-resistant core, essentially gypsum, surfaced on the face with water-resistant glass mat partially or completely embedded into the core.

4.2 *Glass Mat Interior Gypsum panel, and Glass Mat Water-Resistant gypsum panel, type X (special fire-resistant)* designates glass mat gypsum panel complying with this specification that provide not less than 1 h fire resistance for panel ⅝ in. [15.9 mm] thick or ¾ h fire resistance for panel ½ in. [12.7 mm] thick, applied parallel with and on each side of load bearing 2 by 4 wood studs spaced 16 in. [406 mm] on center

[1] This test method is under the jurisdiction of ASTM Committee C11 on Gypsum and Related Building Materials and Systems and is the direct responsibility of Subcommittee C11.01 on Specifications and Test Methods for Gypsum Products.

Current edition approved Dec. 1, 2006. Published January 2007.

with 6d coated nails, 1⅞ in. [48 mm] long, 0.0915 in. [2.3 mm] diameter shank, ¼ in. [6.4 mm] diameter heads, spaced 7 in. [178 mm] on center with glass mat gypsum panel joints staggered 16 in. [406 mm] on each side of the partition and tested in accordance with Test Methods E 119.

NOTE 1—Consult manufacturers for independent test data on assembly details and fire resistance classifications for other types of construction. See fire test reports or listings from recognized fire testing laboratories for assembly particulars, materials, and classifications.

4.3 *Glass Mat Shaftliner gypsum panel*, type X, designates glass mat gypsum shaftliner panel complying with this specification that meets the acceptance criteria for temperature rise for not less than panels 1-in. [25.4 mm] thick, when applied in a double layer solid non-load bearing partition as described in 4.3.2 and tested in accordance with Test Methods E 119 with thermocouple locations as specified in 4.3.2.

4.3.1 Two layers of glass mat gypsum shaftliner panel applied vertically and friction fit into vertical 25-gauge steel "H" members, 2-in. [50.8 mm] deep for panels 1-in. [25.4 mm] thick, spaced 24-in. [610 mm] on centers and 25-gauge steel track at the perimeter of the partition. "H" members shall be formed with a single web or shall be two pieces of perimeter track fastened together along the web with screws spaced 24-in. [610 mm] on centers.

4.3.2 Temperature rise on the unexposed surface shall be measured using not less than five thermocouples; one shall be located at the center of the assembly and one shall be located at the center of each quadrant. Thermocouples shall be located not less than 3-in. [76 mm] from an "H" member.

4.4 Glass mat gypsum panels shall have a flame spread index of not more than 25 when tested in accordance with Test Method E 84.

4.5 *Physical Properties, Dimensions, and Tolerances of Glass Mat Gypsum Panel*:

4.5.1 Specimens shall be taken from the samples obtained in accordance with Specification C 1264.

4.5.1.1 Specimens shall be tested in accordance with Test Methods C 473.

4.5.2 *Core, End, and Edge Hardness*—The specimens shall have an average hardness of not less than 15 lbf [67 N] when tested by Method A or by Method B.

4.5.3 *Edges and Ends*—The edges and ends shall be straight.

4.5.4 *Length*—The tolerance in length shall be ± ¼ in. [± 6 mm].

4.5.5 *Tapered Edge Depth*—The average thickness of the edge of recessed or tapered edge glass mat gypsum panel shall be not less than 0.020 in. [0.51 mm] but not more than 0.090 in. [2.29 mm] less than the average thickness of the glass mat gypsum panel.

5. Glass Mat Interior Gypsum Panel

5.1 *Physical Properties of Glass Mat Interior Gypsum Panel*:

5.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A or B Load, lbf [N] Bearing edges perpendicular to the panel edge	Load, lbf [N] Bearing edges parallel to the panel edge
¼ [6.4]	50 [222]	40 [178]
½ [12.7]	100 [445]	80 [356]
⅝ [15.9]	140 [623]	100 [445]

5.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, sixteenths of an in. [mm]
¼ [6.4]	not required
½ [12.7]	5 [8]
⅝ [15.9]	4 [6]

5.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A or B lbf [N]
¼ [6.4]	40 [178]
½ [12.7]	80 [356]
⅝ [15.9]	90 [400]

5.2 *Dimensions and Tolerances of Glass Mat Interior Gypsum Panel*:

5.2.1 *Thickness*—The nominal thickness shall be from ¼ to ⅝ in. [6.4 to 15.9 mm] with tolerances in the nominal thickness of ± 1/64 in. [± 0.4 mm], and with local variations of ± 1/32 in. [± 0.8 mm] from the nominal thickness.

5.2.2 *Width*—The width shall be up to 48 in. [1220 mm], or up to 54 in. [1370 mm], with a tolerance of 3/32 in. [3 mm] under the specified width.

5.2.3 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the board.

5.3 *Edges*:

5.3.1 The edges of glass mat interior gypsum panel shall be either square, beveled, featured, tapered, or featured and tapered.

6. Glass Mat Coreboard Gypsum Panel, and Glass Mat Shaftliner Gypsum Panel

6.1 *Physical Properties of Glass Mat Coreboard Gypsum Panel and Glass Mat Shaftliner Gypsum Panel*:

6.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Method A or B Load, lbf [N] Bearing edges perpendicular to the panel edge	Load, lbf [N] Bearing edges parallel to the panel edge
1 [25.4]	230 [1023]	80 [356]

6.2 *Dimensions and Tolerances of Glass Mat Coreboard Gypsum Panel, and Glass Mat Shaftliner Gypsum Panel*:

6.2.1 *Thickness*—The nominal thickness shall be 1 in. [25.4 mm] with tolerances in the nominal thickness of ± 1/32 in. [± 0.8 mm], and with local variations of ± 1/16 in. [± 1.6 mm] from the nominal thickness.

6.2.2 *Width*—The width shall be from 16 to 48 in. [406 to 1220 mm] with a tolerance of ± ⅛ in. [3 mm] under the specified width.

6.2.3 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the board.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.3 *Edges*—The edges shall be either square, beveled, round, V-tongue and groove, or featured.

7. Glass Mat Water-Resistant Gypsum Panel

7.1 *Physical Properties of Glass Mat Water-Resistant Gypsum Panel*:

7.1.1 *Flexural Strength*—The specimens shall be tested face up and face down. The average breaking load shall be not less than the following:

Thickness, in. [mm]	Load, lbf [N] Bearing edges perpendicular to the panel edge	Method A or B Load, lbf [N] Bearing edges parallel to the panel edge
½ [12.7]	100 [445]	80 [356]
⅝ [15.9]	140 [623]	100 [445]

7.1.2 *Humidified Deflection*—The specimens shall have an average deflection of not more than the following:

Thickness, in. [mm]	Deflection, sixteenths of an in. [mm]
½ [12.7]	5 [8]
⅝ [15.9]	4 [6]

7.1.3 *Nail Pull Resistance*—The specimens shall have an average nail-pull resistance of not less than the following:

Thickness, in. [mm]	Method A or B lbf [N]
½ [12.7]	80 [356]
⅝ [15.9]	90 [400]

7.1.4 *Water Resistance*—The specimens shall have an average water absorption of not more than 5 weight % after 2-h immersion.

7.1.5 *Surface Water Absorption*—The specimens shall have an average face surface water absorption of not more than 1.6 g after 2 h of elapsed time.

7.2 *Dimensions and Tolerances of Glass Mat Water-Resistant Gypsum Panel*:

7.2.1 *Thickness*—The nominal thickness shall be ½ or ⅝ in. [12.7 or 15.9 mm] with tolerances in the nominal thickness of ± 1/64 in. [± 0.4 mm], and with local variations of ± 1/32 in. [± 0.8 mm] from the nominal thickness.

7.2.2 *Width*—The width shall be up to 48 in. [1220 mm], or up to 54 in. [1370 mm], with a tolerance of 3/32 in. [3 mm] under the specified width.

7.2.3 *End Squareness*—Corners shall be square with a tolerance of ± ⅛ in. [± 3 mm] in the full width of the board.

7.3 *Edges*—The edges shall be either square, beveled, featured, tapered, or featured and tapered.

8. Finish and Appearance

8.1 The glass mat gypsum panel surface shall be true and free from imperfections that would render it unfit for use with or without decoration.

9. Sampling, Inspection, Rejection, Certification, Packaging, Marking, Shipping, Handling, and Storage

9.1 Sampling, inspection, rejection, certification, packaging, marking, shipping, handling, and storage of glass mat gypsum panel shall be in accordance with Specification C 1264.

10. Keywords

10.1 ceiling; coreboard; glass mat; glass mat gypsum panel; partitions; shaftliner; type X; wall; water-resistant

APPENDIX

(Nonmandatory Information)

This appendix gives general information and also suggestions for inclusions to be made elsewhere by the specifier. They are not part of this specification.

The definition of type X as given in 4.2 and 4.3 and the alternate definition given in this appendix, are intended only as a test to define the glass mat gypsum panel as meeting the requirements of type X products. These tests do not indicate a preferred application nor do they limit the use of the product in other fire rated assemblies.

All gypsum panel products for which type X is defined, except shaftliner gypsum panel, use the same test for type X products, therefore the type X definition indicates a consistent level of fire resistance.

X1. ALTERNATE DEFINITION FOR TYPE X

X1.1 Glass mat gypsum panel, type X (special fire-resistant) designates glass mat gypsum panel providing a greater fire-resistance than regular glass mat gypsum panel of the same thickness. Type X (special fire-resistant) glass mat gypsum panel, when tested in accordance with Test Methods E 119, shall provide the following minimum fire resistance ratings for the assemblies described:

X1.1.1 One hour for a ⅝-in. [15.9-mm] thickness applied to a partition in a single-layer application on each side of 3 ⅝-in. [92-mm] deep non-load bearing galvanized steel studs complying with Specification C 645, spaced 24 in. [610 mm] on center. The ⅝-in. [15.9-mm] thick gypsum board 48 in. [1220 mm] wide shall be attached using 1-in. [25-mm] long drywall screws spaced 8 in. [203 mm] on center along the edges and

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:31 EDT 2010

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

ends, and 12 in. [305 mm] along intermediate studs. All joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly, and

X1.1.2 Two hours for a ½-in. [12.7-mm] thickness applied to a partition in a double-layer application on each side of 2 ⅝-in. [64-mm] deep non-load bearing galvanized steel studs complying with Specification C 645, spaced 24 in. [610 mm] on center. The 48-in. [1220-mm] wide base layer shall be attached using 1-in. [25-mm] long drywall screws spaced 12 in. [305 mm] on center along board edges, ends, and along intermediate studs. Joints shall be oriented parallel to and located over studs and staggered on opposite sides of the assembly. The 48-in. [1220-m] wide face layer shall be attached using 1 ⅝-in. [41-mm] long drywall screws spaced 12 in. [305 mm] along board edges, ends, and along intermediate studs. Joints shall be oriented parallel to and located over studs, offset 24 in. [610 mm] from the base layer joints, and staggered on opposite sides of the assembly.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1679 – 08

Standard Practice for Measuring Hydration Kinetics of Hydraulic Cementitious Mixtures Using Isothermal Calorimetry[1]

This standard is issued under the fixed designation C 1679; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice describes the apparatus and procedure for measuring relative differences in hydration kinetics of hydraulic cementitious mixtures, either in paste or mortar (See Note 1), including those containing admixtures, various supplementary cementitious materials (SCM), and other fine materials by measuring the thermal power using an isothermal calorimeter.

NOTE 1—Paste specimens are often preferred for mechanistic research when details of individual reaction peaks are important or for particular calorimetry configurations. Mortar specimens may give results that have better correlation with concrete setting and early strength development and are often preferred to evaluate different mixture proportions for concrete. Both paste and mortar studies have been found to be effective in evaluating concrete field problems due to incompatibility of materials used in concrete mixtures.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning—**Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

3. Terminology

3.1 *Definitions*—For definitions of terms used in this practice, refer to Terminology C 125 and Terminology C 219.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *baseline*, *n*—the signal from the calorimeter when there is an inert specimen in the instrument.

3.2.2 *calibration coefficient*, *n*—a factor that relates the value recorded by the data acquisition system to the thermal power output.

3.2.2.1 *Discussion*—Normally recorded data are in volts and the calibration coefficient has units of watts per volt (W/V). Some calorimeters may have internal automatic calibration and will give the output in watts without the user having to specify the calibration coefficient.

[1] This practice is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.48 on Performance of Cementitious Materials and Admixture Combinations.

Current edition approved June 1, 2008. Published July 2008. Originally approved in 2007. Last previous edition approved in 2007 as C 1679 – 07.

www.technobetar.ir

3.2.3 *combined mixture*, *n*—combination of all the materials that are introduced into the calorimeter for measuring hydration kinetics.

3.2.4 *hydration time*, *n*—the elapsed time from initial contact between the cementitious materials and the mix water.

3.2.5 *inert specimen*, *n*—specimen placed within the isothermal calorimeter made of a non-reactive material of similar thermal properties (mainly heat capacity) as the reacting specimen made of the cementitious test mixture.

3.2.5.1 *Discussion*—The output from the calorimeter is the difference between the heat flow from the test specimen and the inert specimen. The use of an inert specimen substantially decreases the noise and drift of the measured heat flow.

3.2.6 *isothermal calorimeter*, *n*—a calorimeter that measures heat flow from a specimen maintained at a constant temperature by intimate thermal contact with a constant temperature heat sink.

3.2.7 *isothermal calorimetry*, *n*—an experimental technique to monitor the thermal power output from a specimen kept at near isothermal conditions.

3.2.8 *isothermal hydration profile*, *n*—the thermal power plotted as a function of hydration time, which provides an indication of the rate of hydration over time at a given temperature.

3.2.9 *main hydration peak*, *n*—the broadest peak in the isothermal hydration profile that starts at the end of the dormant period and for a well-balanced mixture lasts for several hours (See Fig. 1).

3.2.10 *near isothermal conditions*, *n*—a constant temperature with a permissible variation of ± 1.0 °C.

3.2.11 *specimen holder*, *n*—container within the isothermal calorimeter that conducts the heat from the specimen in the vial to the heat flow sensor.

3.2.12 *stock solution*, *n*—a solution of admixture in water prepared to enable more precise volumetric addition of small quantities of admixture, typically made by pipetting known volumes of admixture into a volumetric flask and diluting it to the flask's fixed volume.

3.2.13 *sulfate addition*, *n*—the addition of a soluble sulfate source (such as gypsum, calcium sulfate hemihydrate, alkali sulfate) to a combined mixture to investigate whether a given combination of materials is in sulfate balance.

3.2.14 *sulfate balance of mixture*, *n*—the situation when the size of the main hydration peak is not increased by sulfate additions; in some cases where the main peak is increased in size by added sulfate, it will also be accelerated in time.

3.2.15 *sulfate depletion point*, *n*—the onset of accelerated aluminate activity that for a portland cement in absence of supplementary cementitious material (SCM) and admixture may take place after the main hydration peak.

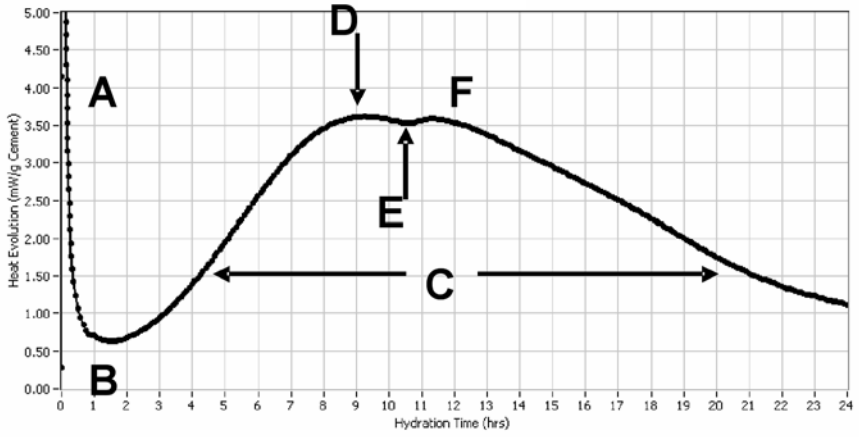
3.2.15.1 *Discussion*—The sulfate depletion point may become impossible to detect without further addition of gypsum or plaster for certain cements and more often in combined mixtures with admixtures or SCMs, or both. In some cases other sources of sulfate might be used to mimic potential conditions in the system. Among these are anhydrite, arcanite, calcium langbeinite, aphthitalite, syngenite, and others. Fig. 2 shows an example of the effect of added sulfate on the sulfate depletion point. Added sulfate may, in some combined mixtures with admixtures or SCMs, or both, accelerate the onset of the main hydration peak. When a combined mixture is at sulfate balance, further addition of soluble sulfate will not increase the size, or accelerate the onset, of the main hydration peak.

3.2.16 *thermal equilibrium time*, *n*—the elapsed hydration time when the thermal power of replicate mixtures do not differ by more than 0.2 mW/g of dry material.

3.2.17 *thermal indicator of setting time*, *n*—the hydration time to reach a thermal power of 50 % of the maximum value of the main hydration peak.

3.2.18 *thermal power*, *n*—heat production rate measured in watts (W) or joules per second (J/s), usually expressed in relation to the mass of cementitious material, as mW/g or J/s/g.

3.2.18.1 *Discussion*—The thermal power is an indicator of the rate of various chemical reactions between cementitious materials, other fine particles, mix water and admixtures.



NOTE—(A) initial thermal power by dissolution of cement and initial cement hydration; (B) dormant period associated with very low thermal power indicating slow and well-controlled hydration: (C) main hydration peak associated mainly with hydration reactions contributing to setting and early strength development, with maximum at (D); and (E) sulfate depletion point,[6] followed by (F) accelerated aluminate activity.

FIG. 1 Example of Thermal Power Curve for Isothermal Hydration of Portland Cement

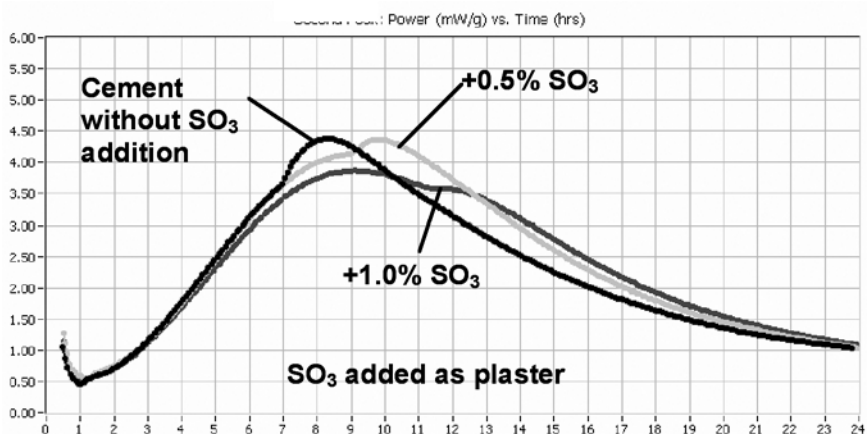

FIG. 2 Example of the Effect of Soluble Calcium Sulfate Addition on the Timing of the Sulfate Depletion Point for a Type I Portland Cement Mixed with Water Only at w/c = 0.45

3.2.19 *vial*, *n*—container into which the freshly mixed cementitious mixture is placed for a measurement.

4. Summary of Practice

4.1 An isothermal calorimeter consists of heat sink with a thermostat, two heat flow sensors and a specimen vial holder attached to each sensor. A vial containing a freshly prepared mixture is placed in contact with one of the vial holders and a thermally inert material is placed in contact with the other. The heat of hydration released by the reacting cementitious specimen is transferred and passes across a heat flow sensor. The calorimeter output is calculated from the difference between the outputs from the test specimen heat flow sensor and the inert specimen heat flow sensor. Because the heat is allowed to flow away from the specimen, the measurement will take place at essentially constant temperature (isothermal conditions).

4.2 Mixtures with cement, SCM, admixtures, water and optional fine aggregate are prepared and introduced into an isothermal calorimeter. Isothermal calorimetry tests are performed on a series of different mixtures for relative comparison of the hydration kinetics. The output of the calorimeter is evaluated by graphical and mathematical means to evaluate retarding and accelerating effects of different combinations of materials. Calcium sulfate may be added as a probe to determine if the addition of admixture, SCMs, or both have increased the mixture's demand for sulfate beyond that which is available in the cement.

5. Significance and Use

5.1 Thermal power curves are used to evaluate the isothermal hydration kinetics of the combined mixture of different materials during the early period after being mixed with water. These isothermal power curves, or hydration profiles, may provide indications relative to setting characteristics, compatibility of different materials, sulfate balance and early strength development. The isothermal hydration profiles can also be used to evaluate the effects of compositions, proportions, and time of addition of materials as well as curing temperature. Special care must be used in evaluating extended retardation with paste specimens, which have been shown to overestimate the retardation of some mixtures containing cement, SCM, and admixtures.

5.2 This procedure can be used to measure the effect of chemical admixtures on the cement hydration profile. In many cases, the addition of chemical admixture changes the kinetics of cement hydration.

5.3 Although this technique has been used historically to understand issues related to setting and slump loss, it must be emphasized that isothermal calorimetry results cannot predict concrete performance definitely, either positively or negatively. Extensive verification in concrete at planned dosages and temperatures, and at higher dosages, is needed. Isothermal calorimetry is an effective tool to identify sensitivities, so that concrete testing can be efficiently planned and performed.

5.4 This practice provides a means of assessing the relative hydration performance of various test mixtures compared with control mixtures that are prepared in a similar manner.

5.5 The procedure and apparatus can be used to monitor the thermal power from pastes and mortars alone or in combination with chemical admixtures.

5.6 The isothermal calorimeter described here can be used to measure the thermal power and heat of hydration of mortars prepared independently or obtained by wet sieving from concrete in accordance with Practice C 172.

6. Apparatus

6.1 Devices for mixing to produce a homogeneous mixture of cement, SCM, admixtures, water and optional other fine materials or aggregate and devices for charging the mixture into the specimen vial.

6.1.1 *Weights and Weighing Devices* shall conform to the requirements of Specification C 1005.

6.1.2 *Graduated Cylinders* shall conform to the requirements of Specification C 1005. The permissible variation for graduated cylinders of less than 100-mL capacity shall be ±1.0 % of the rated capacity.

6.1.3 *Graduated Syringes* of suitable capacities to contain the desired volume of liquid admixture or stock solution at 20 °C. The permissible variation of the measured volume shall not exceed 3 % of the volume to be delivered. When admixture quantities required are less than 2 mL, or are viscous in nature, optionally prepare stock solutions at appropriate dilution, to avoid problems with small volumes measured volumetrically.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:26 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

Care shall be taken to inspect stock solutions for separation and any admixture that is prone to separation in stock solution must be added in an alternative fashion, such as by analytical syringes.

6.1.4 *Mixing Apparatus*:

6.1.4.1 *Mortar Preparation*—The mixer shall comply with Practice C 305.

6.1.4.2 *Paste Preparation*—A high shear blender,[5] or similar variable speed blender capable of maintaining a no-load speed of at least 15 000 r/min, with optional cooling device. A handheld household mixer capable of mixing paste at not less than 400 r/min or other mixers for paste or mortar preparation are also permitted.

6.1.4.3 The repeatability of results for any mixing method must be measured and reported as described in 12.5.

6.1.5 *Vials* that can be sealed and fit into the specimen vial holders of the calorimeter.

6.1.6 *Pipette, Funnel or Syringe* to facilitate charging the sample to the vials. The neck of the device must be large enough to avoid sample segregation.

6.2 *Calorimeter and Data Acquisition System* of suitable capacity and calibrated to monitor the thermal power of mortar or paste in a repeatable fashion. The actual design of an individual instrument, whether commercial or custom-built, may vary, but it shall meet the following criteria, and shall be verified to do so on a yearly basis or at any time that equipment is modified.

6.2.1 The standard deviation in thermal power for six replicate specimens sampled from *one mixture* of a portland cement paste without chemical admixture at w/c 0.45 tested at 23 ± 4.0 °C shall be no greater than 0.5 mW/g of dry material measured at the maximum of the main hydration peak (See Fig. 1 for identification of the main hydration peak). For calorimeters which do not allow external mixing, prepare six replicate mixtures.

6.2.2 The baseline measured with an inert specimen of similar thermal properties (mainly heat capacity) as the test specimen shall exhibit a low random noise level and be stable against drift. The baseline measured at 23 ± 4 °C during a time period of 24 h shall have a long-term drift of less than 0.5 mW per day per gram of inert material used and a baseline random noise level of less than 0.2 mW per gram of inert material used. In practice, the baseline is measured for 24 h or longer and a straight line is fitted to the data using a linear least squares procedure. The long-term drift is the slope of the line and the baseline random noise level is the standard deviation of the data about the best-fit line.

6.2.3 The vials shall be vapor tight so that endothermic heat of evaporation does not significantly influence the measurements. This shall be verified with a 24 h measurement with water instead of the mortar or paste specimen. The difference between the measured thermal powers of an empty vial and one containing water shall be less than 0.2 mW per gram of water when calculated according to the procedure in 13.1.

[5] Mixing devices described in API Specification RP 10B-2/ ISO 10426-2 have been found suitable for this purpose.

6.2.4 The data acquisition equipment shall be capable of performing continuous logging of the calorimeter output with a time interval between the measurements that is no larger than 60 s.

7. Materials

7.1 *Sand*:

7.1.1 Unless specified otherwise, use standard graded sand as defined in Specification C 778 for preparing mortar samples.

7.1.2 When specified, use job-specific sand when performing a specific mortar test series that is related to field application.

7.2 *Water*:

7.2.1 Unless specified, use potable water as defined in Specification C 1602/C 1602M.

7.2.2 When specified, use job-specific water when performing a specific test series that is related to field application. Follow Specification C 1602/C 1602M in reporting the type of water used.

7.3 *Sulfate Source*:

7.3.1 Unless specified otherwise, use reagent grade calcium sulfate dihydrate or hemihydrate prepared from reagent grade calcium sulfate dihydrate to verify whether a mixture is in sulfate balance. See Appendix for examples.

7.3.2 When specified, use a source-specific calcium sulfate for performing a specific test series that is related to field application.

8. Temperature and Humidity

8.1 *Sample Preparation Temperature*—Unless specified otherwise, maintain the temperature of the air in the vicinity of all equipment and materials used in accordance with the requirements for cement mixing rooms in Specification C 511.

8.1.1 When specified, different temperature conditions are permitted for research purposes or to simulate field conditions.

8.1.2 To reduce the time to reach thermal equilibrium, it is permitted to cool the mixture during mixing. It is also permitted to adjust the temperature of the mix water or the starting materials, or both, in order to obtain a temperature of the prepared mixture close the temperature of the calorimeter. This is especially needed when using high shear mixing.

8.2 *Isothermal Calorimeter Test Temperature*—The temperature of the isothermal calorimeter shall be set at 23.0 ± 4.0 °C and allowed sufficient time to stabilize at that temperature.

8.2.1 When specified, a different calorimeter test temperature is permitted for research purposes or to simulate field conditions. Take precaution to prevent condensation of moisture inside the calorimeter if the calorimeter test temperature is set below the temperature of the laboratory.

NOTE 2—Condensation inside the calorimeter cells can be prevented by controlling the humidity inside the calorimeter, or by controlling the humidity or temperature of the testing environment that is in direct contact with the calorimeter. Condensation will not occur inside the calorimeter cells if the temperature of the testing environment is at or below the temperature of the thermostat.

9. Test Specimens

9.1 The number of specimens and number of test batches depend on the purpose of the test program. Replicate testing of

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:26 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

specimens sampled from a single prepared batch shall be done initially to establish acceptable repeatability of the apparatus as defined in 6.2. Replicate testing of separately-prepared specimens is also required in 12.5 to establish the repeatability of results for each mixing method. The number of replicates for routine testing is addressed in 12.2.1.

NOTE 3—See the Appendix for examples of different test programs.

9.2 The specimen size placed in the calorimeter depends on the instrument used as well as the type of mixture (paste or mortar).

NOTE 4—Typical specimen sizes for paste and mortar are 5 to 10 g and 50 to 100 g, respectively. A smaller specimen will reduce the time to reach isothermal conditions if the initial specimen temperature differs from the calorimeter test temperature.

10. Composition of Paste or Mortar Mixtures

10.1 Mixture proportions depend on the purpose of the test program (See Note 4).

10.2 Record mixture proportions for each mixture that is tested, including complete description of mixing method, order and timing of admixture addition.

11. Preparation of Apparatus

11.1 *Determination of Baseline*—Baselines are determined during calibrations or before each measurement, preferably when the calorimeter contains inert specimens, as this reduces the noise. If baselines are stable over time as defined in 6.2.3, they need only be determined at calibrations. If they are not stable, they shall be determined before each measurement.

11.2 *Calibration*—Calibration shall be made according to manufacturer's recommendations at regular intervals of one year or less to determine the calibration coefficient. If the calibration coefficient differs more than 5 % from one calibration to the next, calibration intervals shall be reduced to 90 days. The length of the time intervals between calibrations depends on the instrument and the personnel. For the purpose of this practice, the calibration coefficient can be assumed to be constant independent of the level of the signal.

12. Procedure

12.1 *Mixing*:

12.1.1 Various mixing methods that have been found useful are described in the Appendix. Because mixing intensity is a variable that may influence the interaction of materials used to prepare cementitious mixtures, in many cases different mixing procedures (speeds or durations) may be needed, depending on the goal of the testing. Unless mixing intensity is a defined variable in a testing program, mixtures prepared under different mixing conditions shall not be compared. External mixing may result in a temperature increase in the sample that may lead to temporary non-isothermal conditions after loading the specimen into the calorimeter. The thermal equilibrium time shall be estimated in accordance with 12.4. The results obtained at hydration times shorter than the equilibrium time are less repeatable and shall only be used if the measured effects are larger than the variation found when estimating the thermal equilibrium time (See Note 5).

NOTE 5—The isothermal calorimeter will bring the temperatures of specimens into thermal equilibrium, but the time required to do so depends on the instrument parameters, specimen size, mixing method, and materials used. Differences in initial thermal power caused by differences in initial temperature can optionally be minimized by keeping all materials at equal temperature, including any water used in cleaning mixing equipment. If needed, the temperatures of the starting materials may be adjusted to compensate for temperature changes during mixing, so that the temperature after mixing is as close as possible to the calorimeter set point.

12.2 *Loading Specimen into Calorimeter*:

12.2.1 Two specimens shall be prepared from one batch, unless the standard deviation of the time to reach the maximum of the main hydration peak for six replicate *separately-prepared* specimens has previously been determined according to 12.5.1 to be less than 60 min, in which case one specimen is adequate (See Note 6).

NOTE 6—A sub-sample of the prepared mixture is used in this method, and it is necessary to obtain a representative sample. Normally, replicate measurements are made initially as specified in 12.5 in order to establish the error associated with variability in specimen composition, preparation, and sampling.

12.2.2 Wear insulating gloves or use tweezers to minimize warming of the vial and specimen by heat from hands.

12.2.3 Weigh and record the empty mass of the vial to be used, or tare the scale to zero with the empty vial on the scale.

12.2.4 Place a representative sample of fresh paste or mortar into the specimen vial resting on the scale. Typically a plastic disposable pipette is used for paste, with the opening cut to size to match the stiffness of the paste, or a spoon is used for mortar. Make sure that masses of all specimens that will be compared with each other do not differ by more than 20 %. Clean and dry the outside of the vials as needed.

12.2.5 Weigh and record the specimen mass to the nearest 0.1 g and seal the vial in order to be vapor tight.

12.2.6 Immediately place the vial into the calorimeter ensuring consistency between the specimens ages at the time specimens are placed in the calorimeter. Typical loading times are 1 to 2 min after the end of the mixing cycle, which for a 4-min cycle yields 5 to 6 min after the cementitious material is added to the water. Record the time the vial was introduced into the calorimeter.

12.3 *Measurement of Thermal Power*:

12.3.1 Start thermal power measurement immediately after specimen has been placed in calorimeter. In the case of internal mixing, start thermal power measurement before initial contact between the cementitious materials and the mixing water.

12.3.2 Measure the thermal power approximately every 60 s until at least two hours after the maximum of the main hydration peak (See Fig. 1). The testing duration and data sampling frequency are permitted to be modified according to the nature of the test program and the rate of change in thermal power.

NOTE 7—Paste studies are generally more repeatable than mortar, because less paste is needed to ensure known and uniform binder content in the specimen. However, certain mixtures may be sensitive to the mixing action. Paste mixtures with water reducing or retarding admixtures generally have longer retardation than the corresponding mortar mixtures. Especially when testing for the effect of admixtures with a retarding component, it is recommended to verify any results obtained in paste by testing in mortar. The larger the specimen, the longer it takes for heat

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:26 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

transfer from specimen to calorimeter sensor. Also, the larger the specimen, the larger will be the temperature rise within the specimen, and the longer will be the time required to reach thermal equilibrium. Mortar studies are, on the other hand, more concrete-like and allow for parallel testing of other properties such as flow, stiffening, strength, and air content.

12.4 *Determination of Thermal Equilibrium Time*:

12.4.1 The thermal equilibrium time shall be determined for a given instrument and type of specimens (defined by specimen mass, initial temperature and type (paste or mortar) by preparing and testing a at least six replicate batches and measuring the elapsed hydration time when the range of the thermal power of replicate specimens falls to 0.2 mW/g of dry material (See Fig. 3).

12.5 *Determination of Repeatability of Results*:

12.5.1 The repeatability of the results of any mixing method must be determined by preparing and testing at least six replicate batches of a paste mixture that has a thermal indicator of setting time that is equal to or exceeds that of the most retarded mixture in the planned test program. The repeatability shall be recorded as the standard deviation of the time to reach the maximum of the main hydration peak (See Fig. 4). The repeatability must be measured annually or when the operator or mixing method has changed.

NOTE 8—It is convenient to develop a chart of repeatability versus time to reach the maximum of the main hydration peak for a particular mixing method used. This allows for estimation of repeatability for any given level of retardation in a particular experiment.

13. Calculation of Results

13.1 *Post-Processing of Data*—The aim of the evaluation is to monitor differences in the evolution of thermal power for different mixtures during the test period, typically 24 or 48 h. The data evaluation method consists of the following steps:

13.1.1 Remove the baseline:

$$V(t) = V_{raw}(t) - V_{bl} \quad (1)$$

where:

V_{raw} = signal from the calorimeter, and
V_{bl} = measured baseline signal of the calorimeter.

13.1.2 Apply the calibration coefficient (ε) and divide by the mass of cementitious materials (m_c) in the specimen to obtain the normalized thermal power P per unit mass of cementitious material (W/g) as a function of time:

$$P(t) = \frac{\varepsilon \cdot V(t)}{m_c} \quad (2)$$

13.1.3 Plot the normalized thermal power as a function of time. For example, see Fig. 1.

NOTE 9—The accumulated energy for a given mixture may serve as an indicator of potential strength development as a function of time. The accumulated energy, normalized to a unit mass of total cementitious materials (J/g), is obtained by integrating the area under the power curve.

14. Evaluation of Test Results

14.1 Calorimetry results are typically evaluated graphically by comparing differences in response from tests of different mixtures.

NOTE 10—The evaluation of calorimetry results depends on the nature of the test program. See examples in the Appendix.

14.2 If presenting results that include the initial, non-isothermal test period, present the data as two separate plots:

14.2.1 The first plot displays the initial thermal power, typically from 0 to 30 min or 0 to 60 min and, if external mixing was used, includes a statement that results were obtained while not at thermal equilibrium. Care must be taken in interpretation of these initial results.

14.2.2 The second plot displays the thermal power starting at the time of thermal equilibrium until the completion of the test.

15. Report

15.1 Report the following information:

15.1.1 Type of instrument used.

15.1.2 Date of last calibration.

15.1.3 Source and identity of all materials tested, method of conditioning them to test temperature, and temperature prior to mixing.

15.1.3.1 The specific type of sulfate source shall be included as part of the description of a sulfate addition, as well as its precise method and timing of addition. If plaster is used, evidence shall be supplied of its hydration state prior to testing.

15.1.4 Mixture proportions.

15.1.5 Temperature, date, starting time, and duration of test.

15.1.6 Mixing method and duration, including sequences and timing of mixing and scraping down, volume of container and speed of mixer.

15.1.7 Thermal equilibrium time determined for the type of mixture tested as determined in 12.4.

15.1.8 Standard deviation of time to reach maximum on the main hydration peak as determined in 12.5.

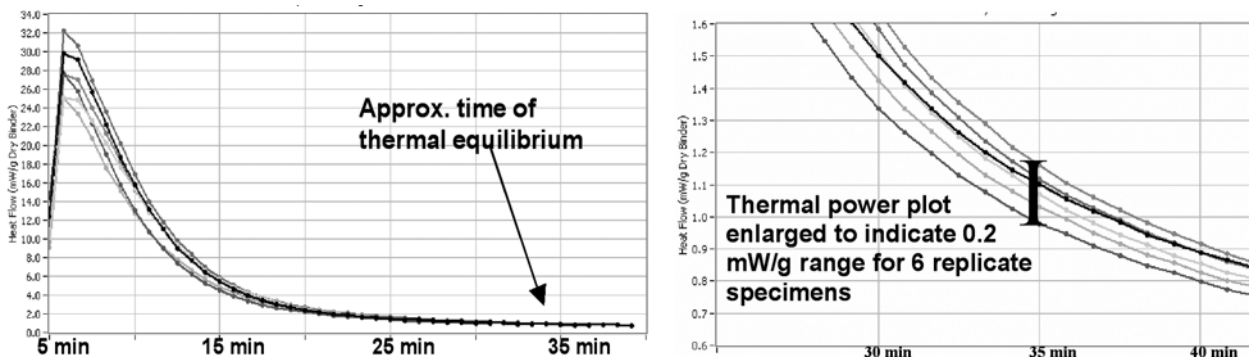

FIG. 3 Illustration of Estimated Time to Reach Thermal Equilibrium Using Six Replicate Specimens

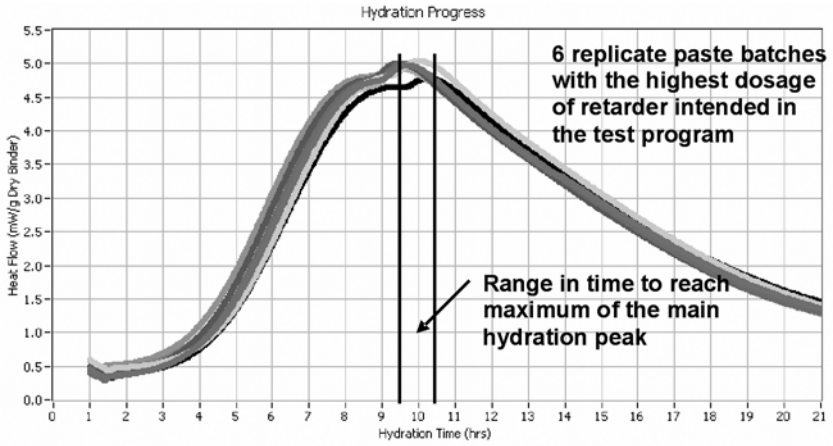
www.technobetar.ir



NOTE—The range of results from which the standard deviation is calculated is shown.

FIG. 4 Procedure for Measuring Repeatability of a Mixing Procedure Using Replicate Batches of a Paste Mixture with Longest Setting Time in the Test Program

15.1.9 Admixture addition sequence, if applicable, and method of addition of admixture including description of any stock solutions used.

15.1.10 Any unusual observations, such as early stiffening during sample preparation.

15.1.11 If thermal indicators of relative setting time are used, method of calculating relative setting time if different from default method.

15.1.12 Plots of thermal power per unit mass of cementitious materials. See Appendix for examples. It is important to adapt the graphs to address each technical point on separate graphs. Plotting many together may cause confusion even among the experienced users of this technique.

15.1.13 Statement that the test was carried out in accordance with this practice and notes of all deviations from the described procedure.

16. Keywords

16.1 cement-admixture interactions; hydration kinetics; hydration performance; isothermal calorimetry; sulfate depletion

APPENDIXES

(Nonmandatory Information)

X1. DEFINITIONS OF TERMS USED IN APPENDIX

X1.1 *delay time, n*—period between initial contact of mix water and cementitious materials and when an admixture is added to the mixture.

X1.2 *delayed addition of admixture, n*—addition of admixture to the mixture when the delay time exceeds 10 s after the initial contact between mix water and cementitious materials.

X1.3 *heat of hydration, n*—total energy released at a given hydration time measured in joules per unit mass of cementitious material (J/g); the time integral of normalized thermal power.

X1.4 *tail end addition of admixture, n*—addition of admixture to the mixture within 2 to 10 s after the initial contact between mix water and cementitious materials.

Discussion—The exact addition time should be defined as needed in the test program; see examples.

X1.5 *upfront addition of admixture, n*—addition of admixture to mix water prior to mixing with cementitious materials.

X2. TYPICAL USES, EXPERIMENTAL DESIGNS AND EVALUATION

X2.1 *General*:

X2.1.1 Experimental designs are typically devised to study the effect of supplementary cementitious materials or admixture type, dosage and addition mode on the hydration kinetics of cementitious systems. Other parameters such as source of water, fine particles, mixing method, or curing temperature can be studied as well. The water content should be sufficient to produce a homogeneous mixture without excess bleeding. Tests of separate mixtures with additional source of soluble sulfate, corresponding to 0.5 % SO_3 by mass of portland cement or other amounts, added before testing, are typically performed to evaluate if additional sulfate would improve the hydration performance of mixtures with high SCM or admixture dosage. Several example experimental designs are shown in this appendix. It should be noted that each example represents a specific set of materials for the purpose of showing experimental designs. The example results cannot be extrapolated to other sets of materials.

Use of different SCMs or admixtures, or both, may result in mixtures with different workability. This can affect the amount of shear imparted to the cementitious particle by the mixing action, which may affect hydration kinetics. In cases where problems are found, it may be useful to alter the water-cementitious materials (*w/cm*) ratio in order to investigate its effect on the results.

X2.1.2 Admixture type, dosages, and addition modes can be selected based on local market conditions, experience, dosing equipment, or recommendations from the supplier. The dosage of admixtures may vary with weather conditions.

X2.1.3 It is strongly recommended to test for the effect of an admixture overdose. Mixtures that are sensitive to minor overdoses are likely to show abnormal performance in the field, given the inherent variability of typical concrete materials and production operations.

X2.1.4 It is also recommended to test for the effects of temperature change. Hot weather typically causes faster loss of workability and therefore higher dosages of water-reducing or set-retarding admixtures are often used. The combination of higher admixture dosage and higher temperature can cause abnormal performance in the field. Similarly, cold temperatures, especially with lower C_3A cements may result in extended setting time, especially when higher admixture dosages appropriate for warm weather are maintained during cold conditions.

X3. SULFATE BALANCE

X3.1 See Fig. 1 of this practice for an example of the portion of the thermal power output associated with aluminate reaction after sulfate depletion, point E, which is the small peak labeled F. This point is of concern as there is a correlation between this peak occurring before the completion of the main hydration peak, and problems with premature or severely delayed setting and slump loss of combined mixtures. In many cases, cements that have enough sulfate for proper control of their own hydration cannot supply enough sulfate when combined with various amounts of other materials, so it becomes of importance to understand the effect of the added materials on the location of the sulfate depletion point.

X3.2 The sulfate depletion point is indicated as the onset of either a sharp or shallow hump on the main hydration peak of the thermal power curve. The sulfate depletion point will move later in time relative to the maximum of the main hydration peak (point D in Fig. 1) and diminish in size when additional source of soluble sulfate is added to the system. This peak seen after the sulfate depletion point may be shallow and difficult to distinguish from the rest of the main hydration peak for some portland cements and in many combined mixtures containing SCM or admixture, or both. The peak typically is more visible with very active aluminate cement such as a high C_3A Type I, and decreases in sharpness as the C_3A content decreases, making it difficult to identify on many Type V cements. In such cases, performing additional tests with various sulfate addition levels may clarify the timing of the sulfate depletion point, (See Fig. 2 of this practice), but there are cases where no depletion point and subsequent peak can be resolved.

X3.3 The nature and position of the sulfate depletion point in most combined mixtures can be verified by monitoring the effect of incremental addition(s) of reagent grade calcium sulfate dihydrate (gypsum), Terra Alba gypsum or calcium sulfate hemihydrate (plaster) to the mixture, as shown in Fig. X3.1. Because few cements have enough sulfate to avoid any signs of sulfate depletion until after 24 h, a point of depletion is typically observed in the hydration profile. However, if the depletion occurs near the maximum of the main hydration peak it may not be discernible, and it is frequently found as merely a slight asymmetry of the peak and shown in curve #3 of Fig. X3.1. Addition of one or sometimes two levels of additional sulfate will cause the depletion point to move to later times, and therefore show up clearly as seen in curve #4 of Fig. X3.1.

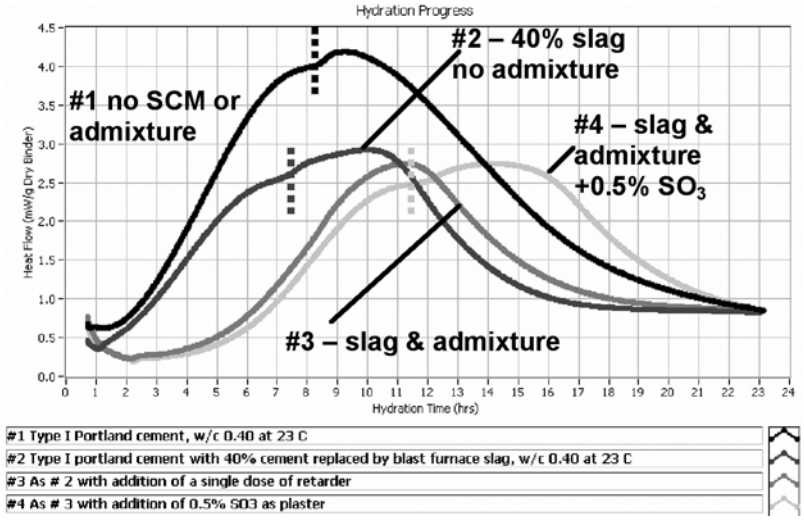

FIG. X3.1 Effect of SCM, Admixture and Sulfate Addition on the Sulfate Depletion Points, as Indicated by Vertical Dotted Lines

X4. MIXING METHODS

X4.1 Mixing intensity may significantly affect the results of isothermal calorimetry. Consistency in mixing method is vital for results to be compared, but as numerous techniques have proven useful, no one method is specified in this practice. Mixing may be either internal in the specimen vial, either by simple absorption of water or by mechanical means.

X4.2 Internal mixing has the advantage of allowing capture of the whole thermal power diagram, but the disadvantage of not being able to achieve shear rates approaching that in concrete. Delayed addition of admixture can be difficult or impossible depending on calorimeter design. Care must be taken that the full sample of paste is wetted equally; a means to verify this is to remove the hardened sample from the sample vial and crush it to see equal color. If significant variation in paste color is seen it should be so noted in the report.

X4.3 External mixing may be used for paste, mortar, or concrete. Depending on calorimeter design, concrete samples may be tested as concrete or as mortar separated according to the method in Practice C 172. Several methods that have been used successfully are outlined below.

X4.4 *Preparation of Paste Using a Hand-Held Kitchen Mixer or Similar Mixer*:

X4.4.1 Add cementitious materials into the mixing container. Add water including any dissolved admixtures, and immediately start the timer. Increase the speed of rotation of the mixing blades to 200 ± 100 r/min while avoiding splashing. Record the time of initial contact between cementitious materials and water.

X4.4.2 Mix at 200 ± 100 r/min to the 1 min 30 s mark.

X4.4.3 Stop mixing and for 30 s scrape corners of container to ensure all dry materials are mixed in, and scrape down any paste that may have collected on the sides of the container.

X4.4.4 Start the mixer at 500 ± 100 r/min and continue to mix at this speed for 2 min to the 4 min mark.

X4.4.5 Add admixtures at any time appropriate to the test program. Typical delay times are 10 s for tail end addition or 45 s for delayed addition. Unless specified otherwise, mix at 500 ± 100 r/min for at least 60 s after all admixtures have been added.

X4.5 *Preparation of Paste Using a High Speed Blender*:

X4.5.1 Add water and any admixture to be added upfront into the mixing jar. Increase the mixing speed over 10 s to 2000 ± 200 r/min while minimizing splashing. Add dry materials, and immediately start the timer. Record the time of initial contact between cementitious materials and water.

X4.5.2 Add admixtures at any time appropriate to the test program.

X4.5.3 Mix at 4000 ± 400 r/min for 10 s.

X4.5.4 Increase mixer speed to 13 000 ± 1000 r/min within 10 s and continue to mix at this speed to the 40 s mark.

X4.5.5 At the 40 s mark, decrease mixer speed to 2000 ± 200 r/min and continue to mix at this speed for 50 s (to the 1 min 30 s mark).

X4.5.6 Stop mixing and let the mixture rest for 60 s (to the 2 min 30 s mark).

X4.5.7 Start the mixer at 2000 ± 200 r/min and increase the mixer speed to 13 000 ± 1000 r/min within 10 s and continue to mix at this speed to the 4 min mark.

X4.5.8 Mix at 13 000 ± 200 r/min for at least 30 s after all admixtures have been added.

X4.6 *Preparation of Mortar (modified Practice C 305 procedure)*:

X4.6.1 Place the water and any admixtures to be added upfront into the mixing container.

X4.6.2 Add cementitious materials; then start the mixer and mix at the slow speed (140 ± 5 r/min), and immediately start the timer. Record the time of initial contact between cementitious materials and water. Mix for 30 s.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

X4.6.3 Add the entire quantity of sand slowly over a 30-s period, while mixing at slow speed.

X4.6.4 Stop the mixer, change to medium speed (285 ± 10 r/min) and mix for 30 s.

X4.6.5 Stop the mixer and let the mortar stand for 1½ min. During the first 15 s of this interval, quickly scrape down into the batch any mortar that may have collected on the side of the bowl; then for the remainder of this interval, cover the bowl with the lid.

X4.6.6 Mix for 1 min at medium speed (285 ± 10 r/min).

X4.6.7 In any case requiring a remixing interval, any mortar adhering to the side of the bowl shall be quickly scraped down into the batch before remixing.

X4.6.8 Add admixtures at the appropriate time according to the test program.

X4.6.9 Mix for at least 30 s at medium speed (285 ± 10 r/min) after all admixtures have been added.

X4.7 *Obtaining Sample of Mortar from Concrete*:

X4.7.1 Mortar test samples may be obtained from concrete following the wet-sieving procedure in Practice C 172.

X5. GRAPHICAL EVALUATION OF RESULTS

X5.1 Prepare comparative graphs including a reference mixture and other mixtures of significance, in order to evaluate hydration characteristics such as:

X5.1.1 Retardation of the main hydration as a function of admixture type and dosage. Thermal indicators of setting time may be taken as the time to reach 50 % of the average maximum power of the main hydration peaks (See example in Fig. X5.1).

X5.1.2 Relation between the time of maximum of the main hydration peak and the time of sulfate depletion. This relationship may be used as an indicator for the overall sulfate balance of each combined mixture according to Lerch.[6] Note if there is any effect of adding extra SO_3 to the combined mixture before testing.

X5.1.3 Acceleration of early aluminate hydration as a function of admixture type and dosage.

[6] Lerch, W., "The Influence of Gypsum on the Hydration and Properties of Portland Cement Pastes," *Proceedings, Vol 46, of the American Society for Testing and Materials* , 1946, pp. 1252-1292.

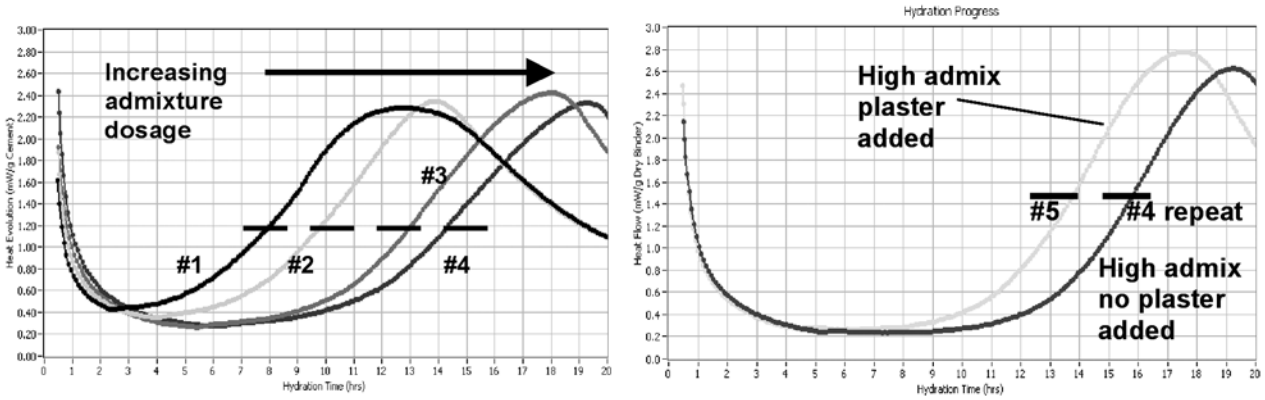

FIG. X5.1 (a) Effect of Admixture Dosage on the Thermal Indicator of Setting Time for This Given Set of Materials; (b) Effect of SO_3 Addition (as Plaster) for This Given Set of Materials

X6. EXAMPLES

X6.1 *Study of Effect of Admixture Dosage and SCM Content on Thermal Indicator of Setting Time at Constant Temperature*:

X6.1.1 Different admixtures and SCM can have a strong effect on the setting time of a cementitious mixture. The relative effect of such changes on thermal indicators of setting time can be investigated by testing a series of mixtures. Table X6.1 shows an example of an experimental design for paste mixtures with a *w/c* of 0.40, Class C fly ash (CFA), and a water-reducing admixture. The sulfate addition test (Mixtures #5 and #8) is important for evaluation of whether a selected set of materials and dosages appears to be in sulfate balance.

X6.1.2 *Evaluation of Setting Time Study*—The thermal indicator of setting time is typically taken as the time to reach one-half the average maximum power of the main hydration peaks. Fig. X5.1(a) shows the response for mixtures 1 through 4 tested at room temperature. Fig. X5.1(b) shows the effect of SO_3 addition (as plaster) for mixture #5 with high admixture dosage. The thermal indicator of setting time is a relative value and can be correlated with a physical setting time method such as Test Method C 403/C 403M for a given mixture.

X6.1.3 *Indications*:

X6.1.3.1 The aluminate reaction peak after the sulfate depletion point appears to overlap the main hydration peak, indicating a mixture that is potentially sensitive to high admixture dosages.

X6.1.3.2 Increased admixture dosages retard the onset of the main hydration peak used to evaluate thermal indicators of setting time.

X6.1.3.3 The plaster addition (mixture #5) accelerated the onset of the hydration peak and also enlarged the height of the peak, indicating that the mixture with the high admixture dose is close to being out of sulfate balance. Note that the addition of sulfate showing in Fig. X5.1(b) did not result in a clear sulfate depletion point.

X6.1.4 Fig. X6.1(a) shows the effect of varying CFA dosage at typical dosage of admixture. Fig. X6.1(b) shows the effect of SO_3 addition (as plaster) to the mixture with high fly ash dosage.

X6.1.5 *Indications*:

X6.1.5.1 The CFA content had a strong effect on the hydration kinetics.

TABLE X6.1 Example of 8-Mixture Calorimetry Test Design

Mixture #	Dosages		Remarks
	SCM-FA	Admixture	
1	20 % CFA	None	Reference
2	20 % CFA	Low	Admixture dosage window of interest,
3	20 % CFA	Typical	(water reducing admixture WRA)
4	20 % C	High	
5	20 % C	High	0.5 % SO_3 added to cement before test
6	10 % C	Typical	Fly ash dosage window of interest
7	30 % C	Typical	
8	30 % C	Typical	0.5 % SO_3 added to cement before test

X6.1.5.2 Mixture # 7 with high amount of CFA displayed abnormal hydration with a strong premature exotherm indicated by the abnormally steep rise in thermal power at 6 to 7 h and no main hydration within 23 h. The abnormal peak may not be used for estimation of the thermal indicator of setting time. Mixture # 7 could stiffen and possibly flash set because of the abnormal exotherm at 6 to 7 h, but would not develop normal strength within 23 h.

X6.1.5.3 The plaster addition test confirmed that the premature exotherm at high dosage of CFA was caused by insufficient amount of available sulfate to control the aluminate hydration (probably as a result of aluminate in the CFA consuming some of the soluble sulfate from the cement).

X6.2 *Study of Effect of Curing Temperature on Hydration Kinetics*:

X6.2.1 Calorimetry is well suited for monitoring the effect of temperature on hydration kinetics. An example is shown in Fig. X6.2 for a portland cement mixture, with *w/c* = 0.45, with and without a water-reducing admixture, and tested at three different temperatures. One mortar mixture was prepared and tested in parallel at three different temperatures. Table X6.2 shows the experiment design.

X6.2.2 *Evaluation of Curing Temperature Study*—Fig. X6.2(a) shows the hydration kinetics for all mixtures in Table X6.2. Fig. X6.2(b) shows the effect of curing temperature on the increase in the thermal indicator of setting time caused by the admixture.

X6.2.3 *Indications*:

X6.2.3.1 The retarding effect of temperature on cement hydration was readily visible by isothermal calorimetry.

X6.2.3.2 The location of the sulfate depletion point, in relation to the main hydration peak, is affected by temperature with or without the admixture present.

X6.2.3.3 The retardation time caused by an admixture is often temperature dependent, as illustrated in this example.

X6.3 *Study of Effect of Admixture Dosage and Sequence of Addition on Setting Time*:

X6.3.1 The sequence of admixture addition can have a strong effect on setting times and early strength. The relative effect of changing the addition sequence can be investigated by a series of mixtures, preferably including a reference mixture with known setting times. Table X6.3 shows an example of an experimental design for mixtures with two different admixtures tested at two fly ash contents. The plaster addition test is important to evaluate whether a mixture appears to be in sulfate balance. In addition, temperature sensitivity can be assessed by testing each mixture at more than one temperature.

X6.3.2 *Evaluation of Admixture Addition Sequence Sensitivity Study*—Fig. X6.3(a) shows the response for mixtures with typical (20 %) CFA dosage and two admixtures at typical

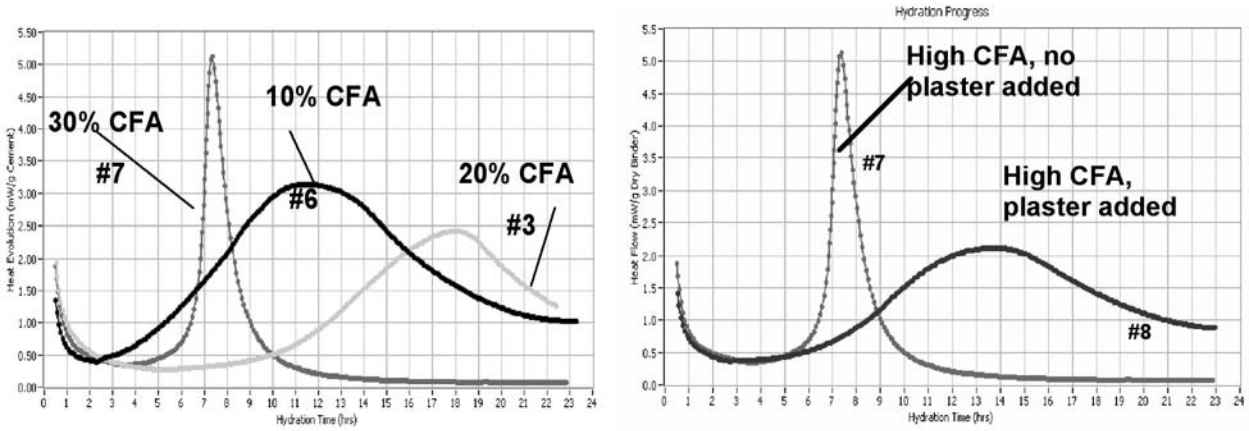

FIG. X6.1 (a) Effect of Fly Ash Dosage on Hydration Kinetics; (b) Effect of SO_3 Addition (as Plaster)

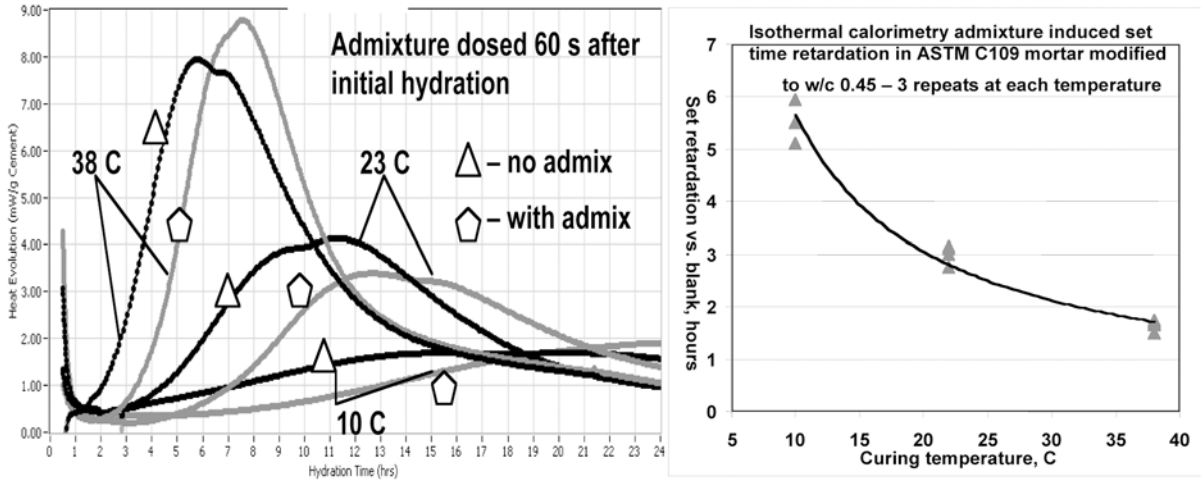

FIG. X6.2 (a) Effect of Temperature on the Hydration Kinetics; (b) Effect of Temperature on Retardation of Setting Time

TABLE X6.2 Example of Calorimetry Test Design

Mixture	Admixture	Temperature
1	No	38 °C (100 °F)
2	Yes	38 °C (100 °F)
3	No	23 °C (73 °F)
4	Yes	23 °C (73 °F)
5	No	10 °C (50 °F)
6	Yes	10 °C (50 °F)

dosages but different dosing sequence, tested at room temperature. Fig. X6.3(b) shows the effect of SO_3 addition (as plaster) to the mixture with both admixtures dosed "tail end" (10 s delayed addition).

X6.3.3 *Indications*:

X6.3.3.1 Tail end addition of both admixtures extended the thermal indicator of setting time approximately 90 min compared with mixtures with same admixture dosages but either admixture or both added upfront.

X6.3.3.2 The plaster addition (mixture #6) accelerated the onset of the hydration peak and also enlarged the height and width of the peak, indicating that the mixture with the tail addition of both admixtures is not in sulfate balance.

X6.3.4 Fig. X6.4(a) shows the effect of overdosing admixture A or B, both added upfront. Fig. X6.4(b) shows the effect of plaster addition (0.5 % SO_3) to the cement prior to testing (#13 and #14).

X6.3.5 *Indications*:

X6.3.5.1 An overdose of admixture A caused abnormal exotherms indicated by the abnormally steep rise in thermal power at 50 % and 100 % overdose (#9 and #10), with no subsequent silicate hydration. Note flatline out to 22 hours.

X6.3.5.2 No abnormal hydration was seen when overdosing admixture B (#11 and #12).

X6.3.5.3 The plaster addition test (#13 and #14) confirmed that the premature exotherms at high dosages of admixture A were caused by uncontrolled aluminate hydration. Note that silicate hydration, although still severely delayed, is seen to start within the 22 hour test period.

SUMMARY OF CHANGES

Committee C09 has identified the location of selected changes to this practice since the last issue, C 1679 – 07, that may impact the use of this practice. (Approved June 1, 2008)

(*1*) Revised Note 2 to clarify how to avoid condensation inside the calorimeter.
(*2*) Made the making of diluted solutions of the admixtures optional in 6.1.3.
(*3*) Removed explanatory test in 12.1.1and placed it in new Note 5; renumbered subsequent notes

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1688/C 1688M – 08

Standard Test Method for Density and Void Content of Freshly Mixed Pervious Concrete[1]

This standard is issued under the fixed designation C 1688/C 1688M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers determining the density of freshly mixed pervious concrete and gives formulas for calculating the void content of pervious concrete.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

1.4 The text of this test method references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this test method.

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this test method, refer to Terminology C 125.

3.2 *Symbols*:

D	=	density (unit weight) of concrete kg/m^3 [lb/ft^3]
M_s	=	total mass of all materials batched, kg [lb] (see Note 1)
M_c	=	mass of the measure filled with concrete, kg [lb]
M_m	=	mass of the measure, kg [lb]
T	=	theoretical density of the concrete computed on an airfree basis, kg/m^3 [lb/ft^3] (see Note 1)
U	=	percentage of voids in the fresh pervious concrete, including entrained and entrapped air voids in the cement paste.
V_s	=	sum of the absolute volumes of the component ingredients in the batch, m^3 [ft^3]
V_m	=	volume of the measure, m^3 [ft^3]

NOTE 1—The theoretical density is a laboratory determination, and is assumed to remain constant for all batches made using identical component ingredients and proportions. It is calculated from the following equation:

$$T = \frac{M_s}{V_s}$$

The total mass of all materials batched is the sum of the masses of the cement, the fine aggregate in the saturated-surface-dry condition, the

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.49 on Pervious Concrete.

www.technobetar.ir

coarse aggregate in the saturated-surface-dry condition, the mixing water in the batch (includes free water from the aggregate), and any other solid or liquid materials used.

The absolute volume of each ingredient is equal to the quotient of the mass of that ingredient divided by the product of its relative density (specific gravity) times the density of water (See Test Method C 29/C 29M). For the aggregate components, the relative density (specific gravity) should be based on the saturated-surface-dry condition (as determined by Test Method C 127 for coarse aggregate and Test Method C 128 for fine aggregate). For cements meeting Specification C 150, Specification C 595, and Specification C 1157, the relative density should be determined by Test Method C 188, and is typically available from the cement manufacturer. A value of 3.15 may be used for Portland cements manufactured to meet the requirements of Specification C 150. The relative density of supplementary cementitious materials should be determined as follows: for fly ash, use Test Methods C 311; for silica fume, use Specification C 1240; and for slag cement, use Specification C 989.

4. Summary of Test Method

4.1 A sample of fresh pervious concrete is placed and consolidated in a standard measure. The concrete is consolidated using a standard Proctor hammer. The density and void content of the pervious concrete are calculated based on the measured mass of the consolidated concrete specimen, the volume of the measure, and the total mass of materials batched.

5. Significance and Use

5.1 This test method provides a procedure for determining the density and void content of freshly mixed pervious concrete.

5.2 This test method is applicable to pervious concrete mixtures containing coarse aggregate with a nominal maximum size of 25 mm [1 in.] or smaller.

5.3 The measured fresh density may be used as verification of mixture proportions.

5.4 The fresh density and void content calculated from this test may differ from the in-place density and void content, and this test shall not be used to determine in-place yield.

6. Apparatus

6.1 *Balance*—A balance or scale accurate to 50 g [0.1 lb] or to within 0.3 % of the test load, whichever is greater, at any point within the range of use. The range of use shall be considered to extend from the mass of the empty measure to the mass of the measure filled with concrete having an assumed density of 2600 kg/m^3 [160 lb/ft^3].

6.2 *Standard Proctor Hammer*—A device used to compact a pervious concrete sample that conforms to Test Method D 698.

6.3 *Measure*—A cylindrical container made of steel or other suitable metal (See Note 2) with a capacity of 7.0 ± 0.6 L [0.25 ± 0.02 ft^3] and a diameter equal to 0.75 to 1.25 times the height. The measuring bowl of a Type B air meter conforming to Test Method C 231 meets the requirements for the measure. The volume of the measure shall be determined as described in Test Method C 29/C 29M. The top rim of the container shall be plane within 0.3 mm [0.01 in.] (See Note 3).

NOTE 2—The metal should not be attacked readily by cement paste. However, a reactive material such as aluminum alloy may be used if, as a result of an initial reaction, a surface film is formed that protects the metal against further corrosion.

NOTE 3—The top rim is satisfactorily plane if a 0.3 mm [0.01-in.] feeler gauge cannot be inserted between the rim and a piece of 6 mm [¼-in.] or thicker plate glass laid over the top of the measure.

6.4 *Strike-Off Plate*—A flat rectangular metal plate at least 6 mm [¼ in.] thick or a glass or acrylic plate at least 12 mm [½ in.] thick with length and width that are at least 50 mm [2 in.] greater than the diameter of the measure with which it is to be used. The edges of the plate shall be straight within a tolerance of 2 mm [1⁄16 in.].

6.5 *Scoop*—Of a size large enough so each amount of pervious concrete obtained from the sampling receptacle is representative and small enough so that the concrete is not spilled during placement in the measure.

7. Sampling

7.1 Obtain the sample of freshly mixed pervious concrete on field placements in accordance with Practice C 172.

7.2 Obtain the sample of freshly mixed pervious concrete in laboratory testing in accordance with Practice C 192/C 192M.

7.3 The elapsed time between obtaining the first and final portions of the composite sample shall not exceed 15 min.

7.3.1 Transport the individual samples to the place where fresh concrete tests are to be performed. Combine and remix the samples with a shovel the minimum amount necessary to ensure uniformity and compliance with the maximum time limits specified in 7.3.2. Protect the composite sample from the sun, wind, and other sources of rapid evaporation.

7.3.2 Start the test for density within 5 min after obtaining the final portion of the composite sample.

8. Procedure

8.1 Place the measure on a flat, level surface free from vibration. Moisten the inside of the measure before placing pervious concrete. Remove any standing water from the bottom of the container using a moistened sponge. Place the pervious concrete in the measure in two layers of approximately equal depth using the scoop described in 6.5. During filling of the measure, move the scoop around the perimeter of the opening to ensure an even distribution of the concrete with minimal segregation. Drop the hammer 20 times per layer at the full 305 mm [12 in.] drop height. For each layer, distribute the position of the tamper so that the entire surface area of the pervious concrete in the measure is consolidated equally. Before consolidating the final layer, fill the measure to overflowing. After completion of consolidation, the measure must contain about 3 mm [¼ in.] of excess pervious concrete protruding above the top of the measure. If after 10 hammer drops to the final layer it appears that there will be insufficient concrete, add a small quantity of concrete to correct the deficiency. If after 10 hammer drops to the final layer it appears that there will be too much concrete in the measure, remove a representative portion of excess concrete with a trowel or scoop. Complete the consolidation of the final layer.

8.2 *Strike Off*—After consolidation, strike off the top surface of the concrete and finish it flat with the strike-off plate so that the concrete surface is level with the top of the measure. Accomplish the strike-off by pressing the strike-off plate on the top surface of the measure to cover about two thirds of the surface and withdrawing the plate with a sawing motion to

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:29:24 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

strike off the area originally covered. Then place the plate on the top of the measure to cover the same two thirds of the surface and advance it with a vertical pressure and a sawing motion to cover the whole surface of the measure; continue to advance plate until it slides completely off the measure. Several final sawing-motion strokes with the edge of the plate, which has been inclined to the top of the measure, will produce a flat finished surface.

8.3 *Cleaning and Weighing*—After strike-off, clean excess concrete from the exterior of the measure and determine the mass of the concrete and measure to an accuracy consistent with the requirements of 6.1.

9. Calculation

9.1 *Density (Unit Weight)*—Calculate the net mass of the concrete by subtracting the mass of the measure, M_m, from the mass of the measure filled with concrete, M_c. Calculate the density (unit weight), D, by dividing the net mass of concrete by the volume of the measure, V_m, as follows:

$$D = \frac{M_c - M_m}{V_m} \quad (1)$$

9.2 *Void Content*—Calculate the percentage of voids as follows:

$$U = \frac{T - D}{T} \times 100\ \% \quad (2)$$

10. Precision and Bias

10.1 Repeatability testing was performed by six laboratories using pervious concrete mixtures proportioned using local materials. Each laboratory prepared three batches and performed two replicate tests per batch. The range of density of fresh pervious concrete was from 1750 to 2000 kg/m^3[109 to 125 lb/ft^3] (See Note 4).

NOTE 4—Round robin testing was performed using the following six consolidation methods:

Proctor Hammer-2 equal layers, 20 times per layer
Marshall Hammer-2 equal layers, 5 times per layer
Marshall Hammer-2 equal layers, 10 times per layer
ASTM C29 Jigging-2 equal layers, 50 drops per layer as per Test Method C 29/C 29M
ASTM C138 Rodding Method-2 equal layers, 25 times per layer
No Consolidation-Fill the empty unit weight bucket.

Of the six consolidation methods evaluated, the method using the Proctor Hammer produced a high degree of repeatability, employed a straightforward process, and was not physically demanding due to the lower weights as compared to the Marshall Hammer.

10.1.1 The single-operator standard deviation of density of freshly mixed pervious concrete has been found to be 22 kg/m^3 [1.4 lb/ft^3].

10.1.2 The multi-operator standard deviation has not been developed.

10.2 This test method has no bias because the density of pervious concrete is defined only in terms of this test method.

11. Keywords

11.1 density; fresh concrete; pervious concrete; Proctor hammer; void content

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C1697 – 10

Standard Specification for Blended Supplementary Cementitious Materials[1]

This standard is issued under the fixed designation C1697; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers blended supplementary cementitious materials that result from the blending or intergrinding of two or three ASTM compliant supplementary cementitious materials, for use in concrete or mortar where hydraulic or pozzolanic action, or both, is desired. The supplementary cementitious materials include slag cement conforming to Specification C989, natural pozzolans and coal fly ash conforming to Specification C618 and silica fume conforming to Specification C1240.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

NOTE 1—The incorporation of supplementary cementitious materials as separate additions or as a manufactured blend may significantly alter the properties of fresh and hardened concrete. The user should be aware of these changes and is referred to the *ACI Manual of Concrete Practice*[2] for information and guidelines. Specific reference is made to:

ACI 232.1R	Use of Natural Pozzolans in Concrete
ACI 232.2R	Use of Fly Ash in Concrete
ACI 233R	Slag Cement in Concrete and Mortar
ACI 234R	Guide for the Use of Silica Fume in Concrete

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[3]

C114 Test Methods for Chemical Analysis of Hydraulic Cement

C125 Terminology Relating to Concrete and Concrete Aggregates

C150 Specification for Portland Cement

C151 Test Method for Autoclave Expansion of Hydraulic Cement

C183 Practice for Sampling and the Amount of Testing of Hydraulic Cement

C311 Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete

C618 Specification for Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

C989 Specification for Slag Cement for Use in Concrete and Mortars

C1240 Specification for Silica Fume Used in Cementitious Mixtures

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of other terms used in this specification, refer to Terminology C125.

3.2 *Definitions of Terms Specific to This Standard:*

3.3 *slag cement*, *n*—granulated blast furnace slag that is ground to cement fineness with or without additions and meets Specification C989.

3.4 *supplementary cementitious material*, *n*—a slag cement or pozzolan that contributes to the properties of concrete or mortar through hydraulic or pozzolanic activity, or both.

3.5 *silica fume*, *n*—as defined in Specification C1240.

4. Classification

4.1 This specification applies to a hydraulic or pozzolanic material composed of a blend of multiple supplementary cementitious materials as defined in Table 1. The supplementary cementitious materials of the blend are identified in accordance with the Type listed in the first column of Table 1. For the purpose of conformance to the requirements of this specification, the blend is classified according to the predominant supplementary cementitious material. For blended supplementary cementitious matierals that have no predominant constituent, the manufacturer selects the blend type.

4.2 The naming practice for reporting blended supplementary cementitious materials is as follows:

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.24 on Supplementary Cementitious Materials.

Current edition approved Feb. 1, 2010. Published March 2010.

TABLE 1 Classification of Supplementary Cementitious Materials

Type	Name
N	Class N Pozzolan meeting Specification C618
F	Class F fly ash meeting Specification C618
C	Class C fly ash meeting Specification C618
SF	Silica Fume meeting Specification C1240
S	Slag cement meeting Specification C989

SCMb−*Axx*/*Byy*/*Czz*

where:

SCMb = designation of the product as a blended supplementary cementitious material,

A = targeted mass % of the predominant supplementary cementitious material in the blended supplementary cementitious material expressed by mass of the final blended supplementary cementitious material,

xx = predominant supplementary cementitious material—use Type designation in accordance with Table 1,

B = targeted mass % of the secondary supplementary cementitious material in the blended supplementary cementitious material expressed by mass of the final blended supplementary cementitious material,

yy = secondary supplementary cementitious material—use Type designation in accordance with Table 1

C = targeted mass % of the tertiary supplementary cementitious material in the blended supplementary cementitious material expressed by mass of the final blended supplementary cementitious material. This would be required only for ternary mixtures, and

zz = tertiary supplementary cementitious material—use Type designation in accordance with Table 1.

NOTE 2—Examples of the naming practice are as follows:
A binary mixture of 65 % Class C fly ash and 35 % slag cement would be:

SCMb−65*C*/35*S*

A ternary mixture of 60 % Class F fly ash, 35 % slag cement and 5 % silica fume would be:

SCMb−60*F*/35*S*/5*SF*

5. Ordering Information

5.1 Orders for material under this specification shall include the following:

5.1.1 Specification number,

5.1.2 The composition of the blend using the naming convention in 4.2.

5.1.3 Any optional requirements as delineated in Table 2.

NOTE 3—In advance of ordering, it is important to check for market availability of blended supplementary cementitious materials.

6. Materials and Manufacture

6.1 All individual constituents used in the manufacture of the blended supplementary cementitious material shall conform to their applicable specification.

6.2 All blended supplementary cementitious materials shall consist of a uniform mixture of constituents within the limits specified in Section 9.

7. Chemical Composition

7.1 The individual constituents and the blended supplementary cementitious material shall be chemically analyzed using applicable analytical methods of Test Methods C311 or Test Methods C114. Analyze for major and minor oxides present in greatest quantity that together, including loss-on-ignition constitutes at least 98 % of the total mass of the material.

7.2 There are no chemical requirements for the blended supplementary cementitious material but the chemical composition of the constituents and of the blended supplementary cementitious material are necessary to verify blend proportions.

8. Physical and Optional Properties

8.1 Blended supplementary cementitious materials shall conform to the physical requirements in Table 3, where the blend type is in accordance with Section 4.

8.2 Blended supplementary cementitious materials shall conform to the optional requirements in Table 2, only when specifically requested by the purchaser. The blend type is in accordance with Section 4.

9. Permissible Variations in Blending Accuracy

9.1 The amount of pozzolan or slag cement in the finished blended supplementary cementitious material shall not vary from the target value by more than ± 2.5 percentage points for silica fume and not more than ± 5 percentage points for other supplementary cementitious materials, with a 99 % probability of compliance.

NOTE 4—To satisfy the 99 % probability of compliance, the blending process must be capable of producing a blend containing silica fume such that the standard deviation of the measured mass percentage of silica fume in the blend is less than 1 %. For constituents other than silica fume, the standard deviations of their measured mass percentages have to be less than 1.9 %.

9.2 The chemical composition of the individual constituents and of the finished blended supplementary cementitious material shall be determined in accordance with Section 7. The composition of the blend in terms of mass percentage of the constituents shall be calculated.

NOTE 5—Appendix X1 provides an example to illustrate how the composition of the blend can be calculated from the various measured chemical compositions.

10. Sampling

10.1 The manufacturer shall sample and test the finished blended supplementary cementitious material in order to verify compliance with this specification.

10.1.1 Upon request of the purchaser, the manufacturer shall furnish the sampling procedure used to certify compliance with this specification.

10.2 If the purchaser desires to verify product compliance with this specification, appropriate sampling and testing procedures shall be used. For guidance, refer to standard Practice C183.

TABLE 2 Optional Requirements

	Blend Type				
	N	F	C	S	SF
Increase of drying shrinkage of mortar bars at 28 days, max, difference, in %, over control[A]	0.03	0.03	0.03	...	...
Uniformity Requirements:[B]					
Density - max variation from average, %	5	5	5	...	...
% retained on 45-μm (No. 325) sieve, max variation from average, %	5	5	5	5	5
When air-entraining concrete is specified, the quantity of air-entraining agent required to produce an air content of 18.0 vol % of mortar shall not vary from the average established by the ten preceding tests or by all preceding tests if less than ten, by more than, %	20	20	20	...	20
Effectiveness in Controlling Alkali-Silica Reaction:					
Expansion of test mixture as percentage of low-alkali cement control, at 14 days, max, %[C]	100	100	100	...	...
Expansion of mortar bars at 14 days, max, %[D]	...	...	...	0.020	...
Reduction of mortar expansion at 14 days, min, %	...	...	...	75[D]	80[E]
Effectiveness in Contributing to Sulfate Resistance:					
Procedure A:[F]					
Expansion of test mixture:					
For moderate sulfate exposure after 6 months exposure, max, %	0.10[G]	0.10[G]	0.10[G]	0.10[D]	0.10[E]
For high sulfate exposure after 6 months exposure, max, %	0.05[G]	0.05[G]	0.05[G]	0.05[D]	0.05[E]
For very high sulfate exposure after 12 months exposure, max, %	...	...	...	...	0.05[D]
Procedure B:					
Expansion of test mixture as a percentage of sulfate resistance cement control after at least 6 months exposure, max,%[G]	100	100	100	...	...

[A]Determination of compliance or noncompliance with the requirement relating to increase in drying shrinkage will be made only at the request of the purchaser. Test method in accordance with Test Methods C311.

[B]Test in accordance with Test Methods C311 or Specification C1240 as appropriate.

[C]Blended supplementary cementitious materials meeting this requirement are considered as effective in controlling alkali aggregate reactions as the use of the low-alkali control cement used in the evaluation. However, the blended supplementary cementitious material shall be considered effective only when used at percentages by mass of the total cementitious material equal to or exceeding that used in the tests and when the alkali content of the cement to be used does not exceed that used in the tests by more than 0.05 %. See Appendix XI, Test Methods C311. Test method in accordance with Test Methods C311.

[D]Refer to the Appendix of Specification C989.

[E]As delineated in Specification C1240.

[F]Only one limit shall be specified.

[G]Blended supplementary cementitious materials shall be considered effective only when the blended supplementary cementitious material is used at percentages, by mass, of the total cementitious material within 2 % of those that are successful in the test mixtures or between two percentages that are successful, and when the C_3A content of the project cement is less than, or equal to, that which was used in the test mixtures. See Appendix X2 of Test Methods C311. Test method in accordance with Test Methods C311.

11. Storage and Inspection

11.1 The blended supplementary cementitious materials shall be protected from the detrimental effects of exposure to the environment and stored in such a manner as to permit easy access for proper inspection and identification.

11.2 Inspection of the material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

12. Rejection and Rehearing

12.1 The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the manufacturer or supplier promptly and in writing. In case of dissatisfaction with the results of the tests, the manufacturer or supplier is not prohibited from making a claim for retesting.

13. 13. Certification

13.1 Upon request, the purchaser shall be furnished certification that all material has been tested as directed in this specification and the specified requirements have been met.

13.1.1 When requested by the purchaser or when specified in the purchase order or contract, a report of individual constituents including source and specification compliance shall be furnished.

13.1.2 When requested by the purchaser or when specified in the purchase order or contract, a report of the blended supplementary cementitious material test results, including chemical composition and physical properties shall be furnished.

14. Packaging and Package Marking

14.1 When blended supplementary cementitious material is delivered in packages, the composition of the blend using the naming practice in 4.2, the name and brand of the manufacturer, and the mass contained therein shall be plainly marked on each package. Similar information shall be provided in the shipping invoices accompanying the shipment of bulk blended supplementary cementitious material.

7 day Index	75[C]	75[C]	75[C]	Report only	105
28 day Index	75[C]	75[C]	75[C]	75[D]	...
Water Requirement, % of control[E]	Report only	Report only	Report only	Report only	Report only
Autoclave, expansion or contraction, max, %[F]	0.8	0.8	0.8	...	...

[A]Refer to Test Methods C311 except compare with water meeting the applicable Activity Index method.

[B]The activity index with portland cement is not to be considered a measure of the compressive strength of concrete containing the pozzolan or slag. The tests are conducted as follows - for N, F, C refer to Specification C618; for S refer to Specification C989; for SF refer to Specification C1240.

[C]Meeting the 7 day or 28 day activity index will indicate specification compliance.

[D]Requirement is for the average of last 5 consecutive samples; no individual sample shall be more than 5 % less than the average requirement.

[E]Refer to test method in Test Methods C311.

[F]In accordance with Test Method C151, except the specimens shall be molded from a paste composed of 25 parts by mass of blended supplementary cementitious material and 100 parts by mass of a portland cement conforming to Specification C150.

APPENDIX

(Nonmandatory Information)

X1. VERIFYING BLEND PROPORTIONS

X1.1 This Appendix provides information for purchasers of blended supplementary cementitious materials about typical methods that manufacturers use to control the blend production process and verify product conformance.

X1.2 Mechanical methods, such as weighing individual constituents as each goes to the blending system are adequate to provide production control but chemical analysis as described below is required by this specification for verifying actual blend proportions:

X1.2.1 Ensure weighfeeders are maintained and calibrated before production. Weigh feeders are to provide for general control and adjustment during production.

X1.2.2 Ensure that the analysis method, X-ray fluorescence (XRF) or other qualified method is calibrated within the ranges of materials being tested.

X1.2.3 Sample and chemically analyze individual constituents before production begins and at established frequencies during production.

X1.2.4 Sample and chemically analyze finished blended supplementary cementitious materials at established frequencies during production runs for quality control purposes and verification of blend proportions.

X1.2.5 Proportion analysis, as used here, is a calculation using the chemical analysis of the individual constituents and the resultant blend.

X1.2.5.1 The individual constituents are analyzed and predominant elements are chosen as chemical identifiers.

X1.2.5.2 Those chosen identifiers are then used to calculate the mass % of constituents in the blended supplementary cementitious material.

An example of this calculation follows. This is a basic example for illustrative purposes using one element. A more detailed analysis using multiple elements can be performed using a spreadsheet program such as EXCEL Solver.

Target: A blended supplementary cementitious material with 10 % silica fume and 90 % slag cement.

Individual constituent analysis: Silica Fume with 90 % SiO_2 and Slag cement with 30 % SiO_2

Finished product analysis: 36 % SiO_2

Calculation:

$$(10\ \%\ \textit{Silica Fume} \cdot 90\ \%\ \textit{SiO}_2) + (90\ \%\ \textit{Slag cement} \cdot 30\ \%\ \textit{SiO}_2) = 36\ \%\ \textit{SiO}_2$$

Evaluation: The proportions of the constituents, mass %, are as targeted (10 % Silica fume / 90 % slag cement) because the finished product SiO_2 equals the calculated SiO_2 at the targeted blend ratio.

Additional analysis to determine if the proportions are within allowable tolerances is shown below:

Target: A blended supplementary cementitious material with 10 % silica fume and 90 % slag cement.

Allowable tolerance of silica fume = ± 1 %

Calculation using the same constituent analysis as above:

$$(9\ \%\ \textit{Silica Fume} \cdot 90\ \%\ \textit{SiO}_2) + (91\ \%\ \textit{Slag cement} \cdot 30\ \%\ \textit{SiO}_2) = 35.4\ \%\ \textit{SiO}_2$$

$$(11\ \%\ \textit{Silica Fume} \cdot 90\ \%\ \textit{SiO}_2) + (89\ \%\ \textit{Slag cement} \cdot 30\ \%\ \textit{SiO}_2) = 36.6\ \%\ \textit{SiO}_2$$

Evaluation: The blend proportions would be within allowable tolerances if the SiO_2 of the blend is between 35.4 % and 36.6 %

X1.2.6 During manufacturing, feeder adjustments would be made as necessary to achieve the targeted proportions. However, it is normal to apply "Statistical Process Control" rules to the proportion results in order to prevent unnecessary reactions to normal process variation.

X1.2.7 Proportion analysis with other equipment such as colorimeter or induction furnace sulfur analyzers can be used for quality control during production but should not be used for "Manufacturers Certification" unless they are qualified to Test Methods C114.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: C 1698 – 09

Standard Test Method for Autogenous Strain of Cement Paste and Mortar[1]

This standard is issued under the fixed designation C 1698; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method measures the bulk strain of a sealed cement paste or mortar specimen, including those containing admixtures, various supplementary cementitious materials (SCM), and other fine materials, at constant temperature and not subjected to external forces, from the time of final setting until a specified age. This strain is known as *autogenous strain*. Autogenous strain is most significant in concrete with low water-cementitious materials ratio (*w/cm*) (See Note 1).

NOTE 1—A low water-cementitious materials ratio (*w/cm*) can be considered to be a water to cement ratio of 0.40 or lower for this test.

1.2 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this test method, refer to Terminologies C125 and C219.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *autogenous strain*, *n*—the bulk strain of a sealed specimen of a cementitious mixture, not subjected to external forces and under constant temperature, measured from the time of final setting until a specified age; negative strain corresponds to shrinkage and positive strain corresponds to expansion.

4. Summary of Test Method

4.1 A specimen of freshly mixed paste or mortar is prepared using a corrugated mold that offers little resistance to length change of the specimen. The mold is sealed to prevent moisture loss and the specimen is stored at constant temperature. Starting at the time of final setting, the length of the specimen is measured using a dilatometer. The change in length is recorded at regular time intervals until the designated age. The change in length and original length of the specimen are used to compute the autogenous strain.

5. Significance and Use

5.1 Autogenous strain is the self-created bulk strain of cement paste, mortar, or concrete during hardening at constant temperature. In conventional concrete, autogenous shrinkage strain is generally negligible, but in concrete with low water-cementitious materials ratio (*w/cm*) or with silica fume it may be considerable (**1**).[5] Restraint of the autogenous strain by

www.technobetar.ir

aggregates or adjoining structural members may result in formation of micro and macro cracks that impair strength, durability and aesthetics. Cracks may also be a problem with regard to hygienic cleaning of surfaces.

5.2 An accurate measurement of the autogenous strain of cementitious mixtures with low *w/cm* is important for evaluating the risk of early-age cracking of concrete structures. Measurements of autogenous strain have been carried out using either volumetric or linear methods. Both methods may show evidence of significant artifacts (**1**); therefore, results of the two methods may disagree considerably if not carried out properly.

5.3 A sealed, flexible corrugated mold system (**2**) combines the advantages of linear and volumetric measurement of autogenous strain, while avoiding most of their disadvantages. The mold effectively prevents moisture loss and minimizes restraint to volume change during hardening. Moreover, results obtained with the corrugated mold system agree with those from the volumetric method, once some artifacts, in particular water absorption through the membrane used to contain the test specimen, have been eliminated in the latter (**3**,**4**). The corrugated mold system is easier to use and shows better repeatability than the volumetric technique (**3**,**4**). Measurements with the corrugated mold system are in good agreement with unrestrained length change measurements obtained using Test Method C157/C157M with sealed specimens (**5**); however, Test Method C157/C157M does not allow measurement of the shrinkage occurring before 24 h (**5**).

5.4 This test method can be used to evaluate the effects of cementitious materials, admixtures, and mixture proportions on autogenous shrinkage strain of paste or mortar specimens.

5.5 The autogenous shrinkage strain of mortar specimens will be less than that of paste specimens for the same *w/cm*. The autogenous shrinkage strain of concrete will be less than that of mortar for the same *w/cm*. The nominal maximum aggregate size for mortar used in this test method is 4.75 mm.

6. Apparatus

6.1 The apparatus to measure autogenous strain is composed of a corrugated mold with two end plugs, a dilatometer bench, a length measuring gauge, and a reference bar (see Fig. 1).

6.2 *Molds*—The molds consist of corrugated plastic tubes, having a length of 420 ± 5 mm and an outer diameter of 29 ± 0.5 mm (see Note 2). The plastic tubes are made of 0.5 ± 0.2-mm thick low-density polyethylene (PE) and have triangular-shaped corrugations in order to minimize restraint in the longitudinal direction (see Fig. 2). The distance between corrugations is 5.8 ± 0.2 mm. The mold is tightly closed with two tapered end plugs having a length of 19 ± 0.5 mm. The diameter of the plastic end plugs tapers from 21 ± 0.1 mm to 22.4 ± 0.1 mm (see Fig. 3).

NOTE 2—The small diameter of the molds limits the temperature differences that may arise during hydration of the cementitious materials. Typical maximum temperature increase in the center of the test specimen, due to heat of hydration of cement paste or mortar has been determined to be 2 °C. The maximum longitudinal restraint stress exerted by the molds has been determined to be 0.001 MPa (**6**).

6.3 *Dilatometer Bench*—The dilatometer bench consists of three stainless steel rods with a diameter of 20 ± 1.0 mm and two stainless steel end plates. Technical drawings of a suitable dilatometer bench are shown in Fig. 4. During measurement, the test specimen is positioned horizontally and is supported longitudinally by the two upper rods.

6.4 *Length Measuring Gauge*—A gauge measures length changes at one end of the specimen. The measuring range of the gauge shall be at least 10 mm and the resolution shall be at least 0.0025 mm, corresponding to a resolution of about 6 µm/m for the calculated strain.

6.5 *Reference Bar*—Measurements in the dilatometer are performed relative to the length of the reference bar. The bar is made of Invar with a length of 425 ± 0.5 mm and a diameter

NOTE—In the foreground a corrugated PE-mold with two specially shaped end plugs and a 425 mm reference bar. In the background the dilatometer bench with a test specimen placed for length measurement. To the right a digital length gauge with remote control.

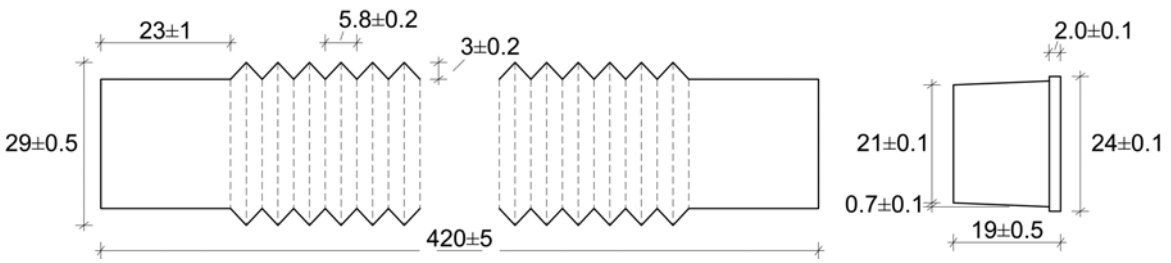
FIG. 2 Corrugated Polyethylene Mold



NOTE—Plastic Tube Wall Thickness 0.5 ± 0.2 mm.

FIG. 3 Outer Dimensions (mm) of Corrugated Low-Density Polyethylene Mold and End Plug

of 20 ± 1.0, tapering to 10 ± 1.0 mm at both ends as shown in Fig. 5. The actual length of the reference bar shall be marked permanently on the bar to the nearest 0.01 mm. Two plastic rings with an external diameter 30 ± 0.5 mm are mounted on the reference bar, as shown in Fig. 1.

6.6 *Reference Masses and Devices for Determining Mass and Volume* shall conform to the requirements of Specification C1005.

6.7 *Support Tube* used to support the corrugated mold during specimen fabrication. The support tube has a length of 400 ± 5 mm and an inside diameter of 32 ± 1 mm (see Fig. 6). The tube is attached to a base that can be fixed to a vibrating table.

6.8 *Vibrating Table* as described in Practice C192/C192M.

6.9 *Tamping Rod* for consolidation of the paste or mortar. It shall be made of a rigid, non-absorptive material that does not react with the cementitious mixture. The length of the rod shall be at least 500 mm and the diameter shall be 6 ± 1 mm. The ends may be flat or hemispherical.

7. Procedure

7.1 *Number of Specimens*—Three replicate specimens shall be tested for each cement paste or mortar (see Note 3).

7.1.1 *Mixing*—Mix cement pastes and mortars according to Practice C305. Record the time when the cementitious materials are added to the water.

7.1.2 *Mixing Apparatus*

7.1.2.1 *Mortar Preparation*—The mixer shall comply with the sequence in Practice C305.

7.1.2.2 *Paste Preparation*—A high shear blender,[6] or similar variable speed blender capable of maintaining a no-load speed of at least 15 000 r/min, with optional cooling device. A hand-held household mixer capable of mixing paste at not less than 400 r/min or other mixers for paste or mortar preparation are also permitted.

NOTE 3—About 185 mL of cement paste or mortar are needed to fill each corrugated mold. For a paste with a water-cement ratio of 0.4, this

NOTE—All dimensions are in mm and tolerances given in the text.

FIG. 5 Technical Drawing of the Reference Bar Shown in Fig. 1

corresponds to approximately 360 g of paste.

7.2 *Filling and Closing of Molds*—Clamp the mounting base of the support tube to a vibrating table. Measure the lengths of the plugs to be used for each specimen. Place a plug into one end of the mold, and position the mold, with the closed end down, inside the support tube. If the cementitious mixture is pourable, slowly pour the mixture into the corrugated mold with the vibrating table turned on (see Fig. 7). For a semi-fluid mixture, fill the mold in four equal layers and compact each layer 5 times with the tamping rod before each subsequent layer is cast. The rod shall just penetrate the underlying layer. For a stiff mixture, hand prepare rolled sections of the cementitious mixture, drop them into the mold, and consolidate with the tamping rod. To ensure that the cast specimens have approximately the same length, do not stretch or compress the corrugated mold during filling. For fluid mixtures, the corrugated mold shall be held only by the support tube during casting. For semi-fluid and stiff mixtures, manually maintain the initial length of the mold during compaction. Fill the mold to approximately 15 mm below the top end of the mold to allow room for the top end plug. Before mounting the top end plug, gently compress the corrugated mold to bring the cement paste or mortar in contact with the end plug. Mount the end plug during relief of the compression of the corrugated mold. Use a screwing motion of the end plug to ease the mounting operation. Immediately after casting, carefully wipe the surface

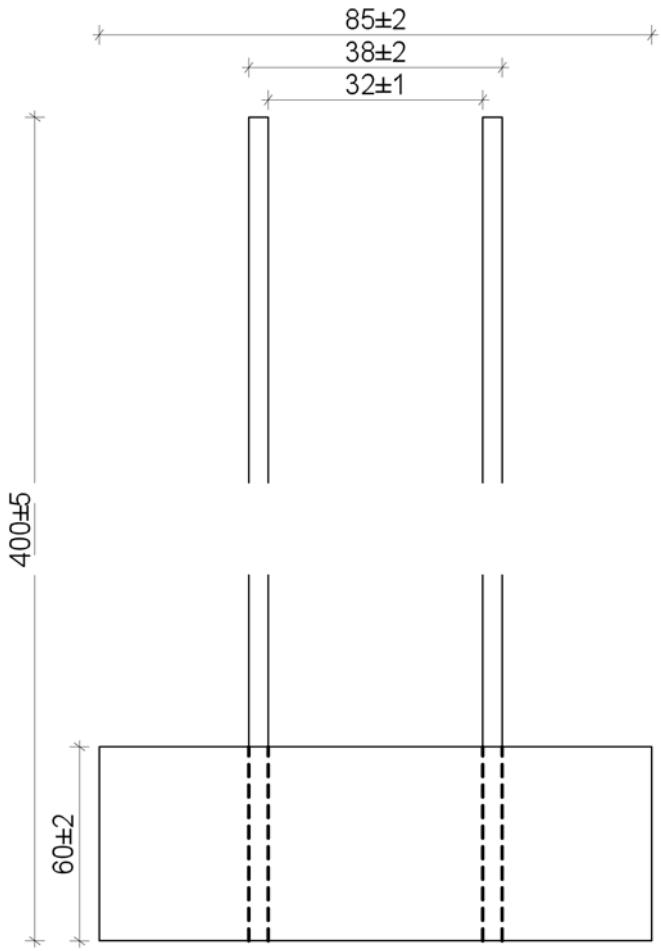
www.technobetar.ir



NOTE—All dimensions are in mm. The base of the support tube allows clamping to a vibration table.

FIG. 6 Suitable Dimensions of the Support Tube That is Used During Filling of the Corrugated Molds

of the corrugated mold with a dry cloth to remove any cement paste, mortar, or water.

7.3 *Measuring Room*—To minimize the influence of temperature variations, both the specimens and the dilatometer shall be kept in a thermostatically controlled room or cabinet at all times during the test. Maintain the surrounding air temperature at 23.0 ± 1.0 °C, unless otherwise specified (see Note 4). Do not store specimens in a water bath due to possible water transport through the corrugated molds.

NOTE 4—The measurement can be performed at any temperature specified by the user, provided that the temperature in the measuring room or cabinet is maintained constant during the test with a tolerance of ± 1.0 °C.

7.4 *Specimen Storage*—After filling and sealing the molds, store the specimens horizontally on a smooth surface, to avoid any restraint to length change. Support specimens along their entire length to avoid damage and to ensure they remain straight (see Note 5). Maintain a separation of at least 30 mm between specimens during the first day of measurement to allow dispersion of their heats of hydration.

NOTE 5—Corrugated plastic sheets as shown in Fig. 8 or other suitable materials can be used to support the molded specimens.

7.5 *Time of First Measurement*—Start length measurements at the time of final setting. Determine times of setting using Test Method C191 for paste or Test Method C403/C403M for mortar on specimens made with the same mixture used to mold the autogenous shrinkage specimens and cured at the same temperature as for the autogenous strain measurement. Protect the specimens used for determination of setting times from moisture loss during the measurement.

7.6 *Length Measurement*—Insert the reference bar in the dilatometer bench and bring the measuring gauge in contact with the end of the bar. Reset the measuring gauge so that it reads zero with the reference bar in position (see Note 6). Remove the reference bar and insert a specimen in the dilatometer bench. Measure the length of the specimen with the gauge (see Note 6). Remove the specimen and measure the length of the next specimen.

NOTE 6—A number of digital length measurement devices have the option of changing the sign of the length measurements. Ensure that the sign for the gauge reading is positive for elongation of the specimen (see Eq 1).

During handling of the specimens, support them at all times with both hands and use care to avoid damage. In particular at

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE—An empty corrugated mold, closed at one end with an end plug, is inserted into the support tube and positioned vertically on a vibrating table. The fresh mixture is slowly poured into the corrugated mold during vibration, until the mold is filled.

FIG. 7 How to Fill the Corrugated Molds

early age the specimens must be supported along their entire length while they are moved to and from the dilatometer bench (Note 7).

NOTE 7—This can be done by moving the specimen together with a corrugated support rack and rolling the specimen into the frame gently onto the dilatometer bench.

To ensure optimal measuring accuracy, place the reference bar and the specimens in the same orientation during each measurement. Draw a line mark with permanent ink on one end of the corrugated mold after the first measurement to indicate both the upside and the measuring gauge position (see Figs. 8 and 9).

7.7 *Frequency and Duration of Measurements*—Frequency and duration of measurements depends on the cementitious mixture and on the scope of the measurements. The specifier of tests shall indicate the frequency of measurements and the duration of testing (see Note 8). In the absence of other specified ages, measure specimen length at the time of final setting and ages of 1, 3, 7, 14, and 28 d from the time of initial mixing of cementitious materials and water. For longer test durations, protect the molds from moisture loss.

NOTE 8—More frequent measurements may be performed at intervals of one to three hours during the first day, twice a day during the first week, once a day after the first week. Typical duration of the measurements varies from one week to several months. For long term measurements, the corrugated molds may be further protected from moisture loss by storing them in sealed tubes between the measurements.

7.8 *Monitoring Mass Change*—Measure specimen mass using a balance with a resolution of at least 0.01 g. Measure the mass of each specimen after the first autogenous strain measurement has been taken at the time of final setting. Measure the mass of each specimen again after each autogenous strain measurement has been performed. Support the specimens along their length while they are moved to the balance and during mass measurement (Note 9).

NOTE 9—This can be done by measuring the mass of the specimen together with a corrugated support rack (see Fig. 8). Ensure that each specimen is weighed with the same support rack during each mass measurement. The measurement of mass loss indicates if drying shrinkage may be occurring, in addition to autogenous shrinkage.

8. Interferences

8.1 *Bleeding*—Bleeding is expected to influence the measured autogenous strain because reabsorption of bleed water after setting may cause expansion. Bleeding has, however, been shown to have minimal influence on the results of the test (see Note 10). For mixtures prone to bleeding, use an apparatus to slowly rotate the filled molds in a horizontal position at a speed of 1 to 3 r/min until final setting has occurred.

NOTE 10—Bleeding should not be a problem in cement pastes or mortars made with values of *w/cm* lower than about 0.4.

8.2 *Entrapped Air*—Before setting, entrapped air inside the corrugated molds as a consequence of less than perfect filling will influence the deformation of the specimens. However, the effect of entrapped air is negligible after setting, when a solid skeleton has developed in the cement paste or mortar.

9. Calculations

9.1 *Time*—The time t is defined as the time elapsed from the first addition of the cementitious materials to the water during mixing.

9.2 *Length*—The length of the paste or mortar specimen at time t is calculated with the following formula:

$$L(t) = L_{ref} + R(t) - 2 \cdot L_{plug} \tag{1}$$

where:

L_{ref} = length of reference bar, mm
$R(t)$ = reading of length gauge with specimen in the dilatometer, mm, and
L_{plug} = average length of end plugs, mm.

9.3 *Autogenous Strain*—The autogenous strain of the specimen at time t, expressed as μm/m, is calculated with the following formula:

$$\varepsilon_{autogenous} = \frac{L(t) - L(t_{fs})}{L(t_{fs})} \cdot 10^6 = \frac{R(t) - R(t_{fs})}{L(t_{fs})} \cdot 10^6 \ \mu m/m \tag{2}$$

where:

t_{fs} = time of final setting, when the first length measurement is performed, min.

9.4 *Mass Change*—The mass change of the specimen is calculated as the difference between the mass of the specimen M_s measured at the conclusion of the test and the mass at the time of final setting:

$$\Delta M = M_s(t_e) - M_s(t_{fs}) \tag{3}$$

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

NOTE—Note pen marks on the ends of the tubes to ensure proper positioning of specimens in the dilatometer bench during length measurements.

FIG. 8 Corrugated Plastic Sheets for Supporting the Specimens During the Test

NOTE—Notice the mark with permanent ink at one end of the specimen showing the upside and measuring gauge position during measurements.

FIG. 9 Placement of Specimen in the Dilatometer Bench for Length Measurement

where:

t_e = time of last mass measurement, min,

$M_s\ (t_e)$ = mass when last mass measurement is made (at the conclusion of the test), g, and

$M_s\ (t_{fs})$ = mass at time of final setting when first mass measurement is made, g.

It is assumed that all the mass change of the specimen is due to exchange of moisture between the cementitious system and the external environment. The exchange of moisture results in an error in the autogenous strain measurement for cement pastes of about 200 μm/m per gram of mass change and for mortars of about 80 μm/m per gram of mass change (7). If the calculated error in the autogenous measurement on this basis exceeds 5 % of the total autogenous strain, the test is considered invalid.

10. Report

10.1 Report the following for each mixture tested:

10.1.1 The mixture proportions in kg/m^3 of water, cement (and other cementitious materials), and aggregates; admixtures in L/m^3; and water-cementitious materials ratio (*w/cm*) to the nearest 0.01.

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:28:37 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.1.2 Measuring room temperature.

10.1.3 Time of first addition of the cementitious materials to water and duration of mixing if different from the mixing time in Practice C305.

10.1.4 Indicate if specimens were rotated before final setting and report the speed of rotation. Also indicate the test method used to determine the time of final setting.

10.1.5 For each length measurement: the time of measurement, gauge reading of each measured specimen at each measuring age, time elapsed from first addition of the cementitious materials to water during mixing, and the autogenous strain value calculated with Eq 1 and 2.

10.1.6 Mass of each specimen at final setting and at end of test. Change of mass (in g) calculated with Eq 3.

11. Precision and Bias

11.1 *Precision*—Preliminary information on repeatability of this test method was derived from single-operator testing in two different laboratories. The standard deviation appears to be constant and is used as the measure of repeatability. For replicate specimens of paste with values of *w/cm* between 0.35 and 0.37, the pooled value of the single operator standard deviation was found to be 110 μm/m. For mortar specimens with values of *w/cm* between 0.30 and 0.43, the pooled value of the single operator standard deviation was found to be 28 μm/m (see Note 11).

NOTE 11—A full analysis of precision, as derived from an interlaboratory program, is expected to be completed by 2013.

11.2 *Bias*—Since there is no accepted reference material suitable for determining the bias of this procedure, no statement on bias is made.

12. Keywords

12.1 autogenous strain; cement paste; length change; mortar

Designation: C 1701/C 1701M – 09

Standard Test Method for Infiltration Rate of In Place Pervious Concrete[1]

This standard is issued under the fixed designation C 1701/C 1701M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the field water infiltration rate of in place pervious concrete.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this standard references notes that provide explanatory material. These notes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 920 Specification for Elastomeric Joint Sealants

2.2 *Other Standards*

Federal Specification A-A-3110 (TT-P-1536A) Plumbing Fixture Setting Compound[3]

3. Terminology

3.1 *Definitions:*

3.1.1 The terms used in this test method are defined in Terminology C 125.

4. Summary of Test Method

4.1 An infiltration ring is temporarily sealed to the surface of a pervious pavement. After prewetting the test location, a given mass of water is introduced into the ring and the time for the water to infiltrate the pavement is recorded. The infiltration rate is calculated in accordance with 9.1.

5. Significance and Use

5.1 Tests performed at the same location across a span of years may be used to detect a reduction of infiltration rate of the pervious concrete, thereby identifying the need for remediation.

5.2 The infiltration rate obtained by this method is valid only for the localized area of the pavement where the test is conducted. To determine the infiltration rate of the entire pervious pavement multiple locations must be tested and the results averaged.

5.3 The field infiltration rate is typically established by the design engineer of record and is a function of the design precipitation event.

5.4 This test method does not measure the influence on in-place infiltration rate due to sealing of voids near the bottom of the pervious concrete slab. Visual inspection of concrete cores is the best approach for determining sealing of voids near the bottom of the pervious concrete slab.

6. Apparatus

6.1 *Infiltration Ring*—A cylindrical ring, open at both ends (See Fig. 1). The ring shall be watertight, sufficiently rigid to retain its form when filled with water, and shall have a diameter of 300 ± 10 mm [12.0 ± 0.5 in.] with a minimum height of 50 mm [2.0 in.]. The bottom edge of the ring shall be even. The inner surface of the ring shall be marked or scored with two lines at a distance of 10 and 15 mm [0.40 and 0.60 in.] from the bottom of the ring. Measure and record the inner diameter of the ring to the nearest 1 mm [0.05 in.].

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.49 on Pervious Concrete.

Current edition approved Aug. 1, 2009. Published September 2009.

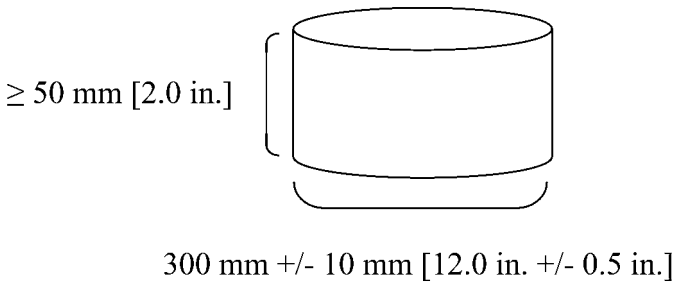

FIG. 1 Dimensions of Infiltration Ring

NOTE 1—Ring materials that have been found to be suitable include steel, aluminum, rigid plastic, and PVC.

6.2 *Balance*—A balance or scale accurate to 10 g [0.02 lb].

6.3 *Container*—A cylindrical container typically made of plastic having a volume of at least 20 L [5 gal], and from which water may be easily poured at a controlled rate into the infiltration ring.

6.4 *Stop Watch*—Accurate to 0.1 s.

6.5 *Plumbers Putty (Non-Hardening)*—Meeting Specification C 920 or Federal Specification A-A-3110.

6.6 *Water*—Potable water.

7. Test Locations

7.1 Perform tests at multiple locations at a site as requested by the purchaser of testing services. Unless otherwise specified, use the following to determine the number of tests to perform:

7.1.1 Three test locations for areas up to 2,500 m^2 [25,000 ft^2].

7.1.2 Add one test location for each additional 1,000 m^2 [10,000 ft^2] or fraction thereof.

7.2 Provide at least 1 m [3 ft] clear distance between test locations, unless at least 24 h have elapsed between tests.

7.3 Do not test if there is standing water on top of the pervious concrete. Do not test within 24 h of the last precipitation.

8. Procedure

8.1 *Infiltration Ring Installation*—Clean the pavement surface by only brooming off trash, debris, and other non-seated material. Apply plumbers putty around the bottom edge of the ring and place the ring onto the pervious concrete surface being tested. Press the putty into the surface and around the bottom edge of the ring to create a watertight seal. Place additional putty as needed

NOTE 2—In a hot environment where the surface temperature is over 38 °C [100 °F] plumbers putty may not adhere to the concrete surface easily. Therefore it is advisable to perform this test during cooler temperature.

8.2 *Prewetting*—Pour water into the ring at a rate sufficient to maintain a head between the two marked lines. Use a total of 3.60 ± 0.05 kg [8.0 ± 0.1 lb] of water. Begin timing as soon as the water impacts the pervious concrete surface. Stop timing when free water is no longer present on the pervious surface. Record the amount of elapsed time to the nearest 0.1 s.

8.3 *Test*—The test shall be started within 2 min after the completion of the prewetting. If the elapsed time in the prewetting stage is less than 30 s, then use a total of 18.00 ± 0.05 kg [40.00 ± 0.1 lb] of water. If the elapsed time in the prewetting stage is greater than or equal to 30 s, then use a total of 3.60 ± 0.05 kg [8.0 ± 0.1 lb] of water. Record the weight of water to the nearest 10 g [0.02 lb] (M). Pour the water into the ring at a rate sufficient to maintain a head between the two marked lines and until the measured amount of water has been used. Begin timing as soon as the water impacts the pervious concrete surface. Stop timing when free water is no longer present on the pervious surface. Record the testing duration (t) to the nearest 0.1 s.

NOTE 3—If a sloped pavement is being measured, maintain head between the two marked lines at the lowest point of the slope.

8.4 If a test is repeated at the same location, the repeat test does not require pre-wetting if conducted within 5 min after completion of the first test. If more than one test is conducted at a location on a given day, the infiltration rate at that location on that day shall be calculated as the average of the two tests. Do not repeat this test more than twice at the same location on a given day.

9. Calculation

9.1 Calculate the infiltration rate (I) using consistent units as follows:

$$I = \frac{KM}{(D^2 * t)}$$

where:

I = Infiltration rate, mm/h [in./h],
M = Mass of infiltrated water, kg [lb],
D = Inside diameter of infiltration ring, mm [in.],
t = time required for measured amount of water to infiltrate the concrete, s, and
K = 4 583 666 000 in SI units or 126 870 in [inch-pound] units.

NOTE 4—The factor K has units of $(mm^3 s)/(kgh)$ $[(in.^3 s)/(lbh)]$ and is needed to convert the recorded data (W, D, and t) to the infiltration rate I in mm/h [in./h].

10. Report

10.1 Report the following information:

10.1.1 Identification number,

10.1.2 Location,

10.1.3 Date of test,

10.1.4 Age and thickness of concrete (label Unknown if not known),

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:28:33 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.1.5 Time elapsed during prewetting, s,
10.1.6 Amount of rain during last event, if known, mm [in.],
10.1.7 Weight of infiltrated water, kg [lb],
10.1.8 Inside diameter of infiltration ring, mm [in.],
10.1.9 Time elapsed during infiltration test, s,
10.1.10 Infiltration rate, mm/h [in./h], and
10.1.11 Number of tests performed at each location, if applicable.

11. Precision and Bias

11.1 Repeatability testing was performed by a single laboratory by making 2 replicate measurements at three locations on a newly placed pervious concrete pavement. The replicate measurements were repeated daily from day 1 to day 10. The single-operator coefficient of variation of the infiltration rate at one test location was found to be 4.7 %.

11.2 The multi-operator variability data has not been developed. The reproducibility of this test method is being determined and will be available on or before October 1, 2014.

11.3 This test method has no bias because the infiltration rate of in-place pervious concrete is defined only in terms of this test method.

12. Keywords

12.1 concrete; infiltration; pervious; water

Designation: C 1701/C 1701M – 09

Standard Test Method for Infiltration Rate of In Place Pervious Concrete[1]

This standard is issued under the fixed designation C 1701/C 1701M; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the determination of the field water infiltration rate of in place pervious concrete.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in non-conformance with the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4 The text of this standard references notes that provide explanatory material. These notes shall not be considered as requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C 125 Terminology Relating to Concrete and Concrete Aggregates

C 920 Specification for Elastomeric Joint Sealants

2.2 *Other Standards*

Federal Specification A-A-3110 (TT-P-1536A) Plumbing Fixture Setting Compound[3]

3. Terminology

3.1 *Definitions:*

3.1.1 The terms used in this test method are defined in Terminology C 125.

4. Summary of Test Method

4.1 An infiltration ring is temporarily sealed to the surface of a pervious pavement. After prewetting the test location, a given mass of water is introduced into the ring and the time for the water to infiltrate the pavement is recorded. The infiltration rate is calculated in accordance with 9.1.

5. Significance and Use

5.1 Tests performed at the same location across a span of years may be used to detect a reduction of infiltration rate of the pervious concrete, thereby identifying the need for remediation.

5.2 The infiltration rate obtained by this method is valid only for the localized area of the pavement where the test is conducted. To determine the infiltration rate of the entire pervious pavement multiple locations must be tested and the results averaged.

5.3 The field infiltration rate is typically established by the design engineer of record and is a function of the design precipitation event.

5.4 This test method does not measure the influence on in-place infiltration rate due to sealing of voids near the bottom of the pervious concrete slab. Visual inspection of concrete cores is the best approach for determining sealing of voids near the bottom of the pervious concrete slab.

6. Apparatus

6.1 *Infiltration Ring*—A cylindrical ring, open at both ends (See Fig. 1). The ring shall be watertight, sufficiently rigid to retain its form when filled with water, and shall have a diameter of 300 ± 10 mm [12.0 ± 0.5 in.] with a minimum height of 50 mm [2.0 in.]. The bottom edge of the ring shall be even. The inner surface of the ring shall be marked or scored with two lines at a distance of 10 and 15 mm [0.40 and 0.60 in.] from the bottom of the ring. Measure and record the inner diameter of the ring to the nearest 1 mm [0.05 in.].

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.49 on Pervious Concrete.

Current edition approved Aug. 1, 2009. Published September 2009.

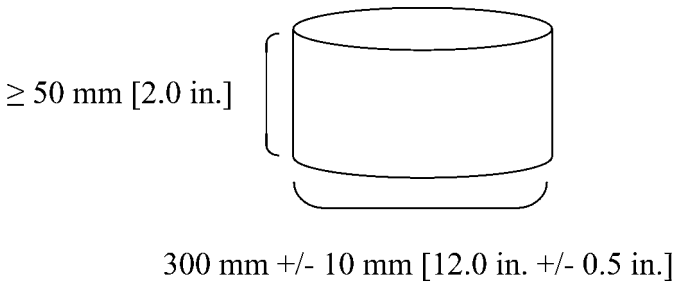

FIG. 1 Dimensions of Infiltration Ring

NOTE 1—Ring materials that have been found to be suitable include steel, aluminum, rigid plastic, and PVC.

6.2 *Balance*—A balance or scale accurate to 10 g [0.02 lb].

6.3 *Container*—A cylindrical container typically made of plastic having a volume of at least 20 L [5 gal], and from which water may be easily poured at a controlled rate into the infiltration ring.

6.4 *Stop Watch*—Accurate to 0.1 s.

6.5 *Plumbers Putty (Non-Hardening)*—Meeting Specification C 920 or Federal Specification A-A-3110.

6.6 *Water*—Potable water.

7. Test Locations

7.1 Perform tests at multiple locations at a site as requested by the purchaser of testing services. Unless otherwise specified, use the following to determine the number of tests to perform:

7.1.1 Three test locations for areas up to 2,500 m^2 [25,000 ft^2].

7.1.2 Add one test location for each additional 1,000 m^2 [10,000 ft^2] or fraction thereof.

7.2 Provide at least 1 m [3 ft] clear distance between test locations, unless at least 24 h have elapsed between tests.

7.3 Do not test if there is standing water on top of the pervious concrete. Do not test within 24 h of the last precipitation.

8. Procedure

8.1 *Infiltration Ring Installation*—Clean the pavement surface by only brooming off trash, debris, and other non-seated material. Apply plumbers putty around the bottom edge of the ring and place the ring onto the pervious concrete surface being tested. Press the putty into the surface and around the bottom edge of the ring to create a watertight seal. Place additional putty as needed

NOTE 2—In a hot environment where the surface temperature is over 38 °C [100 °F] plumbers putty may not adhere to the concrete surface easily. Therefore it is advisable to perform this test during cooler temperature.

8.2 *Prewetting*—Pour water into the ring at a rate sufficient to maintain a head between the two marked lines. Use a total of 3.60 ± 0.05 kg [8.0 ± 0.1 lb] of water. Begin timing as soon as the water impacts the pervious concrete surface. Stop timing when free water is no longer present on the pervious surface. Record the amount of elapsed time to the nearest 0.1 s.

8.3 *Test*—The test shall be started within 2 min after the completion of the prewetting. If the elapsed time in the prewetting stage is less than 30 s, then use a total of 18.00 ± 0.05 kg [40.00 ± 0.1 lb] of water. If the elapsed time in the prewetting stage is greater than or equal to 30 s, then use a total of 3.60 ± 0.05 kg [8.0 ± 0.1 lb] of water. Record the weight of water to the nearest 10 g [0.02 lb] (M). Pour the water into the ring at a rate sufficient to maintain a head between the two marked lines and until the measured amount of water has been used. Begin timing as soon as the water impacts the pervious concrete surface. Stop timing when free water is no longer present on the pervious surface. Record the testing duration (t) to the nearest 0.1 s.

NOTE 3—If a sloped pavement is being measured, maintain head between the two marked lines at the lowest point of the slope.

8.4 If a test is repeated at the same location, the repeat test does not require pre-wetting if conducted within 5 min after completion of the first test. If more than one test is conducted at a location on a given day, the infiltration rate at that location on that day shall be calculated as the average of the two tests. Do not repeat this test more than twice at the same location on a given day.

9. Calculation

9.1 Calculate the infiltration rate (I) using consistent units as follows:

$$I = \frac{KM}{(D^2 * t)}$$

where:

I = Infiltration rate, mm/h [in./h],
M = Mass of infiltrated water, kg [lb],
D = Inside diameter of infiltration ring, mm [in.],
t = time required for measured amount of water to infiltrate the concrete, s, and
K = 4 583 666 000 in SI units or 126 870 in [inch-pound] units.

NOTE 4—The factor K has units of $(mm^3 s)/(kgh)$ $[(in.^3 s)/(lbh)]$ and is needed to convert the recorded data (W, D, and t) to the infiltration rate I in mm/h [in./h].

10. Report

10.1 Report the following information:

10.1.1 Identification number,

10.1.2 Location,

10.1.3 Date of test,

10.1.4 Age and thickness of concrete (label Unknown if not known),

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:28:38 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

10.1.5 Time elapsed during prewetting, s,
10.1.6 Amount of rain during last event, if known, mm [in.],
10.1.7 Weight of infiltrated water, kg [lb],
10.1.8 Inside diameter of infiltration ring, mm [in.],
10.1.9 Time elapsed during infiltration test, s,
10.1.10 Infiltration rate, mm/h [in./h], and
10.1.11 Number of tests performed at each location, if applicable.

11. Precision and Bias

11.1 Repeatability testing was performed by a single laboratory by making 2 replicate measurements at three locations on a newly placed pervious concrete pavement. The replicate measurements were repeated daily from day 1 to day 10. The single-operator coefficient of variation of the infiltration rate at one test location was found to be 4.7 %.

11.2 The multi-operator variability data has not been developed. The reproducibility of this test method is being determined and will be available on or before October 1, 2014.

11.3 This test method has no bias because the infiltration rate of in-place pervious concrete is defined only in terms of this test method.

12. Keywords

12.1 concrete; infiltration; pervious; water

Designation: C1702 – 09a

Standard Test Method for Measurement of Heat of Hydration of Hydraulic Cementitious Materials Using Isothermal Conduction Calorimetry[1]

This standard is issued under the fixed designation C1702; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method specifies the apparatus and procedure for determining total heat of hydration of hydraulic cementitious materials at test ages up to 7 days by isothermal conduction calorimetry.

1.2 This test method also outputs data on rate of heat of hydration versus time that is useful for other analytical purposes, as covered in Practice C1679.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C186 Test Method for Heat of Hydration of Hydraulic Cement

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

C1679 Practice for Measuring Hydration Kinetics of Hydraulic Cementitious Mixtures Using Isothermal Calorimetry

3. Terminology

3.1 *Definitions of Terms Specific to This Standard:*

3.1.1 *baseline*, *n*—the time-series signal from the calorimeter when measuring output from a sample of approximately the same mass and thermal properties as a cement sample, but which is not generating or consuming heat.

3.1.2 *heat*, *n*—the time integral of thermal power measured in joules (J).

3.1.3 *isothermal conduction calorimeter*, *n*—a calorimeter that measures heat flow from a sample maintained at a constant temperature by intimate thermal contact with a constant temperature heat sink.

3.1.4 *reference cell*, *n*—a heat-flow measuring cell that is dedicated to measuring power from a sample that is generating no heat.

3.1.4.1 *Discussion*—The purpose of the reference cell is to correct for baseline drift and other systematic errors that can occur in heat-flow measuring equipment.

3.1.5 *sensitivity*, *n*—the minimum change in thermal power reliably detectable by an isothermal calorimeter.

3.1.5.1 *Discussion*—For this application, sensitivity is taken as ten times the random noise (standard deviation) in the baseline signal.

3.1.6 *thermal power*, *n*—the heat production rate measured in joules per second (J/s).

3.1.6.1 *Discussion*—This is the property measured by the calorimeter. The thermal power unit of measure is J/s, which is equivalent to the watt. The watt is also a common unit of measure used to represent thermal power.

4. Summary of Test Method

4.1 *Principle*—An isothermal heat conduction calorimeter consists of a constant-temperature heat sink to which two heat-flow sensors and sample holders are attached in a manner resulting in good thermal conductivity. One heat-flow sensor and sample holder contains the sample of interest. The other heat-flow sensor is a reference cell containing a blank sample that evolves no heat. The heat of hydration released by the reacting cementitious sample flows across the sensor and into the heat sink. The output from the calorimeter is the difference in heat flow (thermal power) between the sample cell and the reference cell. The heat-flow sensor actually senses a small temperature gradient that develops across the device, however the heat is removed from the hydrating sample fast enough

[1] This test method is under the jurisdiction of ASTM Committee C01 on Cement and is the direct responsibility of Subcommittee C01.26 on Heat of Hydration.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 2009. Last previous edition approved in 2009 as C1702–09. DOI: 10.1520/C1702-09a.

www.technobetar.ir

that, for practical purposes, the sample remains at a constant temperature (isothermal).

4.2 The output from the heat-flow sensor is an electrical voltage signal that is proportional to the thermal power from the sample. This output must be calibrated to a known thermal power. In this method this is accomplished by measurements on a heat source that emits a constant and known power level. The integral of the thermal power over the time of the test is the heat of hydration.

4.3 Two methods are described. In Method A the sample and water are both temperature equilibrated and mixed inside the calorimeter. This method is the most direct way to determine heat of hydration. In Method B the sample is mixed outside of the calorimeter then put into the calorimeter. This method offers certain practicality, but depending on the materials being analyzed and procedures used for mixing and handling, this method may suffer from small errors due to periods of hydration being missed or spurious heat being introduced or taken away from the calorimeter during setup or combinations thereof. Methods of correction are offered for these potential errors.

5. Significance and Use

5.1 This method is suitable for determining the total heat of hydration of hydraulic cement at constant temperature at ages up to 7 days to confirm specification compliance. It gives test results equivalent to Test Method C186 up to 7 days of age (Poole (2007) (**4**)).

5.2 This method compliments Practice C1679 by providing details of calorimeter equipment, calibration, and operation. Practice C1679 emphasizes interpretation significant events in cement hydration by analysis of time dependent patterns of heat flow, but does not provide the level of detail necessary to give precision test results at specific test ages required for specification compliance.

6. Apparatus

6.1 *Miscellaneous Equipment*:

6.1.1 *Balance*—Accurate to 0.01 g.

6.1.2 *Volumetric Dispenser*—A device for measuring volume or mass of water, accurate to 0.1 mL. This could be a syringe, pipette, or weighing device.

6.1.3 *Sample Holder*—A device that holds the cement paste and provides intimate contact with the calorimeter heat sensing device and prevents evaporation of mixing water. If using commercially manufactured equipment, consult the recommendations of the manufacturer in choosing sample holders.

6.1.4 *Resistance Heater*—An electrical device fabricated from material with similar heat capacity and shape as the test sample, but containing a resistor connected to a constant-voltage power supply such that a stable output of 0.010 ± 0.0002 J/s can be generated (see Note 1).

NOTE 1—A simple procedure for fabricating heaters and blanks having the same approximate shape and heat capacity as a sample is to make specimen similar to one used in a determination out of plaster of Paris embedded with a small resistor. Plaster of Paris has only a transient heat of hydration and is not aggressive to electronic components. A resistance of 100-300 ohms is a convenient value when using voltages of 0.1-10 volts to drive heat production.

6.1.5 *Reference Specimen*—A sample fabricated from an inert material with similar heat capacity and shape as the test sample. This is used in the reference cell.

6.1.6 *Multimeter*—An instrument for measuring DC voltage and resistance values for the resistance heater described in 6.1.4 to an accuracy of 1 %. This instrument is only required if the calorimeter does not contain built-in calibration capability.

6.1.7 *Power Supply*—A constant voltage DC power supply with a power output range sufficient to simulate the maximum output of a hydrating cement sample (see Note 2). This equipment is only required if an instrument does not contain built-in calibration capability.

NOTE 2—A power output of at least 0.33 J/s is needed for most applications.

6.1.8 *Insulated Container*—Used in the Method B described in 8.3.5.1. This device can be fabricated using a 500 mL (approximate volume) container insulated with at least 30 mm of polystyrene on the sides and top.

6.1.9 *Temperature Measuring Device*—Used in Method B described in 8.3.5.1. The device shall be capable of measuring temperature changes to the nearest 0.1 °C and of a physical configuration that allows it to operate in the confines of the insulated container described in 6.1.8.

6.2 *Calorimeter*—The schematic design of a calorimeter is given in Fig. 1. It shall consist of a sample holder for the test and reference specimens, each thermally connected to heat flow sensors, which are thermally connected to a constant-temperature heat sink. The actual design of an individual

www.technobetar.ir

instrument, whether commercial or homemade, may vary, but it should follow the criteria given below. Any other suitable arrangement that satisfies sections 6.2.1, 6.2.2, and 6.2.3 is acceptable.

6.2.1 *Instrument Stability*—The baseline shall exhibit a low random noise level and be stable against drift. This property shall be verified on a new instrument and whenever there are questions about performance. The rate of change of the baseline measured during a time period of 3 days shall be ≤20 μJ/s per gram sample per hour of the test and a baseline random noise level of ≤10 μJ/s per gram sample (see Note 3). In practice the baseline is measured for 3 days and a straight line is fitted to the power (J/g/s) versus time (h) data using a linear regression procedure. The long term drift is then the slope in the line J/g/s/h and the baseline noise level is the standard deviation (J/g/s) around this regression line.

NOTE 3—The rationale for these limits is found in Poole (2007) (**4**).

6.2.2 *Instrument Sensitivity*—The minimum sensitivity for measuring power output shall be 100 μJ/s.

6.2.3 *Isothermal Conditions*—The instrument shall maintain the temperature of the sample to within 1 K of the thermostated temperature.

6.3 *Data Acquisition Equipment*—Data acquisition equipment may be built into the calorimeter instrument package, or it may be an off-the-shelf, stand-alone, item. The data acquisition equipment shall be capable of performing continuous logging of the calorimeter output measurement at a minimum time interval of 10 s. It is useful, for purposes of reducing amount of data, to have the flexibility to adjust the reading interval to longer times when power output from the sample is low. Some data acquisition equipment is designed to automatically adjust reading intervals in response to power output. The equipment shall have at least 4.5-digit-measuring capability, with an accuracy of 1 %, or comparable capabilities to condition the power output into the same quality as integrated signal amplifiers.

7. Instrument Calibration

7.1 *Instrument Calibration*—Commercially manufactured instruments designed for measuring heat of hydration of cementitious materials may have instrument specific calibration procedures. Conform to these procedures if they exist. In addition, the instrument shall be capable of providing data described in 7.1.1.1, 7.1.2.1, and 7.1.2.2, and calculations in 7.1.4. If there are no instrument calibration procedures, calibrate the instrument according to the following procedure. Calibration shall be at least a two-point process. This is illustrated schematically in Fig. 2.

7.1.1 Mount the resistance heater and the blank specimen in their respective measuring cells and start data collection. This step measures the baseline calorimeter output (in units of V or mV) when no heat is being generated.

7.1.1.1 Measure this baseline when it reaches a constant value (drift ≤ 20 μJ/s per gram sample per hour).

7.1.1.2 Record this output as V_0 for $P_0 = 0$ (see Note 4).

NOTE 4—V_0 may not be zero voltage, but may be a positive or negative number. The practice of using a test cell and a reference cell usually results in the V_0 being a relatively small number but, depending on the variability in properties of some hardware, it may not be zero.

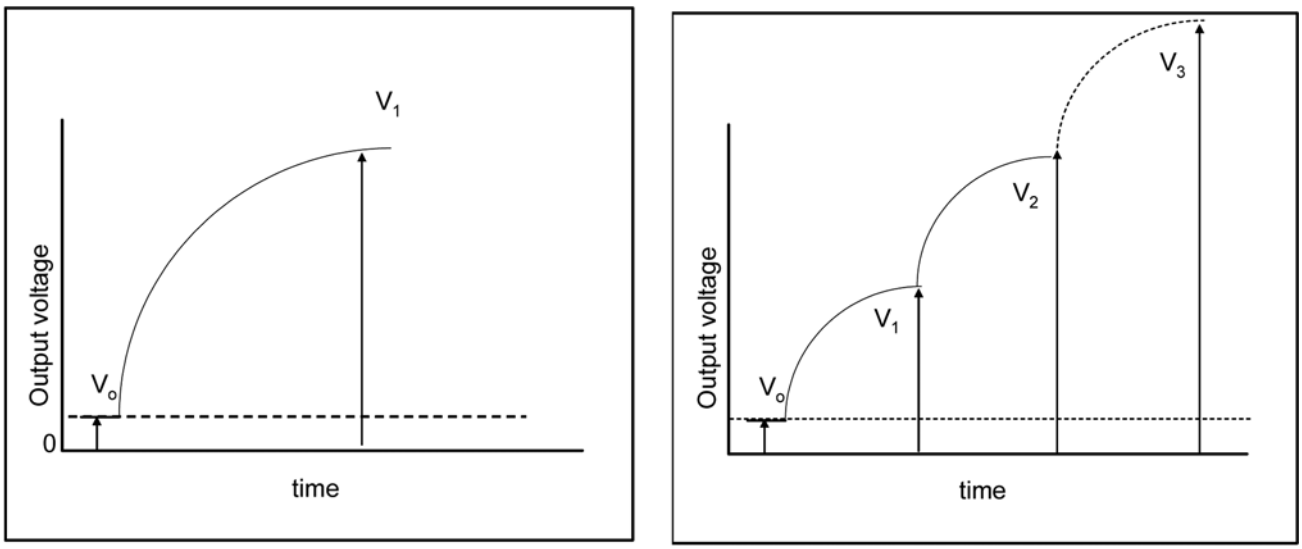

FIG. 2 (A) Schematic Steady-State Calibration Using A 2-Point Calibration Process And (B) Multi-Point Calibration Process

www.technobetar.ir

7.1.2 Power in the heater circuit is related to voltage and resistance by the following equation:

$$P = I^2R \quad (1)$$

where:
P = power, J/s,
I = applied current, amperes, and
R = resistance, ohms.

Apply sufficient voltage to the heater circuit to generate a heat output of approximately 0.1 J/s, measured to an accuracy of 5 %.

7.1.2.1 Allow the output to stabilize signal at a drift of ≤0.1 % over 60 min or ≤0.05 % over 30 min.

7.1.2.2 Record this output as V_1 for a power P_1(see Note 5). This is the minimum requirement for a calibration sequence. At the users discretion any number of voltage levels may be used to characterize the operating range of the calorimeter.

NOTE 5—The early C_3A reaction of a typical portland cement evolves a maximum power of about 0.02 J/s/g. The alite phase typically evolves heat at a maximum power of about 0.002 J/s/g during the first 24 h of hydration. A5 g sample then generates power peaks in the range of 0.10 J/s/g in the first few minutes after adding water, and in the range of 0.010 J/s/g in the first 24 h.

7.1.3 *Calibration Coefficients*—Calculate calibration coefficients by fitting the power versus voltage output data to a to a mathematical relationship using standard curve fitting techniques. Power (P), in units of J/s (or watts), is the dependent variable (y) in the calibration equation, and output voltage (V), in units of mV, is the independent variable (x). This equation is then used to translate mV output to power units meaningful for calculating heat flow (see Note 6).

NOTE 6—A linear calibration equation is found to be suitable in many instruments over the operating range necessary to analyze portland cements, as in the following equation: P = A + BV. In this case, the fitted coefficients A (y-axis intercept) and B (slope) are in units of J/s and J/s/mV, respectively.

7.1.4 In a multi-channel instrument containing several calorimeters, all channels shall be calibrated individually. However, it is possible to calibrate all calorimeters simultaneously using multiple resistance heaters and having the same current passing through the heaters in all calorimeter cells.

7.1.5 Calibration shall be executed at regular intervals to determine the calibration coefficient. The length of the time intervals between calibrations is dependent on the instrument and the personnel, and must be determined empirically. If the calibration coefficient differs more than 2 % from one calibration to the next, then calibrations intervals must be reduced until this stability limit is reached.

8. Procedure

8.1 Turn on the calorimeter equipment and data acquisition unit. Determine that the calorimeter is at temperature equilibrium by verifying that the baseline is stable over a period of a few minutes. The temperature of the heat sink during the test shall be 23.0 ± 1.0 °C, unless a different temperature is required by the analysis.

8.2 *Method A*—This method is used when an instrument is configured so that cementitious materials and water can be temperature equilibrated and mixed while in place in the calorimeter cell.

8.2.1 Weigh at least 3 g of cementitious material (see Note 7), the mass recorded to the nearest 0.01 g, and place in the calorimeter cell. Weigh or determine volumetrically sufficient water to give a paste water-cementitious materials ratio of at least 0.40, but in any case sufficient water to completely wet the sample, and place the water holder in the cell. Higher water-cementitious materials ratios may be required to get thorough mixing of cement and water (see Note 8). Allow any change in the calorimeter output caused by this process to return to the baseline level.

NOTE 7—Amount of sample required varies among calorimeter designs. Since the exothermic reaction tends to slow down after the first 24 h, a sample that is too small will generate a signal late in the test period that is too weak to detect reliably. If inconsistent results are obtained, then a larger sample size may be required. Sample sizes between about 3 and 15 g have been reported to be useful for maintaining a strong signal late in the test for portland-cement based cements. Normally a signal of at least 10 μJ/s/g at the end of the test is sufficient to give good results. Tests designed to run for 1-3 days can use a sample mass at the smaller end of this range, while longer tests, such as 7 days, require a sample mass at the larger end of this range.

NOTE 8—The w/c required for good mixing will probably have to be determined empirically by examining specimens after completion of testing for evidence of poor mixing.

8.2.2 Start data collection, then mix the water with the cementitious materials to form a uniform paste. Some commercial calorimeters and data acquisition equipment are programmable to collect data at prescribed interval lengths or at intervals that vary with the rate of change of power levels. Data are collected more rapidly when power output is high than when it is low. If this flexibility is not a feature of the data acquisition component of the calorimeter, then collect readings every 30 s throughout the length of the test (see Note 9).

NOTE 9—It is only necessary to collect data every 10 s through the period of an early and short-lived heat evolution peaks. In portland cements this is over within approximately 30 min. Data collection every 10 min is adequate after this point. Adopting this practice will reduce the size of data files.

8.3 *Method B*—This method is used when cement paste is mixed outside of the calorimeter and then loaded into the calorimeter cell. In this procedure, a small amount of the early heat-of hydration data may be lost. For non-portland-based cements, the error could be more significant. Also, the baseline may also be disturbed during the early period of the test due to spurious heat gains to the sample or losses from the sample while outside of the calorimeter, e.g. during mixing and handling. Procedures for correcting these errors are included in paragraphs 8.3.5.1 and 8.3.5.2, respectively.

8.3.1 *Conditioning Materials*—All materials shall be at a temperature of 23 ± 2 °C before mixing unless a different temperature condition is required for the analysis.

8.3.2 *Mixing and Charging of Cement Paste*—The mixing of the cement paste shall be made in such a way that the time between the addition of water and the time when the sample is put into the calorimeter is less than 5 min. Mix sufficient

Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

cement paste at a water-cementitious materials ratio of 0.40 or higher to give a sample containing a mass of dry cement in the range described in Method A. Determine the mass of the paste sample to the nearest 0.01 g, put it into the calorimeter sample holder, and cover to prevent evaporation of mixing water.

8.3.3 Care should be taken that the incidental warming or cooling of the sample and the sample holder due to handling are minimal. Although the method provides a correction for such temperature effects, it is not designed to handle large temperature differences between the sample and the calorimeter (see Note 10).

NOTE 10—Use of insulating cotton gloves may be helpful in minimizing heating of the sample from handling.

8.3.4 Load the sample and sample container into the calorimeter. Start data collection 10 min after adding water to cement during mixing, and collect data as described in 8.2.2.

8.3.5 *Error Corrections for Method B*—Two corrections may be needed for Method B. One is a correction for early hydration data lost during the first 10 min, while mixing, handling, and equilibrating the sample in the calorimeter (8.3.5.1). The other is a correction for heat gained or lost from or to the environment during mixing and handling before the sample is put into the calorimeter (8.3.5.2).

8.3.5.1 *Correction for Early Hydration*—Equilibrate a 500 g sample of cement, 250 mL of water, and the polystyrene insulated container described in 6.1.8 to 23 ± 1 °C. Record the starting temperature. Place the cement and water in a plastic bag and mix quickly by kneading the bag. Place the bag in the polystyrene insulated container as soon as mixing is complete along with a thermocouple. Cover and measure temperature at 10 min after adding water to the cement. Record the temperature rise to the nearest 0.1 °C. The calculation of the heat-of-hydration during this 10 min period is described in 9.2.1.

8.3.5.2 *Correct for Temperature Change Due to Mixing and Handling*—A determination of the heat increase or decrease in the sample during mixing and handling of the sample is determined by mixing an inert sample with water, using the same mass of materials and the same procedure as in a heat of hydration determination, then introducing equivalent mass of paste used in a determination into a calorimeter cell that has been running at baseline. Collect data at 10 s intervals, as in a normal determination, until the signal has returned to the baseline. The calculation of the heat is described in paragraph 9.2.2.

9. Calculation

9.1 *Method A*—For Method A, the total heat of hydration, Q_t, is the integrated value of the power versus time data, collected as described in 8.2 without further correction.

9.1.1 *Remove Leading Edge Data*—For both Methods A and B, there may be data collected during instrument setup and thermal equilibration that is not pertinent to the final determination. These data shall be removed.

9.1.2 Many data acquisition units and commercial calorimeters incorporate the calibration equation into the software and present the raw output data in units of J/g of cement. If this is not the case, then the output data will be in units of mV, and must be transformed into thermal power using the calibration coefficients determined from Eq 2.

$$P_n = A + BV_n \tag{2}$$

where:

P_n = power input level used in the instrument calibration, and

V_n = voltage output level used in the instrument calibration.

9.1.3 *Calculation of Q_t*—The total heat of hydration of the sample, Q_t, is calculated by integrating the power/g versus time data over the time interval of the test (t_0 to t_e, in units of seconds) as in Eq 3:

$$Q_t = \int_{t=t_0}^{t_e} P dt \tag{3}$$

where:

t_0 = the time the cement and water are mixed, taken as zero (in Method A), and

t_e = the end of the test.

t_0 will be different for Method A and Method B.

9.1.4 Operationally, the integration is executed by averaging the power output from two consecutive readings and multiplying by the time interval of the reading, giving an output for each time increment in units of J/g. The heat so calculated in each time increment is then summed over the duration of the test, as in Eq 4.

$$Q_t = \sum_{t=t_0}^{t_e} \left(\frac{P(t_i) - P(t_{i+1})}{2} \right) \times (t_{i+1} - t_i) \tag{4}$$

where:

$P(t_i)$ = the power output at time t_i, and

$P(t_{i+1})$ = the power output at the next time interval (t_{i+1}).

In Method A, t_0 is taken as zero when water is added to the cement.

9.2 *Method B*—The total heat evolved during the calorimeter run, Q_t is calculated as in Eq 3 and 4, but t_0 is the 600 s (10 min). Q_t must be corrected for heat evolved prior to introduction of the sample into the calorimeter, denoted as Q_2, and for any heat gained or lost during sample mixing and handling, denoted as Q_3. The total heat, Q_t' is then calculated from Eq 5.

$$Q_t' = Q_t + Q_2 + Q_3 \tag{5}$$

9.2.1 *Determine Q_2*—From the temperature rise and sample composition data in 8.3.5.1, calculate the heat evolved during the first 10 min of hydration using Eq 6.

$$Q_2 = \frac{\Delta T(F_c \times C_c + (1-F_c) \times C_w)}{F_c} \tag{6}$$

where:

ΔT = the temperature rise during the test described in 8.3.4,

F_c = the mass fraction of the cement in the paste,

C_c = the heat capacity of dry cement (nominally 0.75 kJ/kg/K), and

C_w = the heat capacity of water (nominally 4.18 kJ/kg/K).

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

9.2.2 *Determine* Q_3—Q_3 is calculated from the data collected according to paragraph 8.3.5.2, and using Eq 2 and 3. The initial time (t_0) will be taken as zero when the sample is first put into the calorimeter, and t_e will be the time when the signal returns to the baseline.

10. Report

10.1 *Test Report*—Report the following information:

10.1.1 Cement sample identification.

10.1.2 Date and time when the test was performed.

10.1.3 Instrument used.

10.1.4 The mass of dry cement in sample.

10.1.5 The name of the data file.

10.1.6 Date of the calibration used.

10.1.7 A figure showing the resulting thermal power curve.

10.1.8 Calculated heat of hydration and the method (A or B) used.

11. Precision and Bias

11.1 *Precision*—A complete interlaboratory study has not been completed for this test method. Therefore the precision of the method has not been determined (Note 11).

NOTE 11—Two sources of published data give indications of the potential precision of the method. Data from Wadso and Arndt (**1**,**2**,**3**) were derived using methods that appeared to most closely resemble Method B in this test method. The program included 18 laboratories, each of which analyzed 2 cements. No within-laboratory repeatability data were reported. From these data, a between-laboratory standard deviation of 10.5 kJ/kg at 3 days was calculated. Two laboratories should be expected to differ by no more than 29 kJ/kg in 95 % of such paired laboratory comparisons. This is the d2s value as described in Practice C670.

The VDZ (2006) (**5**) round robin included 20 laboratories each conducting analysis on 5 cements. Tests are believed to be 7-day results. Analogs to Methods A and B of this test method were represented, but the precision data were not separated according to this classification. A within-laboratory standard deviation of 4.6 kJ/kg was reported (d2s = 12.9 kJ/kg). A between-laboratory standard deviation of 13.6 was reported (d2s = 35.3 kJ/kg).

11.2 *Bias*—Bias cannot be determined because there is no standard material having an accepted reference value (Note 12).

NOTE 12—Bias relative to solution calorimetry, as in Test Method C186 is of interest. Poole (2007) (**4**) compared heat of hydration determinations by solution calorimetry and conduction calorimetry among laboratories and found no consistent bias between the two methods.

12. Keywords

12.1 heat of hydration; hydraulic cement; isothermal conduction calorimetry; portland cement

Designation: C 1707 – 09

Standard Specification for Specification for Pozzolanic Hydraulic Lime for Structural Purposes [1]

This standard is issued under the fixed designation C 1707; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This standard covers four types of pozzolanic hydraulic lime for structural purposes which include use in mortar, scratch, brown, and finish (stucco) coats of interior or exterior plaster.

1.1.1 *PHL*—Pozzolanic hydraulic lime for use in mortar, scratch, brown, and finish (stucco) coats of interior or exterior plaster.

1.1.2 PHL_c—PHL with a maximum 20 % binder weight of hydraulic cement.

1.1.3 *PHL-A*—Air-entrained PHL.

1.1.4 PHL_c-*A*—Air-entrained PHL_c.

1.2 This specification classifies pozzolanic hydraulic lime by minimum hydrated lime content, maximum hydraulic cement content, and specific performance requirements.

1.3 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard. Appropriate conversion can be done using IEEE/ASTM SI 10.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

be used if shown not detrimental to the soundness of the material. If Type SA or Type NA hydrated limes are used, an additional air entraining agent shall not be used.

3.1.3 *air entraining pozzolanic hydraulic lime with hydraulic cement (PHL$_c$-A), n*—as PHL$_c$ with exception that Type SA hydrated lime of Specification C 207 shall be used, or Type NA of Specification C 207 shall be used if shown not detrimental to the soundness of the material. If Type SA or Type NA hydrated limes are used, an additional air entraining agent shall not be used.

3.1.4 *pozzolanic hydraulic lime (PHL), n*—a powder produced by the blending or intergrinding of not less than 25 % by binder weight of Specification C 207 Type S hydrated lime with one or more pozzolan and inert filler. Type N hydrated lime of Specification C 207 shall be used if shown not detrimental to the soundness of the material.

3.1.5 *pozzolanic hydraulic lime with hydraulic cement (PHL$_c$), n*—as PHL with not more than 20 % by binder weight of hydraulic cement of Specification C 150, Specification C 595, or Performance Specification C 1157 blended or interground.

4. Requirements

4.1 PHL, PHL$_c$ PHL-A and PHL$_c$-A shall conform to the requirements prescribed in Table 1.

5. Test Methods

5.1 *Water Soluble Alkali*—Water soluble alkali shall be tested according to the procedure in Test Methods C 114, Section 17.2.

5.2 *SO_3*—Sulfur trioxide content shall be tested according to the procedure of Test Methods C 25, Section 23.

5.3 *CO_2*—Carbon dioxide content shall be tested according to the procedure of Test Methods C 25, Section 22.

5.4 *Fineness*—Fineness shall be tested according to the wet sieve method of Test Methods C 110, Section 5.

5.5 *Time of Set*—Determine the time of initial and final set according to Test Method C 266, the Gilmore needle procedure, with the following changes:

5.5.1 Determine the first penetration value after 1 h of rest, and every 4 ± 2 h after that.

5.6 *Autoclave Expansion*—Autoclave Expansion shall be measured using the method described in Test Methods C 110, Section 9.3, with the following modification:

TABLE 1 Standard Requirements

Properties	PHL, PHL$_c$	PHL-A, PHL$_c$-A
water soluble alkali, max %	0.2	0.2
SO_3, max %	3.0	3.0
CO_2, max % (as produced basis)	16.0	16.0
Fineness		
retained on 30 mesh sieve, max %	<0.5	<0.5
retained on 200 mesh sieve, max %	<15	<15
Time of initial set, max h	24	24
Time of final set, max h	48	48
Autoclave expansion, max %	0.80	0.80
Air content		
max %	7.0	12.0
min %		>7.0
Water retention, min %	70	70
Compressive strength min, N/m^2(psi), 28 days	>2.4 (>350)	>2.4 (>350)

5.6.1 Weigh 25 ± 0.1 g of one of four types of PHL. Add 3.0 ± 1.0 ml water to the weighed sample and mix by hand until wetted. If the balance allows it, work directly in the specimen mold. If this is not possible, work in an intermediate container and transfer the mixture to the specimen mold in as complete a state as possible. Press to 5.0 ± 1.5 N/m^2 (725 ± 218 psi) for 10 s and demold the specimen and autoclave as described.

5.7 *Preparation of Mortar*—Mortar, plasters and grout are specified by volume proportion of the binder materials to the aggregate in a ratio of 1 volume part binder to 3 volume part aggregate or sand. Laboratory mixed mortars used for air entrainment, water retention and compressive strength testing for this specification shall be measured by weight by converting proportions by volume to proportion by weight.

NOTE 1—Appendix X4 of Specification C 270 provides examples of calculating material proportioning.

$$\textit{Batch factor} = \frac{1440}{(80 \times 3\ (\textit{sand volume proportion}))} = 6 \qquad (1)$$

Determine weight one of the four PHL as follows:

$$\textit{Weight of PHL}\ (g) = 1(\textit{PHL Volume Proportion}) \times \textit{Bulk Density}\ (\textit{Packed Density})\ \textit{of PHL} \times \textit{Batch Factor} \qquad (2)$$

Bulk density of PHL will vary and shall be provided by the manufacturer or determined according to Test Methods C 110 Section 20.

Sand will be a 50-50 blend of graded and 20-30 standard sand meeting Specification C 778.

5.8 *Air Content*—Air content shall be measured according to the procedure of:

5.8.1 Test Methods C 110, Section 8. W_1, W_2, S_1, and S_2 are dropped from the equation to be replaced by W_4 (weight of one of four PHL, g) and S_4 (specific gravity of one of four PHL). The specific gravity of the PHL shall be provided by the manufacturer as determined by the method of Test Methods C 110, Section 21, or determined by a gas pychnometer.

NOTE 2—The specific gravity of the four PHL will vary with composition and a single value cannot be recommended.

5.8.2 Test Methods C 110, Section 8.4.3, using the air pail method.

5.9 *Water Retention*—The water retention value shall be measured following Test Methods C 110, Section 7.

5.10 *Compressive Strength*—Prepare the mortar in accordance with Practice C 305 with the exception that the binder and water are initially placed in the mixing bowl together and allowed to wet for 1½ min prior to mixing. Store the mortar in the molds for 60 ± 12 h in sealed plastic bags prior to de-molding. Determine compressive strength in accordance with Test Method C 109/C 109M. A minimum of three 2-in. cubes is required.

5.11 *Specimen Storage*—Test specimens shall be stored at not less than 95 % R.H. in a moist room or cabinet following the requirements of Specification C 511. The storage surface shall be in equilibrium with the space to ensure no moisture loss.

www.technobetar.ir

6. Sampling and Inspection

6.1 The sampling, rejection, retesting, packing, and marking shall be conducted in accordance with Practice C 50.

7. Special Package Marking

7.1 When delivered in packages, the name and brand of the manufacturer, the type under this specification, and the words "AIR ENTRAINING" shall be plainly indicated on the package or in the case of bulk shipments, so indicated on shipping notices.

8. Keywords

8.1 hydrated lime; mortar; plaster grout; pozzolan; pozzolanic hydraulic lime

Designation: C 1712 – 09

Standard Test Method for Rapid Assessment of Static Segregation Resistance of Self-Consolidating Concrete Using Penetration Test[1]

This standard is issued under the fixed designation C 1712; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the rapid assessment of static segregation resistance of normal-weight self-consolidating concrete (SCC). The test does not measure static segregation resistance directly, but provides an assessment of whether static segregation is likely to occur.

1.2 The test apparatus and protocol were developed based on tests with SCC mixtures containing saturated surface dry (SSD) coarse aggregates ranging in relative density from 2.67 to 2.79 and in nominal maximum size from 9.5 mm to 25 mm. For SCC mixtures outside these ranges, testing is recommended to establish a correlation between penetration depth and static segregation measured in accordance with Test Method C1610/C1610M. This test method shall not be used to assess the static segregation resistance of self-consolidating concrete containing lightweight aggregates or heavyweight aggregates without prior testing to establish a correlation.

1.3 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.4 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes shall not be considered as requirements of the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.[2])

C1610/C1610M Test Method for Static Segregation of Self-Consolidating Concrete Using Column Technique

C1611/C1611M Test Method for Slump Flow of Self-Consolidating Concrete

3. Terminology

3.1 *Definitions*:

3.1.1 For definitions of terms used in this test method, refer to Terminology C125.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *static segregation resistance*, *n*—resistance of a concrete mixture to segregation of the mortar component from the coarse aggregate while the concrete is at rest and before initial setting.

4. Summary of Test Method

4.1 This test method uses a penetration apparatus (shown in Figs. 1 and 2) and an inverted slump mold (Fig. 3). A sample of freshly mixed self-consolidating concrete is placed in an inverted slump mold without tamping or vibration. The hollow cylinder attached to a metal rod is aligned in the center of the inverted slump mold as shown in Fig. 3. The hollow cylinder is then lowered onto the surface of the concrete and released to freely penetrate into the fresh concrete. The penetration depth

[1] This test method is under the jurisdiction of ASTM Committee C09 on Concrete and Concrete Aggregates and is the direct responsibility of Subcommittee C09.47 on Self-Consolidating Concrete.

Current edition approved Oct. 1, 2009. Published November 2009. DOI: 10.1520/C1712-09.

FIG. 3 Penetration Test

mixture development in the laboratory as well as prior to placement of the mixture in the field. Test Method C1610/C1610M for static segregation of SCC is not sufficiently rapid, and the non-mandatory Visual Stability Index as determined through the procedure described in Appendix X1 of Test Method C1611/C1611M is highly subjective and qualitative.

5.3 Appendix X1 provides non-mandatory criteria that may be used to indicate the degree of static segregation resistance of self-consolidating concrete mixtures.

6. Apparatus

6.1 *Mold*—The slump mold is used in this test method and shall conform to Test Method C143/C143M.

6.2 *Penetration Apparatus*—The penetration apparatus, shown in Fig. 1, consists of a support frame, a metal sleeve, a set screw, a penetration head and a reading scale. The penetration head, consisting of a non-corrosive hollow cylinder and a metal rod, has a mass of 45 ± 1 g. The rod is bolted vertically into the center of the top of the hollow cylinder and acts as a unit with the cylinder. The inner diameter, wall thickness, and height of the hollow cylinder are 75 ± 1 mm, 1.5 ± 0.1 mm, and 50 ± 1 mm, respectively. Holes are symmetrically drilled on the top surface of the hollow cylinder to allow air to escape during the penetration test. At least two holes with a minimum diameter of 6 mm must be provided (see Note 1). The reading scale shall be 55 mm long and marked in 1 mm increments. The scale is mounted on the support frame and adjacent to the metal rod, as shown in Figs. 1 and 2. With both the support frame and the hollow cylinder resting on a flat surface, the top of the metal rod shall be 5 mm below the top of the reading scale (see Note 2). The diameter of the metal rod shall be 4.5 ± 0.5 mm. The inner diameter of the metal sleeve shall be 0.7 ± 0.1 mm larger than the diameter of the metal rod to minimize friction as the rod slides.

NOTE 1—The number and size of the holes may be chosen to be greater than the minimum stated in 6.2 to achieve the required mass (45 ± 1 g) of the penetration head. The hollow cylinder shown in Fig. 2 is made of Polyvinyl Chloride (PVC) and has six holes on the top surface; each hole has a diameter of approximately 10 mm.

NOTE 2—This enables the top of the metal rod to be used as the mark for taking both the initial and final readings since it will always lie within the range of the reading scale when the surface of the concrete in the mold is properly leveled (see Section 8.5).

6.3 *Base Plate (Optional)*—As described in Test Method C1611/C1611M.

6.4 *Strike-off Bar*—As described in Test Method C173/C173M.

6.5 *Sample Receptacle*—The receptacle shall be a heavy-gauge metal pan or wheelbarrow of sufficient capacity to allow easy remixing of the entire sample with a shovel, trowel, or scoop.

6.6 *Small Tools*—Tools and items such as shovels, plastic pails, trowels, scoops, and rubber gloves shall be provided.

7. Sample

7.1 Obtain a sample of freshly mixed self-consolidating concrete in accordance with Practice C172 or Practice C192/C192M, and place it in the sample receptacle.

8. Procedure

8.1 Perform the rapid static segregation resistance test on a flat, level, nonabsorbent surface such as a pre-moistened concrete floor or base plate. Do not subject the testing surface and inverted slump mold to any vibration or disturbance.

8.2 *Conditioning the Penetration Apparatus*—Dampen the hollow cylinder, then hold the apparatus in the horizontal position and release the set screw. Spin the penetration head to

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:28:23 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

ensure that the space between the metal sleeve and the metal rod is free of any obstruction. Tighten the screw softly to hold the rod in the sleeve.

8.3 *Setting Up the Inverted Slump Mold*—Dampen and place the slump mold, with the smaller opening facing down (inverted position), in the center of a flat base plate or moistened concrete surface.

8.4 Remixing of Sample: Remix the sample obtained in accordance with 7.1 in the sample receptacle using a shovel or scoop so that the concrete is homogeneous.

8.5 Filling the Mold: Immediately after remixing, take approximately 6 L of the concrete in a plastic pail and fill the inverted slump mold in a continuous manner. Pour the concrete mixture uniformly into the mold. Slightly overfill the concrete above the top of the inverted mold. Strike off the surface of the concrete with strike-off bar and allow the concrete to stabilize for 80 ± 5 s after finishing strike-off before measuring penetration.

8.6 *Positioning the Penetration Apparatus*—While the concrete is stabilizing, place the penetration apparatus on the top of the inverted slump mold, making sure that the hollow cylinder is aligned in the center of the inverted mold (see Fig. 3 and Note 3).

NOTE 3—Aligning the corners of the frame approximately on the circumference of the slump mold will ensure alignment of the hollow cylinder in the center of the mold.

8.7 *Measuring the Penetration Depth (Pd)*:

8.7.1 *Initial Reading*—Hold the metal rod attached to the hollow cylinder with one hand and release the set screw. Lower the hollow cylinder carefully so that it just touches the surface of the concrete. Tighten the screw and take the initial reading on the reading scale at the mark that is in line with the top of the metal rod.

8.7.2 *Final Reading*—At the end of the period over which the concrete is allowed to stabilize (80 ± 5 s after completion of strike-off), release the set screw so that the hollow cylinder freely penetrates the fresh concrete. Wait for 30 ± 2 s after releasing the set screw and take the final reading on the reading scale at the mark that is in line with the top of the metal rod. After taking the reading, remove the penetration apparatus. Between uses, wash the penetration apparatus and remove any free water on the surfaces of the hollow cylinder and the metal rod with a cloth or paper towel.

8.7.3 *Calculation*—Calculate the penetration depth, *Pd*, using Eq 1.

$$Pd = d_2 - d_1 \quad (1)$$

where:
d_1 = initial reading (mm), and
d_2 = final reading (mm).

9. Report

9.1 Concrete mixture designation.

9.2 The penetration depth (*Pd*) to the nearest 1 mm.

10. Precision and Bias

10.1 Precision – The estimation of the precision of this test method is provisional. Repeatability standard deviations were determined on five replicate batches of SCC mixtures at each of four levels of mean penetration depth (5). At a mean penetration depth of 3 mm, the repeatability standard deviation was 1 mm; at a mean penetration depth of 13 mm, the repeatability standard deviation was 2 mm; and at mean penetration depths of 23 mm and 30 mm, the repeatability standard deviation was 3 mm. The differences in repeatability standard deviation are small over the range of mean penetration depths of 3 to 30 mm. The average repeatability standard deviation over this range of mean penetration depths is 2 mm.

10.2 *Bias*—This test method has no bias because the values determined can only be defined in terms of the test method.

11. Keywords

11.1 penetration depth; penetration test; rapid test; segregation; self-consolidating concrete; stability; static segregation resistance

APPENDIX

(Nonmandatory Information)

X1. DEGREE OF STATIC SEGREGATION RESISTANCE OF CONCRETE MIXTURES

X1.1 The criteria for the different degrees of static segregation resistance are provided in Table X1.1 and are based on evaluations of SCC mixtures with nominal maximum aggregate sizes in the range of 9.5 to 25 mm. These criteria were developed through a correlation between penetration depth and static segregation measured in accordance with Test Method ASTM C1610/C1610M (**1-5**).

TABLE X1.1 Degree of Static Segregation Resistance[A]

Penetration depth (*Pd*)	Degree of static segregation resistance
$Pd \leq 10$ mm	Resistant
10 mm < Pd < 25 mm	Moderately resistant
$Pd \geq 25$ mm	Not resistant

[A] These criteria were developed based on use of the penetration apparatus with an inverted slump mold and are valid for SCC mixtures with a total aggregate volume fraction of less than 65 %. The criteria may be different if a sample container other than the inverted slump mold is used.

Designation: D 1985 – 03 (Reapproved 2008)

Standard Practice for Preparing Concrete Blocks for Testing Sealants, for Joints and Cracks[1]

This standard is issued under the fixed designation D 1985; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This practice covers the preparation of concrete blocks used for testing of joint and crack sealants for portland cement concrete and asphaltic concrete pavements. There are numerous standard material specifications that use concrete blocks prepared according to this practice. Refer to the specific standard material specification of interest to determine which tests apply and refer to the test methods for each specific test.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 33 Specification for Concrete Aggregates

C 150 Specification for Portland Cement

C 192/C 192M Practice for Making and Curing Concrete Test Specimens in the Laboratory

E 171 Specification for Atmospheres for Conditioning and Testing Flexible Barrier Materials

3. Significance and Use

3.1 It is intended that this practice may be used by manufacturers, users, and testing agencies. The use of this practice establishes a uniform procedure for preparing concrete blocks for the testing of sealants. It is not intended to establish test procedures or conditions of test which are associated with each of the joint sealants.

4. Standard Conditions

4.1 The laboratory atmospheric conditions, hereinafter referred to as standard conditions, shall be in accordance with Specification E 171, (23 ± 2°C (73.4 ± 3.6°F) and 50 % ± 5 % relative humidity).

5. Concrete Block Preparation[3]

5.1 *Materials*—The aggregate shall conform to Specification C 33, except as specified herein. The aggregate grading shall be as shown in Table 1. The coarse aggregate shall consist of crushed limestone (plus 95 % $CaCO_3$) having a water absorption of not more than 1.5 %. The fine aggregate shall consist of crushed limestone and shall be manufactured from the same parent rock as the coarse aggregate.[4] The portland cement shall conform to ASTM Specification C 150, Type II. The concrete shall have a water-cement ratio of 0.49, a cement factor of 335 ± 30 kg/m ^{3}(6.0 ± 0.5 bags of cement per cubic yard), and a slump of 63 ± 13 mm (2½ ± ½ in.). The ratio of fine aggregate to total aggregate shall be approximately 40 % by solid volume. The air content shall be 5.0 ± 0.5 % and shall be obtained by the addition to the batch of an air-entraining agent such as a neutralized thermoplastic resin.[5] Prepare the concrete in accordance with the procedure described in Test Method C 192/C 192M.

5.1.1 *Alternate Block Materials*—As an alternate to the materials specified in 5.1, the blocks may be prepared using a concrete mixture which meets local requirements for concrete pavements. Use the materials specified in 5.1 for all referee testing.

www.technobetar.ir

TABLE 1 Aggregate Grading

Type	Sieve Size	% Passing
Coarse aggregate	19.0 mm (¾ in.)	97 to 100
	12.5 mm (½ in.)	63 to 69
	9.5 mm (⅜ in.)	30 to 36
	4.75 mm (No. 4)	0 to 3
Fine aggregate	4.75 mm (No. 4)	100
	2.36 mm (No. 8)	82 to 88
	1.18 mm (No. 16)	60 to 70
	600 mm (No. 30)	40 to 50
	300 mm (No. 50)	16 to 26
	150 mm (No. 100)	5 to 9

5.2 *Block Preparation*—Use a minimum 100 mm by 300 mm by 75 mm (4 in. wide by 12 in. long by 3 in. deep) mold, made from metal or plastic and provided with a metal or plastic base plate. Provide means for securing the base plate to the mold. Make the assembled mold and base plate water-tight and oil with mineral oil before use. Fill the mold with concrete, prepared in accordance with 5.1 or 5.1.1, to overflowing and vibrate externally for 30 s. Screed (level) the concrete to a smooth surface with a wooden float and level off with a metal straightedge drawn across the top with a sawing motion. Cure as specified in Test Method C 192/C 192M. After curing for not less than 14 days, cut the slab of concrete into individual blocks using a 40 by 60-grit diamond saw blade rotating at a peripheral speed of 3050 ± 150 m/min (10 000 ± 500 ft/min.) (see Fig. 1). Each test block should be 25 by 50 by 75-mm (1 by 2 by 3-in.), leaving 25 mm (1 in.) strips for discarding from the slab that were in contact with the vertical sides of the mold. While the blocks are still wet from the sawing operation, scrub the surfaces of the blocks lightly with a non-metallic stiff-bristle brush while holding under a stream of running water. Stocks of prepared blocks may be stored under standard conditions indefinitely, but store such blocks in a 100% humidity enviornment for not less than 7 days prior to use.

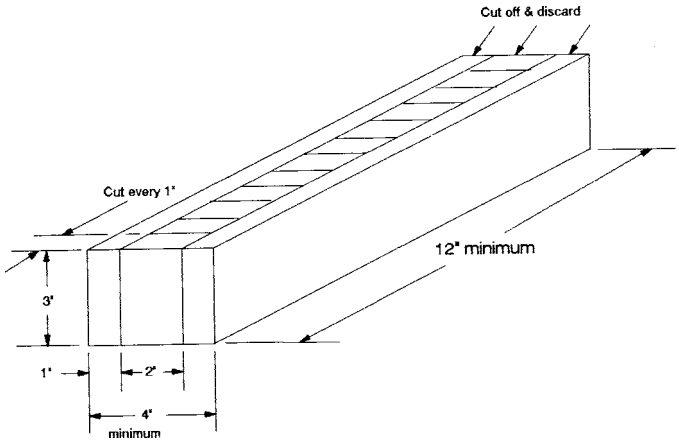

FIG. 1 Concrete Block Slab (after removal from mold)

Designation: D 6249 – 06

Standard Guide for Alkaline Stabilization of Wastewater Treatment Plant Residuals[1]

This standard is issued under the fixed designation D 6249; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This document provides guidance for use of reactive alkaline materials (quicklime, hydrated lime, high lime fly ash, or other byproducts) for treating wastewater solids (biosolids) to reduce pathogen levels and achieve compliance with regulatory requirements. Federal (40 CFR, Part 503) regulations for use or disposal of biosolids became effective on March 22, 1993; refer to USEPA regulations and guidance documents for information on other treatment processes or for specific requirements for use or disposal of biosolids.

1.2 Additional requirements may be imposed by individual states, and these are available through state regulatory agencies that issue permits for treatment and use or disposal, or both, of biosolids.

1.3 *This guide does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:* [2]

C 25 Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

C 110 Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone

2.2 *USEPA Publication:*

Title 40, Code of Federal Regulations (CFR), Part 503, Standards for the Use or Disposal of Sewage Sludge; Final Rules, 58 FR 9248-9404[3]

3. Terminology

3.1 *Acronyms:acronyms*—these are defined by operating parameters (for example, time, temperature) whose values must be met in order for biosolids to be used in various ways as a nutrient source/soil conditioner. Ref. 40 CFR Part 257.

3.1.1 *PFRP*—Processes to Further Reduce Pathogens (equivalent to 503 Class A).

3.1.2 *PSRP*—Processes to Significantly Reduce Pathogens (equivalent to 503 Class B).

4. Significance and Use

4.1 Operators of power and other plants producing alkaline by-products and wastewater treatment plant operators needing to treat and manage wastewater solids will find this guide helpful in dealing with their materials.

4.2 This guide provides the tests, procedures, and parameters that should be considered to significantly reduce pathogens in wastewater treatment plant solids by the addition of manufactured or by-product alkaline materials (**1**).[4]

5. Alkaline Materials Characteristics

5.1 *Chemical Composition*:

Alkaline materials may be tested for Available Lime Index (ALI) in accordance with the optional chemical test of Table 1. Other chemical components, if required, may be determined in accordance with the appropriate procedure when requested by the purchaser.

5.2 *Reactivity*:

5.2.1 Alkaline materials should be tested for pH and heat of hydration (heat rise or slaking rate) in accordance with the recommended tests of Table 2.

5.3 *Physical Characteristics*:

5.3.1 Alkaline materials should be tested to determine the particle size in accordance with the recommended physical tests of Table 3.

6. Process Performance

6.1 *PFRP (Class A) Alkaline Treatment of Biosolids*:

6.1.1 *Mixing*—Thorough mixing of the biosolids and stabilization reagent must be provided to ensure uniform pH distribution and pathogen reduction throughout the biosolids

[1] This guide is under the jurisdiction of ASTM Committee C07 on Lime and is the direct responsibility of Subcommittee C07.02 on Specifications and Guidelines.

Current edition approved June 1, 2006. Published June 2006. Originally approved in 1998. Last previous edition approved in 2004 as D 6249 – 98(2004).

TABLE 1 Optional Chemical Test

Test Method	Component	Specification
C 25	Available Lime Index (ALI), %	[A]

[A] To be specified only as required by purchaser.

TABLE 2 Recommended Reactivity Tests

ASTM Test Method	Component	Specification
C 25	pH	≥ 12.0[A]
C 110[B]	Heat rise, C	[C]

[A] Based on 40 CFR Part 503 for pH >12 for 2 h or more.
[B] Modify Test Method C 110 to proportion alkaline reagent in lieu of quicklime. Alkaline material and water ratio may need to be modified to obtain measurable results. Any modification of Test Method C 110 must be clearly stated on the analysis report.
[C] To be specified only as required by purchaser.

TABLE 3 Recommended Physical Test

ASTM Test Method	Component	Specification
C 110	Amount retained on 600 µm (No. 30 mesh), %	[A]
C 110	Amount retained on 75 µm (No. 200 mesh), %	[A]

[A] To be specified only as required by purchaser.

mass (**2**). Effective mixing depends upon achieving the appropriate ratio of alkaline material to biosolids cake uniformly distributed throughout the treated biosolids.

6.1.1.1 Biosolids with a high moisture content will require less mixing energy than high-solids biosolids cake.

6.1.1.2 Biosolids characteristics will determine the proper type of equipment or system required for adequate mixing. Incomplete mixing can cause odor release during product storage or application and may lead to failure to meet regulatory requirements for pathogen and vector control.

6.1.2 *Particle Size*:

6.1.2.1 Given an adequate moisture supply using alkaline agents (for example, CaO) with smaller particle sizes will facilitate rapid and efficient mixing of agents with biosolids and increase reaction rates and pH, resulting in higher temperatures and greater pathogen reduction.

6.1.2.2 Since dusts are more easily generated from finely divided particles, precautions should be taken to prevent exposure to eyes and mucous membranes, which may result in irritation.

6.1.2.3 Reactivity and particle size also affect the rate of dust and mist emissions from reactors or mixing devices, or both. Particulate release may require scrubbing, water spray, or other emission controls on reactors or mixing devices for aesthetic reasons or to meet regulatory requirements.

6.1.2.4 Very small particle size may also lead to "air slaking" or recarbonation of active lime particles if the material is exposed to high humidity. Air slaked/recarbonated materials will not achieve the pH necessary to meet regulatory requirements.

6.1.3 *Reactivity (Heat and pH Elevation)*:

6.1.3.1 Reactivity is dependent upon the interaction between the alkaline reagent and the material to be treated. Reactions occur as the alkaline material contacts the biosolids. The finer the alkaline product, the greater the potential for a more rapid pH/temperature elevation.

6.1.3.2 Reagent reactivity affects mixing time and dosage rate and must be considered in process design.

6.1.4 *Moisture Content*:

6.1.4.1 Adequate moisture must be present to react with the free CaO (as measured by Available Lime Index, ALI, as per Test Methods C 25) to generate heat and elevate pH. Generally, dry biosolids cakes (18 to 30 %) require a more intimate mix to ensure proper penetration and reaction than is required by wet biosolids (less than 18 %).

6.1.4.2 The calcium oxide in the reagent must react with the moisture in biosolids (hydration) producing calcium hydroxide and heat. The moisture content in the biosolids mass must be sufficient to allow the hydration reaction to occur between the selected reagent (CaO concentration and fineness) and biosolids mass.

6.1.4.3 Biosolids cakes with a high moisture content will tend to react faster than biosolids with a low moisture content.

6.1.5 *Biosolids Type*:

6.1.5.1 Case-by-case alkaline material demand should be determined for each biosolids type through pilot testing using the actual biosolids cake and proposed reagents for each project. Develop process guidelines for alkaline additions by biosolids type and alkaline additive characteristics.

6.1.5.2 Biosolids with a high moisture content may require a higher dose ratio than drier dewatered biosolids cake when dosage ratios are expressed on a dry weight basis.

6.1.6 *Reaction Time and Curing Time*:

6.1.6.1 Heat will be generated as hydration of calcium oxide occurs. The reaction time will vary depending on reagent composition moisture content of the biosolids mass, and mixer efficiency.

6.1.6.2 Reaction times to effect pathogen reduction are established by applicable federal and state regulations. Reaction/cure times depend upon a number of variables and should be pilot-tested using the actual biosolids cake, alkaline admixture, mix unit, cure vessel, and testing protocol and acceptance criteria to assure compliance with regulatory standards.

6.1.6.3 For alkaline treatment processes, one of the three performance criteria is required:

(1) The time-temperature relation established in 40 CFR 503.32 (a) (3) (Alternative 1). Selected time-temperature values are as follows:

Biosolids	Temp, °C	50	55	60	65	70	75	80
Moisture >7 %	Time, hours	316	63	13	2.5	0.5	0.10	0.020
Moisture <7 %	Time, hours	120	24	4.8	0.95	0.19	0.04	0.008

(2) The pH-time, temperature-time, drying procedure in 40 CFR 503.32 (a) (4) (Alternative 2). Basically, the biosolids are held at a pH above 12 for 72 hours with a 12-hour period in which the temperature exceeds 52°C, followed by air drying to a solids content exceeding 50 %.

(3) Pasteurization (40 CFR 503, App. B, Part B—PFRP Option 7) in which the biosolids are maintained at a minimum temperature of 70°C for 30 minutes.

6.1.6.4 Ammonia or other odors released may require water spray, scrubbing, gas capture, or control of emission.

6.1.7 *Reaction/Cure Vessels or Containers*:

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:28:21 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

6.1.7.1 Consideration should be given to minimize heat losses through materials management, configuration, and materials of construction for processes that require extended curing times.

6.1.7.2 Proper temperatures can be maintained without an insulated vessel by adding adequate alkaline reagent to compensate for heat loss. However, some situations may benefit from an insulated vessel to efficiently retain the heat to meet PFRP temperature requirements.

6.1.7.3 For processes using a windrow, at a minimum, the mixture should be at least 18 inches thick at all locations in the pile to ensure heat retention throughout the entire mass for the applicable curing time. Thin areas at the pile extremities should be avoided as they will not retain adequate heat and can lead to potential regrowth and recontamination of the entire mass.

6.1.8 *Process Testing Requirements*:

6.1.8.1 Process testing requirements vary with the specific alkaline process selected.

6.1.8.2 Temperature and pH measurements for the requisite time periods should be recorded to comply with pathogen reduction (and vector attraction reduction). Daily testing may include monitoring and documenting the elevated temperature and pH for a predetermined period of time (see 6.2.6 for details). Some methods also require documentation of reduced moisture content and mixing.

6.1.8.3 Procedures to monitor or collect samples for analysis are developed for each project based upon site-specific conditions considering the process selected, equipment utilized, volumes of materials to be processed, local state and federal regulatory requirements, and local conditions (**3**).

6.1.9 *Process Testing Schedule*:

6.1.9.1 Testing must be conducted in accordance with federal, state, and local regulations. Product testing, to meet end-use requirements, will be site-specific. Under 40 CFR Part 503 regulations, pathogen (salmonella, virus, protozoan, and helminth egg) or indicator organism testing and pollutant concentration (metals) testing requirements are:

Amount of Biosolids (dry metric tons/365 days)	Frequency
> 0 and < 290	Once per year
≥ 290 and < 1500	Once per quarter
≥ 1500 and < 15 000	Once per 60 days
≥ 15 000	Once per month

6.1.9.2 In addition, at a minimum, daily operating records should be maintained documenting compliance with applicable requirements (for example, process time/temperature, pH, solids concentrations, and fecal coliform levels) (**4**).

6.1.10 *Product Solids Content*:

6.1.10.1 Product utilization may be affected by solids content to aid in control of microbial regrowth during storage to minimize odor potential at application sites and during storage or to improve end-product marketability and physical handling characteristics.

6.1.11 *On-Site Storage*:

6.1.11.1 On-site storage may be required for a land application or marketing program of the tested product. Programs that produce an end-product for sale should consider on-site storage capacity to meet the seasonal fluctuations in market demand, the scheduling needs of the consumer, and production rates of the generator.

6.1.11.2 On-site storage may require odor control for end-products with high moisture content or a low alkaline reagent dosage rate.

6.2 *PSRP (Class B) Alkaline Treatment of Biosolids*:

6.2.1 *Mixing*—Thorough mixing of the biosolids and chemical reagent must be provided to ensure uniform pH distribution and pathogen reduction (**2**). Mechanical mixing to achieve a homogeneous blend of reagent throughout the biosolids mass depends upon a number of factors, including achieving the proper ratio of alkaline reagent to biosolids, and sufficient moisture to enable the reaction to occur.

6.2.1.1 Incomplete mixing or an inadequate reagent dosage rate can cause odor generation and release during product storage or application and failure to meet regulatory pathogen or vector control requirements.

6.2.2 *Alkaline Reagent Particle Size*:

6.2.2.1 Reactions occur as the alkaline reagents contact the moist biosolids particles. The rate of reaction of the alkaline reagent tends to increase with: (1) finer reagent particle size, and (2) increased free moisture content. Reagents with a finer (smaller) particle size distribution generally are more easily and uniformly blended into the biosolids.

6.2.2.2 When using an alkaline slurry, or treating liquid biosolids, particle size may not be as critical as long as sufficient mixing and reaction time are provided.

6.2.3 *Reactivity (pH elevation)*:

6.2.3.1 Care must be taken to ensure moisture will not come into contact with the reagent prior to entering the mixer. Air slaking of the alkaline reagent can be a problem in long-term storage or pneumatic transfer systems. Guidance for proper storage of reactive alkaline materials can be found in Lime—Handling, Application and Storage, National Lime Association Bulletin 213.

6.2.3.2 Increasing the alkaline reagent oxide concentration may increase potential for reactivity.

6.2.4 *Moisture Content*:

6.2.4.1 Moisture content affects the pH by permitting the alkaline reagents to dissociate, releasing hydroxide ions, increasing the pH. As moisture increases, it is easier for the alkaline material to disperse, penetrate, react, and dissociate, thus generating hydroxide ions throughout the mixture.

6.2.4.2 Care should be exercised when working with biosolids cakes with greater than 30 % solids content to ensure a complete uniform reaction is achievable.

6.2.5 *Biosolids Type*—Biosolids characteristics will impact on the required dosage rates for specific alkaline reagents. Therefore, site-specific process guidelines should be developed through actual pilot studies for alkaline additions by biosolids type and alkaline additive characteristics. Liquid biosolids require less mixing energy to achieve a uniform distribution of alkaline reagent (and therefore uniform pH) throughout the mixture than do cake biosolids.

6.2.6 *Reaction Time*:

6.2.6.1 For dry reagents, after uniform mixing with biosolids is complete, the alkaline metal oxides must hydrate to

Copyright by ASTM Int'l (all rights reserved); Thu Apr 22 19:28:21 EDT 2010
Downloaded/printed by
University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

hydroxides and penetrate the biosolids mass. The presence of hydroxides will increase biosolids pH.

6.2.6.2 When working with biosolids cake with low moisture content or reagents with low reactivity due to particle size or oxide content, longer curing time (contact period) may be required to allow the hydration reaction to occur.

6.2.6.3 At elevated pH values, ammonia compounds in the biosolids or water dissociate to release ammonia gas (NH_3). The biosolids may exhibit a transient pH of 12 or more due to unreleased ammonia in the form of unstable ammonium hydroxide (NH_4OH). Once the NH_4OH dissociates and the ammonia dissipates, the pH may fall. Therefore, the amounts of reagent added should take this factor into account and not be based on the short-term NH_4OH effect on pH. The strong odor of ammonia release is a signal to be alert to this process occurring.

6.2.7 *Process Testing Requirements*—pH > 12 for two hours.

6.2.7.1 When testing a liquid/solid mixture with a system designed for liquids (pH probe), care must be taken to keep flow of sample moving across the pH probe surface for accuracy. Clean the electrode frequently, paying particular attention to the reference electrode junction. Bits of adherent biosolids or alkaline agent can strongly alter the measured pH, resulting in erroneous values not representative of the entire mass of material. pH measurements should be made at 25°C, or corrected for sample temperature differences as shown in Table 4, which demonstrates the temperature/pH relationship as the measured pH approaches the regulatory limit.

NOTE 1—At high pH (above 11), temperature has a significant effect on pH readings. Therefore, at high pH levels, the reading must be corrected to 25°C, standard temperature. Table 4 and following examples may be useful for a better understanding.

NOTE 2—pH meters often have temperature correction controls. These controls correct for probe temperature and conductivity only. Changes in the concentration of the test sample due to solubility that changes with temperature are not compensated by these controls. For example, at 30°C:

$$\text{Correction Factor (CF)} = 0.03 \text{ pH units} \times (T_{meas} - 25°C)$$
$$CF = 0.03 \times (30 - 25);\ CF = 0.03 \times 5$$
$$CF = +\ 0.15$$
$$\text{Actual pH} = \text{Measured pH} \pm \text{the Correction Factor}$$
$$\text{Actual pH} = 12.304 + 0.15 = 12.454$$

6.2.7.2 pH—Calibrate routinely with laboratory-grade standards developed for high pH monitoring.

6.2.8 *On-Site Storage*:

TABLE 4 pH Temperature Correction Factors at Varying Temperatures from Standard

Temperature Measured,° C	pH Meter Reading	Correction Factor (CF), +/–		
30	12.304	+	0.15	
29	12.334	+	0.12	
28	12.364	+	0.09	
27	12.394	+	0.06	
26	12.424	+	0.03	
25	12.454		0.00	12.454[A]
24	12.484	–	0.03	
23	12.514	–	0.06	
22	12.544	–	0.09	
21	12.574	–	0.12	
20	12.604	–	0.15	

[A] pH of a saturated lime solution at 25°C.

6.2.8.1 PSRP (Class B) biosolids have regulatory restrictions preventing application of material to a site during inclement weather, standing water, ice- or snow-covered fields.

6.2.8.2 On-site storage should be considered to hold biosolids, unless backup options are available when application sites cannot be used. Storage design must address regulatory concerns for runoff or leachate and local site-specific concerns for odor. Storage capacity should be consider worst-case weather conditions.

6.2.8.3 Microbial recontamination and regrowth is possible at pH < 10, with concomitant odor potential.

7. End Use Criteria

7.1 *Matrix of Product Factors*:

7.1.1 Table 5 addresses various factors that influence specific product criteria for alkaline-treated biosolids. The relative importance of these criteria will depend on the type of product and its intended use; for example, for agricultural liming material, $CaCO_3$ equivalency and friability for handling will be important, along with metal levels, which must meet Table 3 of EPA's 503 Rule for a product to be sold or distributed.

EPA 40 CFR Part 503.13 (13 (Table 3)
Metal Concentration Limits

Metal	Pollutant Concentrations (mg/kg)
Arsenic	41
Cadmium	39
Copper	1,500
Lead	300
Mercury	17
Molybdenum	75[A]
Nickel	420
Selenium	100
Zinc	2,800

[A] This is the ceiling concentration for Molybdenum. EPA is still developing a pollutant concentration value.

8. Federal Regulations

8.1 *Introduction*:

8.1.1 *Pathogen reduction*—Alkaline materials reduce pathogens in municipal wastewater solids by creating a series of stresses on the microbial population in the solids. The addition of an alkaline material raises the pH of the mixture to levels that are toxic to some microbes, resulting in their reduction or elimination (**5**). The exothermic reaction of quicklime with water also releases heat (often intense) and the resultant temperature rise helps inactivate pathogens. Hydration of alkaline oxide materials helps dry the biosolids, further stressing the microorganisms.

8.2 *Class A Pathogen Reduction*:

8.2.1 All 40 CFR Part 503 Class A alternatives must meet the following criteria:

8.2.1.1 Either the density of fecal coliform in the biosolids must be less than 1000 most probable numbers (MPN) per gram total solids (dry-weight basis), or the density of *Salmonella* sp. bacteria in the biosolids must be less than 3 MPN per 4 g of total solids (dry-weight basis).

8.2.1.2 Either of these requirements must be met at one of the following times: *(1)* when the biosolids are used or disposed; *(2)* when the biosolids are prepared for sale or

TABLE 5 Matrix of Product Factors

End-Use Criterion	Related Process Parameter			
	Input Biosolids	Alkaline Additive	Process Heat	Other Parameters
Percent solids	Percent solids	Percent solids	Heat of hydration and evaporative heat loss	
Friability/particle size/plasticity	Percent solids	Amount added		Percent solids of final mix; bulking agent; type and amount of mixing
Nutrient content	Nutrient content	Amount added (dilution)		Amount of ammonia driven off; amount of ″mineralization″ of nitrogen in chemical reaction; nutrient content of bulking agent
Organic matter content	Percent volatile solids	Amount added (dilution)	Loss of volatile organics	″Mineralization″ of organic content in chemical reaction; organic content of bulking agent
Metals content	Metals content	Metals content		Metals content of bulking agent
Liming potential	$CaCO_3$ equivalency	Ca content Mg content		Ca, Mg content of bulking agent
pH level and duration	pH, percent solids, ammonia and alkaline metals content, buffering capacity	CaO $Ca(OH)_2$		Final pH of product; granularity or plasticity of end-product (permeability to air and water allowing reaction to product carbonate)
Pathogen reduction		pH 12 (CaO and $Ca(OH)_2$ content)	Heat level and duration	Dryness of end-product; chemical destruction of pathogens
Odor potential	Percent ammonia, percent volatile solids, digestion process, polymer type and content	pH-driven ammonia release; neutralization of malodorous organics	Volatilization of organics	Thoroughness of mix; odor stripping during process
Bearing strength	Non-volatile solids	Material available for forming carbonates; silicates; aluminates; aluminoferrites	Vaporization of water	Time since product was made; CO_2 reaction producing carbonates; characteristics of bulk agent(s)
Permeability		Cementitious compounds		Time since product was made; CO_2 process producing carbonates; plasticity/friability of bulking agent; characteristics of bulking agents; density

give-away in a bag or other container for land application; or *(3)* when the biosolids or derived materials are prepared to meet the requirements of CFR 503 (**6**).

8.2.1.3 Vector attraction reduction must take place before or at the same time as pathogen reduction except when the pH adjustment, percent solids vector attraction, injection, or incorporation options are met for vector attraction reduction.

8.3 *Alkaline Processes for Meeting Class A Pathogen Reduction Requirements*:

8.3.1 Alternative for Meeting Class A: Biosolids Treated in a High Temperature Process (through Chemically Produced Heat).

8.3.1.1 The time-temperature relation established in 40 CFR 503.32(a)(3) (Alternative 1). (See 6.1.6 for time-temperature examples.)

8.3.2 Alternative 2 for Meeting Class A: Biosolids Treated in a High pH-High Temperature-Air Drying Process 40 CFR 503.32(a)(4).

8.3.2.1 Elevating the pH to greater than 12 (measured at 25°C) for 72 h or longer,

8.3.2.2 Maintaining the temperature above 52°C for at least 12 h during the period that the pH is greater than 12,

8.3.2.3 Air-drying to over 50 % solids after the 72-h period of elevated pH, and

8.3.2.4 Meeting all the requirements in 6.2.

8.3.3 Alternative 5 for Meeting Class A: Treated in a PFRP (Pasteurization) Process Listed in 40 CFR 503, App. B, Part B-Option 7

8.3.3.1 Combined with an Alkaline Method of Vector Attraction Reduction 40 CFR 503.33(b)(6),

raise the temperature to ≥70°C for a minimum of 30 minutes, and

8.3.3.2 Combined naturally with the vector attraction reduction, raise the pH to ≥12 for a minimum of two hours, and maintain the pH ≥11.5 for an additional 22 h.

8.4 *Alkaline Process for Meeting Class B Pathogen Reduction Requirements*:

8.4.1 Alternative 2—PSRP listed in Appendix B, 40 CFR Part 503: Alkaline stabilization—sufficient alkaline reagent is added to the biosolids to raise the pH of the biosolids to 12 after two hours of contact time.

8.4.2 Unlike the comparable Class A requirements, this alternative does not require microbiological monitoring for regrowth of fecal coliform or *Salmonella* sp. bacteria.

University Of Waterloo pursuant to License Agreement. No further reproductions authorized.

www.technobetar.ir

8.5 *Alkaline Process for Meeting Vector Attraction Reduction*:

8.5.1 Option 6 Alkali[5], addition under specified conditions:

8.5.2 Biosolids are considered to be adequately reduced in vector attraction if sufficient alkaline material is added to achieve the following:

8.5.2.1 Raise the pH to at least 12, measured at 25°C, and without the addition of more alkaline material, maintain a pH of at least 12 for two hours, and

8.5.2.2 Maintain a pH of at least 11.5 without addition of more alkaline material for an additional 22 h.

8.5.3 The conditions required under this option are designed to ensure that the biosolids can be stored for at least several days at the treatment works, transported, and then used or disposed without the pH falling to the point where putrefaction occurs and vectors are attracted.

8.6 *Septage Treatment*:

8.6.1 *Option 12–Alkaline Treatment for Domestic Septage:*

8.6.2 This option pertains only to vector attraction reduction for domestic septage. Under this option, the pH of domestic septage must be raised to at least 12 and remain at pH 12 or above for a minimum of 30 min during which no additional alkaline material may be added.

[5] 40 CFR Part 503 uses the term "alkali" for any alkaline material. For beneficial use options, sodium (Na)-based alkaline materials are usually unsuitable due to the negative effects of sodium on soil physical properties.

9. Keywords

9.1 alkaline stabilization; biosolids; high-lime byproducts; sewage sludge; stabilization; wastewater treatment plant

Designation: F1869 – 09

Standard Test Method for Measuring Moisture Vapor Emission Rate of Concrete Subfloor Using Anhydrous Calcium Chloride[1]

This standard is issued under the fixed designation F1869; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This test method covers the quantitative determination of the rate of moisture vapor emitted from below-grade, on-grade, and above-grade (suspended) bare concrete floors.

1.2 This quantity of moisture shall be expressed as the rate of moisture vapor emission, measured in pounds of moisture over a 1000 ft^2 area during a 24-h period.

1.3 This test shall not be used to evaluate moisture emissions over gypsum concrete.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices, and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*[2]

C670 Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

F141 Terminology Relating to Resilient Floor Coverings

2.2 *Resilient Floor Covering Institute Standard:*

Recommended Work Practices [3]

2.3 *Military Standard:*

Mil Spec B-131H Type 1, Class III[4]

2.4 *ICRI Guide:*

Guideline No. 03732: Selecting and Specifying Concrete Preparation for Sealers, Coatings, and Polymer Overlays[5]

3. Terminology

3.1 *Definitions:* See Terminology F141 for definitions of the terms, above-grade (suspended), below-grade, concrete, on-grade, and resilient flooring.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *moisture vapor emission rate (MVER)*—amount of water vapor in pounds emitted from a 1000 ft^2 area of concrete flooring during a 24-h period (multiply by 56.51 to convert to µg/s m^2).

4. Significance and Use

4.1 Use this test method to obtain a quantitative value indicating the rate of moisture vapor emission from a concrete floor and whether or not that floor is acceptable to receive resilient floor covering. The moisture vapor emission rate only reflects the condition of the concrete floor at the time of the test. All concrete subfloors emit some amount of moisture in vapor form. Concrete moisture emission is a natural process driven by environmental conditions. All floor coverings are susceptible to failure from excessive moisture vapor emissions. The moisture vapor emitted from a concrete slab is measured in pounds. This measurement is the equivalent weight of water evaporating from 1000 ft^2 of concrete surface in a 24–h period. The calcium chloride moisture test has been the industry standard for making this determination and is a practical, well-established and accepted test of dynamic moisture. It will produce quantified results directly applicable to flooring manufacturer's specifications. The results obtained reflect only the condition of the concrete floor at that time.

5. Apparatus

5.1 *Test Unit Contents*:

[1] This test method is under the jurisdiction of ASTM Committee F06 on Resilient Floor Coverings and is the direct responsibility of Subcommittee F06.40 on Practices.

Current edition approved Dec. 1, 2009. Published January 2010. Originally approved in 1998. Last previous edition approved in 2004 as F1869–04. DOI: 10.1520/F1869-09.

5.1.1 *Cylindrical Plastic Dish Containing Anhydrous Calcium Chloride*, heat sealed in a heat sealable bag meeting Mil Spec B-131H Type 1, Class III, to protect from moisture intrusion.

5.1.1.1 Anhydrous calcium chloride shall be in the form of prilled beads and shall have a minimum purity of 94 %. Net weight of the anydrous calcium chloride shall be 16 ± 1 g.

5.1.1.2 Dish shall be made of a material that does not absorb moisture. Dimensions of the dish shall be 69 ± 1 mm outside diameter, 16 ± 1 mm height, wall thickness less than 1 mm. Dish shall be supplied with a tight-fitting cover. The cover shall be secured to the dish with pressure-sensitive-adhesive backed vinyl tape.

5.1.2 *Pressure Sensitive Label*, to be used to identify the container of calcium chloride and to record the date, time, and container weight when the test is started and completed.

5.1.3 *Transparent Cover*, with 0.5 in. (12 mm) flanges around the perimeter, approximately 0.5 ft^2 (460 ± 46 cm^2), as measured between the inside of the flanges, is required to seal the test area of the floor. The plastic cover shall have a depth greater than the height of the container of anhydrous calcium chloride. The height of the container shall be 1½ in. ± 0.125 (38 ± 3.2 mm).

5.1.4 *Strip of Sealant*, to secure the plastic cover to the floor in an airtight fashion.

5.1.5 *Brightly Colored Warning Label*, to be placed on the plastic cover as a protective warning while the test is being conducted.

5.1.6 *Mailing Bag*, for the return of the sample to the party responsible for calculating the test results.

5.2 *Gram Scale*, capable of measuring 0.1 g. This scale will be used to weigh the calcium chloride container at the start and end of the test. On-site measurement is preferred to mailing the container back to the supplier for results.

5.3 *Thermometer*, capable of measuring room temperature.

5.4 *Hygrometer*, capable of measuring the relative humidity of the test site.

6. Conditioning

6.1 The test site should be at the same temperature and humidity expected during normal use. If this is not possible, then the test conditions should be 75 ± 10°F (23.9 ± 5.5°C) and 50 ± 10 % relative humidity. Maintain these conditions 48 h prior to, and during testing.

6.2 Prior to placement of the anhydrous calcium chloride tests, the actual test area shall be clean and free of all foreign substances. All residual adhesives, curing compounds, sealers, paints, floor coverings, etc. shall be removed. Removal shall be accomplished using approved OSHA work practices. For removal of existing resilient floorings or residual adhesive, strictly observe the Warning that follows and Notes 1 and 2. (**Warning**—Do not sand, dry sweep, dry scrape, drill, saw, beadblast, or mechanically chip or pulverize existing resilient flooring, backing, lining felt, or asphaltic cut-back adhesives. These products may contain either asbestos fibers or crystalline silica. Avoid creating dust. Inhalation of such dust is a cancer and respiratory tract hazard. Smoking by individuals exposed to asbestos fibers greatly increases the risk of serious bodily harm. Unless positively certain that the product contains non-asbestos material, presume it contains asbestos. Regulations may require that the material be tested to determine asbestos content. RFCI's recommended work practices are a defined set of instructions addressed to the task of removing all resilient floor covering structures whether or not they contain asbestos. When RFCI's recommended work practices are followed, resilient floor covering structures that contain (or are presumed to contain) asbestos can be removed in a manner that will comply with the current occupational exposure to asbestos standard's permissible exposure limits (PEL) issued by the Occupational Safety and Health Administrations (OSHA).

NOTE 1—Various federal, state, and local government agencies have regulations covering the removal of asbestos-containing material. If considering the removal of resilient floor covering or asphaltic cut-back adhesive that contains or is presumed to contain asbestos, review and comply with the applicable regulations.

NOTE 2—Certain paints may contain lead. Exposure to excessive amounts of lead dust presents a health hazard. Refer to applicable federal, state, and local laws and "Lead-based Paint: Interim Guidelines for Hazard Identification and Abatement in Public and Indian Housing"[6] regarding: (*1*) appropriate methods for identifying lead-based paint and removing of such paint, and (*2*) any licensing, certification, and training requirements for persons performing lead abatement work. (Use only qualified of certified lead abatement contractors to remove lead-based paint.)

7. Procedure

7.1 Expose a minimum area of 20 by 20 in. (50.8 by 50.8 cm) to conditions specified in 6.1 and 6.2 for a minimum period of 24 h prior to starting each test. Weigh the container of anhydrous calcium chloride, including the tape used to seal the container, the container lid, and the label which should be affixed to the lid. Record the weight to the nearest 0.1 g on the container label along with the starting time to the nearest ± ¼ h.

7.1.1 If not provided by the $CaCl_2$ test kit manufacturer, obtain the actual area of the test site. Measure the length and width of the plastic cover between the inside of the flanges, and multiply to obtain the area. Measure the bottom of the dish containing the $CaCl_2$ to obtain the radius. To calculate the area of the dish, use the following equation:

$$A = \pi r^2 \quad (1)$$

where:

π = 3.14

Deduct the area of the dish from the area of the plastic covering. Record this as the actual test area. This will be used to make the final calculation at the end of the test.

7.2 Apply the sealant to the flanges of the plastic cover in a continuous bead. If the sealant has been preinstalled by the kit manufacturer, expose by peeling off the protective covering. The purpose of the sealant is to form an airtight seal around the perimeter of the plastic cover.

7.3 Carefully remove the sealing tape from the calcium chloride dish and attach it to the side of the plastic container. This tape will be used again to reseal the same container.

[6] Available from U.S. Department of Housing and Urban Development, Washington, DC. Use September 1990 or subsequent editions.

www.technobetar.ir

Remove the container lid and invert it under the dish. Set the dish (and lid) onto the concrete surface. (**Warning**—Do not spill any of the calcium chloride from the container. If spillage occurs that test kit is to be discarded requiring test to be performed with a new test kit.

Immediately place the plastic cover over the calcium chloride dish. Firmly press down on the cover's flanges compressing the sealant providing an airtight seal around the cover.

7.4 After test has been in place for 60-72 h, remove the plastic cover. It may be best to cut the top open with a razor blade so the dish can be easily retrieved. Replace the lid on the container and immediately reseal using the original sealing tape. Immediately reweigh the sealed container. Record the new weight, the date, and time the test was stopped. Record if performed at the test site.

NOTE 3—If test container is to be return-mailed for results, immediately place in mailing bag ensuring bag is properly sealed. Follow mailing instructions provided with kit.

7.5 The formula for computing moisture vapor emission rate (MVER) is as follows:

$$\text{MVER} = \frac{24\ 000 \cdot \Delta M}{453.612 \cdot A \cdot T} = \frac{52.91 \cdot \Delta M}{A \cdot T} \quad (2)$$

where:

MVER = moisture vapor emission rate, lb/1000 ft^2/24 h,
ΔM = change in mass (weight gain) of anhydrous $CaCl_2$ in g,
A = contact area of the flanged cover on concrete in ft^2 deducting the area of the $CaCl_2$ dish, and
T = exposure time in hours.

7.6 To convert test results to SI, multiply by 56.51 to obtain results in μg/(s m^2).

7.7 Use the following guidelines to determine the number of test locations to be utilized simultaneously.

7.7.1 Three test locations for areas up to 1000 ft^2(100 m^2).

7.7.2 Add one additional test for each 1000 ft^2(100 m^2) or fraction thereof.

NOTE 4—When conducting moisture emission tests, the test units should not be concentrated but shall be located in various parts of the floor area. One unit shall be placed near the center with others being placed around perimeter. Selection of test sites shall include areas of potential moisture, that is, joints and perimeter of building.

8. Precision and Bias

8.1 Precision, characterized by repeatability *Sr*, *r* and reproducibility *SR*, *R* has been determined for the following materials to be:

Material	Average	*Sr*	*SR*	*R*	*R*
Concrete slab 6–8	5.94 lb/100 ft^2/24 h	0.24	0.32	0.68	0.90

8.1.1 This precision statement is provisional.

8.2 No information can be presented on the bias of the procedure in Test Method F1869 for measuring moisture vapor emission rates from concrete because no material having an accepted reference value is available.

9. Keywords

9.1 anhydrous calcium chloride; moisture vapor emission rate; quantitative calcium chloride; resilient flooring; RMA referee test
